REPRESENTING SELF-STUDY IN RESEARCH AND PRACTICE

SECTION 4
SELF-STUDY IN TEACHING AND TEACHER EDUCATION

PREFACE

For a considerable period of time there have been calls for teacher educators to teach in ways commensurate with the learning expectations they have for their student-teachers. Such calls have encouraged many teachers of teaching to carefully examine their own practice in order to develop deeper understandings of practice as well as to enhance the learning of their students. Such research has been termed self-study. Many involved in self-study have found it to be an empowering way of examining and learning about practice while simultaneously developing new opportunities for exploring scholarship in, and through, teaching. Hence, although the term rose to prominence through the work of teacher educators, others involved in teaching, and for that matter, professional practice more generally have also been attracted by the possibilities inherent in such work. However, although self-study may well be appealing, it does not diminish the need to constantly examine what is being done, how and why, in order to further our understanding of the field and to foster development in critical and useful ways so that the learning through self-study might be accessible and informative to others.

As a recognisable body of work self-study began to emerge early in the last decade of the twentieth century. At that time, self-study of teaching and teacher education practices expanded and developed as substantial interest in the field was generated. Not surprisingly then, the self-study community was concerned to consolidate the range of work available within the research literature so that the learning from and through self-study might be more easily available to the increasing number of educators seeking to develop their own scholarship in the field. As a direct result of this concern, initiatives were enacted that led to the development of this *International Handbook of Teaching and Teacher Education Practices*

This Handbook offers an extensive international review of research and practice of self-study as chapter authors have questioned: critical issues for self-study; the research and practice of self-study; that which comprises relevant and related literature; and, exemplars of self-study that highlight the importance and impact of such work to the field itself.

As self-study brings together the worlds of research and practice this Handbook offers practical and theoretical arguments in a symbiotic manner as each are highlighted and explicated in an examination of how they inform self-study as a whole. In so doing, the approach to self-study of teaching and teacher education practices used to shape this Handbook draws on the view that the creation of experiences from which theory, knowledge and practice are created

should, as much as possible, be modelled through the text so that chapters reflect the theoretical approach being examined through practical application through concrete examples. This approach has been used to shape this Handbook so that the Handbook itself is a real representation of the work on which it extensively reports. The Handbook has therefore been structured in four sections namely:

- Section 1:   Understanding the nature and development of self-study
- Section 2:   Developing a professional knowledge base for teaching
- Section 3:   Representing self-study in research and practice
- Section 4:   Self-study in teaching and teacher education

Each section was co-ordinated by a leading international scholar who accepted responsibility for the organisation of authors, reviews and editing of a section within the conceptual framework of the Handbook.

The Handbook has been designed so that each section is a coherent entity in its own right. In so doing, the introductory and concluding chapters for each section are critical as they define the issues within their section and examine how and why they are important to the work of self-study. Each section then forms an individually strong review of a given aspect of self-study. Further to this, the cumulative nature of the collective influence of sections is equally important as each section is conceptualised to build on, develop and extend the ideas, issues and approaches across a range of contexts, methods and practices such that the Handbook itself is constructed as a major text that fully encompasses the field of self-study. Therefore, Section 1 introduces the Handbook and does so by creating a major overview of the field drawing on a range of important issues and approaches that are central to an understanding of self-study. Section 2 moves into the specific realm of the knowledge base of teaching and examines the research, practice and argument germane to this aspect of self-study. Section 3 offers a close examination of the nature of representation and portrayal and purposefully explores the range of approaches developed, adapted and adjusted to respond to the needs and concerns of those involved in the work of self-study. The Handbook closes with Section 4 which focuses on teaching and teacher education through a concentration on the nature of practice and research through particular approaches within specific contexts.

The Handbook is therefore a coherent whole that allows the reader to move through it in a sequential fashion either at the big picture level of the Handbook as a complete entity in its own right, or by given individual sections. It also offers access to issues, approaches and themes as stand alone, authoritative examinations and reviews, through the way in which each chapter has been structured and written as an important source of information on a particular topic.

The CD-ROM that accompanies this Handbook provides supporting materials for four chapters; for two chapters, the materials are extensive.

The supporting materials for Chapter 25, by Sandra Weber and Claudia

Mitchell, are presented within a PowerPoint presentation that provides access to four resources:

- *The fishbowl effect* by Cherri Killam (photographs and text)
- *The monochrome frame: Mural-making as a methodology for understanding 'self'* by Max Biddulph (images and text)
- *An arts-based research bibliography*
- *Just where do you think you're going?* by Katharine Childs (video in PC and Mac formats)

The supporting materials for Chapter 27, by Nona Lyons and Helen Freidus, consist of three portfolios in HTML format produced at the Bank Street College of Education:

- *Authenticity portfolio* by Julie Parker
- *The slow way is the fast way* by Jennifer M. Suesse
- *Reading and literacy portfolio* by Marilyn Wiles-Kettenmann

In addition, supporting images are included for Chapter 8, by Susan Wilcox, Jinx Watson, and Margot Paterson and for Chapter 26, by Garry Hoban.

The authors who accepted the challenge to write for this Handbook did so in a most gracious and supportive manner for no task of this magnitude could easily be completed without the co-operation and assistance of dedicated academics. The fact that this Handbook was fully developed within the original time lines and that all participants willingly worked to complete their part of the project on time is a true reflection of the strength and nature of the self-study community. Beyond the authors, the chapter consultants completed their reviews in ways that offered assistance and advice such that authors received constructive and insightful criticism that helped them to strengthen their work and to extend their ideas in meaningful ways.

As an International Handbook, the sixty-one chapter authors range from countries as close to one another as the U.S.A. and Canada, and The Netherlands and Belgium, to those as distant from one another as Iceland and Australia, and the United Kingdom and New Zealand. Importantly though, the fact that these authors represent a diversity of states, countries, educational settings and experience in teaching and teacher education further reinforces the global perspectives brought to bear in this Handbook.

In addition to the Handbook offering an extensive review of research related to the topics under consideration, as noted earlier, it also features cases of particular self-studies that are designed to highlight the issues under discussion so that tangible examples of the work are not only reviewed but also demonstrated in ways that help the reader to more fully comprehend what such work really looks like. This feature has been included partly as a response to the need for the text to model that which is under consideration within a chapter, but also as an attempt to create real access to examples of research that have helped to shape the field. In so doing, these exemplars, while not intended as templates

or recipes of self-study, offer ways of conceptualising self-study so that others can adapt, adjust and extend these ideas and approaches in their own work.

Finally, there is little doubt that all of those involved in this project have worked long and hard in developing this Handbook. However, beyond the efforts of the chapter authors and consultants, I express my deepest gratitude to the section editors whose time, effort, support and co-operation have led to the quality product that is the *International Handbook of Self-study of Teaching and Teacher Education*. The section editors' careful attention to detail, ability to manage a complex and demanding process over an extended period of time and to do so cheerfully and with unstinting care has made this project a most rewarding experience for all involved. Thankyou.

SECTION 1

Understanding the Nature and Development of Self-Study

Section Editor: J. John Loughran

FOREWORD TO SECTION ONE

This section introduces the *International Handbook of Self-study of Teaching and Teacher Education Practices* and does so by setting a context for understanding the nature and development of self-study. The section opens with an examination of the history and roots of self-study by exploring the impetus for involvement in such work in concert with other research traditions that have influenced the field (e.g., reflective practice, teacher thinking and action research). This opening chapter also illustrates how purpose stands out as an important issue as it is a driving force for involvement in self-study due to participants' desire to teach in ways that are commensurate with the learning intentions they have for their students. Inevitably then, this creates a need for new ways of approaching research of practice as the researched and the researcher are inextricably linked. Thus, defining self-study emerges not so much as alignment with a particular method but rather through distinguishing aspects which not only shape the nature of self-study, but also offer: insights into the learning outcomes; relevance for others; and, applicability in different contexts.

An examination of the relationship between teaching and learning is crucial in understanding the nature of self-study and chapter two explores how views of learning influence approaches to teaching such that a desire to research those influences becomes another shaping force in constructing approaches to self-study. Chapter 2 brings into focus the importance of self-study in purposefully seeking to better align teaching and learning. In so doing, both intended and unintended outcomes are apprehended and consciously acted upon in the search for enhanced understanding of the complex world of teaching and learning; and more specifically, the teacher education world's concern for teaching and learning about teaching.

Chapter 3 focuses on self-study as teaching and begins to unpack the nature of self through a detailed examination of context and practice in relation to one's beliefs and actions in pedagogic situations. Personal aspects of self are played out against the academic need for explication of, and knowledge about, effective practice in ways that illustrate the importance to the pedagogue of being better informed about teaching. Therefore, self-study as teaching is embodied in approaches to pedagogy whereby one's own taken-for-granted assumptions about practice need to be made explicit so that meaningful questioning of practice might be encouraged.

Chapter 4 introduces self-study as research by examining the distinction between the "high theory of academe and the rich chaos of situated practice". In conceptualizing the distinction between each through dichotomy, it appears almost inevitable that differences between: university and school; theory and practice; academic and teacher; and, researcher and practitioner, emerge as ways of separating these worlds in ways that are not necessarily helpful. However, through such differentiation, questions about the nature of research, epistemological issues associated with the involvement of self, and, the influence of the political discourse of the academy surface. Consequently, this chapter illustrates how research discourse itself is embedded in the political context of the academy and how that too creates difficulties for different research fields as another binary, the insider and outsider, creates further challenges to be addressed. How these issues influence the work of teaching and teacher education is then important to the topic of this Handbook.

Chapter 5 builds on the work of self-study as teaching and research by drawing attention to the learning from and, teaching about, teaching. With learning as a major focus, context becomes an issue that is crucial in shaping the nature of the self-study as well as the understandings that emerge through such work. Therefore, the practitioner perspective on approaches to teaching and teacher education are important in terms of the explication of learning and its impact on practice. One major aspect of this chapter is in making concrete how self-study offers insights into understandings of practice so that meaningful changes in practice are not only encouraged but also documented, portrayed and disseminated to others.

Chapter 6 offers a detailed analysis of a body of self-study research drawn on the biennial CASTLE conferences held at Herstmonceux, England. This chapter discusses that which is gained from a systematic analysis of the basic features or "commonplaces" of self-study of teacher education practices. In so doing, many exemplars are drawn on in order to highlight these features and also to give access to the most prominent features for further analysis and consideration. As a result of the study of this literature, reflections on how the field might be enriched and advanced are considered in ways that help to create new challenges for the field.

Chapter 7 approaches self-study through an examination of voice. In this chapter, the notion of voice is used as an important way of reconsidering teaching and teacher education through a focus on that which is portrayed, by whom, and how. This review illustrates the heterophonic and polyphonous nature of voice in self-study and how that leads to an understanding of the authoritative and authentic nature of such work. However, voice in self-study also brings to the surface the sense of dissonance and contradictions that exist within the contexts of teaching and teacher education and so become important shaping forces in creating a discourse that is responsive to these very contexts. It is then argued, that such consideration of voice leads to a new discourse in teacher education. One that is borne of the participant practitioners whose concerns,

interests and struggles are germane to the work of teaching and teaching about teaching.

Chapter 8 considers self-study in fields allied to teaching and teacher education and argues that it is vital to professional practice because it allows practitioners to "engage in inquiry that contributes to their own capacity for expert and caring professional practice while also contributing to the growth of their professions". By drawing on the notion of reflection and paying careful attention to actively questioning individual and communal stories of practice, the authors of this chapter suggest that these processes lead to a deeper understanding of self and practice. Therefore, practitioners are empowered to transform their practice and in so doing situate themselves as lifelong learners. This matters as it through documenting and sharing the learning from different approaches to examining personal motives and assumptions that the development of ways of knowing about professional practice might be enhanced.

The section closes with a careful examination of all eight chapters through the eyes of two critical friends. This chapter is specifically designed to offer an example of the questioning, probing, framing and reframing that is at the heart of self-study. It is indeed a daunting task but the purpose is to aid both readers of this Handbook and the individual chapter authors in seeing other ways of considering the work of self-study. In accepting this difficult task, Bullough and Pinnegar "write from the perspective that in order for self-study to prosper as an intellectual enterprise and practice that it must at its heart be oppositional". They consider the difficulty of defining self-study yet highlight the importance of ongoing vigorous conversation as one way of averting the loss of engagement and inspiration that can occur when a definitive stance stands in the way of methodological creativity and development. They explore the problem of ontology and highlight the value of a "commitment to a quest for understanding and to a way of being with and for children, colleagues and our students". They examine the problem of form and the importance of audience in influencing that which is reported, and how it is reported. However, close examination of practice must surely be in order to further the cause of teaching and teacher education. Finally, they raise the problem of scholarship and carefully consider the obligations that must be met if "self-study is to impact in more than peripheral ways the academic conversation and scholarship of teaching and teacher education".

This section of the Handbook offers a big picture view of the field and the way that it is structured, dissected, analyzed and critiqued. It is designed to offer the reader access to a wealth of ideas and understandings drawn from a diverse range of self-study and related literature. The section also includes, as an appendix, a reprint (with publisher's permission) of a paper from the American Educational Research Journal (1992) by Diane Holt-Reynolds. This paper is an example of the type of work that was a precursor to the formation of Self-study of Teacher Education Practices. Diane was a founding member of the S-STEP SIG and this paper is included in recognition of her work in shaping the nature of self-study and as an example of the research issues, questions and dilemmas

that influenced the growing concentration on teaching and teacher education at that time.

I trust that the approach adopted in this section of the Handbook is beneficial to the reader in offering a beginning point for exploring that which is self-study of teaching and teacher education practices.

J. John Loughran

1

A HISTORY AND CONTEXT OF SELF-STUDY OF TEACHING AND TEACHER EDUCATION PRACTICES*

J. John Loughran
Monash University

Abstract

For a growing number of teacher educators, Self-study of Teacher Education Practices (S-STEP) has become an empowering way of examining and learning about practice while simultaneously developing opportunities for exploring scholarship in, and through, teaching. Over the past decade, the work in self-study has been increasingly shared, scrutinized and extended so that emerging understandings of some of the issues in self-study might be further encouraged and debated. This chapter is designed to offer insights into some of the factors that have led to the development of self-study of teaching and teacher education practices and to begin to describe and articulate some of the distinguishing aspects of this work that appear important in defining this field of study.

Korthagen (1995) reminds us that despite the popularity of the notion of reflection and reflective practice among teacher educators in the early 1980s, that it still took almost another decade for teacher educators to see the importance of doing themselves what they were encouraging teachers to do – study their own practice. One reason for this slow uptake may be related to the conflicting demands of the work of teacher education as opposed to the expectations of the academy:

> For a long time, the academic world was not supportive of the position of creative researchers who tried to build on another epistemological basis ...

---

*Chapter Consultant: Vicki LaBoskey, Mills College, U.S.A. and Deborah Trumbull, Cornell University, U.S.A.

teacher educator/researchers who dared to carry out this difficult task [self-study] in an area in which this is largely unprecedented: the world of teacher education practices … these people are intimately familiar with the two worlds: the world of scientific research on education **and** the world of practice. And they try to combine the best of both worlds. (Korthagen, 1995, p. 100)

This attempt to combine the best of both worlds is one way of understanding why and how self-study has emerged as an approach to carefully examining teaching and learning. This chapter aims to explore the nature of self-study and in so doing, to also explore the historical roots of self-study of teaching and teacher education practices. The chapter begins with a brief overview of different uses of the term self-study over time in order to build a picture of how self-study is currently understood in the research literature. This is followed by an examination of the reasons for conducting self-study, a review of the historical context that led to the formalizing of self-study, then closes with an exploration of how self-study is framed, interpreted and portrayed.

Background

A simple search of the ERIC database shows that almost 2000 papers have been written in which self-study is used as a major descriptor. However, analysis illustrates a diversity of ways in which self-study has been used and interpreted over time. For example, a predominant early use of the term was related to the notion of students individually completing tasks through self-paced/self-evaluation approaches to learning (Glasser, 1966; Impellitteri, 1967; Kellett, 1966). In this understanding of self-study, the focus was largely on participants instructing themselves through the completion of diagnostic tests or other forms of information/knowledge attainment. This approach was no doubt innovative at the time as it placed more emphasis on the individual learner and suggested that responsibility for learning might be influenced by factors other than just the teacher. This use of self-study was one way of questioning the more traditional approach to classroom instruction.

Self-study was also used as a descriptor for exploring individuals' concept of self and was the focus of psychological studies whereby associated views about, and influences on, one's personality and the development of self image were examined in an attempt to better understand shaping factors in the development of, for example, beginning teachers (Tuska & Wright, 1966) or academic success (Simmons, 1968). In a similar vein, self-study was also used to explore understandings and practices of self-disclosure (DeLeon *et al.*, 1970) as well as the influence of introspection (Cosgriffe, 1966).

The use of self-study in many of these (and related other) works was then a window into some of the psychological aspects of self and offered a small but significant entry point into examination of one's own teaching (e.g., Blumenthal, 1977). Interestingly, in this early literature there are also examples of self-study

whereby the self was an institution (e.g., University or College) rather than an individual.

The purpose of studying the self, when the self was an institution, was related to questioning existing structures and functions within the institution, or finding new ways for that institutional self to carry out its role (Coffelt *et al.*, 1966; Minter & Thompason, 1968; Huberman, 1969; Sinclair Community College, 1969). In this case, the use of the term self-study relates more to notions of institutional evaluation and could in many ways be interpreted as auditing programs in order to determine whether the espoused intentions of a program are in accord with the practices within the program. This institutional use of the term self-study is one that has dominated the literature for a considerable period of time and although it is used across a range of disciplines and professional fields, it has also consistently been linked to evaluating institutional approaches to teacher education (Behling, 1984; Bender, 1984; Coombs & Allred, 1993; Mortimer & Leslie, 1970). A feature that all these interpretations (above) have in common is the expectation that beliefs and practices should be closely aligned and that the self (however that might be described, from the individual through to the institution) carries a major responsibility in establishing this alignment.

In respect to this handbook, the use of the term self-study is used in relation to teaching and researching practice in order to better understand: oneself; teaching; learning; and, the development of knowledge about these. Through this use of the term, the recent literature illustrates that there exists a clear impetus for practitioners to coalesce around these ideals of self-study in ways that encourages ongoing involvement in such work.

Self-study in relation to teaching and teacher education practices has emerged from the work of teachers and teacher educators themselves. That is, that their attempts to better understand the problematic worlds of teaching and learning have led to an increasing focus on their work so that researching their practice better informs them about their teaching and enhances their students' learning. Therefore, from the initial use of the term self-study has grown a strong and vibrant educational community that generally seeks to, "… investigate question[s] of practice … that are individually important and also of broader interest to the teacher education community" (Pinnegar & Russell, 1995, p. 6).

The Purpose of Self-Study

It is interesting to reflect upon the way in which educators have come to embrace the notion of self-study and how this field has spawned a diversity of practices across a range of settings. One reason for this variation appears to be related to the appeal of the underlying purpose of self-study and the desire for individuals to study and better understand their practice. Self-study has become a focal point for those pursuing a better knowledge of their particular practice setting and the work of those with a concern for teaching and learning in parallel fields (such as reflection, action research, teacher research, participant research and

practitioner research) has been influential in shaping how self-study is perceived and conducted.

An important touchstone for understanding the nature of self-study is the book *Reconceptualizing Teaching Practice: Self-Study in Teacher Education* (Hamilton *et al.*, 1998). This book considers the philosophical and methodological perspectives of self-study then explores these through individual and collaborative case-studies that are designed to bring these perspectives to life. Although it is not intended as a recipe for self-study, Hamilton's book is certainly a valuable starting point for coming to understand self-study. It offers reasons as to why teacher educators choose to pursue studies of this kind.

> As teacher educators, we recognize that we are teachers. We believe that research on teaching practice by teachers holds invaluable promise for developing new understandings and producing new knowledge about teaching and learning. Formalizing such study of practice through self-study is imperative. … The value of self-study depends on the researcher/teacher providing convincing evidence that they know what they claim to know. … This book provides evidence that self-study undertaken with rigor … will lead to both reconstruction and reconceptualization of teacher education. (Hamilton & Pinnegar, 1998, pp. 243–244)

Hamilton and Pinnegar suggest that the purpose for conducting a self-study is an important facet of such work and one does not need to delve too deeply into self-study reports to see that many authors make a point of the purpose for conducting their self-study. A common 'big picture' purpose for many self-studies is linked to the desire of the teacher educator to teach in ways commensurate with the hopes for their student-teachers' teaching (i.e., the notion of 'practice what you preach' or modeling). At first glance, this purpose seems more than reasonable and certainly highly appropriate to the world of teaching and teacher education, yet any reading of the literature immediately demonstrates that this purpose itself creates tensions, difficulties and dilemmas and, consequently, demands new ways of managing and responding to both the research and its outcomes. Although there are many purposes for conducting a self-study, it is perhaps helpful to consider one purpose in detail in order to highlight the interplay between a purpose for conducting a self-study and the problematic nature of such work.

Modeling

> Since the purpose of teacher education is to shape how student teachers will act when they eventually find themselves in schools, it is of central importance to see to it that their learning becomes deeply embedded in their perceptions of schooling and of their own future role in schools … That is why it is so valuable to involve students in the processes of self-study since it will demand of them precisely the critical reflection that they require as learners. (Barnes, 1998, ix–xiii)

Modeling is an important term in self-study. 'Practicing what you preach' has long been recognized as a powerful teacher as students learn much more from what a teacher does than what a teacher says. Therefore, teaching student-teachers using the methods and approaches that they themselves are encouraged to use in their own teaching matters – a lecture on co-operative group work does not necessarily offer great insights to teaching or learning through group work. Modeling through self-study may then entail involving students and sharing the steps of the investigation with them as well as illustrating how the classroom is a site for reflection and inquiry. However, the term modeling can create difficulties for it is easily misconstrued as, in some cases, it is viewed as a synonym for mimicry, or the creation of a model or template for easy replication.

Tochon (1992) recognizes this difficulty in his consideration of educators' narratives when he notes that modeling the self may be seen, by some, as an invitation to indoctrination. Fenstermacher (2002) similarly noted this possibility in his discussion about that which constitutes validity in research on self-study and the scholarship of teaching. Despite the possibility for misinterpretation of the term, modeling itself is often to the forefront of a teacher educator's mind, and through self-study, the language, intent and outcome of modeling is better understood.

For example, consider LaBoskey (1997) who highlighted the possibility for misinterpretation of modeling in her consideration of her teaching about the construction and use of teaching portfolios. Her self-study was driven by a purpose to do herself that which she asked her students to do. In participating in the process in the same way as her students, by placing herself in the same vulnerable position as her students and, in doing so in a public forum which was real and risky for her, she was modeling actions that she hoped would explicitly illustrate (to her students) the value of being seriously involved in the process of learning through developing a teaching portfolio. At the same time she was also conscious that her modeling could be misinterpreted as offering a 'model' or 'prototype' for the 'right way' to construct a portfolio and how to respond to questions about it, despite the fact that she explicitly intended her modeling to be a way of helping to show the value in the process (of portfolio construction) through real and personal involvement.

The literature suggests that an important intent in modeling, despite the possibility for misinterpretation, is that it is a way of illustrating that, "… experimenting and the inevitable mistakes and confusions that follow are encouraged, discussed, and viewed as departure points for growth … [and, in so doing, the teacher educator] make[s] this evident to the student-teacher" (MacKinnon, 1989, p. 23). In LaBoskey's (1997) case, she was hoping to illustrate for her students that learning through experience is an important shaping force in better understanding not only oneself, but also one's teaching. However, as she noted, a most important outcome for her was in the development of her understanding about, and empathy with, students in terms of their learning to articulate their views about their teaching. In this case, she came to feel what it was like to do the tasks she was setting for her students and in so doing came to better

understand and shape that work in more meaningful ways. Through modeling she learnt more about what she was doing with, and for, her student-teachers. Hence, although she had a clear purpose, she could not have anticipated some of the outcomes (cognitive and affective) that she would be confronted by in doing her self-study.

Modeling may be performed in many ways. There is the modeling of specific teaching practices (Goos & Moni, 2001; Hoban, 1997; LaBoskey, 1997), the exploration of teacher thinking during teaching (talk aloud approach, Hutchinson, 1996; Loughran, 1996), journal writing (Schiller & Streitmatter, 1994; Trumbull, 1996) and educative relationships (Whitehead, 1998), to list but a few. At the core of these teacher education practices is the practitioner's desire to influence their students' learning. Examining in detail the learning as a result of modeling illustrates interesting insights into the difficulties and dilemmas that can be created by pursuing this purpose in self-study.

Consider, for example, Schulte's (2001) work. As a graduate assistant, Schulte supervised student teachers in their final semester of an elementary education program. Her duties as a supervisor were to observe student teachers and hold pre- and post-observation conferences and to observe student teachers in their field placements as well as conducting seminars for all of her students each week. She was well aware from her reading of the literature that success in changing pre-service teachers' beliefs were often far from successful. However, she also knew that building upon pre-service teachers' beliefs was more likely to be successful than trying to replace them. With this knowledge in mind she embarked upon a self-study whereby she asked herself the question, "How am I able to help student teachers challenge their assumptions about teachers, students, and schooling?" As her study developed, she modeled her own approach to challenging her own assumptions and in so doing learnt that:

> Doubts and insecurities about my teaching continued to plague me despite my best efforts to understand them and learn from my mistakes … My coping mechanism was to share the process with my students so I was explicitly modeling the same kinds of fears and anxieties they were having. If I truly wanted my students to be life-long learners of teaching, then it makes sense that I should demonstrate the same by exposing my process to them … I was insecure and doubtful, but this study also led to a certain confidence. Forcing myself to "risk" my relationships with students so that I might challenge them to better understand multiple perspectives has provided me with a base of experiences to draw upon in the future. My students have said that many of the strategies and activities I used were successful, at least in the short term, in helping them to challenge their assumptions about teaching and themselves … Practice and my students' positive feedback have given me courage. (Schulte, 2001, pp. 109–110)

It seems clear then that when self-study practitioners explore their own modeling of practice, when they genuinely attempt to practice what they preach, they gain

new insights into teaching and learning. As opposed to the transmission of propositional knowledge (White, 1988) so common to the traditional lecture format of tertiary education classes, the interplay between teaching and learning becomes more accessible and valuable as this purpose of self-study (modeling) creates ongoing experiences that offer opportunities for both teachers and students to experience meaningful learning for themselves. As noted by Schulte (above) learning through self-study by modeling creates new ways to understand and shape teaching and learning environments by inviting learners to learn rather than expecting them to absorb information, ideas, and points of view. Further to this, it creates genuine situations whereby the teacher is also a learner and invites new ways of seeing into teaching and learning situations – it can give one the courage to continue to take risks and approach teaching and learning in new and meaningful ways.

Modeling also highlights the belief by many involved in self-study that learning about teacher education practices evolves over time (Schulte's study was based on work in her fourth and fifth semesters as a graduate assistant). By approaching the development of teaching about teaching in this way, teacher educators may learn how to challenge the traditional view of teacher education as training as they begin to learn how to address the privilege of public theory over private theory – theory grounded in personal experience (Bullough & Gitlin, 2001) – which is so often tacit and at the centre of the dilemmas, concerns, issues and tensions that trigger self-study.

In considering this modeling purpose of self-study, it becomes immediately apparent that self-study places personal demands on participants and creates situations and learning outcomes that require (in some cases) immediate response. Therefore, one might well question why self-study continues to attract the attention of teachers and teacher educators. The answer is bound up in the conditions that encouraged a call for work of this nature. These conditions are reviewed through a history of the formalization of self-study of teacher education practices (S-STEP) that came into being as a Special Interest Group (SIG) of the American Educational Research Association (AERA) in 1993.

Historical Roots of Self-study of Teacher Education Practices

In terms of formalizing self-study, a 'coming together' of like-minded people with similar interests, issues and concerns[1] occurred through a 1992 AERA Division K symposium titled 'Holding up the Mirror: Teacher Educators Reflect on their own Teaching'. The papers presented (Guilfoyle, 1992; Hamilton, 1992; Pinnegar, 1992; Placier, 1992 – collectively known as the Arizona Group – and Russell, 1992) in this symposium were critiqued by Fred Korthagen from the University of Utrecht, The Netherlands, and his critique of these papers, based on his extensive work in the field of reflection, helped to push the boundaries of the presenters' views of practice in such a way as to encourage others to similarly respond to the challenges being raised – both by Korthagen and the participants.

In this symposium, much interest focused on the manner in which the presenters publicly articulated, and honestly portrayed their personal and professional struggles in interactions with their students as they endeavored to enhance their learning about teaching. Through this process the participants were openly questioning the very nature of the way they themselves conducted their own teaching and were conscious of wanting to know if and how their teaching made a difference for their students' learning about teaching (which strongly links to the previous section on purpose and intent in self-study).

In the case of the Arizona Group, they were also confronted by an ongoing difficulty in terms of attempting to understand the unspoken rules about gaining tenure. For them, their interest and concern about the relationships embedded in teaching about teaching and learning about teaching were becoming increasingly important. However, for them, this created a dilemma – and was a point of identification with many in the audience – for it appeared (to them) that such research was not necessarily acceptable to the academy – a point noted by Korthagen in the introduction to this chapter. Thus to pursue such work (which now would be described as self-study) was perceived as inhibiting their chances of gaining tenure.

While the Arizona Group as emerging academics were concerned for their future prospects and were partly mystified by the unspoken rules of tenure, Russell, as an experienced and well established professor, was questioning many of the taken-for-granted assumptions of teacher education that he considered negated the very essence of what teacher education purported to do; to teach about teaching. Russell's questioning of the taken-for-granted assumptions about teacher education and the Arizona Group's concerns had many aspects in common yet the two parties were very different in terms of academic status. So although the issues may have been similar, perceptions of their relative position in the academy influenced how such questioning might be conducted as well as the standing that exploration of such questioning might carry.

Russell was, in effect, beginning to conceptualize what he would later publish as the tensions of teaching about teaching through the authority of position (as is commonly used in teacher education) and contrasting it to valuing and responding to the authority of experience (Munby & Russell, 1994; Russell, 1995). This differentiation of pedagogies underpinning approaches to teacher education (Russell's views) combined with the personal struggles associated with attempting to teach in meaningful ways (The Arizona Group) seemed to embrace a growing groundswell of interest at that time. Hence, the gathering of like-minded (teacher) educators was encouraged as others rallied around, driven by similar tensions in their own practice.

It could well be argued that the questioning of practice and the place of research on practice that began to be played out through this symposium was one public response to earlier calls for studies of teaching about teaching and of teacher educators themselves in line with the issues and concerns raised by Lanier and Little (1986). Hence, the Arizona Group were raising personal concerns about the difficulties experienced by new faculty members (see for

example, Boice, 1991; Diamond, 1988; Ducharme & Agne, 1989; Whitt, 1991) in conjunction with concerns about the nature of learning to teach about teaching (Knowles & Cole, 1991; Trumbull, 1990) that were being reported at the time. Yet in this particular case, the combined effect of the symposium (later published see Korthagen & Russell, 1995; Guilfoyle *et al.*, 1995) could well be regarded as having pricked the consciousness of many teacher educators as the right issues were being raised at the right time and in the right place. It invited others to respond to some of the earlier calls for action, to be involved, and to name their concerns so that they could act upon them.

At that time, Self-study of Teacher Education Practices had not yet been formally named, but there is little doubt that it was, in part, an extension of the notion of reflection (Dewey, 1933; Schön, 1983, 1987). Reflection was being encouraged through the work of other teacher education scholars (for example Calderhead & Gates, 1993; Clift, Pugach & Wilson, 1990; Grimmett & Erickson, 1988; LaBoskey, 1994; Russell & Munby, 1992; Tom, 1985; Zeichner, 1983; Zeichner & Liston, 1987) and its growing popularity was further impetus for questioning the taken-for-granted assumptions of practice. Those researchers involved in reflective practice were also questioning teacher education practices and they added to the groundswell that further pushed forward the ideas beginning to take shape around self-study. One outcome of this questioning was encompassed in a challenge to teacher educators to seriously look into their own teaching practice.

This questioning of practice was also developing through studies in other associated fields by individuals involved in, for example, action research (McNiff, 1988) and teacher as researcher (Cochran-Smith & Lytle, 1993). A confluence of questions, challenges and actions that could barely be ignored by the teacher education community led many to pursue studies that could be characterized as teacher educators as researchers of their own practice.

The threads of these areas of research were resonating in the lives and practices of many teacher educators. Collectively, these teacher educators were beginning to respond with a common sense of purpose as they tackled some of the salient questions that they perceived as needing to be answered. Some of these questions were, "How can I better help my students to learn?" and, "How do I live my values more fully in my practice?" Some teacher educators were also beginning to publicly examine and respond to instances in practice of being, "a living contradiction" (Whitehead, 1993). Importantly though, it was not that these questions were necessarily new, but more so, that they were being seriously considered and responded to by those involved in teaching about teaching.

The desire to help students better learn about teaching and to do so in ways that involved much more than telling became a recognizable characteristic of, and purpose in, the growing field of self-study. Therefore, a renewed focus on the complex nature of teaching and learning about teaching was a catalyst for careful attention to teacher education practices by the very people responsible for conducting that practice. Through this focus, teaching itself was being

re-examined in ways that highlighted the difficulties associated with many of the implicit aspects of practice.

This crucial need to question and articulate the tacit understandings of practice in ways that could make clear pedagogical reasoning (Shulman, 1986) drew on another emerging field of research, teacher thinking. This need to be able to access and examine the thoughts and actions of practitioners overtly linked to developments in studies of teacher thinking (e.g., Clark & Peterson, 1986). A point of difference though was that the examination and articulation of the thinking associated with self-study was being conducted by the practitioners themselves. The similarity in intent and purpose was nonetheless apparent and Clark's (1988) question certainly struck a chord with many as it reflected the very essence of the important challenge of the time:

> Do teachers of teachers have the courage to think aloud as they themselves wrestle with troubling dilemmas such as striking a balance between depth and breadth of content studied, distribution of time and attention among individual students ... teaching disasters, and the human mistakes that even experienced teacher educators make ... (Clark, 1988, p. 10)

Responding to questions such as Clark's was one way of casting light on the pedagogy of teacher education and for those teacher educators being drawn to self-study it spawned a number of responses.

One important outcome was the new access offered into teacher educators' thinking about their own teaching as it was beginning to be made much more explicit – for themselves and their student-teachers. The modeling and think aloud approach to teaching about teaching that developed illustrated ways of helping students learn about teaching in new ways. Some of the resultant research (Loughran, 1994, 1996) simultaneously highlighted aspects of teacher educators' knowledge of teaching about teaching that was a direct result of making the tacit explicit and was a clear indication to some of the possibilities for knowledge claims resulting from the process of self-study.

There was a growing commitment amongst teacher educators to this work and a desire to move it forward in a systematic fashion. By 1994 Self-Study of Teacher Education Practices was a fully functioning AERA SIG and self-study (carrying this new meaning as a descriptor) appeared for the first time in the AERA conference index. With the work now being categorized and therefore more easily recognizable, it also became more readily accessible to others.

The S-STEP SIG has built on these foundations by developing more formal professional networks and creating opportunities to further develop the work of self-study. To date, S-STEP has conducted four CASTLE Conferences and published Proceedings (Richards & Russell 1996; Cole & Finley, 1998; Loughran & Russell, 2000; Kosnik, Freese, & Samaras, 2002) and it is through these conferences that much of the work of self-study of teaching and teacher education has been sustained. Questioning, critiquing and debating the nature of self-study of teacher education practices have been common features of the CASTLE

conferences as a development of such things as language, method, rigor and practice of S-STEP have been examined and re-examined. One purpose for this form of public debate is linked to the need for enhanced understanding of the field and the importance of developing common meaning so that ideas, issues, concerns and practices can be shared and built upon by others.

As this section illustrates, self-study has become more formalized and the ideas more readily accessible through the development of the S-STEP SIG of AERA. In so doing, what once may have been viewed as individuals pushing ideas and interests about teaching and learning in less traditional ways has led to a transition in the position, or status, of self-study through questioning mainstream methodologies and practices. However, the organization of the S-STEP SIG should not be interpreted as limiting self-study to teacher educators or teacher education practices alone. More so, it is that this group has been more active in the manner in which they have worked to shape the nature of their teaching and learning environments by documenting their research and interrogating their findings within the self-study community.

Yet despite the development, refinement and clarification that has occurred through S-STEP it is clear that the 'one true way', the template for a self-study method, has **not** emerged. Rather self-study tends to be methodologically framed through the question/issue/concern under consideration so that it invokes the use of a method(s) that is most appropriate for uncovering evidence in accord with the purpose/intent of the study. Pinnegar (1998) offers one way of understanding this situation when she states:

> While the methods and methodologies of self-study are not much different from other research methods, self-study is methodologically unique. ... [self-study] is not another challenge in some kind of paradigm war, but instead ... although participant observation, ethnographic, grounded theory, or statistical methods might be used in any single study, self-study involves a different philosophical and political stance ... researchers who embrace self-study through the simple act of choosing to study their own practice, present an alternative representation of the relationship of the researcher and the researched ... as they explore the development of understanding in a practice context. (Pinnegar, 1998, pp. 31–32)

Hence across the self-study literature, a remarkable range of methods is used and, as a consequence, a range of reporting styles is equally evident. Therefore, to understand what a self-study might look like requires a consideration of the range of factors that shape the research as well as the nature of the subsequent portrayal that is constructed in order to communicate the findings to others.

Factors that Influence the Nature of Self-study

Despite the fact that there is no specified method for self-study, there is a range of factors that influence how a self-study might be conducted and communicated.

For example, Loughran and Northfield (1998) describe ten features that they see as shaping both a self-study and its subsequent portrayal in response to the purpose and demands of the research and the perceived audience of the report. This section of the chapter examines these factors through examples from the literature.

Self-study Defines the Focus of Study, Not the Way the Study is Carried Out

This feature is characterized by a need to understand the context of a given self-study and to use data gathering approaches that are determined by the study rather than being predefined.

Clandinnin and Connelly (1995) focused attention on context when they began to make the knowledge of context explicit as they, like many others (see for example, Bauman, 1996) illustrated that context matters because it can not be assumed that simply stating the site of an inquiry, or the main features of a study, will carry sufficient understanding with which others might identify. There may be some elements in common across different "similar" sites, but points of difference are in themselves sufficient to create issues, concerns and questions for others who might be attempting to apply the learning from a given self-study to their own context.

It has been made abundantly clear that teacher educators are practitioners who are continually adapting, adjusting and altering their practice in response to the needs and concerns in *their* context (Richert, 1997; Schuck & Segal, 2002). The same applies to the way in which they interpret and utilize others' learning in their own work. Hence a thorough understanding of the context in which a study is conducted is important in shaping how teacher educators might construct their own interpretation of others' results in their own situation. Understanding the context of a given self-study is then important in shaping the perceived relevance – or extent of application – of others' work to one's own.

Examples of this contextual factor abound in self-study reports. It is particularly strong in the work of Oda (1998) as she explains how her personal images and memories of growing up as an Asian-American influenced her self-study of teaching about cultural and linguistic diversity. Her explanation of her context becomes an important signpost in informing others involved in similar work about particular views and understandings that emerge in, and shape, her practice. In a very different context, Lomax, Evans and Parker (1998) make clear the issues surrounding their collaborative self-study as teacher educators in terms of both their expectations of themselves and their students as they attempt to make explicit how the experience of action research unfolds with their students. Their context embraces two aspects of their work: working with teachers in action research; and, working with teachers who teach pupils with special needs. Both of these contextual factors need to be clear to the reader as they impact on the nature of the work from both perspectives.

Another aspect of the importance of context and how it shapes a self-study is

in the work of Nicol (1997) and Hoban (1997). Each of these authors build a strong sense of context into their self-studies as they report on their approaches to dealing with what they view as inherent dilemmas in methods teaching in pre-service courses of mathematics and elementary science respectively. The system in which Nicol works in Canada is different to that of Hoban in Australia and so the contextual differences matter in shaping the way their studies progress and are reported. However, because they account for the particular nature of their contexts, a reader who might also be a method lecturer in a pre-service teacher education program is encouraged to see beyond context alone and to abstract the learning from the mathematics and science situations to their own.

All of these examples (above) illustrate the impact of context in different ways. Interestingly though, there is not necessarily a major heading in these reports informing the reader that context is the issue under consideration – although this could also be appropriate. The point is that an understanding of the context is integrated into the report, informing the reader throughout the account in ways that reflect how the study itself is buffeted by the nature of the setting and the associated influencing factors (an excellent example of this point is in the work of Brown, 2002). Through a consideration of context, the relationship with research and the subsequent learning by the researcher is made available in meaningful ways.

The next four aspects of importance to self-study I group together to consider as a whole for they are intertwined in the way they build on each other. These features are:

- the need for an individual to illustrate a commitment to checking data and interpretations with others. "It is through the involvement of others that data and interpretations can be viewed from perspectives other than one's own and therefore be scrutinized and professionally challenged" (Loughran & Northfield, 1998, p. 12);
- the difficulty for individuals in genuinely challenging interpretations of their own experiences. Being personally involved in experiences can limit one's ability to recognize oneself as a living contradiction and therefore impact the self-study;
- Colleagues are more likely to frame an experience in ways not thought of by the person carrying out the self-study and is, "a natural progression [from the two preceding points] in that the need to work with others broadens the possibilities for validation and clarification as well as reframing" (Loughran & Northfield, 1998, p. 13); and,
- Valuable learning outcomes are more likely if self-study is a shared task.

Thematically grouped, these four aspects comprise the challenge to the individual paradox of self-study and encompass the need to seriously pursue alternative perspectives on experience.

Seeking Alternative Perspectives

The term self-study does not universally convey an understanding of a commitment to checking data and interpretations with others, so to the unwary, it is

easy for self-study to be a misleading descriptor. An initial response to the term self-study may well conjure up notions of withdrawn, self-reflective individuals, more concerned for themselves than the world around them. It is not surprising then that, for some, there is unease with the term as a descriptor of their interest and actions, and this very point has been made (Barnes, 1998; Loughran & Northfield, 1998; Munby, 1996). In such cases, the term appears to carry with it constraints or barriers that are not intended but which nonetheless arise. Yet paradoxically, the involvement of others, the checking of data and interpretations is crucial in addressing this very 'egocentric' concern.

Louie *et al.* (2002) highlighted the prime importance of this point and made it abundantly clear as they illustrated how their individual views and interpretations were challenged, buffeted and changed through checking their data – and the subsequent conclusions – with each other. Berry (2001) also illustrated the importance of this aspect of self-study through the manner in which she reflected on her teaching through her journal, but then made these reflections public through the world wide web for feedback from her students. In so doing, she found that her students challenged some of her initial responses to situations as they highlighted different perspectives and interpretations on the same experiences.

> Writing a weekly public journal helped me in ways that may not have occurred if the journal had been private. ... In addition to learning from my own writing, students' responses to the journal entries helped me better understand my students' learning and my teaching practice. After one session I wrote that I had been feeling disappointed that I had not handed control of summarising the session over to the students (Open Journal – week 3). Soon after posting this entry, I received an e-mail from a student who described how my summary helped her learning at that point in her development. She helped me to understand the session through her eyes, in a way that I had not previously considered. (Berry, 2001, p. 5)

An extension of this feature of self-study is what Whitehead (1993) terms as being a "living contradiction". When he introduced the phrase to the (then) emerging self-study community, it immediately resonated with others. Being a living contradiction carries with it a recognition that being personally involved in a given situation may in fact negate the ability to apprehend contradictions in one's own practice – it is very difficult to step back from personal experience and examine it in a detached manner. Self-study calls for this stepping back to happen, it is central to the work of self-study. Therefore, being able to illustrate that one does respond to this difficulty is important in demonstrating that self-study is not about simply rationalizing existing behaviors, but honestly examining practice.

Kuzmic (2002) described how he was confronted by his own contradictions in practice only when he 'stepped back' from his work and then came to see that what he was advocating for his students was something that he was unwittingly negating. Through his self-study he learnt how his hopes and aspirations

for his students as teacher researchers were being supplanted by his implicit understandings of his university researcher position – with all the power and dominance that that entailed. He found it hard to see this in himself until he saw it in others; he subsequently came to recognize the same within. Being personally involved in the situation, initially, limited what he could see about himself.

Recognition of this aspect of self-study is also well noted by Hamilton (2002) as she pays particular attention to her position and the privileges she is afforded as a white woman. She considers carefully how her white privilege is, "too often an unseen barrier to social justice that dams the progress that might be made … As visible change agents, white scholars must ask questions and confront issues that are too easily overlooked in a privileged environment" (Hamilton, 2002, p. 187). Interestingly though, it was not this position of privilege that was the focus of her self-study, yet, perhaps, it was because of this different focus that she was able to see things in herself that caused her to begin to question her position and her actions in relation to her work in teacher education. As a consequence, she makes a clear and unequivocal call for others to begin to see in themselves issues that they might otherwise easily overlook because of who they are and the position of privilege that they are afforded.

This feature of self-study leads to a consideration of the notion of reframing (Schön, 1983). It is not sufficient to simply view a situation from one solitary perspective. Reframing involves seeing the situation through others' eyes in order to gain alternative perspectives. Hence there is an ongoing need to be able to view the teaching and learning situation from different perspectives. Thus the value of collaboration and the notion that self-study is enhanced when it is a shared adventure.

There are important differences between individual and collaborative self-studies. At the heart of this issue is the argument that reframing is much more difficult from an individual and personal perspective as opposed to acting in collaboration with others. This point stands out most in studies that report on the nature of framing and reframing that was realized through collaboration (for example, Arizona Group, 1996; Maltbie *et al.*, 1996; Cole & McIntyre, 1998; Feldman & Rearick, 1998; Freese, Kosnick & LaBoskey, 2000; Clift *et al.*, 2000). Such studies demonstrate how the link between reframing and collaboration has created new ways of seeing 'the taken for granted' and/or opened up new possibilities for the development of understanding. For some, the way of doing this has been through an overt concentration on their students' understandings and although this issue is considered in much more detail in chapter 5, a brief overview here is warranted.

Listening to Students

Zeichner (1999), Fenstermacher (1997) and Barnes (1998) all noted the importance of the explicit link between self-study and the students of teaching. The S-STEP literature also illustrates that students are crucial as participants and

mirrors for information, feedback and advice (e.g., Hutchinson, 1996; Freese, 1998; Trumbull & Cobb, 2000).

Within the S-STEP literature, students are not simply part of the study; they are also fundamental in shaping and responding to the study, because the purpose of studying one's own practice is often linked to a desire for practice to impact on student learning. Hence students' views, understandings and participation are of more importance than an 'easily accessible' or 'simple data source'; students are fundamental to understandings of practice.

Consider, for example, the work of Russell and Bullock (1999). Bullock, a student in Russell's class, is a source of feedback and data for: framing and reframing; pedagogy; learning; and, evaluation. But how this occurs is far from simple. In their account Russell makes explicit to his students his pedagogical reasoning and risk taking, which includes the highs and the lows of his practice, in order to help them see 'learning about practice in practice' and to therefore hopefully help them to make links with their own teaching experiences. Bullock grasps the opportunities offered by Russell and begins to illustrate how the experiences created for him begin to shape his own practice as he apprehends similar possibilities in his own teaching.

> Tom was adept at not giving 'the right answer' ... instead he would ask more questions ... I now realize that he was avoiding the pitfalls associated with ... 'Answerland' – the near-universal tendency of teachers and students to focus on the pursuit of right answers ... He could have just as easily said 'I disagree because ... ', but instead he asked me questions that required me to look at deeper issues. I have since explored the notion of interpreting experiences in different ways. (Russell & Bullock, 1999, pp. 138–139)

This (quote) may have been a cue to Russell that his modeling of *My Teaching Is The Message* was perhaps being recognized. However, without a sustained and thoughtful study of his practice and his students' learning, he would surely only be interpreting, or assuming, that what he was attempting to portray was being apprehended by his students. The importance of genuine involvement and collaboration with students in S-STEP is further underlined when Bullock goes on to write,

> ... 'How we teach is the message'. It is a concept I have taken very much to heart. If I want students to construct an understanding of the world around them, I must create an environment rich in experience. Through questioning, Tom helped me create links between various ideas and philosophies that I was discovering ... and [I was] seeing independently. ... [that I had a] concern about students being active learners as opposed to 'theory sponges'. (Russell & Bullock, p. 140)

The data in this study is rich and strong and together teacher and student examine their learning about teaching and how they came to better understand their teaching and their students' responses to their teaching. They highlight

how developing new and powerful perspectives on practice is intensive and time consuming, but they also make a plea that in sharing their experiences of their research it might help others, "… to take similar risks to overcome the invisible and private nature of most teaching and thinking about teaching" (p. 150).

There are many equally powerful S-STEP reports that include similar attitudes and approaches to including students' perspectives (Freese, 1999; Hoban, 1997; Hutchinson, 1998; LaBoskey, 1997; Nicol, 1997). However, one issue fundamental to all of these studies is that the students are at least as important to the study as the teacher educator. Hence the question is not the usual, "Should students be included in this study?" more so the question is, "How can I include students in ways that will help me (and them) learn more through this study?"

Clearly, students of teaching are the best placed to be critical judges of the day to day experiences 'dished up' in teacher preparation programs. Consequently, students' interpretations, acceptance or rejection of such experiences inevitably influences their personal and collective understandings of the complexity of teaching and learning. And how appropriate, helpful and applicable their own learning about teaching might be to their subsequent practice as teachers, an issue surely at the heart of teacher education. If students of teaching are offered opportunities to be collaborators and sources of feedback in self-study, then their learning might also be enhanced so that they similarly question, and learn through their own experience of practice. Therefore by acknowledging the involvement of students in self-studies, there is a greater likelihood that these students will also be positively influenced in their experiences of teaching and learning – thus enhancing the likelihood of educational change in their own post-teacher education teaching that has long been highly sought and consistently called for in the teacher change and learning literature, yet so rarely achieved (see for example, Cochran-Smith & Lytle, 1999; Fullan, 1993, 1995, 1999; Fullan & Hargreaves, 1992; Wilson & Berne, 1999). This work of self-study, however, demands confidence as such work is risky business.

Self-confidence and Vulnerability

The sixth aspect pertains to the self-confidence that is so important in conducting a self-study and relates to the need to be comfortable with the sense of vulnerability necessary to genuinely study personal conflicts and the sense of dissonance that is so often the driver for self-study as a professionally rewarding experience. Berry (see section 4 of this Handbook) outlines a number of tensions that she sees as crucial (cognitively and affectively) in influencing the nature of self-study.

In choosing to examine any of these tensions as a focus for one's own research there is an implicit expectation that a real sense of self-confidence would be necessary in order to carry through with the personally challenging and confronting aspects of so doing for the differences between the personal images of one's beliefs and the public images of one's practice must highlight discrepancies. This issue was studied in detail by Kelchtermans (1996) when researching teacher vulnerability whereby he came to articulate the nature of such discrepancies in

terms of two, "interwoven domains: the professional self (a teacher's conceptions about her/himself as a teacher) and the subjective educational theory (the personal system of a teacher's knowledge and beliefs about teaching) ... [and he noted that] teachers' sense of vulnerability [emerge through critical incidents] ... and always provoke emotions of distress, unease, doubt and uncertainty" (p. 308). This makes clear the need for self-confidence to accompany exposing such vulnerability.

For example, there is little doubt that attempting to better understand how one manages the tension of, "making explicit the complexities and messiness of teaching and helping student teachers feel confident to proceed" could call into question one's perceived 'expert status' as a teacher of teachers, consequently any such investigation would inevitably expose one's own shortcomings, doubts and concerns; an obvious invitation to be confronted by one's own vulnerability (cf. Berry & Loughran, In Press). The demand that self-study requires self-confidence and unmasks vulnerability is also explained by Hamilton and Pinnegar (2000) through the notion of trustworthiness and the critical role the self-study plays in illuminating this perspective:

> Basing a teacher education program on trustworthiness has two main problems. The first between the teacher educator and the future teacher and has to do with our students' perceptions of us. The second resides in our own integrity ... The larger problem for using trustworthiness as the basis for teacher education lies not in the misjudgment our students might make of us (as their teachers, we already have that vulnerability); more importantly, it is the judgment we must make of ourselves. As teacher educators, are we willing to act with complete integrity? Are we willing to be trustworthy? (Hamilton & Pinnegar, 2000, p. 238)

In paying careful attention to the development of self-confidence and ensuring that being vulnerable is not a 'destructive' action, there is also a need to respond appropriately to the learning from self-study as it unfolds. This leads to the seventh aspect.

The Outcomes of Self-study Demand Immediate Action

A common aspect of researching teaching about teaching for teacher educators is that new findings and teaching become interwoven (similar to that noted by Baumann (1996) when he was considering the situation for teacher researchers). In teaching there is a sense of the need to act immediately on new possibilities and to adjust one's teaching in accord with these possibilities. The research focus therefore alters and, as adjustments are made, new insights and possibilities emerge. Hence the intertwining of teaching and researching is such that as one alters so does the other, so the traditional notion of research whereby *holding the problem in place while it is researched* is not so straightforward in self-study. In researching teaching, the problem under investigation develops, shifts and changes in response to the continual shifts in the teaching.

This means that one outcome of teacher educators researching their own practice is that they commonly design and implement new approaches – classroom interventions that are intended to achieve change. These are not always successful, and may be 'failures'[2] especially when first tried. An emerging difficulty for teachers then is that, unlike traditional researchers, they have to deal with the consequences of their interventions as part of their daily routine with their class(es). Negative consequences can affect a class for the remainder of the program/course and that is also a matter of concern for teachers concerned with the teaching and learning environment in which they and their students collaborate. This means that research can be a high-risk activity for teachers and can therefore significantly affect their primary role as a teacher and illustrates again why self-confidence and vulnerability impact on self-studies.

Jeppesen (2002) illustrates this point well through her efforts to encourage students to use linking as a learning strategy. Mid-way through her teacher-research project she responded to a particular learning situation (see vignette, overloading students with all this thinking, Jeppesen, 2002, pp. 108–111) in a manner that forced her to be confronted by the consequences of her actions. In this case, her research focus led her to make dramatic (and instantaneous) changes in her teaching practice that rebounded on her research in ways not common in more traditional studies of researching teaching. Being the teacher and the researcher meant that actions in either domain demanded immediate attention and response. This leads to the next important feature of self-study and it is one that hinges on a subtle but crucial differentiation between reflection and self-study.

There are Differences between Self-study and Reflection on Practice

> Self-study builds on reflection as the study begins to reshape not just the nature of the reflective processes but also the situation in which these processes are occurring … reflection is a personal process … self-study takes these processes and makes them public, thus leading to another set of processes that need to reside outside the individual. (Loughran & Northfield, 1998, p. 15)

At the heart of both reflection and self-study is the 'problem' that initiates the investigation. Yet, problem in this case is not a negative term, it is, as explained in the next section, linked to the notion of a curious or puzzling situation or dilemma, tension, issue or concern. It is something that causes one to stop and pay more careful attention to a given situation.

Reflection is a thoughtful process, but it is something that largely resides within the individual. Reflection may be indicative of a way in which a teacher might learn and develop professionally, however, self-study pushes the virtues of reflection further. It may build on the work of reflection; it may be an extension of this reflective approach and/or attitude to learning about practice, because self-study demands that the knowledge and understanding derived be communicated (and as has become clear in the literature, this occurs in a variety of ways),

so that it might be challenged, extended, transformed and translated by others. And, this is due to the fact that a defining feature of self-study is that it is available for such public critique and dissemination, rather than solely residing in the mind of an individual. The next aspect is one that develops as a result of the focus of self-study and sits comfortably within the 'researching practice' traditions.

Dilemmas, Tensions and Disappointments Tend to Dominate Data Gathering in Self-study

As experienced teacher researchers have consistently noted (see for example Boyle, 2002; Berry & Milroy, 2002; Mitchell, 2002; Mitchell & Mitchell, 1997), it is not so much "that which works well" that attracts the researcher's attention as that which does not work as anticipated. Hence, "successes tend to be glossed over in an almost 'to be expected' fashion as the mind focuses on the unexpected and the unexplained … constant attention to apparent 'failures' is demanding and somewhat unrepresentative of the total situation being experienced" (Loughran & Northfield, 1998, p. 15).

The normally helpful notion of the "research question" might, in many self-studies, be better described as a dilemma, contradiction or tension derived from or created through particular approaches or expectations of practice. In some instances these dilemmas, tensions or contradictions might be framed in terms of the Whitehead (1993) questions, "How do I help my students to learn better" or "When/why am I being a living contradiction". As such, self-study may be an attempt to better understand how to manage the dilemma (as a dilemma itself is something that is continually problematic), rather than a search for *the correct* response to a specific question.

This way of viewing the problem is similar to that described by Shulman (1992) and Mitchell and Mitchell (1997) in their extensive work in the development of cases. Their studies highlight how the nature of *what it is that is being investigated* is qualitatively different when the practitioner defines the problem rather than the problem being introduced/imposed by an external observer whose own work is at a distance from the practitioner.

This point is illustrated well by Clandinnin (1995) whereby her dilemma centered on coming to recognize and understand her story of, and therefore consequent approach to, becoming a teacher educator.

> As a student in my teacher education class, I was a student character in what we call the sacred theory-practice story. I was there to be filled with theory that I could then apply to my teaching practice … my unnamed dilemma, however, was that I knew I needed to be judged as adequate … by the university teachers. So even as I recognized the inauthentic nature of the sacred story, I needed to live and tell a 'cover story' that would convince my university teachers that I both knew enough theory and could apply it well enough in practice. … Dissatisfied and uncertain about the constraints of what I can now name as the sacred story, the alternative

[teacher education] program offered new possibilities [as] … we attempted
to live out a new plot line, one that would be a competing story to the plot
line of the sacred story. (Clandinnin, 1995, pp. 28–29)

Through being dissatisfied Clandinnin came to frame that which created/encouraged this sense of unease or discomfort. And, because teacher educators commonly focus on the big picture in teaching and learning situations, examination of a dilemma or contradiction in practice carries with it different expectations and demands to traditional research. Therefore, investigating features of being a living contradiction and seeking to better understand the complexity of teaching and learning influence self-study in ways that a more traditional approach to the research question may not so readily encapsulate. This is not to denigrate a more traditional approach but rather to highlight that recognizing the difference has as much to do with what is being studied as it has with the purpose for that study; examining a tension, dilemma or contradiction then leads to a different form of research question and different conceptualization of a research program.

One way of considering this element of self-study is through the work of Bullough (1997). He offers rich detail in explaining the factors that have shaped his development as a teacher educator as he grapples with the question, "Why do I teach teachers as I do?" He explains how his principles of practice have been influenced, "Through seeking an active conversation between private and public theory, played out in my classroom, I have come to behold teacher education more richly and more fully, albeit still only partially" (p. 20). Therefore an answer for Bullough is not confined to the question, "Why do I teach teachers as I do?" Rather, his answer is enmeshed in his ways of examining his practice and his students' learning as well as in ways that foster a recognition of his framework of principles of practice largely derived from seeking to develop an understanding of the big picture of his practice.

In his discerning overview of his own practice, Bullough does not appear to seek solutions to his questions, rather he hopes to explore them with his students so that such examination might shed light on how his principles of practice are enacted – as they are continually being tested and challenged in their teaching and learning situations. This approach could well be described as an ongoing filter for instances of being a living contradiction, and importantly, is an illustration of a search for meaning rather than a search for a solution to a given problem (Bullough & Gitlin's (1995, 2001) collaborative work illustrates how these ideas can also be pursued to shape teacher preparation programs more generally).

The final aspect that appears crucial in influencing the nature of self-study is the audience for whom the report is intended.

The Importance of the Audience in Shaping the Nature of Self-study Reports

There is little doubt that, "If self-study is to move beyond the individual, it needs to resonate with others in similar situations. Therefore, the way self-study is

reported is important in helping to make the findings clear and meaningful to others" (Loughran & Northfield, 1998, pp. 15–16).

There have been ongoing calls for the evidence on which the assertions, knowledge and conclusions from self-studies are based to be to the fore in S-STEP reports (Whitehead, 1994, 1995; Munby & Russell, 1995; Allender & Whitehead, 2000) and what the call for evidence generally highlights is the diverse nature of the data used in self-studies. For some, this has created tension; for others, it has been liberating in opening their eyes to what counts as data and how such data might be reported. Much of the argument about evidence is embodied in questioning, "Who is the self-study for and what is the intended audience for the report?" In viewing the argument this way, Barnes (1998) in reviewing the first CASTLE conference noted:

> On the one hand, there was reflective investigation of one's own teaching, often highly informal. On the other, was a version of self-study that approached formal research with all the priorities and concerns that implies. The difference appeared to be related to the different audiences to whom the self-study was to be addressed. When the reflective investigation of a course was solely intended to enlighten those who were teaching it, there could be an emphasis upon openness. ... Such studies could be systematic and based upon collected material. Since everyone concerned had been involved in its collection and interpretation, its validity could be assumed ... in contrast ... once self-study becomes public, once it is involved with the micro-politics of status and power in academia, then the validity of its methods, its evidence and its interpretive arguments become extremely important ... [those] papers that fell into this category were profoundly concerned with validity and persuasiveness and the standing of their studies in the institutions where they worked. (Barnes, 1998, p. x)

As Barnes suggests, a self-study designed for oneself (e.g., Hamilton, 1995; Pinnegar, 1995) will carry different expectations of evidence and acceptability of data, than will a self-study intended for teacher educators considering their teaching approaches together (e.g., Schuck & Segal, 2000; LaBoskey & Henderson, 2000; Louie *et al*., 2000) or indeed a self-study that focuses on an educational institution and its practices (Myers, 1995, 2000; Russell, 2000). However, it may not be so much that the need for the type of data changes with the expectations of the study, but, that although a diversity of data are always available, the relative importance of some data is highlighted over others in particular settings and for particular audiences.

For example, Mindscapes (Cole, Elijah, Finley, & Knowles, 1994) was a collaborative self-study whereby analysis of data became the basis for the 'script' of the performance that became the public reporting of these participants' learning through self-study. Performance has also been important in reporting self-studies such as those by Austin *et al.* (1996, 1999), Cole and McIntyre (1998), Mitchell and Weber (2000) and Weber and Mitchell (2002). In these cases, the

performance was purposely organized so that the audience would be further engaged in discussion and debate about the nature of the particular self-study. And, it would seem fair to assert, that through performance, that which is being represented offers new ways of accessing thoughts, ideas, actions and feelings in ways that are not possible when they are simply displayed as text on a page. Performance then is an attempt to offer a lived example of the "practice what you preach", or the "walk the talk" expectation central to many self-studies as the form of representation adopted is explicitly chosen in an attempt to better reflect the nature of the study itself. Performance then is an extension of the learning from self-study for both the author(s) and the audience.

The interplay of the inquiry, its value, and form of representation, inevitably impact on whether or not a self-study will speak to those envisaged as its audience. As is the case with all research, the audience is the final arbiter of the integrity of the work and is an increasingly strong determinant in shaping the manner in which self-studies are portrayed for others. Audience is also important in terms of community, whereby many of those involved in S-STEP see themselves as working together to be a positive influence in their field of endeavor – teaching and learning about teaching.

The S-STEP community itself is an important audience and it serves a number of functions. Community offers support in encouraging the examination of the work of teachers and teacher educators while simultaneously creating an informed audience for critique and modeling (Hamilton & Pinnegar, 1998). Through developing an S-STEP community and capitalizing on the collective intellectual assets available, there are immediate opportunities and forums for sharing experiences and developing understanding of self-study.

As has become obvious, and expected, through the CASTLE conferences, this community also offers an environment in which the audience encourages approaches to teaching and learning about teaching through risk-taking as well as honest sharing of teaching and researching successes and failures in teacher education, each of these being pushed further by an explicit call to present reports in new and engaging ways and in ways that are more congruent with the self-study itself. A community also offers valuable support through networking and linking to other teachers, teacher educators and teacher education programs and approaches. This broadens participants' access to, and understanding across, diverse fields of academic endeavor.

Finally, community also offers extensive possibilities for mentoring and modeling that can help with one issue that has often created confusion, anxiety, tension and distress in the academy – tenure and the challenge to develop, and have accepted, one's scholarship. This issue was one of the original catalysts for the development of the S-STEP SIG and the community that has subsequently developed has done so in ways that purposefully attempt to move beyond the sometimes singular, isolated and unduly competitive nature of academia by placing a high priority on people.

Overview

Generally then, self-studies of teaching and teacher education practices tend to be recognized more by the manner in which they respond to these features and the underlying purpose which initiates the study, rather than by a particular method or context, despite the fact that an early contentious issue surrounding S-STEP was related to method. However, as has become increasingly clear, questions pertaining to method might equally be asked of any form of research so that answering questions such as: "Does the method employed actually help to shed light on the problem being examined?" and "Is the method used able to uncover data that is valid and convincing for others?", is, in terms of method, what matters most. It is then perhaps more helpful to consider questions related to "the method of self-study" in terms of Cole and Knowles' (1996) expectation that concrete and public ways of sharing self-studies must be employed in order that such research will be accessible and transparent to others; how that happens is a matter of academic choice.

Conclusion

Feiman-Nemser and Floden (1986) highlighted the importance of the individual or the 'self' in research on practice and the shift in the research focus (over the previous two decades) from studying teaching at a distance to trying to understand how teachers defined their own work. This shift in focus, they argued, was important because the knowledge of teachers (which is largely untapped) is an important source of insights for the improvement of teaching. The same clearly applies to self-study, as the knowledge that might be made available through such research is of immediate importance in informing other educationalists not only about teaching, but also teaching about teaching and, learning about teaching.

   As this focus on those involved in teaching has intensified, so too has the growing interest in self-study as the participants in teaching and teacher education have espoused their desire to do more than just deliver a subject, course or program. Self-study then is an academic activity that is responsive to these individuals' desire to better understand the nature of teaching and teaching about teaching and in so doing, improve the quality of teacher education. Self-study of teacher education practices can be perceived as offering both an invitation and a challenge for teachers and teacher educators. The invitation involves using self-study to better understand one's own practice and, from the learning through this, to influence the very nature of teaching and teacher education programs. The challenge is for self-study to demonstrate rigorous, valid and meaningful responses to this invitation that enhance our understanding of the complex worlds of teaching and teacher education. Zeichner (1999) showed little doubt about his view of the response to this challenge when he noted that:

   Contrary to the frequent image of the writings of teacher educators in the

> wider educational research community as shallow, under-theorized, self-
> promotional, and inconsequential, much of this work has provided a deep
> and critical look at practices and structures in teacher education. ... This
> disciplined and systematic inquiry into one's own teaching practice provides
> a model for prospective teachers of the kind of inquiry that more and more
> teacher educators are hoping their students employ. (Zeichner, 1999, p. 11)

Self-study allows teachers and teacher educators to maintain a focus on their
teaching and their students' learning – both high priorities. At the same time,
self-study also offers opportunities to improve teacher education through an
application of the learning about teaching practice. However, just because self-
study may be seductive to many teachers and teacher educators there is no
suggestion that the nature of such work should be unquestioningly accepted.
There is a constant need to examine what is being done, how and why, in order
to further our understanding of the field and to foster development in critical
and useful ways so that the learning through self-study might be informative,
accessible and useable for others.

In teaching and teacher education, for numerous reasons, there has been a
long history of research that has had little influence on practice. One reason
often cited by teachers themselves is that much of the research from the 'Ivory
Tower' has little to say to them as the end users of such research. However,
when these 'end users' of research shape the focus of inquiry and, conduct the
inquiry, then research has an immediate value to them.

As I trust this chapter has made clear, for those involved in self-study, the
focus of such study matters and, the subsequent research is inevitably directly
applicable and valuable in their work – otherwise there would be little point in
pursuing it. Through an exploration of the context and history of self-study the
hope is that it will be informative, useful and applicable to those who might
also be encouraged to 'make a difference' in teaching and teacher education.

Notes

1. An example of the type of work that was a precursor to the formalization of S-STEP is that of
   Diane Holt-Reynolds. One of her papers (published in AERJ in 1992 and reprinted with permis-
   sion as an appendix at the end of section one of this Handbook) highlights the types of issues,
   concerns and research in teaching and learning about teaching that were influential in shaping a
   growing understanding of the need and value of self-study. Diane was a founding member of
   S-STEP whose work was particularly influential in the field of personal history, beliefs and
   practices in teaching about teaching.
2. Failure in this case refers to the fact that what was being implemented did not work 'as planned'.
   In light of the development of understanding of teaching through risk taking and learning from
   experience, failure is in fact an aid to the learning and understanding of pedagogy so that as
   Dewey (1933) describes it, "... failure is not mere failure. It is instructive" (p. 114). Therefore,
   failure is an important learning event in teacher research.

THE NATURE OF TEACHING AND LEARNING IN SELF-STUDY*

Anthony Clarke and Gaalen Erickson
University of British Columbia

Abstract

Understanding the relationship between teaching and learning is essential to an appreciation of self-study as a field of inquiry in its own right. The individual research trajectories in the fields of teaching and learning, particularly in recent years, illustrate sufficient common ground to support the contention that enhanced teaching practice is dependent upon teachers problematizing the ways and contexts in which they learn and make sense of that practice. While this shift, and its current recognition within the academy, is cause for celebration, we suggest that teachers' problematizing their practice is a not new phenomenon. Indeed, we argue that Schwab was only partly correct when he characterized teaching as having four commonplaces. We contend that self-study is, and always has been, the fifth commonplace and, as such, is the cornerstone of professional practice. Without self-study teaching becomes repetitive not reflective – merely the duplication of models and strategies learned elsewhere and brought to bear unproblematically in one's own classroom. Tracing the interconnectedness between teaching, learning, and self-study is instructive for appreciating how inquiry is construed, defined, and enacted within the profession.

For much of our professional careers we have been directly involved in teacher education and the preparation of beginning teachers in our Bachelor of Education program. In 1997 our increasing dissatisfaction with both the existing teacher education program at our institution and our existing practices within that program led us to establish an experimental teacher education cohort for our one-year after-degree elementary students. This experiment, which continues

today, sought to overcome the most significant challenge we faced as teacher educators: fragmentation. While we were able to identify many areas of the existing program that suffered from fragmentation, there were two areas in particular that constrained the nature of teaching and learning for student teachers and instructors: the fragmentation between the ten on-campus courses that students are required to undertake and the fragmentation between the on-campus and the practica components of our one-year B.Ed. program.

As a focus for the cohort, we chose the concepts of community and inquiry and these are reflected in the cohort name: Community and Inquiry for Teacher Education (CITE). In addition to making some fundamental changes to the administrative and instructional dimensions for framing the cohort, we added a third dimension, inquiry (or research if you like). We believed that not only was it important for our students to be active inquirers into their evolving practices as teachers but also for us to be active inquirers into our own practices as teacher educators. We believed it was essential that research be an explicit part of the way we framed the cohort as our previous experience had demonstrated that too often teacher educators in pre-service programs become buried under administrative demands and programmatic details that limit any substantive engagement in the assumptions and approaches to education that give meaning to their work. By nominating inquiry as an essential element of our participation in CITE, we signaled our intention to not only model a key focus of the cohort but also live that focus as educators within the CITE community.

Since the inception of CITE, the instructors, in concert with the student teachers, have generated over 30 different research publications and presentations at local, national, and international forums on education. Our investigations have, among other things, explored issues such as creating and sustaining community (e.g., Erickson & Clarke, 2001; Erickson, Darling, Clarke, & Mitchell, in press; Farr Darling, 2000, 2001), technology and teacher education (e.g., Clarke & Mitchell, 2001; Erickson, 1999; Mitchell, in press; Mitchell & Wakefield, 2001), student teacher identity (Farr Darling, 2000; Clarke & Kelleher, 1999), researching practice (Korteweg & Mitchell, 2001), and school/university partnerships (Clarke, 2002; Mitchell, Wakefield & Nishi, 1999; Mitchell, Williams, & Panteleo, 1999). These explorations continue today with the outcomes guiding reform efforts across the broader teacher education program at our institution.

While the substance of the above explorations is not the focus of this chapter, they provide the backdrop and the impetus for the way in which we have framed this chapter. Although we characterize the above inquiries as research, in the early days of our work within CITE we did not appreciate nor consciously think about our investigations as self-study. However, we were engaged in self-study, and like our colleagues in other institutions at that time who were pursuing similar work, we lacked the language of the self-study genre and a community of self-study practitioners that in more recent times has enabled a coherence to emerge around the defining features of self-study in education.

In this chapter we, and the authors in succeeding chapters, will explore these features but before embarking upon that journey we are reminded of Mishler's

(1979) provocative title for his seminal article "Meaning in context: Is there any other kind?" In an attempt to contextualize self-study, and to appreciate the significance of its development in education in recent years, the task we have set ourselves in this chapter is addressing three questions essential to the nature and substance of such inquiries in teaching and teacher education: What is learning?; What is teaching?; and, What is inquiry? In responding to these questions, we place self-study within the broader context of educational practice and at the same time provide some parameters under which such studies are currently undertaken.

What is Learning? Who is the Learner?

These two deceptively simple questions are in many respects at the heart of most of our educational endeavours. Whether we are dealing with pupil learning or adult learning, becoming clearer about what we mean by saying that 'someone has learned something' and providing an account of 'how someone learns something' remains an important aim of educational inquiry in general. This claim is reminiscent of Schwab's (1969) analysis of the four commonplaces of teaching – the learner, the teacher, the subject matter and the milieu. We will return to Schwab's frame later in our chapter. Further, we will argue, as others have before us, that learning is central to many of the issues facing those engaged in the practices of self-study. For example, Barnes's (1998) statement that, "… good teaching is a form of learning" (p. xii) and McNiff's (1993) book title, "Teaching as Learning" illustrate this tight coupling between teaching and learning. Our answers, as an educational community, to questions about the nature of the learning process have changed considerably over the past fifty years as we have shifted from a predominantly behaviourist model of learning to more cognivist and phenomenological models. In fact, there is a much greater diversity of perspectives on learning now than fifty years ago with respect to the preferred ways of thinking about and studying these questions. A review of key changes related to the issues addressed here will be pursued later in this chapter. However, it is not our intent to provide an in-depth analysis of these changes in learning perspectives, as others have undertaken this task very capably in book-length analyses (e.g., Davis, Sumara, & Luce-Kapler, 2000; Hoban, 2002). Our purposes in this chapter are much more modest – we wish to provide an overview and bring some clarity to those issues related to the nature of learning and of the learner that are germane to the field of self-study of teaching and learning practices.

Some Distinctions: Who is the Learner?

We begin by making some distinctions that are based in part upon the extensive literature in the field of learning and in part upon our own agenda and preferred analysis of these issues. Our first such general distinction is revealed by choosing to address the question of 'Who is the Learner?' The very act of posing this

question suggests that there is some conceptual clarity to be gained by distinguishing between different types of learners, particularly because self-study projects most often entail an analysis of one's own learning as an educator and/or the learning of our students. In addition to individual learning agendas, there are also accounts of group or collaborative learning (LaBoskey, Davies-Samway, & Garcia, 1998; Lomax, Evans, & Parker, 1998; Loughran & Northfield, 1996, 1998; Tidwell & Heston, 1998).

There are fairly distinct literatures on 'student as learner' and 'teacher as learner'. An early bifurcation of this literature was based upon a movement in the adult learning literature wherein a strong case was made for distinguishing between adult learners and younger children and adolescent learners. In fact, the term andragogy was introduced to the educational literature by Knowles (1970) as a counterpart to pedagogy in an effort to establish a separate field of inquiry into the nature and conditions for promoting adult learning. He proposed that five basic issues needed to be considered and addressed in establishing formal learning environments for adults:

- letting learners know why something is important to learn;
- showing learners how to direct themselves through information;
- relating the topic to the learners' experiences;
- people will not learn until they are ready and motivated to learn; and,
- people must be helped to overcome inhibitions, behaviors, and beliefs about learning.

Although many subsequent writers claimed that andragogy represented an approach to adult learning that was distinctly different from younger learners, that claim was disputed by others in the field and even Knowles himself admitted that four of the five conditions for learning, outlined above, applied equally well to children, with the primary difference being that children have fewer experiences to draw upon – the third issue above (see http://www.learnativity.com/andragogy.html).We think these learning conditions represent a very structured and formalized organization of the learning environment with a strong distinction between the roles of the teacher and the learner where the teacher is taking most of the responsibility for the learning. As such, teacher-centred (versus student-centred) learning is predominant in each of the five issues considered by Knowles. Although this perspective is somewhat surprising coming from an adult educator, given that the more recent emphasis in adult education has been on self-directed learning (Candy, 1991), it is likely consistent with the overall perspective on establishing formal learning environments that were prevalent at that time.

How do We Best Think About Learning?

Since Knowles first introduced this distinction between adult and younger learners close to thirty years ago, we have gradually seen a convergence in the dominant learning theories that inform both the adult education and the student

learning literatures with a significant shift towards more cognitivist and phenom-enological models, particularly at the level of analysis of examining the under-lying conditions that influence and promote learning (Candy, 1991; Pratt, 1998). We are encouraged by this shift in the adult education literature on learning and we think that it would be a worthwhile development if there were to be more interaction between the community of adult educators and the self-study community of educators.

While we are aware of the many variants of cognitive-based learning theories, the dominant family name that has gained general acceptance is that of con-structivism and we are now seeing its strong influence in both the 'student as learner' and 'teacher as learner' literatures (e.g., Candy, 1991; Cobb, 1994; Cobb & Bowers, 1999; Hoban, 2002; Richardson, 1997; Schoenfeld, 1999; Davis & Sumara, in press). One of the upshots of this convergence is a general agreement that most claims about learning are largely dependent upon the context of the learning environment. In other words, the search for universal type laws of learning, which apply equally well to all contexts, has been largely abandoned. Hence, many of the more recent accounts of learning recognize the inherent situated and contextually-bound nature of learning and are described in terms such as situated cognition, social constructivism, phenomenography and, com-plexity theory (Brown, Collins, & Duguid, 1989; Brown & Duguid, 2000; Davis *et al.*, 2000; Hoban, 2002; Marton & Booth, 1997; Wenger, 1998). It is this inherent situatedness of learning, or what Spillane, Reiser and Reimer (2002) call "situativity theory" (p. 412), that makes the self-study of the learning prac-tices of ourselves and our students so germane to both contemporary theoretical perspectives on learning and to the improvement of teaching practices.

This shift in learning perspectives towards a greater recognition of the complex interplay of personal factors and social learning conditions, which transcends the study of a single individual learning a specific concept, leads us to another of the dominant distinctions that we wish to consider. In other words, the notion that learning is described in terms of an individual constructing personal meaning in relation to their interactions and experiences with phenomena has been challenged by a description of learning as a social phenomenon resulting from the multi-faceted interactions between an individual and a complex set of social and cultural forces. Bruner's work on learning and cognition spanning over fifty years represents a very interesting representation of this shift from a focus on the individual learner constructing new ideas and hypotheses based upon their existing cognitive structure (Bruner, Goodnow, & Austin, 1956; Bruner, 1960, 1966) to a research program on learning that is predominantly socio-cultural in its emphasis (Bruner, 1986, 1990, 1996). His current focus might best be summa-rized as, "The study of situated learning in pursuit of particular goals in a particular cultural setting constrained by biological limits is the stuff not only of good policy research but good psychological science" (Bruner, 1996, p. 173).

A forum for the expression of this tension in the student learning literature occurred in an issue of *Educational Researcher* in 1994 when Cobb drew together a group of three papers devoted to a discussion of the personal and the social

construction of knowledge (Bereiter, 1994; Cobb, 1994; and Driver, Asoko, Leach, Mortimer, & Scott, 1994). At the time Cobb argued that this tension represented two different approaches that are complementary (using a figure and ground metaphor) and the choice of which approach to use ought to be determined by the particular problem of learning that we are trying to understand. Driver *et al.* (1994) expressed the view that, "learning science thus involves being initiated into the ideas and practices of the scientific community and making these ideas and practices meaningful at an individual level" (p. 6); an approach that they described as an enculturation view. This enculturation view of learning is also dominant in the work by Lave and Wenger (Lave & Wenger, 1991; Lave, 1996; Wenger, 1998) and Nespor (1994). While Driver *et al.* were employing this enculturation view of learning to explain student classroom learning, Nespor's work shifted to university students and Lave and Wenger's work was primarily in adult settings. The underlying convergence of the approaches taken to studying learning in these different settings is much greater than the specific differences in the type of learning that was studied in their respective works.

Teacher Learning

The field of teacher learning does not have as long a history as does the literature on student learning. Furthermore it has two main branches – one which is focused primarily on contexts associated with beginning teachers enrolled in teacher preparation programs, sometimes called "The Learning to Teach" literature (Kagan, 1992; Wideen, Mayer-Smith, & Moon, 1998), and another literature that is associated with examining the professional growth of experienced teachers – most often referred to as the "Professional Development" or "Staff Development" literature. Both of these literatures are germane to our concern of examining the nature of learning in 'self-study practices' as the former literature constitutes the practice context in which many teacher educators carry out their own inquiries and the latter context has provided many of the theoretical models for conceptualizing teacher learning. We will elaborate on this point below.

One of the primary tensions in the Learning to Teach literature has been the ongoing debate between whether the nature of learning to teach is best described in terms of developmental stages or in terms of a more "ecological model" (Wideen *et al.*, 1998). The former literature dates back to work done in the sixties and seventies by Francis Fuller and her colleagues as they created a developmental model referred to as a "Concerns-based Model of Teaching" (Fuller, 1969; Fuller & Bown, 1975). Kagan's (1992) interpretation of the learning to teach literature from the 1980's was that the literature provided empirical support for a developmental model, although this conclusion was contested, initially by Grossman (1992) on conceptual and methodological grounds and later by Dunkin (1996) who was critical of the methods used by Kagan in her synthetic review. Wideen *et al.* (1998) also undertook an extensive synthetic review of the learning to teach literature six years later, but arrived at a very

different conclusion than did Kagan. They argued that the complexity of the effects of the many different factors and contexts that characterize most teacher preparation programs are such that a more "ecological model" should be adopted by researchers as they attempt to understand the myriad of different relationships which are operative as individuals gain increasing competency in the social practices of teaching. In many ways this conceptual difference mirrors the differences outlined earlier in the student learning literature between a focus on the individual slowly maturing and developing increased competencies and understanding of their physical and social worlds versus a focus on the various social-cultural factors which shape and socialize individuals into a particular "community of practice" (Wenger, 1998).

If we turn to the extensive literature on learning with regards to experienced teachers we see a number of perspectives and themes that have emerged over the past thirty years. An earlier dominant paradigm for studying both teaching practice and teacher learning might be called 'the teacher thinking' model, wherein researchers attempted to identify and document the thinking processes that teachers were using in their practice (Clark & Peterson, 1986). This was accomplished either through inferential techniques from video and audiotapes of classroom activities or through self-report data gained from interviewing teachers or using techniques such as stimulated recall, where teachers could watch video tapes of themselves teaching and then try to recall or reconstruct what they were thinking at the time (Leinhardt, 1983). A natural extension of this perspective was the "expert – novice" studies (Berliner, 1986; Carter, Sabers, Cushing, Pinnegar, & Berliner, 1987; Leinhardt, 1983a) that emerged in the 1980's where researchers compared the performances and/or reasoning of experienced teachers with those of novices with a view to revealing potential pathways of progress for the novice teachers and to better understand the nature of expertise in teaching. The teacher-thinking paradigm was strongly rooted in the cognitivist camp of learning and clearly was a very individualistic approach to learning. In the early 1980's a number of alternative perspectives on ways of thinking about professional practice and expertise emerged. As was the case in the student learning literature, there was a widespread concern that the approach of trying to articulate the 'mental models' constructed by individuals to account for their understanding and performance was much too simplistic and reductionistic. Furthermore, it did not take into account the very different teaching contexts faced by teachers (cf. Leinhardt, 1990). One response to this discontent was a revival of Dewey and his 'pragmatist approach' to knowledge and teacher thinking (Garrison, 1994; House, 1994). One proponent of this change was Donald Schön and his reworking of Dewey's ideas with his introduction of a series of constructs and terms focusing on "reflective practice" (Schön, 1983, 1987, 1988). While Schön engaged in a variety of case studies in a large number of allied professional fields, a number of teacher educators actively explored the implications of the notions of reflective practice in both the learning to teach context (Clarke, 1995, 1998; Erickson & McKinnon, 1991; Loughran, 1996; McKinnon & Erickson, 1988) and the experienced teacher contexts (Clift,

Houston, & Pugach, 1990; Russell & Munby, 1991). While the work on reflective practice was strongly situated in professional practice settings, nonetheless the analysis of the nature of teacher learning (or as Schön would call it, 'reflection-in-action' and 'reflection-on-action') was still largely undertaken at the individual teacher level. The on-going tensions between the personal and the social, as outlined above, was also present at the height of Schön's popularity in the eighties.

> Accompanying this ambitious program of inquiry into professional knowledge are several caveats. These can perhaps best be described in terms of the tension that exists between those theoretical perspectives which focus primarily upon the personal context versus the social context of knowledge constructions. Schön, in grappling with the problem of how it is that individual practitioners can act competently in an uncertain and complex practice setting, has clearly opted for the former. (Erickson, 1988, p. 204)

Accompanying the move to reflective practice was another largely individualistic approach to understanding the nature of teachers' knowledge, which came to be known as "personal practical knowledge" (Connelly & Clandinin, 1985, 1999) or as "craft knowledge" (Grimmett & McKinnon, 1992). In some important respects this work on personal and craft knowledge, which focused extensively on the use of narratives, teacher stories, and autobiographical methods to explore teachers' understanding of their own practice, was an important precursor to the field of self-study as it exists today. Not only did it provide the field with an important repertoire of methods for describing and analyzing teaching practice, it also provided a rich language, set of conceptual frames, and a rationale for conducting the rich diversity of self-study practices evident in many of the chapters in this handbook and in the existing literature, as discussed in a section below. We will revisit aspects of this brief history within the context of self-study and the politics of knowledge later in the chapter.

Returning to the tension between the personal and the social influences on learning, there have been a number of proposals to create some form of synthetic position to bring these two perspectives together as illustrated by Bruner's more recent writings (1991, 1996) on the relationships between culture and agency, and Cobb's (1994) analysis of a 'figure – ground' relationship between the personal and the social. Salomon (1993) also rejected the separation of the personal and the social as a necessary dichotomy and argued that the best way to conceptualize learning is to think of it as a complex interplay between an individual's personal understandings and the social setting in which she/he is engaged.

> The claim that individuals' representations [or learning] totally account for their intellectual activity is an overstatement as much as is the claim that partnerships with tools or peers totally account for the quality of the process or that the activity itself fully accounts for it. Different factors participate

in the process interactively, although their specific influence may vary under different circumstances. (Salomon, 1993, p. 125)

Similarly Hoban (2002) takes up the challenge to try to bring a synthesizing perspective on teacher learning by opting for what he refers to as "systems thinking approach". He argues that the field of teacher learning has been fragmented as a result of the oscillation of researchers between the personal and social influences with the end result that no consensual and coherent theoretical framework has emerged to orient efforts at planning long-term teacher learning – an outcome he suggests also explains the lack of any systematic educational change in our schools. His response is to argue for a systems-based framework, grounded in complexity theory, that, "incorporates the central tenets of both perspectives by focusing on the relationships between and among personal, social and contextual conditions for teacher learning" (Hoban, 2002, p. 65).

Another comprehensive account of teacher (and student) learning, derived from a complexity perspective, is that offered by Davis, Sumara, and Luce-Kapler (2000). They posit that a complex learning theory involves thinking about learning as potentially occurring in the interplay between and within a series of nested complex systems or subsystems, each having its own integrity, but with no firm boundaries between them. According to Davis *et al.* (2000),

> To understand the phenomenon of personal cognition, one must simultaneously regard the learner as an autonomous agent working to fit in with her or his context, as a component of a larger social order, as a complex collection of dynamic bodily subsystems, and so on. In this way, such popularly held dichotomies as mind/body, self/other, individual/collective, and human/natural are replaced with the assertion that such phenomena are enfolded in and unfold from one another. (p. 73)

In other words, they extend their purview well beyond the relationships of personal vs. social to bring in other biological systems such as bodily subsystems of organs and cells at the micro level and the biosphere at the macro level. They draw upon an evolutionary model to argue that learning occurs at each level of these subsystems through similar processes of adaptation and change. In their words, "At each level, cognition is seen as a complex process of co-evolution – that is, of agents (whether species, societies, social groups, person, or cells) adapting to and affecting one another and their dynamic circumstances. This is not a mechanical process, but a complex choreography" (p. 73).

The preceding has been a necessarily brief tour of some of the significant issues and trends characterizing the teacher and student learning literatures over the past thirty years. For our purposes in this chapter we now must ask whether and how these issues are played out in the field of self-study practices – the issue that we turn to next.

How is Learning Construed in the Self-Study Literature?

Because the field of self-study is still developing it is difficult to articulate its boundaries, not to mention more specific issues like preferred methods, underlying theoretical frameworks and perspectives on learning. While the idea and concept of a self study of some type of practice, or more likely an institution, has been in existence for some time, its emergence as a research approach for studying particular educational practices has been attributed by Bullough and Pinnegar (2001) to the coalescence of a group of teacher educators at the American Educational Research Association (AERA) in 1992. Within the North American context, this forum illustrated a substantive interest by the academy in self-study scholarship. The importance of this turn cannot be underestimated as the potential impact on both teaching and teacher education was palpable for those present, as we were, and for the potential influence upon legitimizing new ways of thinking about, researching, and writing about professional practice.

To be sure other researchers were writing about their own self-studies prior to the establishment of the Self-Study of Teacher Education Practices (S-STEP) special interest group (http://www.ku.edu/~sstep/) at AERA in 1992, but the formation of this group provided a critical community for the deliberation of purposes, methods and theoretical frames which would serve to provide both research exemplars and eventually an academic identity for its constituents. Furthermore, this community was able to create two important forums for their collective writings – the AERA conference itself, where many papers on self-study have been presented over the past 10 years and an accompanying biennial conference called "The Castle Conference", which is held at Herstmonceux Castle in England.

To illustrate the various ways in which issues of learning have been addressed in the self-study literature we have decided to look at selected papers from the first Castle Conference as published in the text "*Reconceptualizing teaching practice: Self-study in teacher education*" (Hamilton, 1998) and the third Castle Conference as assembled in the proceedings "*Exploring myths and legends of teacher education*" (Loughran & Russell, 2000).

While some of these papers explicitly discuss the author's preferred theoretical perspective on learning that they are using in their self-study inquiry, many do not. This is not surprising for several reasons. First, a number of these contributions have a focus not directly related to the author's own learning or their students' learning, rather the articles are devoted to discussing more general issues in the field, such as: clarifying the nature of self-study research; methodological and ethical issues in self study; and, comparative pieces outlining the processes and outcomes of self-study in contrast to other research genres. Second, many papers in this field are experimenting with alternative methods for the representation of their findings such as 'readers theatre', poetry, and other 'arts-based' presentations and hence standard discussions of one's theoretical frame are not a part of the genre. And finally, as Bullough and Pinnegar (2001) indicate, many researchers use narrative and auto-biographical techniques in their case

studies, which often take on the form of story telling as their primary mode of communicating the findings. The use of stories in this manner often results in the telling of an "underlying story" (Schön, 1991), which reveals indications of the theoretical perspectives that are directing the telling of "manifest stories". According to Schön, underlying stories contain, "... fundamental messages or arguments the various authors seek to communicate through the telling of a manifest story. They have a generic, prototypical character, often linked, more or less explicitly, to the author's favored theoretical perspective. An author tends to carry an underlying story around, embodying it now in one manifest story, now in another" (Schön, 1991, p. 346). The challenge for readers is to disembed the "underlying story" or theoretical commitments being used by the authors of these stories.

Let us begin with those articles and papers that explicitly discuss either their own preferred perspective on learning that is guiding their work or include a section on the relationship between self-study and learning. We might well begin with Barnes's (1998) commentary on the first Castle Conference where he openly asserts that "good teaching is a form of learning", which parallels exactly the title of McNiff's (1993) book entitled *Teaching as Learning*. Since one of the purposes of self-study is about improving our teaching, it follows that it is also about improving the learning for both teachers and students. Loughran and Northfield (1998), in developing a framework for self-study practices, explicitly state that self-study should, "lead to genuine reframing (Schön, 1983) of a situation so that learning and understanding through reflection might be enhanced ..." (p. 7). They are clearly signaling the central focus of this relationship between self-study and learning as well as indicating their preference for a theory of learning based on a Schönean or Deweyan notion of personal reflection. Similarly this strong focus on learning was present in their earlier book *Opening the Classroom Door* (Loughran & Northfield, 1996). The explicit use of Dewey's view of learning from experience and/or Schön's notion of reflective practice as a frame for understanding how professionals learn from an on-going reflective analysis of their practice was a common framework used in many of the papers that we examined. This was true for those papers where the discussion of this theoretical frame was quite explicit, such as those listed above and others (Dinkelman, 2000; Goninan, 2000; Kaplan, 2000; Kniskern, 2000) as well as where this frame seemed to be a part of the "underlying story" (Berry & Loughran, 2000; Hutchinson, 1998).

Other self-study authors who explicitly discuss their views on learning include Tidwell and Heston (1998), who provide us with some insight into their own journey from thinking about learning as a form of transmission to taking on more of an 'information processing' view of learning to finally seeing the nature of a constructivist approach to learning (pp. 56–57). In a similar vein, McAndrews (2000) explicitly addressed three learning-related questions: how her understanding of reading and learning theories changed over the course of her inquiry; how to enhance her students' learning and to engage them in thinking more about their learning; and, how best to teach reading from a

constructivist perspective. Typically most authors who acknowledged that they were drawing upon a constructivist perspective of learning left the degree of specification of this perspective at a very general and abstract level, although Tidwell and Heston outlined some of the pedagogical features that followed from their own reframing of this perspective. In their words:

> Much of what [we] now try to do in class is informed by three fundamental beliefs: (1) the value of frustration; (2) the importance of transforming students' understanding; and (3) the need to restructure students' emotional frameworks for learning. (Tidwell & Heston, 1998, p. 58)

In addition to the strong reflective practice orientation to learning in the self-study literature another dominant interpretive frame that is used to provide accounts of learning and/or changes in practice is that of "narrative inquiry" (Clandinin & Connelly, 1991, 1996) and "biography" (Cole & Knowles, 1995; Goodson, 1992). As with the reflective practice frame, some of the papers were very explicit in declaring the purpose and rationale for using this frame to better understand their own positioning and their subsequent learning about their practice from their use of these methods. Oda's (1998), "self-study that explored the effects of my own Asian-American cultural influences on my teacher education classes" (p. 113) is a good example of how Oda used autobiographical work to delve into the importance of themes like "harmony and conflict" in both her own upbringing as well as in her practice as a teacher educator. Similarly, Brown (2000) asks, "How did societal meanings embedded in my own racial identity as an African American woman and racial identities of my European American students inform my course revision and my reexamination of my role as an educator?" (p. 30).

The use of the narrative framework in the self-study literature has taken on many different manifestations in terms of data collection and analysis. Freese, Kosnik and LaBoskey (2000) used e-mail correspondence in their collaborative inquiry into their own understanding of what it means to undertake self-study inquiry. It constituted a type of, "chronicle over time; a record of the realities of three teacher educators' lives; and the ups and downs of self-study" (p. 77). Freidus (2000), on the other hand, drew upon the discourse of teacher focus groups, which she argued comprises a set of narrative practices that enabled them, "to develop a better understanding of self and context, a greater repertoire of instructional strategies, a vision of themselves as a community of learners, and a stronger foundation for working collegially and collaboratively" (p. 84).

Another group of researchers (Labosky & Henderson, 2000; Lyons, 2000; and Mulligan, 2000) have employed narrative methods to elicit understandings from both pre-service and experienced teachers and represented these understandings using portfolios. Johnson, Lewis, Dahl and Prieto (2000) and Pinnegar, Lay, and Dulude, (2000) relied on more conventional story writing as a means of promoting changes in educators' understandings of their practices. Johnson *et al.* (2000), in commenting on the effectiveness of their teacher study groups, claim

that, "... our experiences in teacher study groups have provided evidence that a key to powerful learning and change is learning that affirms a continuous sense of self. We also learned that the patterns we observed occur across all levels of practice, from university to primary classrooms" (p. 121).

From the above claims we can see that there are strong connections, both theoretically and practically, between self-study and learning. Perhaps this linkage was most directly stated by Pereira (2000) when he asserted that, "... mathematics teachers must change the way they learn before they can change the way they teach. They must reconstruct themselves as learners before they can reconstruct themselves as teachers" (p. 205).

In the above sections we have provided a brief sketch of how the contemporary perspectives on learning have evolved over the past fifty years and how some of the earlier tensions and distinctions between a focus on the individual learner has been shifted to more complex, socio-cultural models of learning. In the process we claimed that there has been a gradual dissolving of some of the earlier distinctions between the ages or developmental stages of the learner, while other distinctions have been accentuated such as the importance of situating our understanding of the learning context. Further we argued that the issue of how best to frame and represent learning is one of the dominant issues at the heart of the emergent self-study literature. Thus the above analysis of learning and learners sets the stage for a closer examination of the related concepts of teaching and teachers in the next section.

What is Teaching? Who is the Teacher?

It is important to distinguish between someone who might legitimately claim to be a 'teacher,' and therefore, is 'teaching,' and someone who is involved in 'teacher-like' tasks but for whom the title of 'teacher' and the ascribed practice of 'teaching' are inappropriate (Lanier & Little, 1986). To assist this process we draw on the concept of a 'profession' and, in particular, two features of that concept essential to this discussion: a profession is regarded as an occupation requiring (i) instruction in a specialized field of study; and, (ii) certification (as judged by a regulatory body) prior to practicing in that field (Hoyle, 1995). Specialization implies that a person has advanced knowledge in a particular field of study. Certification implies that a person has demonstrated a satisfactory level of competence within that area of specialization. These features of a profession allow for the construction of definitions for teacher and teaching that avoid the ambiguity noted at the beginning of the paragraph.

Next, we define teaching as the professional practice of engaging learners in the construction of knowledge directly related to a particular area of study. The use of the concept profession here allows for a distinction between those who may legitimately claim to be teaching as opposed to those whose work is similar to teaching but falls into a distinctly different category (e.g., counselors, mentors, coaches, educational assistants, etc.). We define a teacher as someone for whom

Table 2.1.   Definitions for the terms 'teacher,' 'teaching,' and 'professional practice'

Term	Definition
Teacher	A teacher is someone for whom teaching is a significant part of his or her professional practice and regular (daily/weekly) responsibility.
Teaching	Teaching is a professional practice where a teacher engages learners in the construction of knowledge related to a particular area of study.
Professional Practice	A professional practice is an occupation requiring advanced instruction in a specialized field of study prior to certification by an independent regulatory body.

teaching is a significant part of his or her professional practice and daily responsibility. The inclusion of 'daily responsibility' is to acknowledge that those claiming to be teachers have current and relevant experience in teaching. This is in keeping with the requirement by many regulatory bodies where professional certification requires practitioners to have recent experience in that field (e.g., in many jurisdictions, if one ceases to practice in a particular profession and, at a later point, wishes to re-enter that profession, there is a requirement to undertake additional course work and field experience before re-certification). These are operational definitions intended to facilitate this discussion and are not intended to capture the multiple nuances that a detailed taxonomic treatment would provide (Table 2.1).

The definitions in Table 2.1 provide the boundary conditions that allow us to identify **to whom** and **to what** we are referring when we talk about teachers and teaching. The definitions also remind us that teaching not only refers to elementary or secondary school teachers but also others for whom teaching is a regular part of their professional practice and daily work, such as museum educators, diabetes educators, nurse educators, etc. Thus, the self-study of teaching encompasses a diverse range of pedagogical contexts, all of which have clear public and judicial ramifications for the practitioner.

What is Inquiry? Who is the Inquirer?

The concept of inquiry has long been associated with making a contribution to knowledge in a particular field of study. As such, most forms of inquiry follow clearly delineated methods that govern the nature and substance of a particular investigation. In some instances these methods are highly specific and referred to as 'cannons of inquiry' (Smith, 1983). In other instances, the methods employed are more flexible and responsive to the context of the investigation. Both approaches, and a mix of possibilities that lie between the two, demand a high degree of rigour and extensive public scrutiny to ensure, at minimum, the

validity of any knowledge claims emanating from a particular inquiry (Erickson, 1986; Yin, 1984). The concept of validity, while varying among different fields of study, is something to which one can refer for well established criteria upon which judgments about particular claims in a field can be made.

As education is a multi-dimensional field ranging from large-scale inquiries that inform Ministry policy to single case-studies that explore individual learning difficulties, educational inquiry draws upon an extraordinary number of inquiry methods. Among these methods are the inquiry practices that individuals who investigate their own practice – self-study – draw upon. Self-study inquiries, as Lewison (2003) notes, are,

> A generally agreed upon set of insider research practices that promote teachers taking a close, critical look at their teaching and the academic and social development of their students. … Although known by many names – teacher research, action research, practitioner research, insider research – teacher inquiry involves classroom teachers in a cycle of inquiry, reflection, and action. In this cycle, teachers question common practice, approach problems from new perspectives, consider research and evidence to propose new solutions, implement these solutions, and evaluate the results, starting the cycle anew. (p. 100)

Furthermore, it is important to note that self-study, as articulated above, *is research*. We emphasize the word research to deliberately signal that self-study in teaching and teacher education is a systematic and rigorous process for teachers to explore what they do and how they do it (Cochran-Smith & Lytle, 1993). The word research here is consistent with the type of activities that Hargreaves (2000) uses to delineate between the pre-professional and professional phases in the history of teaching. In the professional phases, characterized by a recognition of complexity and uncertainty, Hargreaves argues that now more than ever, it is imperative for teachers to engage in systematic and sustained inquiry that, "lifts teachers out of the pre-professional prejudice that only practice makes perfect" (p. 167). Failure to do this, Hargreaves cautions, will result in deprofessionalization forces wresting control of curricula and pedagogical practices from teachers (witness recent calls for "centralized curricula, and testing regimes)" (p. 168).

Self-study takes on many forms of inquiry and includes practitioners at all levels of the educational enterprise. Underlying all forms, is the analysis of one's own practice with all the attendant challenges and celebrations associated with such scrutiny. These inquiries represent an active enterprise with outcomes sometimes represented as *teacher knowing* (implying learning that is in a state of evolution) rather than *teacher knowledge* (implying learning that is fixed and stable). The former lies as the centre of new ways of thinking about the scholarship of teaching and has enabled concepts such as 'uncertainty' and 'doubt' to enter the academic lexicon on teaching, which, some argue, allow for more authentic renderings of teaching practice.

Further, it is no coincidence that paralleling the recognition of self-study as a legitimate from of research, is the development of richer and more varied representational forms that capture the essence of these inquiries that were noted earlier; forms that were unheard of in educational research 25 years ago. Indeed, some of these forms, drawing upon new digital tools and media, are extremely difficult to represent in purely textual forms.

Mindful of Cochran-Smyth and Lytle's (1993) admonishment about the dangers of shuttered insularity within self-study communities, we believe it is important to contrast and cross-reference self-study practices, methods, and models. This comparative dimension is particularly important as self-study – largely a case literature – requires peer review, commentary, and critique to ensure robust and defensible forms of inquiry. A crucial aspect of legitimacy is public credibility, that is, negotiating the tension between one's own practice and the more public understandings of that practice. Bullough and Pinnegar (2001) astutely capture this tension in their analysis of self-study researchers and the broader context in which their studies are situated.

> Quality self-study research requires that the researcher negotiate a particularly sensitive balance between biography and history … such study does not focus on the self per se but on the space between self and the practice engaged in. There is always a tension between those two elements, self and the arena of practice, between self in relation to practice and the others who share the practice setting. (Bullough & Pinnegar, 2001, p. 15)

Often the question, "What is the nature of teaching and learning?" has had two different answers depending upon who is the inquirer. For example, in the not too distant past, an emphasis by universities on a particular conception of knowledge – technical rational – was so pervasive that little else other than research conducted by academics informed generally accepted notions of teaching and learning. From this perspective, knowledge about teaching and learning was something externally produced and often at arms length from the classroom teacher. At an appropriate time and place, the 'knowledge' emanating from this research would be 'passed on' to teachers. This issue, taken up more fully in a section that follows on the politics of knowledge had significant consequences for practitioners. McNiff (1993) – an ardent supporter of self-study – notes the pervasive influence of the technical rational view on her own early career as an educator:

> I was a child of the empiric initial and in-service training that cripples the individual … I had fitted my practice into others' forms of thought. I had accepted their claim that knowledge was theirs, not mine, and that I had to perform a certain way in order to acquire knowledge. (p. 3)

However, despite the constraints that McNiff describes, teachers in schools have always enjoyed a status and claim to knowledge (or knowing) that is distinctly within the practitioner domain. This is one reason why enacted curricula in the

classroom are often different from the Ministry mandated curricula. The curriculum in the classroom always bears the mark of teacher knowledge gleaned, examined, and reconstructed through experience at 'the chalk face.' Teachers draw on their own wits, observations, intuitions, and articulation of what it is that they do and how they do it to guide their practice. Often idiosyncratic, rarely documented, and always complicated, this knowledge is the essence of their teaching and bears the imprint of an authentic rendering of the complexities associated with a highly social and inherently situated practice.

Teaching: Professional Practice or Technical Work?

Sachs (1997) argues that inquiry is a hallmark of professional practice but, following Fullan (1993), worries that, at times, teachers become so preoccupied with pupil learning that they often neglect their own learning as professionals:

> One of the hallmarks of being identified externally as a professional is to continue learning throughout a career, deepening knowledge, skill judgment, staying abreast of important developments in the field and experimenting with innovations that promise improvements in practice (Sykes, 1990). Here lies one of the paradoxes for teacher professionalism for as Fullan (1993) notes, as a profession, we are not a learning profession. While student learning is a goal, often the continuing learning of teachers is overlooked. While continuous learning and the improvement of our practice should be at the core of teacher professionalism in many instances this is not so. (Sachs, 1997, p. 7)

We share this concern but believe there is an important distinction between a preoccupation with student learning (which includes class scheduling, record keeping, and report writing) and a preoccupation with how students learn. Schön (1988), among others, argues that the latter is the cornerstone of professional practice. He calls this process "giving kids reason" (p. 19). It is a process whereby teachers are continuously alert to the ways in which learners' actions and words provide glimpses in to the ways in which they construct and make sense of the world. We argue that a focus on how students learn is a necessary precursor to being curious about one's own practice – a defining feature of self-study! Indeed, Schön's conceptualization of reflective transformation is strongly evocative of current self-study practices.

> We can encourage one another to tell stories about experiences that hold elements of surprise, positive or negative. Stories are products of reflection, but we do not usually hold onto them long enough to make them into objects of reflection in their own right. When we get into the habit of recording our stories, we can look at them again, attending to the meanings we have built into them and attending, as well, to our strategies for narrative description. When we can pay attention to the assumptions and ways of

framing experience … [we] can see ourselves as builders of repertoires rather than accumulators of procedures and methods. (Schön, 1988, p. 26)

When inquiry is reframed in terms of 'how students learn,' then it becomes embedded in practice and teacher learning is a natural (even unavoidable) outcome. Without inquiry, one's teaching practice becomes perfunctory and routinized. We argue that when teachers cease to be inquisitive about their practice – inquisitive about how students learn – then their practice ceases to be professional. This is an important distinction for us since inquiry is a defining feature of professional practice that distinguishes it from labour or technical work.

As the authors in this handbook amply illustrate, inquiry is embedded in professional practice. Their accounts demonstrate how self-study is enacted and propositions are developed to enhance daily teaching practice. Their studies are carried out in the, "indeterminate, swampy zones of practice" (Schön, 1987, p. 3) and require the support of colleagues engaged in similar enterprises to sustain on-going and critical engagement of the issues and challenges that such investigations present. These authors' accounts confirm Hamilton and Pinnegar's (1998) observation that, "the multilayered, critically imbued, reality-ladened world is the text of the self-study scholars" (p. 235); an observation no doubt familiar to readers of this handbook but for a long time rarely valued or recognized beyond self-study practitioners.

Self-Study – The Fifth Commonplace

The recent ascent of self-study as a legitimate form of inquiry in the research literature is not due to its sudden adoption by teachers and teacher educators. We argue that self-study has always been an essential element of professional practice. As noted above, the early works of Dewey (1916) around the concept of 'deliberation,' and more recently Schön's (1983) notion of reflection represent attempts to explain how it is that professionals engage in and improve their practice. Others who have provided similar explanations include: Clandinin (1986) – Personal Practical Knowledge, Fenstermacher (1994) – Practical Arguments, and Grimmett and MacKinnon (1992) – Craft Knowledge. Each of these researchers have understood that problematizing and acting upon curiosities, challenges, and surprises, etc., that arise in daily practice constitutes the hallmark of professional practice. Further, Davis, Sumara, and Luce-Kapler (2000) emphasize that it is both the conscious and unconscious elements of professional practice that must be subject to such examination, and that this informs our on-going practice.

As such, we argue that self-study is not a new phenomenon to the world of teaching and teacher education. Indeed, we argue that Schwab was only partly correct when he characterized teaching as having four commonplaces, whereby he noted that for teaching to occur, someone (a teacher) must be teaching someone (a student) about something (a curriculum) at some place and some

time (a milieu) (Schwab, 1978). There is, and always has been a fifth common-place. For teaching to occur, there must be a **some how**, a way for an educator to know, recognize, explore, and act upon his or her practice. For us that **some how** is self-study.

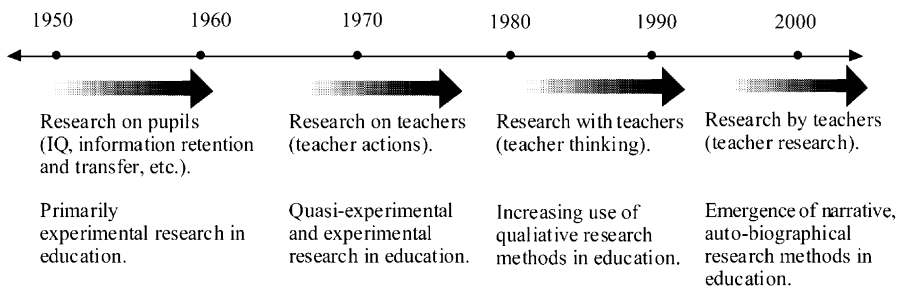
This fifth common place is a cornerstone to professional practice; it is the essence of the teaching and learning dynamic. Without this commonplace teaching becomes repetitive, not reflective – merely the duplication of models and strategies learned elsewhere and brought to bear unproblematically in one's own classroom. Although self-study may not have been recognized as such by researchers over the years, we contend that only through self-study have professionals come to know, problematize, and improve their practice.

Therefore, the emergence of self-study on the landscape of teaching and teacher education literature has more to do with the 'politics of knowledge' as it is played out within the academy rather than its practice by teachers in their daily engagement with learners. This is not a trivial point and bears further scrutiny to fully understand why self-study is suddenly receiving so much attention as this point in time.

Self-Study and the Politics of Knowledge

There have been at least four distinct trends in educational research since the 1950's. Each trend has had a distinct impact on the role played by the academy in recognizing the value of self-study research: research on pupils; research on teachers; research with teachers; and, research by teachers (see Figure 2.1).

The first trend is associated with a behaviorist psychological perspective on student learning (e.g., a focus on I.Q. tests, knowledge retention, knowledge transfer, etc.). Educational research at this point was characterized by attempts to isolate elements of student learning into discrete units for intensive study. Although these studies purportedly contributed to teaching, for the most part their impact on teaching, and to our understanding of the daily practice of teachers and their work with pupils, was not enduring.



| 1950 | 1960 | 1970 | 1980 | 1990 | 2000 |

Research on pupils (IQ, information retention and transfer, etc.).

Research on teachers (teacher actions).

Research with teachers (teacher thinking).

Research by teachers (teacher research).

Primarily experimental research in education.

Quasi-experimental and experimental research in education.

Increasing use of qualiative research methods in education.

Emergence of narrative, auto-biographical research methods in education.

Figure 2.1.   Trends in research that have influenced self-study research in education.

Note: The use of the arrows to depict the four trends are intended to represent the on-going development of each trend rather than one replacing another.

The second trend coincides with a dramatic shift in interest in teaching and learning. Events such as Sputnik in 1957 focused widespread political and public attention on education. For the first time in North America there was a nation-wide effort to research student learning in terms of teacher actions (Erickson, 1986). These efforts were based upon linear causal models that implied that professional practice could be regarded as the field of theoretical application (Connelly & Clandinin, 1986), and further, that the knowledge, skills, and competencies required by teachers could be specified in advance (Zeichner, 1987). Much of the process-product, teacher effectiveness, and teacher competency research is based upon this positivist perspective (Shulman, 1981; Boydell, 1986). Within this trend, researchers assumed that the phenomena they explored were natural and therefore stable, and that under intensive analysis and experimentation these phenomena could yield "scientific generalizations" (Gage, 1980, p. 14). Thus, experimental and quasi-experimental studies dominated educational research during this period. Unfortunately much of the research failed to fulfill the promise that its adherents advocated. Indeed, the long-term contribution to teaching and learning, like that of its predecessor in the 1950s, was limited.

In both the first and second trends, the academy did not recognize teacher knowledge as being very important, and, as such, this attitude constrained early efforts to recognize and validate the inquiries that teachers were engaged in as practitioners working in the immediacy of the action setting (Schön, 1993). The next distinct trend gained momentum just prior to and through the early 1990s. As dissatisfaction with a technical rational approach to teacher education became more widespread, there was a move to explore teacher thinking which required alternative research methods (Houston, Haberman, & Sikula, 1990). For the first time the academy were engaged *with teachers* in research, acknowledging teachers as more than just research subjects. Further, research on teacher thinking required the academy to adopt new relationships and methods of inquiry with teachers. One outcome was that qualitative research methods, such as case study research, became increasingly popular and recognized as legitimate and acceptable forms of inquiry in education. This shift coincided with changing conceptions of learning that encompassed more complex socio-cultural models of learning reviewed earlier.

The mid-1990s saw a further evolution to include research *by teachers*. Evidence of this movement can be found in special theme issues on self-study in main-stream publications, for example Teacher Education Quarterly (Volume 22, number 3), and in the emergence of special interest groups on self-study at public forums, for example, Special Interest Group (SIG) on Self-Study of Teacher Education Practices (S-STEP) at the American Educational Research Association (AERA), noted earlier in this chapter and fully detailed in chapter 1, and the growing interest in the newly formed International Conference on Teacher Research (ICTR). As with the research with teachers movement, the research by teachers movement saw an introduction of inquiry methods that were virtually unknown in educational research 15 years earlier (e.g., autobiography, arts-based research).

Finally, an eclectic approach to understanding teaching and learning incorporating contributions from multiple inquiry modes (not dissimilar to that proposed by Soltis, 1984) is likely to promote rich discussion and vigorous debate essential to informed critique and development of self-study as a mature field of study in its own right.

Conclusions

In this chapter we have argued that there has been a long history in the educational literature that demonstrates the strong coupling between conceptions of teaching and learning. Further, we have claimed that the 'self-study of teaching' movement that has evolved over the past ten years is likewise firmly anchored in this tradition of considering teaching and learning as two sides of the same coin. However, we submitted that the notion of self-study itself was not particularly new, in fact, we posited that it has always been present in the professional practice of teachers as a fifth commonplace – the **some how** of teaching. What is distinctive at this point in time is the legitimacy that self-study has gained within the academy.

The recognition of this dimension of teaching has only received systematic scrutiny and study in recent years as a result of a challenge to the dominant epistemological paradigms in education research and the gradual evolution of alternative genres of educational inquiry. These developments have paved the way for the emergence of a generative space for self-study to develop as a field in its own right, as can be evidenced, not only by some of the claims made in this chapter, but by the very existence of an International Handbook of Self-Study of Teaching and Teacher Education Practices. Nonetheless, the field of self-study is still in its infancy and the development of more complex theoretical and empirical renderings of professional practice have yet to be fully realized in the literature. Some of the more recent efforts to begin to collect together these elements of teachers' professional knowledge – both manifest and underlying, to use Schön's terms – are to be found in edited texts such as Hamilton (1998); Weber and Mitchell (1999); Wells (2001); Loughran, Mitchell and Mitchell (2002); and Clarke and Erickson (2003). However, the most sustained and ambitious effort to date to codify and synthesize much of the literature on self-study practices is this current Handbook. It should serve to provide a welcome guide for those educators based in either school or university settings who are concerned with advancing their understanding of self-study practices and supporting such work in their own educational communities.

SELF-STUDY AS TEACHING*

Deborah Tidwell and Linda Fitzgerald
University of Northern Iowa

Abstract

The title of this chapter reflects an interesting connection between the process of self-study and the process of teaching, the notion that self-study is indeed teaching. With self-study, the teacher – whether in a classroom in a school setting or in a classroom at a university – searches for connections between beliefs and practices with a desire to make positive meaningful change in the learning environment. This chapter makes the case for self-study as teaching. To make this case we use the story of one teacher-researcher, an associate professor of literacy education at a teaching university in the Midwestern United States. She will share her journey into self-study through the spiraling nature of her research focus: self as the evaluator, effective practice process, actions in practice related to beliefs, and the construction of self. Through the story of her journey we will examine the similarities across the cyclical dynamics of research, of reflection, and of teaching.

The Context for the Journey

As an educator, I (Deborah) have long been interested in the connection between actions and reactions, between the assumptions embedded in instructional planning and the interactions of those assumptions within the learning environment. It is not surprising that these interests found connections with the field of action research in the classroom. Lewin (1946, 1952), who is often credited as the originator of action research as a term in English, described action research in cyclical spiraling steps, involving planning, acting, observing and evaluating the results of the action. He overlapped action and reflection in his model, acknowledging the complex nature of social situations where reflection on actions would

---

change actions, which would then lead to a different focus in the reflection, and so on. This intrigued me, this description of a spiraling effect where reflections lead to changed actions that lead to new reflections from a different (more informed) perspective. This spiraling nature made sense to me as a teacher. In my own teaching, I could see where reflection on my teaching (such as the effectiveness of using visuals from a podium in terms of student understanding), led to changes in my actions (moving away from lecture-visual format and using more student discussion and small group interactions) which changed the focus of my future reflections (questioning how dynamic are these student interactions).

Lewin's (1952) tenet that all variables in action research cannot be anticipated up front is realized in the way that action research allows for changes in plans for action as researchers learn from their experiences. This focus on *building* a plan of action over time using experience to inform the plan parallels for me the nature of teaching, where, for example, through experience with a group of learners a teacher's plan of action for instruction is shaped. In self-study, Whitehead (2000) sees the method for studying "I" as a series of action-reflection spirals moving forward toward an understanding. This cyclical reflective process can be seen in teaching as well. The nature of reflection is both over time and instantaneous. The nature of action is constantly changing in terms of what is learned through reflection. Throughout this chapter the dynamics of teaching and of research are seen as spirals of reflective experience that cycle forward engaged by action, informed through reflection, and expanded by change.

Earlier action research studies from the Horace Mann-Lincoln Institute at Teachers College, Columbia University, were based on the notion that teaching and researching were parallel in nature in terms of defining a problem, hypothesizing, testing and generalizing (Horace Mann-Lincoln Study Group, 1948; McFarland & Stansell, 1993). While these studies were often in collaboration with a researcher outside of the classroom context, one of the great values the Institute found was in the teachers working together in groups in their action research efforts. This collegial nature of action research is reflected in self-study.

An integral part of the self-study process is the need to work with a critical friend, a colleague who will provide support and listen, be a sounding board, a critic, an evaluator; whatever role is deemed necessary (McNiff, Lomax, & Whitehead, 1996). This role of the critical friend is instrumental to the rigor and validity of self-study (McNiff *et al.*, 1996). Some in self-study (Boody, East, Fitzgerald, Heston & Iverson, 1998) refer to this role of the critical friend as a collegial voice – less evaluator/expert and more reflective sounding board. In either case, the use of another's voice in self-study is critical to move beyond self to examine practice. This type of research is also about taking chances, being open, exposing one's practice willingly, allowing for both the positive and the negative aspects of practice to be seen and explored. This can be a very daunting experience. But it is through this process of self examination, of collaboration with a critical/collegial friend (or two), that self-study emerges as an experience with the potential to create an informed, entuned, opened *self*, interacting with others in ways that encourage and sustain learning for self and others. The

results of such an experience in self-study about one's beliefs and practices can be long ranging and widespread, affecting more than just the researcher, but also the environment in which the researcher teaches.

This connection between beliefs and practices is a complex dynamic. It is more than just *what I think* or *what I do* in my practice. Beliefs and practices are a compilation of a life of experiences, from contexts early on and ongoing in one's life that shape and create an individual's world understandings. Examining these contexts and experiences provides a backdrop for connections between beliefs and practices. For me, my journey into self-study was born out of my experiences in science, art and education. However, my family was an important and initial influence in my development of world understandings. I came from a family of *doodlers and painters*. My father, a high school mathematics teacher, coach and avid reader, also enjoyed drawing. His mother had been a home-grown artist who enjoyed oil painting. My mother was an avid reader who enjoyed art as well. Her mother, also a home-grown artist, painted with oils. Her brother was a professional artist/cartoonist. Though we did not live close to our extended family, the context of art and reading as *natural* was a part of my environment. Growing up as the middle child of three daughters, I was surrounded with people who read constantly and enjoyed art. This *normalcy* of daily reading and of drawing/painting influenced how I perceived myself.

The sputnik era greatly influenced my academic life. In response to sputnik and the Russian space program, the federal government funded new programs in science and mathematics. The school district, which I attended in the early elementary grades, developed a science/math academic focus for a small group of first-grade children who demonstrated an orientation towards mathematics. I was one of ten children chosen to participate in this program. Beginning in second grade, we were provided special instruction in mathematics and science, with a curriculum that allowed for more problem solving activities and instructional experiences different from those provided to other children in the same grade. The ten of us formed a cadre that went through school together. Intended as a program that would run through our high school years, I left after fifth grade when my family moved thirty miles away to another district. While the focus of this special curriculum was to provide in depth science and mathematics experiences, my strongest memories are of the sense of community I developed being a part of the group of ten. I never felt the program influenced me much in terms of science and mathematics, until I attended university and was asked to declare a major. Without batting an eye I responded, "Science."

Science was not only a logical major for me in general, but geology and the physical sciences were areas in which I had real interest. I liked the order I found in science and mathematics. I also enjoyed art and the performing arts. I participated in theatre at the university and took courses in drawing and painting. And at some point in my sophomore year, I declared an interest in teaching as well. I have often referred to this move toward teaching as my desire to continue in the family business (my father having been a high school teacher). But the truth is, I had always enjoyed working with children. I had been a camp

counselor and a tutor, and always had enjoyed teaching (mostly explaining and demonstrating activities) both in and outside of school.

California's teaching credential is a five-year program. At the time that I was enrolled, the credential program had gone through a major revision. If I wanted to become an elementary classroom teacher, I could either change my major to liberal arts and student teach my fifth year (the credentialing year), or complete my science major early and student teach my fourth year. I chose the latter option. But I was still required to complete a fifth year in order to receive a teaching credential. So, after a full year of student teaching, I took an additional 30 hours of courses to fulfill that fifth year requirement. That meant I could take more or less whatever I wanted, so I took courses in areas that would expand my understanding of teaching (courses highlighting teaching practices and approaches in mathematics, science/social studies, and the fine arts).

As a classroom teacher, I found my teaching often focused in the sciences, mathematics and art. I taught elementary school for eight years in the western United States. And during that time, I was often the designated science teacher for whatever grade level I taught. But I also taught literacy (reading, writing, spelling, grammar), mathematics, and, sometimes, social studies. And across all these subjects I embedded art and opportunities for students to respond through art. In fact, in many of my science, mathematics, and reading/writing activities, I encouraged students to represent what they knew by drawing.

In my sixth year of teaching, a college in the region brought a masters program in elementary education to our district. I signed up for the program mostly as a way to move up the pay scale. But in the process of taking courses, I became intrigued with the area of reading instruction and the process of reflection and reflective practice. During this same time, the district in which I worked offered a summer bilingual education program for migrant children in the area. And though I could not speak Spanish fluently, I was hired for two summers as a teacher for this summer school program. This experience working with children who were English Language Learners in a classroom with an English-speaking teacher and a bilingual translator raised questions for me on the efficacy of programs designed for English Language Learners, and set the stage for my future studies in a doctoral program.

The Journey Into Self-Study

After completing my masters in elementary education, I realized that I needed to know more. The graduate program had whetted my appetite for further study and I moved to Arizona to begin a doctoral program in reading with a minor in bilingual education. The reading program in the university at that time had a strong focus on theory and the science of reading (assessment, evaluation, text analysis). My studies in research at the university focused mainly on quantitative design. Coming from a science background, the order and control that I found in the development of a quantitative design made sense to me. The culmination of a research project into statistical results showing that a treatment was either

significant or not also made sense to me and provided additional support in my understanding of the scientific world. Though I had some instruction in qualitative design, it was through my work in research projects as a research assistant that I began to use qualitative research design and methods. These methods intrigued me, but at the same time, I felt a stronger alliance with quantitative research design that focused on statistical significance over the patterns and dynamics described in qualitative research.

It was during my work on one particular research project (Richardson, Anders, Tidwell, & Lloyd, 1991) that I was introduced to Fenstermacher's (1994) notions of practical argument, reflection through the use of an informed other, and the study of one's own practice through an examination of one's actions, interactions, and reactions. Through this project I had the opportunity to see practical argument used to elicit teachers' beliefs about their practices. In this setting, teachers met with researchers to discuss their videotaped teaching. The researcher's role was that of an informed other, providing prompts and feedback, and acting as a sounding board to teachers' comments about their own practice. It was through the researchers, through their role as the informed other, that teachers' beliefs were elicited. This was my first experience with research that used the notion of a *critical friend* (McNiff *et al.*, 1996). Though the role of the informed other in Fenstermacher's theory is more like an expert providing grounding for, and assistance in, uncovering beliefs, it is that critical ear to the teacher's discussion of practice that is shared with the idea of a critical friend.

Through university research projects I worked with professors and other doctoral research assistants who had very different views of research and very different experiences that led them to their studies at the university. This group of researchers and research assistants challenged me. They talked of reflection and the voice within the teacher. They talked of validating experience through the experience itself. They talked about research in ways that were new to me. In fact, I was not sure they were talking research at all. After all, they were not scientists; they had not come from a science or a mathematics background. Surely their interest in research was limited by their lack of understanding about the scientific method. I often listened to their discussions of the use of observation, description, and constant comparative analyses. The use of context-based information about the nature of classrooms and instruction was exciting. As a teacher I could see the value of examining the context of the classroom in researching the nature of teaching. But at the same time, I believed real research lay in the discovery of quantifiable significance.

I also saw myself as a reading major who came into the field of reading through the side door – through science. I did not have the reading major's more typical background of English and language arts. I believed this was a good thing, as my background in science and math prepared me for the science of reading research. And yet, the context for teaching and for learning, the multi-tasked nature of teaching combined with the multiple variables found in the classroom environment, seemed difficult to express and address in a quantitative design. As my experiences in research projects furthered my understanding of

qualitative design, of anthropological approaches to research, of sociological approaches to classroom dynamics, I began to question my faith in the quintessential scientific research.

The momentum of a science background and of formal graduate studies in quantitative, quasi-experimental design for educational research carried me through a dissertation using a quantitative method to study the effects of an instructional practice. In the dissertation I examined the efficacy of a rereading strategy with elementary grade school readers aged ten and eleven. The students were randomly assigned to one of three groups, a treatment group that learned the target strategy, a treatment group that learned a modified version of the strategy, and a control group. The effectiveness of the strategy was determined through comprehension assessment using established passages and comprehension questions that had been used successfully with those passages in previous research. The design and implementation of the research was well received by the committee evaluating my study. The results showed no significant difference for the target treatment (the rereading strategy) when compared to the modified strategy or to the control group. My interest in studying rereading had come out of three years of working with fourth and fifth grade students at a school where the teachers found this strategy to be very helpful with young readers. The lack of statistical significance surprised me and also raised questions for me about the limits such research design may have in capturing the effectiveness of practice.

As I began my work as an assistant professor, I found that my experiences as a research assistant with qualitative approaches seemed a better match for the kinds of questions I posed as I began my own research agenda. As a teacher, I was more interested in how students were able to think about their practice as they worked in field experiences in the schools. I adapted the practical argument frame (Fenstermacher, 1994) to my work in a reading clinic and began studying the effectiveness of using an informed other with undergraduate and graduate tutors. I was interested in encouraging meaningful discussions among students (discussions that elicited their beliefs about teaching and learning) in order to connect their actions in tutoring with their beliefs. Through discussing what they believed about how reading worked and comparing this to what their actions during teaching represented, my intent was for them to be able to *see* the connection or lack of connection between what they said and what they did. I initially designed this study to see what preservice and in-service teachers were able to do with practical arguments. And, from an instructional standpoint, I saw practical argument as a way to show students the connection between their actions and their beliefs. My intention as a teacher was to be that *informed other* that was the sounding board for students to examine their actions and beliefs. My role as the teacher, then, was that of an outside expert looking in on the context of the students' learning experience.

This connection of beliefs to actions became a focus of my research agenda. I also worked with other colleagues from the university to study elementary classroom teachers' beliefs about their literacy practices in a district that had

embraced whole language. In my research as well as my teaching, I was able to implement the practical argument frame as a tool to elicit preservice and inservice teachers' beliefs. My role as a researcher was that of an informed outsider, an onlooker researching the context and environment of others.

At the same time that I began my assistant professorship, many of my doctoral program colleagues from Arizona were out in the field beginning their professional work at universities as well. Several were involved in a special interest group on Self-Study of Teacher Education Practices (S-STEP), which they had helped form at the American Educational Research Association (AERA). It was through my participation in AERA annual meetings, and meeting with this group of colleagues that I became involved with S-STEP. I was not sure what they meant by self-study. But they encouraged me to pursue my research in self-study and to participate in S-STEP. I was interested in studying my own practice, and thought the kind of work I had been doing with practical argument was a way for me to examine my own practice. I saw practical argument as a tool for researching my practice through my students' discussions, as a reflection of the effectiveness of my own teaching (Tidwell & Heston, 1998). And this is where my understanding of self-study as teaching began, especially within the context of understanding the role of self in self-study. In the following sections, my first four self-studies will be discussed in terms of the spiraling nature of my research foci: self as the evaluator in the discussion of the role of self, effective practice process in the discussion of the role of teacher and the role of learner, actions in practice grounded in philosophical beliefs, and the reconstruction of self.

The Role of Self

The role of self in a self-study project is less about looking at the self than it is about looking at what is going on between self and practice (Bullough & Pinnegar, 2001).

> There is always a tension between those two elements, self and the arena of practice, between self in relation to practice and the others who share the practice setting. Each self-study researcher must negotiate that balance, but it must be a balance – tipping too far toward the self side produces solipsism or a confessional, and tipping too far the other way turns self-study into traditional research. (p. 15)

This balance of self and the arena of practice is an important one. Coming to grips with the understanding of what it means to study self was an evolving one for me as a researcher. My earliest efforts in self-study framed the reliability of the data in terms of outsiders' views of my teaching (Tidwell & Heston, 1998). Through the use of students' practical arguments and my role as the evaluator of those arguments, I examined how my students used practical argument to discuss their actions and the beliefs that stem from those actions. Using the content of their language, and the way in which they were able to connect

reading theory to reading practice, I examined their language and their connections to the content I had been teaching. In this self as evaluator position, my research focused on the question: Did their understanding of concepts being taught come through in their discussions of their rationales for their practice? I was tipping too far to the side of traditional research. From an action research standpoint, I could argue that I was following Lewin's (1946, 1952) frame of planning, acting, observing and evaluating my practice. But the locus of my study was actually others, their understandings and their voice. At that time in my research, I felt comfortable studying my practice through others' voices and perceptions. It gave me a sense of being objective in my research. And, indeed, it was a way to look at the manner in which the content I taught was manifested in my students' language. While this was not a self-study that placed *self* in the center of the research focus, it was a form of action research that answered questions about my own teaching, about my *self as teacher* through the lens of my students. Yet for me, it was a large step away from the science model of research. It made me somewhat uncomfortable to not be able to demonstrate statistical significance. However, I realized the importance of examining the environment of my teaching in a way that could not be quantified. My research in teacher beliefs had used qualitative methods of inquiry to examine patterns in the ways teachers talked about and represented their beliefs. Specifically, I used the constant comparative method of analysis to develop categories emerging from the data. This type of research provided me with a handle to hold on to in discussing self-study. It was important for me to be able to justify my self-study research method using a triangulated design for data gathering and a recognized method for data analysis.

My second self-study began much as the first study, using the students' voices to study my own practice. But early on, a reviewer of my conference proposal encouraged me to put my students' reflections in the background and put my own self-study forward. This was a turning point in the way in which I thought about self-study. It was the first time someone had said, "Stop that" in reference to my choice of data sources. Importantly, I was at a place where I was ready to hear this. By now I had read several self-study papers from other members of S-STEP, and had begun to question my use of students' practical arguments as a way of examining self. It seemed a bit distant or disconnected to use outside voices as the basis for my own self-study of my practice. But I think what really changed for me is that I was perhaps more comfortable because of my experience with self-study, which enabled me to let go of some traditional educational research views on data and objectivity.

In my second self-study, I had spiraled beyond the voices of my students during practical argument to my own voice in the context of the teaching moment. I became more interested in the role I played as a teacher. What was I doing in my teaching that affected learning?; that affected students? I now saw their practical arguments as data tied indirectly to the study of my practice rather than directly. Their language about their teaching was *their* voice, *their*

perspective, not mine. And while this is helpful additional information, in studying the self I needed to look at my voice and at my perceptions. I needed to look at my role as the teacher.

The Role of Teacher and the Role of Student

In his chapter on the philosophy of the research on teaching in the third handbook of research on teaching from the American Educational Research Association, Fenstermacher (1986) posed what he termed an "ontological dependence" (p. 39) of teaching to learning, but not vice versa. His premise was that without learning there would be no need for teaching. However, he argued that learning may often occur long after teaching, or not be directly in relation to the teaching itself, causing difficulties in determining causal or ontological relationships between the two. He suggested a more parallel concept to the notion of teaching in the term "studenting or pupiling" (p. 39). This notion of studenting focuses the responsibility of the teacher on enabling students to perform tasks of learning. Learning then becomes an outgrowth of studenting. This studenting notion became important in developing my self-study research. In asking the questions: What are my roles in teaching?; What are the students' roles in learning?; my second self-study examined the dynamics of teaching and studenting.

When I revisited my first study, I began to see the use of others' voices to examine their understandings as a way of actually distancing myself from my own practice through examining others' perceptions of that practice. This notion of distance became intriguing, and led to what I felt was my first *real* self-study where I examined my role as teacher through my own actions, course documents, and my interactions with students to investigate the dynamic between teaching and studenting that occurred in my classroom (Tidwell, 1998). I had spiraled beyond the focus of self as the evaluator, as in my first study, and shifted to a broader focus on the process of effective practice with a specific focus on my actions as the teacher in this process. In this second self-study, I examined documents that reflected my thinking, such as debriefing notes after each class meeting, course documents for lecture and student discussions, and notes from sessions with a colleague in which we discussed my interactions with students in the class. This study came out of my understanding that the relationship between teaching and studenting connects directly to learning, that beliefs about my role as the teacher should be reflected in my actions as the teacher.

In self-study, as within any form of research, the values of the researcher are imbedded in the decision of a research focus, on data collection, and on data analysis. In my earlier dissertation study of an instructional practice, I had designed the research to assess reading through a set of questions derived from an analysis of the text. Embedded in this decision was the belief that an expert can develop an appropriate measure of a student's understanding of text *a priori*. Using such an instrument for assessing comprehension reflected the belief that

a reader's understanding of the text could be realized through a set of predetermined questions and answers. If the reader is unable to answer the expert's questions correctly, then comprehension has not occurred. This assessment also reflected the belief that meaning was housed in the text. In this example, the importance of an informed outsider, an expert who had analyzed the text and provided previously validated comprehension questions, provided a sense of objectivity to the research. Each decision made in research reflects such beliefs and values about that research focus. However, with self-study, the values held by the researcher are more forthcoming, are considered integral to the study and are made public as the foundation for making decisions on what is to be studied and for what purpose (McNiff *et al.*, 1996; McNiff, 2002).

A basis for self-study research is in the global question, how do I improve my practice? (Whitehead, 2000). In this question, the "I" becomes the central focus, studied against the backdrop of the values driving the research. This creates what Whitehead refers to as a "living contradiction" (p. 93). It is this living contradiction of the actions and reactions of "I" (what is really being done/happening) studied within the context of the values of what is deemed important (of what should be) that creates the synergistic relationship between self-study and change. This living contradiction came alive in my second self-study, which resulted in a disturbing revelation for me. While I saw myself as a gregarious and outgoing teacher, the self-study revealed that I often kept my students at a professional distance that prevented the social connection and sense of community I so valued. This living contradiction pits my belief that being a part of a community within my class is important in establishing a learning environment against my actions that suggest the role of the teacher is not that of a community member but of an outside observer of the community dynamic. This is important in informing my teaching, as I see the parallel between the outside observer in scientific research manifesting itself in my own role as a teacher, in my own actions in the classroom. My actions suggested that I was still embracing the notion of the informed other disconnected from the learning environment, disconnected from being in that environment as a learner as well.

The role of the teacher is one I have *talked about* at length with my students, describing the teaching role as one and the same as the studenting role. Yet, my actions did not seem to support that talk. This contradiction helped me to understand how powerfully the beliefs derived from experiences can shape the actions within one's teaching. My background in science and my early academic focus in scientific research methods had a strong influence on my perceptions of value as realized through my actions. While I had questioned my faith in the scientific method, questioning the sense of control such method provided, my actions still reflected the value I had placed on the informed outsider and expert as the role of the teacher. This living contradiction between my beliefs and my actions also helped me understand the importance of self-study in being able to peel away the layers to examine the actions beyond the chatter of the practice.

My experiences in self-study had reshaped my research focus from the efficacy

of specific instruction on content into the broader context of my values as a teacher. I had moved from an initial study of how well students understood the content I was teaching through the dynamic of self as the evaluator, to a second study of the process of effective practice through examining my own interactions with students within the context of the class as a community of learners. My next study moved beyond my interactions with students within the context of the learning environment to encompass my actions/interactions/reactions within the context of my beliefs and values. I focused my third self-study on valuing the individual student (Tidwell, 2002a), a concern that emerged from my inter-actions of distance from my second study. The importance of valuing students was a belief I held and a value statement I often professed as grounding my teaching. This self-study was designed to examine my actions/interaction/reac-tions within the notion of valuing students. Three students enrolled in courses in which I taught or supervised were chosen to be the catalyst for my self-study as they represented the three different levels of academic programs at my univer-sity. One student was an African-American male enrolled in a literacy course in the undergraduate program in teacher education. The second student was a European-American female enrolled in a practicum in the masters program in literacy. The third student was a Chinese female enrolled in a research course in the doctoral program in education. The data included notes from meetings with each student, debriefing notes following the meetings, documents related to the course in which each student was enrolled, and notes from meetings with a colleague to discuss my interactions with these students. This collegial friend taught in the clinical setting at the university and was familiar with my coursework and with my students. Though I believed strongly in the importance of valuing all students, and in the need for teachers to make sense of students' actions in order to understand their context and their reality, the data on my actions did not fully support my belief. I discovered that I privileged those students who demonstrated roles in *studenting* that supported my role as the informed teacher, the outside expert. I most valued students who appeared to need my help/instruction/guidance, who responded to my help/instruction/guid-ance in ways that demonstrated appreciation, and who were proactive and independent but not too independent in deference to my guidance. The power of the scientific expert emerged again. Allender and Allender (2001) would suggest that this is not surprising. The notion of the "teacher self" (p. 129) as the authority over content creates this phenomenon of teacher as expert. Allender and Allender suggest an historical view of the rigid teacher authority is embedded from early experiences in schooling, in beliefs forming from these early experi-ences that configure the role of student and the role of teacher in the subcon-scious. And while new understandings and beliefs about teaching and the role of teacher can take shape through study, embedded beliefs from experience often surface in teaching actions.

Actions Grounded in Philosophical Beliefs

A critical component of self-study is the examination of one's own beliefs to determine the focus and purpose for self-study. Values and beliefs drive the

research agenda in self-study and become an integral part of the self-study design. McNiff (2002) describes a set of questions she uses to show the development of her ideas within her research:

> What is my concern?
> Why am I concerned?
> What do I think I can do about it?
> What will I do?
> How will I be able to show whether I am influencing the situation for good?
> How will I judge whether any conclusions I come to are reasonably fair and accurate?
> What will I do then? (p. 7)

Grounded in these questions are the beliefs and values she holds that determine what it is she researches. Whitehead (2000) also provides a series of statements that reflect the action-reflection spirals used in developing a methodology for self-study. The impetus for these statements (and the corresponding research) comes from the values held.

> I experience a concern when my values are negated in my practice.
> I imagine a way forward.
> I act.
> I evaluate.
> I modify my concerns, ideas and actions in the light of my evaluation. (p. 93)

The premise for this type of self-study of practice must be grounded in values held that lead to a focus in practice that is to be studied, and the need for change in practice to best address and/or represent those values. As a teacher, my greatest interest is in understanding the dynamics in my classroom and how those dynamics affect learning. For my first self-study on students' practical arguments reflecting my teaching, I realized that undergraduates had more difficulty providing a theory-based reason for their practice. This suggested to me that my teaching was not providing enough experience with connections between theory and practice. For me, the relationship of theory to practice in literacy instruction is critical. This led me to provide more opportunities to discuss theory and its relationship to practice and actions in practice so that students would be able to make the connection more clearly. Over the next semester, this change in my teaching practice did help improve students' use of theory in their discussion of practices.

In my second self-study, which revealed a formal distance between my students and myself, I began to make a more concerted effort to be a part of the community in the class. Initial changes in my teaching practice included implementing many small group discussions where I participated as one of the discussants. I diligently tried to be available to students for one-to-one and small group meetings to discuss anything related to the class. This self-study on my interactions with students led to my third self-study on the issue of valuing

students. I saw that how I interacted with students, in terms of distance, conflicted with my belief about valuing students. If I value students I should not be putting myself at a distance. My third self-study then examined my belief of valuing students through my actions, interactions, and reactions. The realization of my lack of balance or equity in valuing my students reiterated a continuous theme in my teaching – the role of the teacher as the outside expert. This theme reflects the values embedded in my science background, the role of the expert as informer to the uninformed. The assumption in this role of informer is that students come to my teaching ready to absorb the information I have to impart. This does not match my ideal view of teaching.

This conflict between what I believe and what I practice mirrors the dynamics addressed in Holistic Resource Management (Savoy, 1988), a reflective approach used in holistic planning. In this model one studies the way things happen, and how to relate to these events as goals are pursued, without being trapped by past experiences (Tidwell & Klinge, 2000). Was I *trapped in my past experiences*? Was I doomed to fall prey to my desire to be that expert? Maybe I was. Or maybe my *style* of teaching was a combination of the influence of my past experiences with my personality, my desire to cast teaching as a performing art. And maybe that was all right. I had argued in my study on distance that formality with students and lecture-style presentations might be a manifestation of my own personality and perhaps a viable way in which to teach. Maybe what I needed was the right environment for that type of teaching. An opportunity to explore this idea came when the university experienced a budget deficit and faculty were encouraged to teach to larger class sizes to accommodate the budget crunch. I jumped at the chance. I could teach to a large group of students in a lecture hall format and have my teaching focus on the role of the expert providing information, performing on stage to an audience of students.

The Reconstruction of Self

My fourth self-study, then, focused on the dynamics of my instruction in the context of a large lecture hall (Tidwell, 2002b). I believed I enjoyed the performance aspect of teaching, and thought this would be an intriguing self-study on how my practice is manifested in such an environment. This study began as a combination of my own reflections and those of others, in order to study efficacy and practice (a return to collecting data from others to study self). The data for efficacy (student feedback, faculty feedback) showed that students involved in (very) large group instruction of this prerequisite course for clinic were able to perform well in their reading clinic work in the following semester. However, this became less interesting to me than my own response to large lecture hall teaching. I began my data collection through the familiar class notes, course materials, and post class debriefing notes, as well as the meetings with three different colleagues to discuss my data and my understanding of the data.

Two colleagues with whom I discussed my data were instructors at the university in the literacy clinic setting. They both were very familiar with the

content I taught in my course. One colleague taught the field course for which students had to co-register in conjunction with my lecture class and was very familiar with all the students in my class. The second colleague worked with the students in my class in subsequent semesters as the instructor of the clinical experience for which my course was preparing students. The third colleague worked outside of the university setting. His work in reflective practice through holistic resource management provided a unique perspective on my own reflections, especially in examining the notion that my past experiences influence my current actions. In addition, I gathered weekly student reports of understanding (end of class responses to open-ended question prompts about the content of the course) during the semester, and I gathered faculty reports in the following semester of the students' performance in the subsequent clinic coursework.

But my data collection for my own class debriefings took a decided change. Rather than writing copious notes about how I felt the class went, I would pick a moment in time, a particular nodal moment, and I would sketch that moment on a notepad. It was this collection of drawn nodal moments that became my most intriguing source of data. These drawings were my own responses to my interactions with students and to the environment of lecture hall teaching. What I found most useful about these nodal moments were the context and emotions that were expressed in the drawings, capturing the interactions of a particular teaching moment in time. In fact, I found the whole process of drawing the nodal moment both cathartic and connecting. I was able to react to my teaching and to the context of my teaching in a way I had not been able to react before. These *reactions* were great pieces of data to analyze as well. They provided context, feelings, attitude, and moment-specific meaning within one data source. Through these drawings I was able to reconstruct a moment in time, to actually construct the dynamic of my *self* in the context of my teaching. By examining the drawing I was able to capture the context of the moment. By using drawing as a source of data, I felt a bridge between my science self (research) and my art self (expression/experience). This bridge or connection melded my research self with my art self in a way that provided an enriched validation of my experience. It was also a discovery of the richness of the subjectivity of drawing that nodal moment, a richness derived from capturing the dynamics of an experience through one's own lens, through the lens of self. Below, in Figure 3.1, is an example of a drawn nodal moment followed by analysis comments.

The analysis of my drawn nodal moments constructed a teaching self embedded in a teaching environment in which I was disconnected from my class. I felt a loss of community and social connection, which changed the teaching/learning environment for me as the teacher. Without the use of self-study, I would not have been able to clearly articulate the issues addressed in the nodal moment data. For me, as a teacher, the quality of the experience was not good. And while the institutional view of student performance had been maintained in these large lecture settings, where students continued to pass the course and were able to successfully demonstrate understanding of subsequent coursework, I was very dissatisfied with my own experience as a teacher. This dissatisfaction was with
Figure 3.1: An issue, in terms of quality of my instruction, is the ability to direct my attention to the information I would like to share while at the same time to be aware of the needs and connections being made by the students. This was not something that could be realized well through my large group instruction. The design of the physical room played a large role in separating me from the very people I wished to connect with and communicate with through my lesson (Tidwell, 2002b).

the role of teacher as expert, teacher as outside observer. The very issues that confronted me in my drawing of nodal moments reflected a change in the values embedded in my actions as a teacher. The earlier desire to be an expert-who-teaches was overshadowed by my stronger desire to create community in the classroom, to make those connections with my students that would allow me, as the teacher, to be involved in their process of learning. In other words, my past experiences had influenced my initial actions, reactions, and interactions, but through the cyclical spiral of self-study, through the cyclical spiral of my teaching and reflections, I was finding a connection between what I theoretically wished to value (my stated beliefs) and my actions in my teaching and in my research.

  This last self-study example, and the history of self-study that led to its inception, exemplifies the value of self-study of teaching. It gets at those aspects of instruction, of instructional environment, of instructional relationships that cannot be found through other research methodologies. The process of my self-study journey can be seen in the spiraling changes in the focus of research, from self-study of self as the evaluator, to self-study of effective practice process, to the connection between practice and beliefs, to the construction of self as seen through my role as the teacher. Self-study provides that connection between the

teacher and teaching, within the context of real practice, among the real partici-
pants, for purposes grounded in values and beliefs. And for me as a teacher and
a researcher, self-study provides an avenue to research my practice that allows
me to evolve and grow in my own understanding of teaching and learning.

"The Microbe is Nothing, the Terrain is Everything"
(Louis Pasteur on his deathbed)

Part of the evolving process of self-study and of teaching for me has been a
move away from my reverence towards traditional scientific method. My realiza-
tion that objectivity is elusive and that the research decisions to create that
objectivity belie subjective beliefs, places the decisions for research questions and
research design in the meaningful base of context. As the heading for this section
suggests, it is more than the object or subject that we study, it is the context in
which the object or subject exists and the relationship between that context and
the object/subject that is the point of study. In teaching, the classroom context
and the relationship between students and teachers in that context provide the
focus for examination of self and practice. In the classroom, self-study of teaching
is the same process as teaching.

Self Study as Teaching

Lewin's (1946, 1952) notion of research and reflection as cyclical phenomenon
can be seen played out in the journey presented above. Planning leads to acting,
observing the actions leads to evaluating the results. And this parallels what
teaching is about. The teacher plans for instruction. The instruction is imple-
mented. The teacher observes the instruction in progress and evaluates the
effectiveness. This cycle of plan, implementation, observation and evaluation,
this spiraling parallels the spiraling nature of research. It takes time to move
from where one is as a teacher/researcher to that goal of where one might want
to be. It cannot be attained in a split second. It requires thoughtful progress
toward a goal, toward a belief, a value. And it is the moving forward toward
that belief and value that leads to new areas of focus, new goals, expanding
the spiral.

The Context for Self-Study as Teaching

So why does anyone use self-study to study one's own teaching practices? The
classroom is a complex environment that requires more from a teacher than just
technical or applicative knowledge (Greene, 1978). It is often that "interpretive
context" (p. 59) tapping into the ways of knowing and of social and cultural
contexts that constitutes the notion of effective teaching. Recent discussions of
the thought processes involved in teaching look at both the theoretical knowledge
(based in reason) and the knowledge in action (based in intuition) to explain
the dynamics involved in teacher planning and teacher practice (Atkinson &

Claxton, 2000). In this notion of knowledge in action as intuitive, intuition is not seen as a nefarious element of whim, but rather the intuitive nature of experience. The more informed, the more practiced one is, the more second nature the actions become. This intuitiveness is grounded in thoughtful dynamic experience. Effective teaching, then, is this combination of reasoning through theoretical understandings combined with actions borne out of experience with specific contexts, specific dynamics, and specific interactions. This model includes contextual knowledge as the basis for teacher reflection. Allender and Allender (2001), in their Gestalt theory for teachers, combine intellectual, emotional and body awareness in the notion of contextual knowledge. In examining context, they look at the development of self in the context of the relationship to others. In teaching, the development of teacher-self emerges through the creation of "permeable boundaries of self that provide opportunities for interpersonal contact in the here and now" (p. 131).

How does one make sense of all these dynamics in one's teaching? Self-study provides a process for contextualizing these complexities and for organizing one's reflective processes around a particular focus. Palmer (1983) suggests that educational systems and instructional practices are designed around creating a reality that simplifies life. He claims that much of what is considered objective teaching (and research on objective teaching) persists because it limits questioning, helps teachers control the environment, and allows us to feel in charge of an "object-world" (p. 38). His concept of learning is based on change and interaction that reflects the real complexities of teaching: "To learn is to face transformation. To learn the truth is to enter into relationships requiring us to respond as well as initiate, to give as well as take" (p. 40). In self-study, the process of research reflects learning as defined by Palmer. Through self-study, teacher-researchers place their values on the table. These values become the impetus for their research. The inquiry into these beliefs and values through practice provides insights into the manner in which the teacher-researchers imbue their teaching with their beliefs and values. These insights are transformational in that they inspire the teacher-researcher to respond, to make change, to transform practice as the teacher-researcher progresses toward the goal that is the envisioned belief.

This progression in self-study characterizes teaching as well. Teaching is progressive in nature insofar as teachers become more informed and adept at instruction, interactions, management, and integration of content, time and materials. In order that teachers progress in their knowledge of teaching, they must also progress in their understanding of reflection. Berliner (1986, 1987) suggests that teachers with different levels of experience organize and negotiate the information and knowledge available to them differently both in the way they conceptualize the classroom and in the way they implement instruction. Earlier research on reflective practices in teaching supports this tiered notion of teacher knowledge through a hierarchical 3-stage model of teachers' use of reflection (Van Manen, 1977). In this model, at the first level teachers appear concerned with applying knowledge and using appropriate strategies. At the

second level, teachers move beyond concern about correct practice choice to concern about the underlying assumptions within those practices. At the third level, teachers are more concerned with the moral and ethical issues surrounding practice.

While the hierarchical model relates well to the novice and master teacher phenomena, a non-hierarchical model can also be used to examine the elements that foster reflection: cognitive, critical and narrative (Sparks-Langer & Colton, 1991). The cognitive element refers to the knowledge about content and pedagogy teachers have that leads to the decisions made about instruction. The critical element relates to the moral and ethical views that influence the decision-making process and, the narrative element is the teacher's actual account of the classroom experiences. In this model, both novice and experienced teachers use these three elements in their teaching, but the degree to which they address these elements may vary by experience, which spirals ever broader as their experiences increase. These elements of reflection work well with the idea of self-study in terms of what knowledge is known, the ethical issues surrounding that knowledge, and the subsequent instruction.

These elements can also be seen functioning in a cyclical spiral. The teacher-researcher uses the cognitive element of knowledge and pedagogy to plan instruction. Yet the plan of instruction is influenced by the critical element of moral and ethical views the teacher holds. This belief and value structure is embedded in the decisions about instruction that are made. And as the teacher-researcher, through the narrative element, accounts for the events that occur in the classroom, the dynamic of the plan embedded in the beliefs and values of the teacher affect the manner in which the teacher takes account of the instruction. The very nature of observing and reflecting on practice changes the teacher's understanding of the instructional plan within the context of the instructional environment. And this is where that spiraling effect begins. For as the teacher-researcher learns from observations, that learning changes what the teacher knows, which challenges the beliefs and values held, and ultimately affects the planning of instruction, which then begins the process all over again. This spiraling effect moves the teacher-researcher forward in reaching the goal of beliefs and values exemplified through practice. But it is elusive. As described in the teacher-researcher's journey in this chapter, as the teacher-researcher's knowledge changes so does the ideal of good instruction. As the teacher-researcher's knowledge changes the moral and ethical dynamics change as well. As the teacher-researcher's knowledge changes, so does the focus of what is deemed important and valued.

Values Expressed through Research

Self-study of teaching and teacher education practices recognizes the complex and multivariable nature of the teaching/learning environment. However, educational changes in the United States in recent years (e.g., a focus in "scientific research" as the sole basis for instructional practices, licensure measures that focus solely on learned skills) have ensconced US teaching in technical rationality,

based on "a set of technical skills that virtually anyone, properly motivated, can acquire" (Brubacher, Case & Reagen, 1994, p. 16). The complexity of the classroom is overshadowed by such a simplistic view of teaching (and therefore learning) as relatively context-free and culturally generic. In such a view of teaching and learning, teachers are seen as technicians possessing the right skills to orchestrate the classroom. Brubacher *et al.* (1994) argue that within the context of the complexities of the classroom, a more accurate description of the role of the teacher is that of decision maker rather than technician. A decision maker combines the use of technical knowledge with the art of teaching to create an environment for learning. It is this decision-making role that becomes a pivotal focus of self-study.

The roles that a teacher embraces are critical to the implementation of self-study and to the impact of self-study on the teacher, on teaching and on the teacher's environment. This impact can be seen both environmentally and politically. Wells *et al.* (1994) argue that teacher-as-researchers in self-chosen inquiry challenges the educational community in two ways. The first is in valuing practice-based knowledge of teachers. This challenges traditional decision making procedures for what is important and what should be done – it democratizes the decision-making process where the folks in the field are the actual decision makers in researching what is going on and what should be changed. The second is in the nature of teacher research with self-chosen inquiry. Such research is very different from traditional research in education and challenges the way research results are realized. Teacher research cannot be reduced to a set of numbers, a set procedure or a packaged approach. It is context specific and purpose-driven by values and beliefs held by that teacher-researcher.

Herein lies the dilemma in the United States. Current national trends in education have placed limits on what is defined as *scientific* research and has placed instruction as well as the role of research in a hierarchical frame. In the example of literacy education, the government has defined literacy and literacy learning through a hierarchical skills model where students have prerequisite skills that must be mastered before real reading can occur. This is only one way in which to talk about reading theory and reading development. This single definition of reading came out of a narrow definition of research. In examining effective practice, the government limited the meaning of research to design that is "scientific," involving a treatment compared to a control. Through this definition of research, the government also defined literacy. To study literacy in this manner researchers typically conceptualize reading in parts and confine their research to one particular piece of the puzzle. In so doing, researchers' efforts elicit practices that are separate from the whole, as well as hierarchical in their importance in reading and reading development. But beyond the hierarchical canon for instruction, this narrow definition of research also limits who can be considered a *researcher*. It supports the notion of the expert scientist coming into the context of the classroom to determine, from expert opinion, what is and is not effective, what instruction should take place, how teachers should instruct in the classroom. Teachers are demoted to technicians, and researchers are

specialists, experts with skills elevated beyond those of the technician. Values of the researcher are not directly stated, but subsumed within the design of the research, and values held by the government are hidden or embedded in a hierarchical view. This approach to research and practice reaffirms Palmer's (1983) contention that school systems and instructional practice objectify to simplify, and as such are devoid of the real context of the teaching environment.

In self-study, the real teaching context is everything. The teacher is the informed expert for that context. To begin research of teaching through self-study, one needs to think about the context of self within the teaching environment and about practice in terms of roles, actions and beliefs. Grounding one's values and beliefs allows self-study to examine issues of relevance that will make a difference in practice.

As was presented in Deborah's story above, her journey spiraled through four evolving areas of focus. From her experiences, these evolving foci were ever expanding and, in some ways, developmental in nature. As Deborah began her self-study, she based many of her decisions about research design on her beliefs and understandings from a scientific model of research. As she began to experience self-study with others (both in readings and through discussions of her research), Deborah's understanding of self-study design changed both in what she studied and in how she studied. It is possible that this understanding is, indeed, a developmental process over time, which is reflected in others' self-study as well. However, an equally intriguing question regarding self-study as teaching is whether others have researched their practice within the same focus areas, not from a developmental model stand, but from a categorizational stand. Are others researching their practice with similar focus areas, and if so, what are some examples of such research?

The Power of Self-Study as Teaching to Inform Teaching Practice

Self-study researchers in teacher education and in teaching have studied their own practice in many different ways. This research has been powerful in making a difference in teacher-researchers' understandings of their practice, awareness of their beliefs in action, and improvement in their practice over time. Critical across their work is the grounding of their research in their values and beliefs. From this grounding arises the purpose for their studies and the action for change, both of which lead them to new understandings of their teaching and of their professional selves.

Informed by the first author's own journey, and impelled by the current context of teacher education, this section highlights work in self-study that reflect similar areas of focus in self-study as teaching, including self as evaluator, effective practice process, practice relating to beliefs, and the construction of self. While these four categories represent the spiraling change in Deborah's research focus over time, it is not suggested that this is a generalizable progression to others' research. However, it is interesting to see these categories reflected in others' self-study of teaching. The following sections provide a discussion of examples

of self-study research where self-study as teaching is reflected in the process of their studies. Primary sources for the selection of literature include the proceedings and books reporting on the first four international conferences on the self study of teacher education practices held biennially at Herstmonceux Castle in East Sussex, England (Cole & Finley, 1998; Hamilton, 1998; Kosnik, Freese, & Samaras, 2002; Loughran & Russell, 2000, 2002; Richards & Russell, 1996). Self-studies were chosen as reflective of the four categories of *self as evaluator, effective practice process, practice related to beliefs*, and *construction of self* through an examination of the stated purpose of the study, of the language of the research focus, and of the dynamics being addressed within the research. As Zeichner (1999) suggests, "… categories, like all category systems, are problematic in certain ways. They gloss over important differences between lines of work grouped within a category and are not mutually exclusive" (p. 8). For example, the category self as evaluator is not devoid of examining the process of a practice, nor is the connection of practice to beliefs omitted from such studies. However, these categories provide an avenue for discussion of self-study that allows an examination of ways teacher-researchers approach their practice.

Self as Evaluator

In some self-study research teachers have examined the rationales behind their evaluation and their evaluative thinking processes. Through their own self-study research they provide reflections on their own rationales for evaluation (e.g., Haley-Oliphant, 1996; Kerr, 1998; Selley, 1998). The two examples that follow (both of teacher educators' self-studies) are interesting in the different ways they approached self-study through the use of data. Haley-Oliphant, in her research on the use of portfolios as a predictor of future teaching success, examined portfolios of students who were secondary science majors. The process of developing her quadrants for examining portfolios took over four years, and involved over 80 students enrolled in their final semester prior to student teaching. The global goal of these portfolios was for the students to develop a portrait of themselves as future secondary science teachers. Included in this summative portrait were pieces of evidence chosen by the students as well as reflections on those pieces. The data for analysis encompassed the portfolios, Haley-Oliphant's observational records of the students from class, and her journal of personal reflection on the process (such as: What am I learning about my own teaching through my interactions with my students? What is occurring that contradicts my thinking and perceptions of the students, the course, and my teaching?). Through these data, Haley-Oliphant conceptualized a four-quadrant frame for evaluating portfolios as a predictive indicator of future teaching success. In her reasoning, Haley-Oliphant highlighted the importance of "living the questions" as a valued process of coming to know. For example, in the question, "What lessons as a teacher can I learn from these portfolios?" Haley-Oliphant used the observations of her students, the data from the portfolios, and most importantly,

her own reflections on the process through her journaling to reveal her role in the portfolio experience, and to examine self as the evaluator.

Her self-study was not so much in the development of the frame, as in her thinking behind the development of each quadrant in the frame. Driving her research were the questions she posed in her journal, and in the reflection of her perceptions of her students' progress against the students' perceptions of progress as demonstrated in their portfolios. Her understanding of her role as evaluator of others was put into question through this process. Her self-study enabled her to examine the notion of success, and the role she played as a teacher evaluating progress.

Selley (1998), on the other hand, provided a very different self-study examining two narratives he wrote of critical incidents in science classes he observed. In both instances, the study was of others' actions refracted in terms of his own beliefs and values. Selley purposefully chose to examine others' actions through the use of what he termed an *objective* narrative format with the intention of focusing on the outside to get into the belief connection within. Specifically, he was concerned over discrepancies between his values on science education and values embedded in educational situations in which he was involved. Using a narrative approach, Selley documented two different teaching events involving trainee teachers. While Selley termed his narrative *objective* in nature, it was not as an outside observer unfamiliar with the individuals involved, but rather as one evaluating a context from the outside. The narrative text included descriptions of actions and reactions in the classroom that included labeling and quality-based comments, such as, "This was met with great lack of enthusiasm, since it was, once stated, so obvious that the class felt that they had been tricked" (p. 70). Selley argued that this type of narrative style allowed for a clear "range of value positions" (p. 70) to be exposed.

Selley's use of these narratives for evaluation of practice enabled him to discern clear differences in two situations that had initially been considered similar. In the first incident the narrative was of a lesson on the seven characteristics of life. In the second narrative, the lesson at an all-girls school was on biological classification. Embedded in the narratives was an overview of the events of each lesson including descriptions of the students' responses, the context for the lesson from the institution's perspective, specific dialogue drawn from both during and after the lesson, and reflective statements of the observer.

The contexts of the narratives provided moment-specific windows into each classroom. These moments provided insights into the values embedded in the instruction as recorded by the observer and a sense of the driving force behind those values. In the first scenario, the values were clearly connected to the school's intention of what was important (regular classroom teacher's response that students are to be taught what to learn, not to waste time discovering on their own). In the second scenario, the needs of the class (a group comprising a large number of English Language Learners) were not being met by the school, but rather than being seen as an intentional effort on the part of the school, the narrative revealed a school's sense of trying to keep up with the correct levels,

without a real understanding of the immediate needs of the students. Selley's self-study examined the efficacy of his role of evaluator through the use of narrative descriptions and found that he was able to better understand the quality of difference in teacher trainee instruction and in the context of classroom teaching through the use of narrative evaluation.

In both Haley-Oliphant's and Selley's self-studies, the values they hold form the basis for their research focus. And through the process of self-study, their understanding of their role as evaluator changes, with new insights informing their teaching (exemplifying self-study as teaching) in a spiral of discovery that moves outward encompassing a broader understanding of their role as teachers.

Effective Practice Process

Self-study research of 'effective practice process' were those studies where teacher-researchers examined a particular practice in their teaching in terms of efficacy, rigor, effective dynamics or application to the context. These studies often presented the journey through a process rather than an evaluation of the outcomes of such practice. Teacher-researchers examined their own instructional practice (some involving the very practice of self-study) as used in teacher education programs, and in some instances teaching in the K-12 classroom (e.g., Allender & Allender, 1998; Freese, 1998; Gipe, 1998; Grunau, Pedretti, Wolfe, & Galbraith, 1998; Hamilton, 1998; Holt-Reynolds, 1998; Hutchinson, 1998; Kaplan, 2000; Mills, 2000; Muchmore, 2000; Richards, 1998; Samaras & Reed, 2000; Schuck & Segal, 2002; Standerford, 1998; Teemant, Harris, Cutri, Squires & Gibb, 2000; Tidwell, 1998). The two examples discussed here (both teacher educators) highlight different ways these two self-study researchers looked at the process they used in their teaching in terms of its effectiveness or usefulness to students.

Kaplan's (2000) self-study, the result of which he called "the beginning of a journey toward self-study" (p. 128), was grounded in the belief that he had a moral obligation to model teaching and the process of self-study as a lifelong movement toward self-realization as a teacher. In his self-study, Kaplan examined data from several different sources, most of which came from students and colleagues responding to his teaching in some form. Kaplan analyzed the data to answer the question, "Does teaching using personal experiences help students inform their own professional knowledge and teaching?" Teaching as a self-reflective process is a cornerstone of Kaplan's belief that self-understanding is crucial to becoming an effective teacher. Three themes emerged from his data that suggest personal experiences do help students inform their professional knowledge and teaching: (1) informal conversations that were commonplace in the classroom were important to the students' sense of community in the classroom, creating an environment in which they were comfortable sharing and learning; (2) student self-realization of the value of their personal lives and experiences played an important role in their teaching and their understanding of teaching; and, (3) Kaplan realized the important role he plays in students'

lives and the need for him to model and share his own personal life as part of the self-realization journey the students must take. Kaplan based his themes on data collected from students' writings, reflections, drawings, volunteer experiences (in class discussions), students' action-research projects, students' portfolios, his own teacher evaluations, interviews with former students, and conversations with colleagues regarding observations of his teaching.

In his conclusions, Kaplan (2000) connects the results of this self-study to the impact it has on his teaching. Following Lewin's (1946, 1952) notion of the spiral of inquiry, and Whitehead's (2000) notion of action-reflection spirals, Kaplan's self-study spiraled beyond his initial examination of others' views of his teaching, to self-study of what that meant in terms of his own understandings through his own personal experiences. This spiraling effect of his understanding that "students revel in self-reflection because they begin to define their own selves in their own words" (p. 129) extended to his own understanding of himself through his self-reflections, defining his own teaching through his own words.

Hamilton (1998) examined the process of self-study and group meetings to explore students' beliefs about and, issues of, diversity. The values and beliefs undergirding Hamilton's study can be seen in the importance she placed on the ability of teachers to know how to teach in diverse settings. Through the use of autobiographies and narrative in a self-study approach to eliciting beliefs, Hamilton examined the accountings of the beliefs and possible shifts in beliefs as the students engaged in this self-study process. Her focus in addressing issues of diversity grew out of her concern that many of her students, coming from the dominant culture, would experience cultural mismatches with ethnic minority student populations in their field experiences and future teaching. Hamilton posited that if understanding teacher behaviors could be realized through examining beliefs (Fenstermacher, 1986) and that if Ladson-Billings (1995) was correct that, "revealing beliefs can lead to the amelioration of this cultural mismatch" (Hamilton, 1998, p. 117), then students must be provided with the opportunity to examine their own beliefs and make connections between beliefs and actions in the field.

Through her self-study, Hamilton (1998) examined self-study itself as an effective approach with university students, as well as the nature of biography and narrative as a method of eliciting students' beliefs to effect change. Biographies and narrative were the vehicles she used to provide students with, "opportunities for critical examination and experience of difference" (p. 118). She asked, "Can the exploration of beliefs through the use of self-study, autobiography and narrative better prepare preservice teachers to teach in diverse settings?" A group of students, formally called XBADAN (Xploring Beliefs About Difference with Autobiography and Narrative) in bimonthly meetings read texts and wrote narratives about their experiences with diversity. However, the students, who volunteered to participate in this group dynamic, experienced great difficulties in discussing diversity in any substantive form. Hamilton was forthcoming in her discussion of her own frustration over what she determined as cautious participation by the students. This conflict between what she expected

from developing this group/club dynamic and what actually transpired became an important force in her understanding the students' beliefs about diversity.

Hamilton found that addressing beliefs through narrative and discussion did move students forward in their own understandings of their beliefs and in the broader awareness of others' beliefs. Through this self-study, Hamilton discovered that narrative and autobiographical texts are effective as vehicles for approaching the issue of diversity with preservice teachers. And as a teacher-researcher, this process of using self-study with students also informed her practice as a teacher educator. The findings of this self-study led to a new focus for her in rethinking ways in which the teacher preparation program at her university could better provide information about diversity to students.

As in the first author's second self-study (Tidwell, 1998), Kaplan (2000) and Hamilton (1998) researched the important dynamics of their practice that influenced teaching and studenting (and ultimately learning). By putting their teaching practice process at the heart of their study, they, too, illustrate self-study as teaching.

Practice/Action Relating to Beliefs

In the category that comprises this section, researchers examined their teaching in relation to a particular pedagogical construct or focus that was reflective of their beliefs as a teacher. This notion of a construct or focus reflecting a teacher-researcher's beliefs moves beyond the confines of a particular practice, such as those cited under the category of effective practice process. The present category incorporates a broader, more global labeling of a pedagogical phenomenon with a clear connection to beliefs and values. In each case, the researchers delineated the purpose for their study in terms of a predetermined pedagogical concern or focus (e.g., Bass, Anderson-Patton, & Allender, 2002; Austin, 1998; Berry & Loughran, 2002; D'Arcy, 1996; Fitzgerald, Farstad, & Deemer, 2002; Griffiths, 2002; Hutchinson, 1998; Johnston, 2000; Lomax, Evans, & Parker, 1998; Louie, Stackman, Drevdahl, & Purdy, 2002; McAndrews, 2000; Penrod, 1998; Tidwell, 2002; Tidwell & Heston, 1998).

Although the two studies highlighted here both deal with departures from a linear model of "teaching as telling," and carry out self-study collaboratively, they nonetheless represent two very different approaches to examining teaching. In each case the techniques for engaging beginning teachers in learning about their own teaching can mirror or model the methods for self-study of this teaching.

Berry and Loughran (2002) carried out a self-study of the pedagogical notion of learning to teach with a group of third-year double degree students at a university. This study was interesting in the way it began as a dialogue between the two researchers revealing the context for the situation and their own feelings about being involved in working with this particular group of students. Their beliefs about the role of the teachers was made evident in their value statement, "What you do in your teaching reflects more strongly in what students take

away from a course than what you say" (p. 26). This sentiment was then reflected in the kinds of teaching elements they discussed in their study, such as professional critiques, teaching decisions, action versus intent, and co-teaching. With the underlying principle of learning through experience, they organized and presented their teaching about teaching to push the students to take risks like those the professors were taking, to embrace rather than to avoid uncomfortable confrontations. Students appeared to have difficulty recognizing the difference between teaching intents and teaching behaviors, as well as being able to professionally criticize each other's work. The vulnerability of the co-teachers reflecting publicly on each other's practice as a model for student critique was particularly powerful, both to the teacher-educators and to their students. Self-study provided a frame for understanding unexpected consequences of such vulnerability, and led to changes in pedagogical decisions for the students as well as to more supportive relations among the co-teachers.

Fitzgerald, Farstad and Deemer (2002) described a move from individualistic conceptions of teaching to a view of teaching as a more inter-subjective practice. Like Berry and Loughran (2002), they too subscribed to a dynamic, interactive model of teacher education. However, they were stymied by institutional operationalization of acceptable practice as indicated by a "teaching as telling" instrument for students to evaluate their instructors, results of which carried great weight in annual reviews and promotion and tenure decisions. Banding together in the face of this institutional threat, these teacher educators worked collaboratively in self-study groups supporting each other's investigations into alternative visions of best practice in their own teaching. This research report includes two different self-studies. One self-study group, searching for a way to lead students to more authentic reflections on their preservice teaching beliefs and experiences, experimented with a Socratic-based technique, known as learning circles. As they tested the technique in the classroom, the instructors collected a variety of data from the students in order to evaluate the effectiveness of the technique. The data were so convincing that colleagues teaching other sections of the same course were challenged to examine their own assumptions about teaching as telling. The other self-study examined the use of feedback from a doctoral student serving as a participant observer of the instructional design and implementation of a co-taught course in curriculum. Reflecting together on a variety of data from students and from the observer, the co-teachers pinpointed a need for explicit instruction for the students about cooperative work group strategies that were used extensively throughout the teacher education program. They also applied what they had learned to subsequent co-teaching situations and to support practicing teachers with whom they worked in their own collaborative teaching.

These two studies have been followed by others in subsequent self-study groups, in which collaborative self-study is having perceptible effects on major changes in the teacher education program as a whole at their institution (Fitzgerald, East, Heston, & Miller, 2002; Miller, East, Fitzgerald, Heston, & Veenstra, 2002). In a way they are pushing the spiral out beyond the classrooms

of those directly engaged in self-study as teaching and offering a model of accountability to their teacher education colleagues.

Construction of Self (roles)

In the category that comprises this section, researchers examine their own identity through the construct of their practice (e.g., Conle & Sakamoto, 1998; Featherstone, Chin, & Russell, 1996; Lighthall & Lighthall, 1996; Lighthall, Lighthall, & Richards (1998); LoGerfo (1998); Pereira, 2000; Pinnegar, Lay, & Dullude, 2000; Russell, 2002; Smith & Stairs, 1998; Trumbull, 1998). In addition to the narrative with which this chapter began, the study discussed below is an example of the use of story, rather than the kinds of data described in the above categories, to elicit the meaning within a self-study.

Pereira (2000) describes a self-study grounded in two value statements: (1) teachers/students need to experience mathematics in a meaningful and connected way; and, (2) the emotional dimensions of teaching mathematics are very important to effective teaching. From these values Pereira developed a statement of construction of self in terms of teaching math: teachers must change how they learn (reconstruct themselves as learners) before they can change how they teach (reconstruct themselves as teachers). Through this construction of self, Pereira asks students to write biographies in story format of their mathematical lives, discussing their experiences with math. Pereira believes this enables their beliefs about mathematics to emerge as well as their feelings. It is through these beliefs and feelings that Pereira encourages his students to reshape their fears and anxieties about math to, "experience mathematics in a meaningful and connected way as an activity they might enjoy" (p. 204). In this process of reconstruction, Pereira carried out a self-study of his own learning about math in terms of where his beliefs came from and the consequences of those beliefs on his actions and professional life. He does this through the use of story. In reflecting on his past learning, Pereira wrote stories from six different times: 1st grade, 8th grade, high school, college, early years of teaching, and recent teaching. In his discussion of this process, he highlights the example of his first grade story. He developed themes from his story, such as safety, obedience and authority, and corresponding polar themes of danger, exhilaration and freedom. It is through this use of story that Pereira is able to capture important aspects of his experience and to help him explore the emotional dimensions of his own teaching. In his story of his early experiences in first grade, Pereira recounts the conflict of being charged by his mother to inform the school that he already knew how to read, and should therefore skip first grade and move on to second grade. However, when he approached the daunting school building and saw the "light and inviting space" that was the first grade classroom, he chose to disobey his mother for the exhilaration of experiencing the safety of the light at the end of the hallway (the first grade room).

Pereira argues that such story writing not only elicits salient themes (he has found consistent themes emerging in his other stories) but it models for students

the ways in which tensions and needs can be expressed through stories of our life histories and prior classroom experiences. He found that the stories he wrote of his life history and classroom experiences helped him focus on the tensions created when "feelings and needs interact" (p. 207) in his classroom. In examining his own history, Pereira struggled with the meaning behind his stories. And it is this struggle for meaning that he argues is most helpful in understanding his relationship to mathematics and his teaching, that is, his understanding of the construction of self as a teacher. He contends that this process of writing stories is not only helpful in making sense of the evolution of one's beliefs and feelings, but it is an ongoing process. As stories are created and examined, they lead to more questions, which lead to connections and explanations through more stories. This form of storytelling is parallel to the first author's fourth self-study (Tidwell, 2002b) where stories were told through the use of drawings. The stories in these studies highlight the context of teaching within the learning environment. And in both these sets of stories, the view of self-study as teaching is once again illustrated.

Self-Study as Teaching in the Broader Context

The spiraling phenomena of self-study research, of reflection, and of teaching provide a frame for thinking about the broader context of learning. As can be seen in Deborah's journey through self-study in this chapter, the learning curve for practice expands with the evolution of experiences in the classroom and with colleagues (both students and teachers). Deborah's journey began by taking the role of evaluator in examining her practice through others' practical arguments (Tidwell & Heston, 1998). She based many of her decisions about research design on her beliefs and understandings from a scientific model of research. As she began to experience self-study with others (both in readings and through discussions of her research), Deborah's understanding of self-study design changed both in what she studied and in how she studied. She had spiraled beyond the role of self as the evaluator, and shifted to a broader focus on the process of effective practice, specifically examining her actions/reactions as the teacher in this process. This examination of actions led Deborah to look more closely at how well her actions embodied her beliefs about teaching and learning. And from this third study on practice and beliefs (Tidwell, 2002a), Deborah's self-study expanded to look at the construct of self as a teacher (Tidwell, 2002b) through the examination of nodal moments expressed in drawings. Across these self-studies, Deborah's evolution has been both in what is researched (focus) as well as methods for research, both in design and data gathering. And in this evolution, the spiraling process captures the dynamics of both research and teaching where the action of practice is informed through reflection and expanded by change.

Other presenters at international conferences on self-study can be seen as researching their practice with similar focus areas. The self as evaluator evident

in Deborah's first self-study (Tidwell & Heston, 1998) can also be seen in Haley-Oliphant's (1996) and Selley's (1998) self-studies. The focus of her second self-study (Tidwell, 1998), effective practice process, appeared also in Hamilton's (1998b) and Kaplan's (2000) self-studies. Connecting practice to beliefs, as in Tidwell's (2002a) self-study, is also presented in self-studies by Berry and Loughran (2002) and Fitzgerald *et al.* (2002). Not only the fourth self-study (Tidwell, 2002b), but also the entire first half of this chapter illustrate the construction of self through self-study, as did Pereira's (2000) story. The spiral of these four self-studies and related categories is a developmental progression for Deborah that parallels the spiral of her teaching. Can those who have been cited tell a similar long-term story that can be framed in a widening spiral of understanding? This same long-term progression might not be claimed by each of these self-study researchers. However, within each individual self-study reviewed here there is a spiraling process that mirrors the teaching process, where the action of practice is informed through reflection and expanded by change. In that way, self-study can be seen as teaching.

Postscript by Linda Fitzgerald, Critical Friend as Co-author

This chapter is Deborah Tidwell's story. Her long history in self-study made her an obvious choice to invite to contribute to a handbook on self-study of teacher education practice. Although we have never been collaborators on a self-study, I credit her with introducing me to the theory and methods represented in this handbook. The co-author on her contribution to the first international conference of the self-study of teacher education practice at Herstmonceux, Melissa Heston, has been a co-author on many of my own self-studies and Deborah and I have attended the last three international conferences at Herstmonceux together. But it was not until she had finished a full draft of this chapter that I began to meet with her to "hear each other to speech" (Palmer, 1998). Rather than just being an editor, my role as critical friend was to ask questions and to mirror her answers, applying aspects of the modified Quaker clearness committee procedure that my collaborative self-study group uses (Miller, East, Fitzgerald, Heston & Veenstra, 2002). This whole process has created a self-study experience for Deborah that embedded a history of her academic and personal experiences within the context of her self-studies and provided a frame for discussing other people's self-studies. Together we need to write up the self-study that is this joint chapter writing. And based on this experience together, another self-study that we might do could be to examine the differences between our own teaching/self-study spirals and how they are twining together in the larger institutional changes in teacher education that we are contributing to in the department that employs us both.

FINDING A WAY THROUGH THE SWAMP: A CASE FOR SELF-STUDY AS RESEARCH*

Vince Ham[a] and Ruth Kane[b]

[a] *Ultralab South, New Zealand;* [b] *Massey University, New Zealand*

Abstract

The point, or points, at which a 'self-study' might become 'research' is a matter of some discomfort and 'dissensus' even among those who work and write in the self-study of teaching and teacher education areas. Those of us in the practitioner research, teacher researcher, action research and self-study in teacher education communities all forage somewhat nervously in the swamplands between the apparently infertile deserts of positivist detachment and the impenetrable jungles of postmodern de/con/structive self-inspection. In our interests we straddle precariously a perceived chasm between the high theory of academe and the rich chaos of situated practice, and in so doing, we often buy into, at the same time as resenting, an unhelpful binarism that opposes rather than reconciles the university to the school, theory to practice, the academic to the teacher and, the researcher to the practitioner.

   Taking a scenario of a rejected research proposal as its starting point, this chapter addresses these issues in relation to three core questions: by what criteria do teacher-researchers judge their studies to be research?; how might the epistemological issues of self involvement be resolved?; and, how is self-study in teaching and teacher education situated in the political discourse of the academy?

   We conclude that establishing an epistemological warrant for self-study as research is still largely an enterprise conceptualized within, and judged against, the contested but nevertheless conventional requirements of the academy. It also seems that the exercise is made particularly problematic because any such research discourse is embedded in the political context of an academy that continues to privilege 'outsider' research approaches at the same time as it struggles to accommodate to the unique position of

---

teaching and teacher education as simultaneously the thing we know about, the thing we do and the thing we research.

Ruth's Story: In 1998, I, along with my colleagues, submitted a research proposal for the annual competitive research grant funding offered by my university. The proposed research project described a longitudinal, purposeful inquiry into the teaching practices of myself as a key member of the teacher education team. The intention was to problematize and reframe my own teaching practice in an effort to identify and to make explicit the ways in which my teaching was related to students' learning as beginning teachers. It sought to understand better the process of learning to teach through making explicit the voices of my student teachers. The design of the research project drew heavily on my own doctoral work. It was motivated by my passion to understand better how beginning teachers experience and understand the process of learning to teach so that I could continue to form and re-form my own teaching practice. In due course I was informed that although my proposal was of an excellent standard, the research committee had declined it on the grounds that the project was deemed "operational" in nature. What I considered valid and worthwhile research, was understood by my colleagues as purely "operational;" or "applied" activities and, as such, was deemed inappropriate for the allocation of competitive research funds within my institution. I was told it was not research but rather it was just part of my work as a university lecturer.

As an early career academic staff member I was facing a dilemma of having to establish a research program (in order to secure tenure) in a context where the nature and value of my research was at the very least called into question, and worse, not recognized as being research. I was thrust into a debate on whether the purposeful and critical examination of my own work as a teacher educator was legitimate research. I found myself asking questions such as:

- *What did they find problematic?*
- *Was it in the methodological forms that the study took, or its modes of data collection or analysis?*
- *Did the study lack rigor or legitimacy as a process?*
- *Was it that the study focused on my own practices and my own students, and as an insider study it could therefore not be 'objective' and could not have significance beyond the operation of my own course? Or,*
- *Was it that teacher education, or teaching in general in the university, was 'off limits' as a phenomenon worthy of study? (Teaching is what you do, not what you research). Or,*
- *More broadly, does self-study call into question methodological assumptions, and the language itself, of the academic tradition?*
- *Does self-study as research represent some kind of paradigm clash with what the university sees or values as research?*

Ultimately, we take Ruth's narrative to signal questions on three fronts that, although presented as theoretically distinct, are as interdependent and, at times

as confounding, as the entangled vegetation of a swamp. Each contributes to understanding better self-study as research. Two of these questions are essentially epistemological. Was this a methodological decision based on a critique of a proposal as justifiable 'research' as the academy defines it – at what point does a study become research? And, are we any closer to truth or knowledge by studying our own practices than by studying the practices of others? The other is political. Was it a decision based on the historically low status of teacher education within the university?

In this chapter we will not resolve such questions, but we can at least outline how we as members of the self-study community in education, broadly taken to be represented within the practitioner research, teacher researcher, action research and self-study of teacher education practices literatures, are attempting to deal with the conflicting world in which we operate. We will illuminate the contradictory ways in which self-study researchers have faced the challenges of negotiating the entangled swamp of academic credibility. The three questions presented above provide a frame for the structure of this chapter.

First we seek to elucidate what counts as research by discarding that which does not. We examine the epistemological and methodological issues surrounding self-study as research as we seek to shed some light on the emergence of teachers as researchers and the associated different ways of knowing and understanding research as theory development, and as method. We identify and confront the dilemmas associated with research in teaching and teacher education and in particular the dilemma of positioning 'self' in self-study research and, what special epistemological 'tests' need to be passed in order to justify a claim to knowledge when a researcher investigates their educational practices and contexts. We draw on an ongoing debate on the contested positions of researcher and practitioner, and argue that it is not who is doing the research that is critical but how the research is done. And finally, we revisit Ruth's story and draw on the experiences of North America and New Zealand to examine the politics of self-study within the traditional research university. We examine ways in which teaching and teacher education have been positioned within scholarship and the academy, and the extent to which research in teaching and teacher education, including self-study research, might either challenge or contribute to the conceptual status quo in the academy.

The Hunt for Not-Research: The Problem of 'Study' in Self-Study as Research

The definitions of research provided in most academic research methods texts are variations on a theme of public knowledge production as an inherent social good. Research is described as multivariate in its methods or forms of data collection, intellectually honest, evidence-based, rigorous, systematic and pre-planned in the quality of its analysis and synthesis, and alternatively exploratory, descriptive, explanatory, predictive, evaluative or emancipatory in its purpose. Research is, "a way of going about finding answers to questions … a collection

of methods people use systematically to produce knowledge" (Neuman, 1997, pp. 1–2). It is, "an activity directed towards the accumulation of knowledge within a discipline" (Hammersley, 1995 p. 102). It is, "a systematic self-critical enquiry … founded in a desire to understand" (Stenhouse, 1981 p. 103). It is, "seeking through methodical processes to add to one's own body of knowledge and, hopefully, to that of others, by the discovery of non-trivial facts and insights" (Howard & Sharp cited in Bell, 1993, p. 2). It is "systematic enquiry made public" (Stenhouse, 1981, p. 104), and so on.

Research as defined by government or other agencies that accredit and fund the academy, however, seem to take a more pragmatic approach which looks at least as favorably upon the use and social application of knowledge as it does upon the generation of knowledge and social understanding for their own sake. According to the OECD, for example, to be classified as research an activity must,

> … comprise creative work undertaken on a systematic basis in order to increase the stock of knowledge … and the use of this stock of knowledge to devise new applications. Any activity classified as research and experimental development is characterized by originality; it should have investigation as a primary objective and should have the potential to produce results that are sufficiently general for humanity's stock of knowledge (theoretical and/or practical) to be recognizably increased. (OECD cited in Edith Cowan University, 2001)

Similarly, the South African National Research Foundation (NRF), drawing on the definition developed for Britain's Research Assessment Exercise, states that:

> Research is original investigation undertaken to gain knowledge and/or enhance understanding. Research specifically includes: the creation and development of the intellectual infrastructure of subjects and disciplines (e.g., through dictionaries, scholarly editions, catalogues and contributions to major research databases); the invention or generation of ideas, images, performances and artifacts where these manifestly embody new or substantially developed insights; the use of existing knowledge to produce new or substantially improved materials, devices, products, policies or processes. (National Research Foundation, 2002)

The definition of the New Zealand Qualifications Authority (NZQA), an accrediting agency for new degree programs, takes an even more inclusive line.

> Learning, at graduate and postgraduate levels; takes place in an environment of developing and advancing knowledge; problem solving, critical evaluation; investigation, and an awareness of the limits of enquiry and understanding. … [NZQA] recognizes that for some subjects or disciplines, a broad interpretation of what constitutes research is necessary. All research activities are conducted in accordance with recognized ethical standards and are open to peer and public scrutiny.

The following kinds of research may be distinguished although they are not mutually exclusive:

> For the Authority, research includes not only theoretical and experimental work undertaken primarily to acquire new knowledge, but also work which develops or tests existing knowledge or evaluates policies or practices, scholarship which synthesizes and interprets ideas and information, and creative work involving the invention and generation of ideas, hypotheses, images, performances or artifacts. (NZQA, 1995, p. 31)

Such definitions, of course, are standard fare, and their common appeal to criteria such as solving problems and advancing knowledge or practice by the application of 'rigorous', 'systematic' or 'original' forms of investigation ethically conducted and open to public critique, represents some sort of practical consensus in the academy and government alike as to what counts as a suitably inclusive definition of research. But as our opening scenario indicates, such 'official' consensus often hides a number of thorny disagreements, ironies and debates within the academy, both as a matter of fundamental epistemological argument about the nature of knowledge and, also in the daily practice and politics of academic research. This has not least been the case among the researchers and practitioners of teaching and teacher education, where in the last decade or so serious discussion has arisen about whether or not practitioner self-study in fields such as education are deserving of some 'special case' status as a form of research or scholarship within the academy. Is self-study and practitioner research on teaching a 'new paradigm', requiring a new or different research epistemology, or can it be accommodated within some broad existing consensus about what a study has to look like to be research, who is most legitimately placed or qualified to conduct it, and who is best placed to make such decisions?

In this regard, the South African/UK and NZQA definitions are interesting, because in addition to outlining what research 'is', they also address specifically the issue of what it is 'not'. The NRF criteria, for example, specifically excludes from its definition of research, "routine testing and analysis of materials, components, instruments and processes … and the development of teaching materials and teaching practices that do not embody substantial original enquiry" (National Research Foundation, 2002). In like manner, the NZQA definition states that, "work which involves the routine application of established techniques on routine problems is unlikely to constitute research … and NZQA does not regard activity mainly concerned with keeping abreast of new developments in subjects as research" (1995, p. 32).

On 'professional practice' the Authority states that this may be "the equivalent" of research, but only, "under certain circumstances … [and] in certain subject areas and professions, [where] the theorization and effectiveness of professional practice are advanced by academic staff who practise and participate in it" (NZQA 1995, p. 32). Clinical psychology would presumably be an example of

the latter special case, but it is unlikely that the authors had in mind teachers or teacher educators. They go on to state, for example, that, "it is assumed that providers will, as a matter of course, ensure that all teachers of degree programs have sufficient time to keep abreast of new developments ... in methods of teaching" (1995, p. 32), without realizing perhaps the dilemma the latter phrase creates for teacher educators, for whom 'methods of teaching' are all of their teaching subject content, their job as teachers, and their area of research interest.

Teachers as Researchers

In the last decade there has been a considerable move in educational research to supplement – some would say replace – research by researchers on practitioners with 'practitioner research': that is, research not 'on', but 'by', or at least 'with', and certainly 'for', practitioners. Research should inform practice, runs the argument for this trend, yet much of traditional outsider research is regarded as irrelevant by practitioners. Much academic research is characterized as too obtuse in its presentation to be understood, too theory laden to be useful, and too often concerned with problems that have little significance in the daily routines of a practitioner's life.

Practitioners are presented as having been variously ignored, used, patronized, and even colonized by outsider researchers, and as a result whole landscapes of knowledge have been at best left unexplored and at worst unwittingly pillaged as knowledge spoils for the researcher rather than the practitioner community. In response, the 'teacher as researcher' movement has set about reclaiming the territory of practitioner knowledge by making a stand, (or more often making a treaty with the more empathetic members of the research community), whereby such landscapes are explored in terms of practitioner's interests, addressing practitioner's questions and intimately involving practitioners in the process of research (e.g., Cochran-Smith & Lyttle, 1999; Elliot, 1991; Zeichner & Noffke, 2001). Teachers 'are doing it for themselves'.

Perhaps the most obvious manifestation of this new found assertiveness around teacher research is in the labeling discourse of both practitioner and researcher communities alike. Reflective practice, reflective enquiry, action research, critical enquiry and other similar expressions have become commonplace descriptors for the ways in which teachers and practitioners might develop as professionals, contribute to curriculum development, test or develop theory, add to the corpus of knowledge of situated educational practice, or become institutional change agents. And part of this discourse throughout has been an often implicit but nevertheless important discussion of the relationship that all of these activities might have to what has been conventionally known as research (e.g., Anderson & Herr, 1999; Reason, 1994; Stenhouse, 1980).

One often-cited attempt to illuminate the shady place where a self-study of teaching might become research from a self-study perspective is Richardson's (1994) distinction between formal research and practical enquiry. The core of Richardson's thesis is a distinction made between practical enquiry and formal

research. By this account formal research is roughly equated with conventional research, characterized as traditionally done by university based academics and aimed at the generation of rule-like principles or theories about teaching. Practical enquiry, on the other hand, is a catchall description for a variety of other forms of investigation done by, or in close collaboration with, practitioners to solve immediate practical problems. Practical enquiry is taken to encompass three conceptual views of teacher research: first, "the notion that *teaching is research*" (1994, p. 7, original italics), in other words the normal, largely internalized data collection and evaluation of our teaching techniques that we do all the time when working with students, which is research-like in its process and product; secondly, the "various conceptions of *teacher as reflective practitioner*" (1994, p. 7, original italics), especially as popularized through the work of highly regarded educationalists like John Dewey and Donald Schön; and thirdly, the various marques and models of action research. Formal research is distinct from these three because it has goals or purposes beyond the solving of particular problems, namely a commitment to the publication of cases in order to expand our general understandings of teaching and, a commitment to theory development.

For us, this highlights the importance of making some distinctions around the idea of research based on its purposes and not just its forms, but it is not ultimately that helpful in clearing the ground between research and not research. Practical enquiry, for example, is alternately talked of as being a form of research on one hand, and yet fundamentally different to formal research on the other. Nor do we see the logic by which the highly data-driven methods of action research are felt to be more closely allied with largely rational-reflective modes of enquiry such as 'normal teaching' and 'reflective practice', than they are to the more empirical methods of conventional research. Moreover, differentiating between the formal and the practical solely in terms of a commitment to theory development and publication, does not allow for the many forms of educational research done by academics which do *not* aim at theory development, nor for the oft claimed purposes of action research and some types of reflective practice being either grounded/personal theory development or theory testing (Mills, 2003; Elliot, 1991). And finally, we do not see how the label 'formal' has any denotative significance, since the distinguishing features of formal research as presented are nothing to do with 'form' in the sense of method or technique, nor 'formality' in the sense of rigor or preplanning, which are indeed ideas common to all of the modes of enquiry discussed. Ultimately, therefore, we are left with a definition that distinguishes not between research and 'not research', but between different types of research. We have a clearer idea of what needs to be discussed in terms of research as a form of purposeful enquiry, but still have not resolved the problem of whether or not, or in what circumstances, simply 'doing teaching' or 'being a teacher', even a very reflective one, might be the same as 'doing research' or 'being a researcher'.

Cole and Knowles (2000) seem to get closer to a coherent resolution of the labeling issue when they speak of "Researching Teaching through Reflexive

Enquiry", Researching Teaching through "Autobiographical Enquiry", "Researching Teaching through Collaborative Enquiry", and "Researching Teaching through Inquiry into the Elements of Practice" (passim.). By this conceptualization critical reflexion, autobiographical inquiry, collaborative enquiry and so on, are all presented not as alternatives to research itself, but as alternative ways of doing research, with research being defined implicitly but very broadly, as any conscious and rigorous way of knowing, or finding out, about something. This broader, and ironically more 'form-related', conceptualization of research also seems to resolve the dilemma inherent in any definition based on calling something research or not research solely or largely on the basis of some exclusive purpose such as developing theory, solving practical problems or developing emancipatory understandings – all of which would seem to us to have a potentially justifiable claim to be legitimate purposes for research. We might under certain circumstances still judge teaching or reflective practice or action research all to be, or not to be, research, but it would be on criteria other than whether or not they aim at public theory development or solve a particular teachers' practical problem. Moreover the criteria we would apply would be something to do with whether or not the thing claiming to be research stood up as a form of enquiry; not as a thing to be done or known, but as a way of doing or knowing.

Teaching as Research

While there are some claims made in the self-study literatures that teaching is, of itself, a practical form of research (Mills, 2003; Patterson & Shannon, 1993; Neilsen, 1990), the greater consensus is that although the process of self-research by teachers necessarily involves teaching, the converse does not apply (McNiff, Lomax, & Whitehead, 1996). Indeed, in a statement from an action research perspective that could almost stand as a manifesto for the self-study of teaching and teacher education movement generally, Kemmis and McTaggart (1988) itemize,

Four things [that] action research is not:
1) It is *not* the usual thing that teachers do when they think about their teaching. Action research is systematic and involves collecting evidence on which to base rigorous reflection.
2) It is *not* problem solving. … It is motivated by a quest to improve and understand the world by changing it and learning how to improve it from the effects of the changes made.
3) It is *not* research on other people. Action Research is research by particular people on their own work, to help them improve what they do, including how they work with and for others. … It treats people as autonomous, responsible agents who participate actively in making their own histories by knowing what they are doing.
4) It is not the scientific method applied to teaching. … Action Research is

> not just about hypothesis testing or about using data to come to conclusions … Action research also concerns the 'subject' (researcher) him or herself. … Action Research is a systematic evolving living process of changing both the researcher and the situations in which he or she acts … the living dialectic of the researcher and the researched. (pp. 21–22)

Thus teacher action research, and by extension any empirical-reflective (self-) study by teachers of their practice, is research on and in (one's own) action. It is more than, and different to, action. It is more than, but must encompass, reflection. And it is more than, but must encompass teaching. Teaching is not, in and of itself, research, and nor, presumably, are less 'rigorous' or self-critical forms of simply thinking about teaching. By such a view, while teaching would remain on the practical enquiry side of Richardson's (1994) formal research-practical enquiry divide, action research and possibly some forms of reflective praxis would clearly belong on the research side.

Research as Purpose

Much of the claim for the *novelty and importance* of, for instance action research lies in it being research conducted by practitioners for practitioners, aimed at solving specific classroom problems and/or at developing a politicized understanding of the located practice of teaching and learning. What seems more at issue in the distinctions among the action research, reflective practice and teacher as researcher movements is the purpose of educational research and, in particular, whose interests it serves. But, in this discussion, what also legitimizes it as *research* is not simply something to do with its emancipatory or explanatory purposes per se, but equally something to do with its base in empirically derived data and the ongoing studious and self-critical reflections made by the teacher-researcher on the basis of this data. A commitment to formality, system, and rigor in data collection and self-reflection, a commitment to the iterative testing of implicit/tacit or explicit/generalisable curriculum or pedagogical theories, and a commitment, at least for many, to the sharing of collective experience in public fora, form the core of the notion of action research as research. Unlike in conventional outsider or theory-producing research, subsequent action rather than public knowledge may be the prime legitimization of the research, but the research also is the methodological legitimization of the action. The research may be judged to have been good research insofar as it leads to effective action or a resolution of a problem, but there is also the assumption that the effectiveness of the action is likely to be dependent, in large measure, on the adequacy of the process of data collection (observation), interpretative analysis (reflection) and publication (collaboration) that embodied the research.

  Others, from what Fenstermacher (1994) calls "the Schön strand" (p. 49) of US practitioner research, or from the British 'teacher as researcher' movement, take a position on the role of self studies as research similar to that of the Australian and British action researchers. Schön's (1983) main target for example is technical rationality and the assumption that the role of research in teaching

is to provide practical rules or theorized models of action for teachers as technicians to implement. Insofar as he connects reflective practice to academic notions of research he sees reflection in and on action as potentially contributing to forms of research including what he calls 'action science'. Like the critical action researchers, who also discuss the study of action or practice as an 'educational science' (Carr & Kemmis, 1986), Schön's central appeal seems to be that research on teaching be sensitized to the nature of reflection in action and to the interests of teachers as practitioners, rather than being based upon Technical Rationalist assumptions that the point of research is to provide theory based product for practitioner consumption. To qualify as research, studies of action and practice must have a rigor and an established set of disciplinary methods that are as coherent and robust as, but not confined to, those of (natural) science. For Schön, while research and reflective practice are not synonymous, the desired relationship between them is that research is to serve practice, not the other way round. Writing from a phenomenological perspective, Van Manen (1990) makes a similar argument for a "human science" based on "investigating experience as we live it" (p. 53). Phenomenological research, must "begin with the lifeworld", but it does not constitute the lifeworld. Research is the textually represented reflection on the experience of pedagogy, not pedagogy itself. Like self-study as action research, and self-study as practitioner research, self-study as phenomenological research is not teaching; but it necessarily involves teaching.

Despite the frequent references to science in these works, and their apparent claims to the status of science, we do understand that this is not positivism, nor is it scientism. The advocates of practitioner research and critical action research are concerned to reconsider a conceptual divide not so much between research and practice, as between theory and practice. In doing this an appeal is often made to revisit Aristotelian notions of phronesis as purpose and praxis as form, and through the concept of praxis to legitimate in teaching, though not necessarily to reconcile, the dual purposes and methods of episteme and techne, theoretical and practical knowledge (Carr & Kemmis, 1986; Korthagen *et al.*, 2001; Wong, 1995).

Thus, the 'critical' and 'reflective practitioner' case that change beyond understanding is, or should be, the ultimate goal of educational research, consciously makes a claim for additional legitimacies for research based in the phronesis of responsible social action, beyond the largely descriptive or interpretive goals of, say, phenomenology, ethnography or history. But in their common appeal to the status of a social science, an educational science or a human science, such arguments do nevertheless share by association science's, and history's, and indeed most other academic disciplines' commitment to the notion that there are more and less justifiable ways of knowing or evoking a (social or natural) phenomenon. There is a shared assumption that there are more rather than less defensible ways of claiming or using public knowledge about those phenomena, and that the word research is in some way reserved to denote or connote those that are more, rather than less, justifiable and defensible in so doing. Research,

as Fenstermacher (1994) points out, is fundamentally about the epistemic warrant one might advance for a theory, or for a practice, as constituting knowledge. It is in itself synonymous with neither theory, nor practice, nor knowledge.

Research as Method

How, then, do we in the self-study and self-research teacher communities distinguish research from not research in terms of its apparent legitimacy or value as a *form* of study, as a way of knowing and showing?

In reflecting on this, we wonder if, in providing a rationale for practitioner research, the teacher as researcher discussion has centered on problematizing issues of perceived and politicized relevance at the expense of problematizing issues of methodology. And so, at the same time as we practitioners appropriate research questions to ourselves, we nevertheless often continue to borrow conventional research's processes for answering them. Thus, while the purpose or specific directions of research may be somewhat different in practitioner research compared to conventional outsider research, the data gathering and analysis/synthesis procedures as implemented are often more remarkable for their similarities than their differences. Only now, perhaps, are we seriously asking the question: are the research questions of teachers' self-research *so* different from those of conventional qualitative research that they require different methodologies to answer?

In the self-study literatures the discussion of the key characteristics of research seems to revolve around the various conventionalized, some would say ritualized, processes of data gathering, analysis/synthesis and presentation that accompany a claim to public knowledge. Thus, for many self-studiers, the justification of the form of a self-study as research lies essentially in the extent to which, and ways in which, any given (self-) study is felt to conform, or not, to academically established, though still contestable, ways of 'getting to know' and 'publishing knowledge claims about'. Research, in short, is conceptualized as practical method.

For most self-researchers of teaching and teacher education, it seems that the shady place where a (self-) study becomes or does not become research as a matter of form, is illuminated by applying one or more of three criteria: a) the extent to which a study is grounded in empirical evidence; b) the extent to which a study has actual or potential generalized, or theoretical, import; and, c) an enacted intention to make public.

The first of these criteria is more or less associated with conventional notions of the application of appropriate tests of validity to the data and argument presented. It requires the researcher to ask, have I shown with any credibility that what I claim or describe is indeed the case for me? Are my claims to knowledge of my practices seen to be grounded in good evidence and based on sound principles of rigorous enquiry as these might be accepted by my (researcher) peers?

Hamilton (2002) addresses just this question in relation to her self-study of institutional change thus:

> In undertaking a self-study of my experience as a (secret) change agent, I was conscious of the need to avoid a narcissistic, self-indulgent exercise in vindicating my position. I could see the need for my work to be a strong, careful self-study that moved from individual experience to program involvement that incorporated a well-grounded exploration of the methods used. Hence my sources included personal journals, field notes, interviews, notes, formal memos, documents, meeting minutes, and informal interviews. All of these comprised my database. Dialogues with colleagues outside the study have also been important. They have served as critical friends, and provided comparative perspectives from other institutions and teaching experiences. (p. 182)

Muchmore and Sayre (2002) justify their self-study of two parent's decision to home school their child as research in a similar way.

> In our full paper, we describe and analyze the ways in which our individual personal histories have shaped our views on home education, and how we might resolve our differences in the case of Grace. Our data sources include transcribed audio-recordings of our conversations, our past autobiographical writing, and various books and mass media articles about home schooling – all of which we have read, discussed, and analyzed in order to better understand our thinking and decision making process. We also contextualize our self-study within the larger political, historical and research contexts of home education in the Untied States. Thus our paper serves not only our personal and professional need to resolve our dilemma, but also contributes to the existing research literature on home schooling. (p. 55)

There is in such discourses the implication that any study of practice, done by self or otherwise, is research in large part according to the extent that it is empirically grounded. That is, it is based on contemporaneous or near contemporaneous archives and records of what the participants in the practice said, thought, felt and did at a particular point in time in a particular social context.

Moreover, even if much of the empirical data is self generated in the form of journal entries, written or recorded reflections etc, it is analyzed, re-reflected upon, and re-viewed at a later stage as 'evidence of what I was thinking/doing/being at the time'. Though this process may involve introspection, it does not constitute introspection – it is the researcher – me, now, investigating the archives and artifacts left by the informant – me, then, with the bonus miles available that the archive can still stimulate the remembering of much more about the situation as I initially experienced it than can be read in the archive itself. When it is self-generated, the archive is thus an ongoing stimulus to even more data, at least about 'my' part in the practice. But it is still *data* in the way in which it is treated in the analytic, synthetic and presentation stages of research.

The second criterion often applied by self-study authors for judging the form of a (self-) study as being research, more or less equates with the questions of generalizability and theory-relevance. In this respect the rationale for generalization is presumably the same as that made for any case study: the particular as exemplar (Stake, 1995; 2000; Eisner, 1998). There is, in other words, at least some attempt to identify what the researcher-author regards him/herself to be 'a case of'.

In self-studies this may take the form of direct appeals to theory, or it may take the form of the conscious setting of the case within a particular context or problem of potential general interest, accompanied by an invitation to compare and contrast with other cases. The connection to explanatory theory may be prominent and explicit, as in situated experiments testing specific propositional theory in the fires of actual classroom practice, such as Williamson-Leadley's (2001) account of the incorporation of multiple intelligence theory in her teaching of her primary school class. In others it may be implicit and focused on the development, in a grounded way, of personal theory as praxis, as in Allender's (2001) account of the Gestalts of his teacher self. Or it may exist in some iterative mixture of the two, as in Samaras' (2002) account of her evolving commitment to Vygotskian theory in her practices as a pre-service teacher educator.

Other self studies, however, provide little direct connection to generalized explanatory theory, though they nevertheless provide a generalisable context for their study in the form of a literature review outlining the extant knowledge relevant to the issue at hand (Hamilton, 2002; Smith, 1998; Louie, Stackman, Dreveddahl, & Purdy, 2002). Presumably for these self-studiers, the aim of understanding and describing, as for historians, are legitimate research goals in themselves (Stenhouse, 1981). As Stenhouse asks, why is theory development or theory testing seen as commensurate or synonymous with research? "Researchers sometimes regard teachers as theoretically innocent", he argues, "But much professional research drawing on, if not feeding, the disciplines is also theoretically innocent. This is true of most surveys, field experiments and evaluations" (p. 110). The same could presumably also be said of most cultural ethnographies, the descriptive typologies of biology, the situated explanations of history, and so on.

For such researchers the aim is not to elicit or develop rule-like principles for action but to draw out those aspects of the case described which are likely to be of interest to others in the wider community. The action research for curriculum development programs of Stenhouse, Elliot and others might also serve as examples of this. They do not appeal to theory per se, but involve a form of what Stake (1995) calls naturalistic generalization. It is an appeal to compare and contrast cases, and by such comparison and contrast to build an accumulating body of published experience. Explanatory or predictive theory may, or may not, derive from this accumulation; it is enough that a body of contested understandings does.

Which brings us to the third criterion, which is often put forward by self-researchers for their *study* to qualify as research: an enacted intent to make

public. Some advocates of practitioner enquiry limit the responsibility of the study to the solving of particular problems and do not see publication as a necessary part of the enterprise. This might be on the basis that understanding or contributing to knowledge are not the primary point of the exercise (Robinson, 1993), or on the assumption that the study does not develop useful theory (Richardson, 1994), or perhaps on the pragmatic grounds that teachers are only interested in, or only have time for, the resolution of their own particular problems (Mills, 2003). For many others, however, research kept private is not research.

Samaras (2002) possibly speaks for many in the self-study community by explaining her decision to publish her self-study thus:

> I use the word self-study to mean critical examination of one's actions and the context of those actions in order to achieve a more conscious mode of professional activity, in contrast to action based on habit, tradition and impulse. ... Self-study is more than an exploration of one's self. The heart of self-study is the application of the knowledge one gains through this process to one's teaching practices. ... I found that telling my own story helped me to understand my teaching better (Samaras, 1995), but I wanted to be sure that I told more than merely my story; I didn't want a narcissist psychoanalytic self-analysis. I reveal myself in this book to model how preservice teachers and professors can tell their own stories to help them understand how their early life lessons shaped their teaching and their perspectives about students who are not like them. ... I am becoming my own theoretician. (pp. 1–5, 7)

Samaras' choice of the phrase 'narcissistic psychoanalytic self-analysis' may be significant here. We read it as a plea that her writing not be seen as just a story, and above all as not purely self-serving. It is a plea that the activities and understandings she reports, and the fact of reporting them, are essentially driven by motives and assumptions that are conscious of the world beyond her particular case and her own particular needs. They are written in the hope, and published on the assumption, that her study may be of use to others. This is perhaps because the self-study of teaching is not purely the study of the personal, but of the personal within the professional. It is a study of self in relation to her educational practices, not just of the psychological 'self' in isolation. It is inherently, therefore, a study of that which binds the particular to the collective, a study of that which assumes a 'we', a collegial society or culture of others who spend much of their waking hours being what I am, doing what I do. It is simultaneously an appeal to a common interest, an appeal to a common experience, and an active invitation to compare and contrast, and by so doing, to better understand. For her at least, and perhaps many others, this is a fundamental requirement for self-study to have crossed the line and become research.

Appeals to a common professional good are prominent in practitioner researchers' rationales for the publication of their own cases, though the extent

to which it is emphasized as a necessity rather than merely a virtue of self-studies as research varies. Carr and Kemmis' (1986) third "minimal requirement" for action research, for example, talks of, "widening participation in the project gradually to include others affected by the practice" (p. 167) which seems to imply certainly some forms of participatory sharing as a way of building a self-critical community, but also seems to stop short of an injunction to contribute to the corpus of general knowledge. Cresswell (2002) seems to adopt a similar position in including as one of his criteria for evaluating action research: "was the action research reported to audiences who might use the information?" (p. 619). For Zuber-Skerrit (1991), however, there is no equivocation: "research is collaborative, critical (and self-critical) enquiry by reflective practitioners who are accountable and make the results of their enquiry public" (p. 2). Wolcott (2001) put it even more bluntly: there is, "no point to research without reporting" (p. 7).

The commitment to publish represents a general commitment to the notion of a steadily accumulating body of reported experience which is useful not only as a necessary foundation of robust theorizing about educational practices, but also useful to the writers themselves, and, more importantly, useful to the community of others. Moreover, in asserting the necessity to publish self-researchers are also saying that in order to meet the academy's criteria for knowledge claims, this second invitation of a self-study (to see if the case for me is also the case for you) is not to be made passively, but actively. In this respect the self-researcher is claiming that their story is not only *not* a fiction, it is not a simple psychotherapeutic confessional either. They are *actively* inviting the reader to see them, or their experience as they have investigated it, as 'a case' of something. For most self-studiers, it seems, to claim a study as research they are under some obligation not just to tell the story but also to actively locate it in some more general issue, debate, problem or theoretical context that is more rather than less likely to be of interest to someone else. This locating is a way of sign-posting where they see their study or experience fitting in terms of the more general body of public knowledge. It is the insider trying to get out. It is the reflexive practitioner trying to be the reflexive researcher as well. It is the movement in stance from being the object of one's own subjectivity to being the subject of one's own objectivity. It is, in Mead's (1934) terms, the 'Me' talking to the 'I", the attempt to see or interpret as others might, and thus to perceive the possible relevance of 'my' story to 'them'. It is not research because it is 'by me, for me'; it is research because it is self-consciously 'by me, for us'.

Hammersley (1992, 1993a, 1993b, 1995), however, makes a legitimate critique of some of these rationales for publication as a necessary criterion for research, when he emphasizes that in conventional outsider research, the purpose of publication *as research* is not primarily to share otherwise taken for granted experience with colleagues, but rather to submit a claim to public knowledge to peer critique. Publication in this notion of research, is done not merely "to have it read by like minded folks" (Mills, 2003, p. 163), but to subject it to quality control processes as an assumed claim to public knowledge. Thus, in moving

from research as a process, a way of enquiring and 'getting to know', to research as a product, a set of published findings representing 'what I know', the question arises of whether to be research a published account must be implicitly or explicitly a claim to contribute usefully to what the OECD definition of research calls "humanity's stock of knowledge" (OECD cited in Edith Cowan University, 2001).

The discussion has thus moved away from research as a (private) process towards research as a (public) product. In this conceptualization research is not simply the mode of enquiry, not simply the technical implementation of a set of data gathering and analysis techniques acceptable to a community of fellow researchers and possibly useful to a community of fellow practitioners. As a product, as an evocation or a representation of some social phenomenon, it is also a claim to be justifiable and/or useful knowledge and, as such, it is subject to criteria for judgment and forms of peer critique and intellectual quality control.

Traditionally in academic research, something is more or less true insofar as it is more or less convincing to those competent to know. And those competent to know make such judgments not only on the coherence of the argument put or the face validity of the knowledge claimed – how consistent or inconsistent it may be with what is deemed to be already known – but also on the bases of the credibility, validity, trustworthiness or authenticity of the methods used, and the reflexivity of its representation. In the academy at least, a legitimation of a study as research is still largely a legitimation of method. The epistemological baby not yet apparently thrown out with the positivist bath water is that quality control of the product we know as research, even in all forms of qualitative research, is still as much about validating *how* something came to be known as it is about validating *what* is claimed to be known.

Thus, in the publishing part of the classic research cycle (pose the question, gather and analyze the data, present the results), arise other dilemmas of style, voice, format and representation that are especially problematic for the self or practitioner researcher. For example, we often think it is ironic, and perhaps indicative of the way in which we in the educational self-study community feel we straddle so many apposing, if not opposing, conceptual and academic rifts, that while presentations at the Self-Study of Teacher Education Practice (S-STEP) Conferences are encouraged to be workshops, role plays, scenarios and even dramatic performances, the prescription for written papers require conventional research reports using headings like 'Theoretical framework', 'Objectives of the study', 'Methods', 'Data Sources', 'Findings', 'Implications of the Study', and so on. The dilemma for self-study here, as Whitehead puts it, is that, "the spiritual, aesthetic and ethical standards of judgment in educational [self] research require multi-media forms of presentation which cannot, by their nature, be communicated through the pages of the linguistically constrained refereed journals" (cited in Mills, 2003, p. 155).

In this statement, as in the ironies of the presentations at the S-STEP conferences, Whitehead is actually highlighting two separate but associated dilemmas for the self studier or teacher researcher. First, there is the general postmodern

dilemma, shared by all social researchers, of the inevitable inadequacy of any linguistic forms as re-presentations, re-productions, or re-creations of a social or intrapersonal phenomenon through the questions: "How can I adequately reproduce an experience, either my own or someone else's, in any language-mediated form, to a third person?" and, "How can any experience, thought or belief be represented validly to anybody?" And secondly, there is the more politically based dilemma specific to practitioner researchers, of how to please both practitioner peers and researcher peers when they read an account of a researched experience with very different purposes in mind indicative of the question: "How can my self-research be reported in a way that simultaneously makes it comprehensible to the audience of practitioner peers who might 'use' it as knowledge, at the same time as making it sufficiently comprehensive for our researcher peers whose task is to 'judge' it as knowledge?"

As Zeichner and Noffke (2001) point out, many of the tests of quality advanced for judging published practitioner research as valid knowledge are the same as those that would apply to any standard qualitative or interpretive research account. On the other hand, attempts at identifying distinct criteria that might only apply to research done by practitioners have been fewer and less convincing. They conclude that, while there is still a case to be made for self-study as requiring new criteria for judgment appropriate to non-traditional forms of presentation, such an epistemology has yet to emerge.

> It is clear to us that, whatever, criteria eventually emerge to define quality in practitioner research, they will need to reflect the different forms and multiple purposes associated with this genre … In some circumstances it may be appropriate to apply criteria of validity or trustworthiness or both that are adapted from those used to evaluate conventional academic research. [But] there will [also] be circumstances where the use of aesthetic, literary, educational or moral criteria will be most appropriate. (Zeichner & Noffke, 2001, p. 322)

One set of tests that specifically address these issues of credibility in representation and form with regard to autobiographical narratives is that advanced by Bullough and Pinnegar (2001). Drawing on the field of (self-) narratives as representations of experience, as well as on Mills' (1959) work on the "sociological imagination" and "intellectual craftsmanship", Bullough and Pinnegar suggest 15 guidelines for reading autobiographical self-studies as research. These tests range in focus from guidelines one would expect for reading traditional ethnographic research reports (such as "attending carefully to persons in context or setting", "offering fresh perspectives on established truths", containing "convincing evidence", and "representing phenomena "completely and complexly"), through to guidelines drawn from the canons of literary critique which acknowledge the narrative as a form of textual (mis)representation of the actual experience. Tests along these lines include aesthetic standards such as pleasant literary style and formal shapeliness, plot resonance and the "authentic voice" of the

writer-researcher (pp. 15–20). Focused as they are on studies presented as auto-biographical narratives, however, these guidelines only start to point to a way towards resolving McNiff, Lomax and Whiteheads' (1996), or Zeichner and Noffke's (2001), problem of the aesthetic, the emotional or the moral in different modes of representing self-studies as research – be they in more radical (e.g., dramatic) or in more conventional (e.g., research report) forms.

As we trust would be clear (from our arguments above) we understand all of this as dilemmas of what counts as research in general, and as dilemmas of validity in published research reports in general. We even understand it as a particular dilemma for us as practitioner researchers, who wish to stake a claim to sit at the high table of public knowledge as researchers at the same time as we want to produce useful 'knowledge', or accounts of experience, accessible to our fellow teachers. We understand it, in short, as a problem of defining any self-study as a *study*. But research is also, now, about the knower, and this has implications for *self*-study, or *self*-research. Hence the question: "What are the special validity, quality or representational issues, if any, that lie in the conduct or publication of research done by me on my own practice or on myself as a practitioner *specifically because it is done by me*?"

The Enlightened 'I': The problem of 'Self' in Self-Study as Research

Increasingly the post-modern turn in the academy has encouraged social researchers to be ever conscious of their role as constructors of their own research and, of the inadequacies of a research stance that claims their findings somehow exist independent of the values, assumptions and interpretations of the researcher. Hence the bracketing of phenomenologists and phenomenographers (Hycner, 1985). Hence the reflexive turn in the writing of outsider ethnographies (Walford, 1991; Woods, 1996). And hence the persistent problematizing of text and voice, and the crisis of representation that informs much post-modern, feminist, and other research conducted from a relativist perspective (e.g., Stronach & McLure, 1997; Trifonas, 2000; Bullough & Pinnegar, 2001; Dadds & Hart, 2001; Tierney & Lincoln, 1997). For interpretive and critical sociologists alike, as has long been the case for historians and phenomenologists, the fact that even 'researched' knowledge is the articulated construction of a knower/enquirer who is just as susceptible to illusions, delusions, assumptions and misinterpretations as any of their informants, is to be acknowledged and illuminated as part of any public claim to know or understand.

The questions arise, then, of the specific role of the knower/enquirer in '*self*-studies' of teaching practice: "To what extent, and in what ways, may our self-studies be more, or less, or differently, problematic as research compared with studies of 'other' simply because they are *self*-studies?" and, "Do the same criteria for judgment apply when a knowledge claim is based on researchers' investigations of their own social actions, as when such a claim is based on researchers' investigations of the social actions of others?" Much of the discussion around who should conduct research on teaching is based upon essentially political

arguments about whose 'constitutive interests' are served by educational research, who could or should 'own' or 'use' any findings, whose knowledge is worth publishing, and whose questions or problems are addressed. These are legitimate issues related to relevance and purpose in self-research and will be dealt with later. But what of issues of productive quality and procedural integrity? Relatively less attention appears to be given in the practitioner research and action research literatures to the epistemological issue of the threats and opportunities that may be present in terms of the credibility, validity, authenticity, relevance, trustworthiness (or whatever other synonym for quality might be used) in relation to the research processes conducted, and thus any knowledge claimed, *when the practitioner and the researcher are the same person.*

Fenstermacher (1994) raises this issue as a matter of epistemological interest in the light of the work of Cochran-Smith and Lytle (1990), though he does not resolve it. In part this may be because, while there is some consensus that practitioner or teacher research by definition serves the interests of the teaching practitioner before those of the academic researcher, there is rather less consensus, as Zeichner and Noffke (2001) show, about the extent to which practitioner research, or action research, can or should, as a matter of epistemological (as opposed to political) principle, be conducted by practitioners themselves.

Authority in Self-Research

Like the action research community, the 'Schön strand' of reflective practitioners makes a basic assumption that only the actor can know an action, by virtue of experiencing it and by means of a constant dialectic self-reflection both 'on' it and 'in' it. But they do not all make the same assumption that therefore the actor (teacher) is necessarily the one best qualified to research it. For Schön (1983), for example, the practitioner-researcher relationship is still one of collaboration.

> In the kinds of reflective research I have outlined researchers and practitioners enter into modes of collaboration very different from the forms of exchange envisaged under the model of applied science. The practitioner does not function here as a mere user of the researcher's product. He reveals to the reflective researcher the ways of thinking that he brings to this practice, and draws on reflective research as an aid to his own reflection in action. Moreover, the reflective researcher cannot maintain distance from, much less superiority to, the experience of practice. Whether he is engaged in frame analysis, repertoire building, action science, or the study of reflection in action, *he must somehow gain an inside knowledge of practice.* Reflective research requires a partnership of practitioner-researchers and researcher practitioners. (1983, p. 322)

For many, the practitioner-researcher is still largely held in promise as the ideal rather than the common reality:

> The reflective researcher may take on the role of consultant to the practi-
> tioner. Reflective research may become a part of continuing education for
> practitioners … The researcher may stand to the practitioner in a relation-
> ship of participant observation. The practitioner may take time out to
> become a reflective researcher, moving in and out of research and practice
> careers. (Schön 1983, p. 333)

Although nearly two decades of teachers' self studies have emerged since then,
and, although to some extent the self-study in teaching and teacher education
groups represented prominently in this handbook are already living beyond that
ideal, ambivalence within the broader practitioner research community about
autonomous teacher research as a necessary and practical virtue has remained.
Advocates of practitioner research have not universally agreed on a distinction
between research carried out 'for' practitioners and research carried out 'by'
practitioners, often coming to the compromise position that it is enough to be
carried out 'with' them (Reason, 1994). To take but a few examples, Robinson's
Problem Based Methodology (1993) assumes, rather like Schön, that research
on a practice is done by specialist researchers in collaboration with, or in support
of, practitioners, rather than by the practitioners on their own. Similarly, Zuber-
Skerritt's (1996) typology of action research has a specialist researcher involved
alongside the practitioner at all stages, even if only in a facilitative role in the
critical/emancipatory form. Kemmis (1993), McNiff, Lomax and Whitehead
(1996), Elliot (1991), and many in the Self-Study of Teacher Education Practices
group, on the other hand, advocate for autonomous self-research in which there
is no distinction, no division of labor, between the actor and the researcher.

Perhaps reflecting such ambivalence, authors of self-studies as research seem
to position themselves in relation to their studies and practices in a variety of
ways. In one sense a self-study might be any level of participative study that
involves one bringing specialist insider knowledge to the study of teaching or
teachers – self-study simply as insider research (e.g., Watson, 1999; Wilcox, 1998).
Alternatively, one might choose to focus on researching one's own students or
own institutions from a semi-detached but nevertheless self-interested participant
perspective – self-study as auto-ethnography (e.g., Hamilton, 2002; Kane, 2002;
Russell, 2002). One might focus on one's own *practices* or classroom interactions,
with such practices as some sort of case or context for addressing an issue related
to teaching as a sociological act – self-study as a case study (e.g., Oda, 1998;
Schmier, 1999; Tidwell, 2002). Or one might focus more on one's own persona
as a teacher, not so much conducting a study of 'doing teaching' as a study of
what it is to 'be' a teacher – self-study as occupational therapy (e.g., Allender,
2001; Kuzmic, 2002). The study might be an intensely individual process, or it
might be just as intensely collaborative: a group of colleagues mutually investigat-
ing and comparing their own experiences (e.g., Louie, Stackman, Drevdah, &
Purdy, 2002; Montecinos *et al.*, 2002; Neville, 1999), or their own institution's
activities and culture (e.g., Conle, Louden, & Milden, 1998), or a teacher working
in close collaboration with a professional researcher from the academy on topics
to solve specific teacher problems (e.g., Watson, 1999).

Such variation makes it difficult to identify and evaluate the epistemological implications of self involvement in self-research, but does not remove the obligation to do so.

Can Practitioners Research Themselves?

According to Zeichner and Noffke (2001) much of the methodological critique of practitioner research focused on the issue of self-involvement seems to start, and often stop, with Hodgkinson's (1957) claim that, "research is no place for an amateur" (p. 146). Teachers, Hodgkinson argued, are too ill-qualified or too busy to conduct research, have contributed little to educational theory by doing so, and find it difficult to rise above their particularized self-interest or to avoid distortion and self delusion. There seems to have been little by way of a substantial methodological critique focused on the specific issue of self-interest in teacher self-research written since that time, although such claims are often repeated or implied in passing (Zeichner & Noffke, 2001). One exception, however, might be in the work of Hammersley (1992, 1993a, 1993b).

Hammerlsey (1993a) argues from a conventional ethnography perspective that when teachers research their own practices they may have certain advantages over specialist outsider researchers, but that each such advantage has countervailing disadvantages. He claims, moreover, that on balance the latter outweigh the former. Reflecting a similar argument made by Huberman (1996), he concludes that, "I do not believe that being an established participant in a situation provides access to valid knowledge that is not available to an outside researcher" (p. 219), and that ultimately, "the proposal that the roles of teacher and educational researcher should be integrated, which is at the core of teacher as researcher … is undesirable from the point of view of both research and of teaching" (Hammersley, 1993a, p. 227).

While disagreeing with Hammersley's conclusion that research done by specialist researchers is to be preferred over research done by practitioners themselves, we cite his critique of the role of self in self-studies at some length because it raises issues that the self-study community needs to take seriously if it is to establish any lasting epistemic warrant for self-study as research.

To what Hammersley describes as the teacher researcher community's claim that, "teachers have access to their own intentions and motives in a way that an observer does not, and so have a deeper understanding of their own behavior than an outsider could ever have" (1993a, p. 218), he counters that, "self knowledge is not immediately given and therefore valid. Furthermore people can deceive themselves about their intentions, motives etc. Indeed, they may often have an interest in such self deception whereas an outsider has less reason to prefer one account above another" (ibid, p. 218).

To the teacher researcher community's apparent claim that, "the teacher researcher will usually have long-term experience of the setting being studied" and therefore more and deeper knowledge than an outsider could acquire, he counters that such information derives from a particular role and thus may be

superficial, distorted or incomprehensive. "An outsider researcher may be able to tap a wider range of sources of information than an insider" (ibid, p. 218).

To the teacher researcher community's apparent claim that the teacher has established relationships with other insiders that can ease the process of data gathering, he counters that, "those relationships may also place political or interpersonal constraints on the enquiry that an outsider may be able to avoid" (ibid, pp. 218–9).

To the teacher researcher community's apparent claim that because they are key actors in the settings studied and thus, "are in a position to test theoretical ideas in a way that a mere observer could never do", he counters that the purposes of teaching on the one hand and, testing or developing theory, are different and, "what is required to test theoretical ideas may well conflict with what is needed for good practice. (To deny this would be to conflate what is true with what works in practice)" (ibid, p. 219).

Overall, then, the virtues of intimate, but potentially conflicted, self-interest are balanced unfavorably against the differing but apparently incommensurate virtues of comprehensively knowledgeable detachment.

There are implicit in Hammersley's critique at least three groups of 'tests' by which research by practitioners on their own practices might be judged as having some warrant for a claim to be listened to. The first are tests related to *practicability* illustrated through questions such as: "How can teacher researchers, as a matter of practical procedure, be both the researcher and the participant, the doer and the observer, at the same time?" and, "How can they observe themselves acting at the same time as acting, and when they try to do it, which hat do they wear when the roles are in conflict?" (see Wong (1995) for an example of this dilemma in a self-study). Moreover, "As full time teachers where do they get the time, and do they have the specialist knowledge, to be researchers as well?"

The second group of tests relate to the evidence provided for the *honesty or self critical transparency* of an account indicative of questions such as, "Are teacher-researchers' vested interests in being practitioners preventing them from being completely open about what they see in their own practice?" – associated with this is the test of 'self-delusion' – and, "Even if they are honest about what they think, are they not still deluded on the basis of hidden or unexplored assumptions and values that may blind them to conclusions about their practice that might be much clearer to the dispassionate outsider?" and, "How do they deal with this possibility in their enquiry?"

The third are tests related to providing evidence of *comprehensiveness* in investigating some issue, and in locating "my" particular practices in terms of more general *relevance or significance*. The test of comprehensiveness asks: "As insiders do teacher-researchers have full access to the wider view of their own practices?" and, "Do they, in investigating them, look at all the possible sources of data that may be relevant or useful, especially those which may be susceptible to theorizing or have theoretical import, or are they confined to the minutiae of themselves as the sole data-source and their unique situation or problem?"

The relevance and significance tests are the 'so what?' question that many self-study writers refer to. One may adequately enquire into one's own practices, one may even solve one's own practical problems by doing so, but what makes that of any relevance or significance to anybody else? How does one as a researcher know what he/she might be a 'case of' as a teacher? Can one really ever see one's own practices through any other lens than that of highly localized and temporary self-interest?

In responding to such critiques of self-research, it is very important to distinguish between its two sets of central elements: those that are about the practicability of researching one' own practice; and, those that are about its validity or trustworthiness. The second are more significant than the first.

Test 1: The Practicability of Self Research

The pragmatic argument against teacher self-research is based on the view that teachers often do not have the time or skill in data gathering and analysis techniques, nor the widely read perspectives of university based academics. They are not, in Hammersley's (1992) terms, 'specialist researchers'. However, we would argue that such pragmatic objections to self-study by teachers are not made on epistemologically defensible, or even logical, grounds. Parts of the pragmatic critique come close at times to assuming not just that self-research is logistically difficult or time-consuming, but that teachers are somehow, by virtue of their primary focus on teaching rather than research, or by virtue of some other inherent incapacity of occupation, simply not capable of self-research.

There are surely no logical grounds for such a claim, either with regard to teacher educators or with regard to school teachers. In the case of the self-study in teacher education community, for example, the pragmatic critiques of teachers as novice or non-specialist researchers with no time to research do not hold. Teacher educators, mostly university-based or College of Education-based, are employed to research as well as to teach, and have, in many countries at least, substantial research qualifications and experience. They are researchers who practice, and study, and teach 'teaching'. For many teacher educators it seems a matter not just of common sense and convenience, but also one of academic obligation that they should research their own practices as teachers as well as their own students and their practices, and not just the practices of teachers in schools or other educational enterprises. However, the same could also be said to be increasingly true of teachers, many of whom already have or are in the process of gaining research qualifications, who are just as committed to professional improvement as their colleagues in universities, and who have contributed to numerous individual chapters, articles and collections of self-research in the last decade (e.g., Patterson & Shannon, 1993; Somekh & Davis, 1997; Passey & Samways, 1997; Wood, 1988). While it is not to minimize the practical difficulties of doing teaching and doing research at the same time, we find ourselves asking: "If teacher self-research is so impracticable, why are so many of them doing it?" To accept that self-research brings with it specific practical difficulties – what

research enterprise does not? – is not to accept that it cannot or should not be done by particular practitioner groups. Above all, it is not to accept Hodgkinson's and others' implication that it is thereby inherently invalid.

Test 2: The Validity of Self-Research

More importantly, though, there are other differences between Hammersley's insistence on the virtues of specialist and comprehensive outsider perspectives and self studiers' insistence on the equal virtues of self as the most intimately known case, which are not simply pragmatic but epistemological. They are embedded in important issues of validity and trustworthiness and thus legitimately invite a discussion of paradigm-level assumptions about the nature of truth, reality and the epistemological way. The tests of honesty/delusion thus invite at least a brief journey through the much traveled but ill-signposted terrain of bias and truth, anecdote and evidence, reflection and reflexion, and even the subjective-objective divide. Just as those of comprehensiveness and importance invite a methodological discussion of the ability of self-focused self-researchers to adequately present themselves or their own practices as a generalizable 'case'.

Guba (1990) argues that one cannot adopt both an objectivist epistemology and a relativist ontology at the same time. If the goal of a piece of research is to understand, and then improve, one's own practice by means of a rigorous investigation of one's own pedagogical actions, then one is implicitly working within a constructivist notion of truth, a relativist ontology, and a participative epistemology which highlights the subjective, or at the very least the intersubjective. The positivist notion of objectivity as being commensurate with truth, has no coherent place as a test of the integrity of such a research process.

However, as Munby and Russell (1995), Loughran and Northfield (1998), and others point out, the 'authority of experience', especially when presented as research, does not derive from the simple fact of having it. It derives from the iterative and repeated self-critical analysis of that experience in a conscious attempt to 'know' or understand it. It derives not from some form of naturally occurring osmosis of realization inherent in having the experience itself, but by the application of techniques of reflective (experiential) and reflexive (methodological) enquiry, dare we call it research, resulting in the articulation of personalized explanations and understandings: teachers' 'personal theories', if you will.

This is not to deny that reflecting on one's own experience is inherently problematic as a form of knowing. There is, indeed, a risk when *I* am the source of so much of *my* own data, a danger that *my* own voice is the only one listened to in a self-study, and of an inbred self-referencing in the representation of that data that dissipates rather concentrates meaning. There is indeed, a sense in which *I* am my own Grandparent when it comes to interrogating my own data, and thus a real risk of doing so on the basis of a priori assumptions *I* may already have about the nature of the experiences *I* am reporting. This is the dilemma of "self as instrument" (Eisner, 1998, p. 33) which exists as much for outsider researchers as for insider researchers. But it is also perhaps the dilemma

that many self-study writers address with their injunction to collaborative modes of self-research in which practitioner researchers actively critique each other's work as both practitioners and researchers (Bass, Anderson-Patterson, & Allender, 2002; Berry & Loughran, 2002; Conle, Loudon, & Mildon, 1998; Labrie, Brdaravic & Russell, 2000; Loughran & Northfield, 1998). It is also seen in the action research ideal of a *self critical community* of practitioner-researchers, and in the distinction made by Schön and others between reflecting-in-action and reflecting subsequently on action.

Moreover, of course, as a matter of the comprehensiveness of evidence in self-study there is also a sense in which no self-study of teacher or teacher education practice can be entirely and exclusively a study of 'self'. Nor can it draw exclusively on unreferenced and uncontextualized rational-reflective data drawn from self. Teacher presupposes learner in the concept educational practice as inexorably as heads presupposes tails in the concept coin, or hen presupposes rooster in the concept chicken. As Bullough and Pinnegar (2001) point out, teacher self-study, "does not focus on the self per se but on the space between self and the practice engaged in" (p. 15). Teaching is by definition a socio-ethical act – it is to try to do good for an other – and the actions or practices being researched are thus inevitably interactions with others and practices involving others. One's study of oneself as a teacher or teacher educator must necessarily therefore involve the gathering of data about student(s) as learner(s). It is to this that any self-generated data may be triangulated or compared, and through this also that multiple perspectives may be brought to bear on self-study as research. Thus Samaras (2002) compares her own reflective journal entries with those of her students; thus Berry and Loughran (2002) report their ongoing conversations as they both co-teach and co-research their preservice class; thus Roth and Tobin (2002) report the benefits of working with students as co-researchers and co-data collectors, thus Hamilton (2002) compares her account of institutional change drawn from her own e-mails, to those of her colleagues through theirs, and so on.

Perhaps it is this that makes some within the practitioner research communities argue that even within the discourse of constructivist or relativist research, the terms objectivity and subjectivity can have a somewhat different, more intermediary meaning, which make them perfectly compatible with relativist/constructivist notions of reality and truth. If one takes objective in a strictly positivist fashion, to mean that which is really real or truly true, or, at the very least, universally acknowledged, then subjective almost necessarily becomes its antonym, the word we use to refer to that which is only apparently real, biased, deluded or simply wrong, and certainly that which is not shared. If, however, one takes objective simply to mean all that which is not within one's own perception, that which is outside of self, then (research) objectivity comes to mean, crudely, the conscious attempt to see something as someone other than oneself might see it, and subjectivity thus becomes something akin to reflexivity, the attempt to see something honestly as "I myself perceive it to be". As a research stance, this is totally consistent with constructivist research philosophies, philosophies which argue for multiple perspectives, including that of the researcher, as a strong

validator of findings, and which, no less than positivism, judge the credibility, authenticity, or validity of research still largely on the extent to which the researcher is able to produce recorded, convincing external evidence, empirically derived data which has an existence outside participants' or researchers' own internalized and unexamined perceptions – outside the self. Objectivity, thus, not as the impersonal, the non-personal, or the unbiased in research, but objectivity as archive and record, objectivity as triangulation, objectivity as multiple perspectives, objectivity as consensual validation, objectivity as collaborative critique. Objectivity, one hopes, without objectivism; subjectivity without subjectivism.

Is this what Carspecken (1996) means when he says that, "researchers must be prepared to become hurt through their work; to allow their contact with others to threaten and perhaps alter their usual ways of conceiving themselves" (p. 167), or when he talks of the objective as that which is available to multiple access and the subjective as that which is privileged and private? Is this what Whitehead (1995) means when he talks of consciously experiencing, "the 'I' as a living contradiction", and grounding self-study in the persuasive foundations of "evidence" and "dialogue" (pp. 117–119)? Or what Lather (1986) means by the need for, "new paradigm researchers ... to offer grounds for accepting a researcher's description and analysis, and [to] search for novel, workable ways of gathering validity data" (p. 78). Or what Altrichter, Posch and Somekh (1993) mean by their advocacy of both methodological and participant triangulation. Or what Bullough and Pinnegar (2001), echoing Mills (1959), mean by, "the particularly sensitive balance between biography and history" (p. 15). Or, what Reason and Rowan (1981) mean by the search for a, "validity of knowledge in process", a "subjective objectivity"? (p. 248).

It certainly seems to be what Pring (1999) means in critically reviewing the claims of the self-studies of several higher education teachers to be research:

> This 'trying to make sense of' with a view to more intelligent planning, decision making and further practice is undertaken in the light of evidence which can be revisited and in the light of others' scrutiny of that evidence. That is what raises it to the level of objectivity. Assumptions and implicit beliefs are made 'objective' – open to public viewing and criticism, which can thus be pursued in the light of the evidence produced by those, the teachers, most able to gather that evidence. (p. 10)

Following this argument through, the validity and power of self-study as research therefore lies in large part not merely in the intimacy that the practitioner has with his/her own practice, but in the special *combination* of perspectives that practitioner-researchers are able to bring to bear on the phenomenon of teaching: the intimate knowledge of the participant, *and* the self critical data collection and analysis abilities of the researcher. Whether one applies to this idea revisionist reconceptualizations of objectivity and subjectivity, or other phrasings about "I" and "Me" (Woods, 1996), "biography" and "history" (Mills, 1959) and so

on, the importance of multiple perspectives on self and other in relation to one's own actions is usually seen as a fundamental part of the validation process in teacher self-study as research (Loughran & Northfield, 1998). At some point, implicitly or explicitly, most self-studies involve the self-study version of the reflexive turn in conventional ethnography: that self conscious attempt to validate one's own data, and to see one's participant-self through alternative lenses. It is a consciousness of Eisner's sensitivity to "self as instrument" in conventional case studies, except that in the case of self-study, I am not only the thing doing the seeing; I am also the thing being seen.

This form of objectivity, or call it self-critical reflexivity if you prefer, thus becomes a way of passing both the test of honesty and the test of self-delusion in judging self-research as valid or convincing representations of how an experience was for me. It derives not from a passive romantic remembering in tranquility of a single experience, but from the iterative and consciously self-analytical reflection on, repetition of, and gathering data about, the purposeful social actions that are the center of the study.

Test 3: The Comprehensiveness and Significance of Self-Research

Therefore, Hammersley's objections about deception and delusion, the tests of honesty and what might be called transparent self-critique, can conceivably be met in self-research. But what of the tests of comprehensiveness, relevance and importance? What of the requirements for a case to clearly involve an exhaustive and sufficiently comprehensive analysis of a full range of available evidence about a practice, and to be convincingly located in some wider context, theory or debate: the need for self-study to go beyond self-service?

Here we revisit the issue of locating evidence from the specific 'case' within a generalizable context that was a criterion for any study to be research discussed at length earlier in this chapter. We will not repeat the argument, except to point out that research done by, and on, self is surely no more susceptible to critique in this regard than research done by, or on, others. There is nothing logically preventing teachers or teacher educators locating their own self-studies within bodies of theory or the broader contexts of educational debates and academic literature, other than the practical extent to which they may have, or have not, as individuals, immersed themselves in such readings and such debates. It would be a fault of logic, not to say occupational arrogance, to assume that simply because one is a teacher, that he/she has neither the intellectual capacity, the awareness of educational issues, nor the academic background to have a clear sense of what he/she might be 'a case of' in Popper's Third World of public knowledge.

Any given self-study may indeed still fail tests of comprehensiveness, relevance or importance on the grounds of inadequately locating or justifying what it is a 'case of', just as any conventional case study may, but it does not do so simply or inherently *because* it is an insider or 'self' study.

Overall, then, we suggest that Hammersley and other critics of self-research

have an unassailable case in defending conventional ethnographic or case study forms in terms of the value added, as research, to the validity of insider or participant knowledge by the empathic but comprehensively knowledgeable outsider. We similarly agree with his argument that being an insider brings with it differently problematic dilemmas in establishing an epistemic warrant for any understandings claimed about one's own experience. Like Bullough and Pinnegar (2001), we agree that, "a claim to be studying one-self does not bring with it an excuse from rigor" (p. 15). However, it also seems that in accepting the virtue as a methodology of the reflexive outsider gaining productive knowledge by being the temporary and empathetic participant, conventional ethnographers and case study researchers must also accept the virtue of the inverse: the reflexive knowing participant gaining productive knowledge by being the temporary and self-critical outsider. Ethnography meets auto-ethnography; case study meets self-study. As Sears (1992) puts the ethnographer's classic dilemma:

> Can a White, middle class, male write with integrity on the experiences of lesbian and gay southern youth? ... The test is not one's ability to remain objective but one's capacity to be empathetic. Proper questions are, Have you immersed yourself into the world of the other? Have you portrayed its richness and complexity? and Have you treated your informants/characters with respect and understanding? (p. 148)

The dilemma for the insider or self-study researcher is the inverse, but not the negation, of this. Proper questions are: "Have you viewed your own experience with fresh eyes, seen your practices as others might and, have you tried to make the richness of your own experience of relevance and significance not only to you but also to your critical peers?" The test is not one's ability to be knowledgeably empathetic but ones capacity to be comprehensively self-critical.

Perhaps it is in the dialectic nexus of the two perspectives, the constant internally and externally reflexive dialogue that both the ethnographic researcher and the practitioner researcher alike have to have between the consciously knowledgeable self and the consciously naive self, Mead's dialectic of the "I" and the "Me", that the justification of both methodologies lies. Hammersley almost concedes as much when he states that, "the chances of the findings being valid can be enhanced by a judicious combination of involvement and estrangement" (1993a, p. 219). When it comes to self-study as research, few in the self-study communities would disagree. We would just point out that one can approach the same territory from either of two directions.

Whose Swamp is it Anyway? The Problem of Academic Politics in the Self-Study of Teaching and Teacher Education as Research

Others have given detailed attention to reviewing the traditions of research in teaching and teacher education (e.g., Clarke, 2001; Wideen, Mayer-Smith, & Moon, 1998; Zeichner & Liston, 1990; Zeichner, 1999) so it is not our intention

to provide another meta-analysis in this forum. We seek to understand the politics of self-researching the practice of teaching and teacher education within the academy and the ways in which the insider study of teaching and teacher education has been constructed and positioned. What is the place of teaching and teacher education within the academy's research agenda? What are the forces that contest the nature and focus of research on teaching and teacher education practice? Who makes the decisions about what is valued as research, and on what basis? Who does (or should) benefit from such research?

The personal experience related at the beginning of this chapter took place at a university where,

> "Research" is broadly defined as the systematic and disciplined activity undertaken to create and advance knowledge. It may take many forms across the discipline base of the University including scientific investigation and discovery, the creation or refinement of concepts and theories, techniques or compositions, or the extension of current understanding through critical analysis. The common features of research in all its forms are systematic and disciplined methodology and commitment to the publication of outcomes and their peer review. The publication element of research also varies with the discipline and can range from the publication of outcomes in learned journals or monographs to the performance of creative compositions. It also includes the appropriate transfer of the outcomes for the betterment of society. (University of Otago, 1997, p. 5)

Surely the conceptions of self-study as research outlined in the previous section are *not* inconsistent with such a definition. The proposed research project described a longitudinal, purposeful, data-driven, empirically based inquiry into the teaching practice of the researcher as a key member of the teacher education team. The intention was to problematize and reframe her own teaching practice in an effort to identify and make explicit the ways in which her teaching was related to students' learning as beginning teachers. Ruth sought to understand better and critically analyze her role as a university teacher who teaches teachers.

The approach proposed included the use of personal reflective journals by Ruth and her students, interviews, and critical conversations with students and colleagues. In gaining a better understanding of the role of the teacher educator in the students' process of becoming teachers, this project would (it could be fair to say) have lead to improved teaching practice and therefore contribute to advancing knowledge of the theory and practice of how one learns to teach. The project, as proposed, presented all the elements of research as discussed earlier, including the intention to disseminate and make public the findings, and clearly fell within the university's own definition of research. The committee responsible for allocation of funds acknowledged as much when it later stated that the proposal had merit but that it was, "rejected primarily on the basis of what the Committee judged to be [its] operational nature" (Personal Correspondence, 2 October, 1998).

We are left to conclude that the experience calls into question the degree to which research on teaching and on teacher education practice is considered to be legitimate scholarship within the academy, not so much as a matter of epistemology, but as a matter of academic politics.

It became apparent through ongoing correspondence challenging the decision of the research committee, that the committee was unable, or perhaps unwilling, to interpret research on teaching as being anything other than operational, and therefore part of the role of an academic staff member and unworthy of serious scholarship.

> … the Committee considers that operational research relates to research to inform teaching, which includes the production of information and materials for teaching purposes, as distinct from project-based research, the chief objective of which is to advance scientific or scholarly knowledge and to disseminate that knowledge through publication. (Personal Correspondence, 15 October, 1998)

As could be expected, the impact of being told that one's carefully constructed research project was not considered worthy of research funds, was, for an early career academic, quite disheartening. Moreover, the committee's correspondence seemed to suggest that it was the focus of the research on teaching within the university that was the most problematic aspect of the proposal. This raised questions about the status of teacher education within the academy and, how teaching as a discipline and as a research focus was construed within the traditional university context.

The discipline of teacher education holds a unique position within the academy. In teacher education the subject area that is taught or researched (teaching), is also that which is done (teaching). This is not the case for other professional disciplines, such as medicine and law. Typically, the content that is taught, and is the focus of research, be it propositional or procedural in nature, can be separated from the practice of teaching. In no discipline other than teacher education is the content, and the process of teaching and researching that content, so entangled. Much like the vegetation within a swamp!

It is therefore appropriate to suggest that research into teaching and teacher education practice, by its very nature, demands an enquiry approach that takes account of the unique complexity of the discipline. This is not to suggest that those of us concerned with self-study of teacher education practice are on the verge of declaring a new paradigm, although this has been broached by others (e.g., Cole & Knowles, 1996; Schön, 1995; Zeichner, 1995). Rather we need to examine the ways in which *dominant* research traditions are appropriate for simultaneously advancing knowledge about teaching and teacher education and informing teaching and teacher education practice. And, if they are found wanting, we need to consider carefully alternative, more appropriate forms of inquiry. We need to ask the question: "What sort of research will best serve teaching and teacher education?"

Until the last two decades in educational research, the voices of teachers and teacher educators were seldom heard, and the situated complexity of the ways in which teachers and student teachers understand and make meaning out of the learning to teach process went virtually unexplored. Only relatively recently, since the 1980's, has research with, by, and for, teachers, begun to give voice to teachers and teacher educators through the rise of qualitative approaches to research on teaching and teacher education. Zeichner (1999) heralds this "new scholarship" in teacher education as a shift from an exclusive reliance on positivistic studies, "to the use of a broader variety of research methodologies and the investigation of a much broader range of research questions and issues" (p. 8). The qualitative/constructivist/relativist paradigm had arrived in education.

Clarke (2001) maps how the roles of teacher educator and scholar over the past 50 years in North America at first diverged, with the move to university settings, and then converged as faculty simultaneously became more skilled and more critical of research in teaching and teacher education. Within the new scholarship in teacher education, Zeichner (1999) credits the birth of self-study in teacher education movement as probably the single most significant development ever in the field of teacher education research (p. 8).

Cole and Knowles (1996) suggest that self-study research of teacher education will continue to face difficulties gaining legitimacy in the academy because it contravenes the dominant epistemology of traditional research universities, that of technical rationality. Research that focuses on the practice of teacher education and teaching falls outside the parameters of this predominant epistemology as it typically involves research on problems and questions that are complex, uncertain, unique and often conflicting in nature. Research on teaching and teacher education practice is located in what Schön (1995) has termed the "swampy lowlands" where problems are messy and confusing and incapable of technical solution (p. 19). This is in contrast to the "high hard ground" of technical rationality where research-based theory and technique promise that problems are predictable and technical solutions achievable through rigorous research grounded in the empiricist quantitative branches of psychology and sociology (Fenstermacher & Sanger, 1998). Knowles (reported in Cole & Knowles, 1996) and Whitehead (1994), both highly regarded teacher educator/ researchers, report ongoing challenges with their institutions over the focus and rigor of their research on their own teaching practice and scholarship.

Clarke (2001), however, argues that self-study of teaching practice is a research methodology that has stood the test of peer critique that is the touchstone of high quality academic publication. The growing legitimacy of self-study research practice is evidenced by the publication of self-study research in a range of peer refereed journals and comprehensive reference texts in teacher education scholarship, and the well attended public meetings of teacher educators (Zeichner, 1999; Clarke, 2001). While it would be possible for those of us from the self-study community to be reassured by Zeichner's and Clarke's claims, we all still work within contexts that are at the intersection of social, political, financial, cultural

and interpersonal influences. The reality is that many of us are (likely) far from the decision-makers within our institutions.

One message in the cautions expressed by Zeichner (1999) and Cole and Knowles (1996) and the rejection of Ruth's research proposal, is that for some (maybe many) engaged in self-study of teaching practice, they will find themselves marginalized, scrambling for meager operational funds and called to continually defend their work to colleagues who may well be unsympathetic to their approach. The options open to faculty who engage in such research are often limited. Those interested in self-study research could decide to change the ways in which they research or they could accept that it is unlikely that their research will attract competitive internal or external funds, resource support or credibility with respect to promotion and tenure. In the world of academia this is tantamount to accepting limited tenure as an academic!

Pushing Boundaries: The Place of Teaching and Teacher Education Within the Academy

For those of us who have a passion for and take intellectual and professional challenge in the preparation of teachers and the study of teaching and teacher education practice seriously, this historical neglect is both puzzling and distressing. Teacher education, and the related study of teaching and learning to teach, does not have an especially salubrious history within the academy. Teacher education, and the study of teaching and teacher education, have been variously avoided by education faculty, neglected by university management, and patently ignored by faculty from other disciplines. What is it about teaching and teacher education that contributes to this position as the Cinderella of academia – available to do the work of teaching others to teach children and young people but not of sufficient status to contribute to academic or intellectual discourse on the advancement of knowledge?

Ducharme and Ducharme (1996), in their review of the history of teacher education faculty, claim that the place of teacher education in higher education is, "ambiguous, complex and in need of clarification" (p. 692). Further, they contend that the continuous debate about the place of teacher education within higher education affects the role and status of teacher educators. Traditionally teachers were prepared in Teacher Training Colleges or Normal Schools, which were practice-based and grounded in apprenticeship models of teacher training. Over time these stand-alone institutions have, in many countries, been grafted onto university faculties of education. In America and Canada the shift to university settings was all but complete in the mid 1950s and, with few exceptions, institutions with the sole purpose of teacher preparation had ceased to exist by the time that countries such as New Zealand and Australia were beginning to explore such transitions. In Australia Colleges of Advanced Education (formerly Teacher Training Colleges) completed amalgamations with local universities during the early 1990's.

Clifford and Guthrie (1988) report that the shift to universities in America

was intended to improve the status of education and teaching through profession-alizing teaching and increasing access to economic resources. It was apparent, however, that on entry to university settings, teacher education was assailed by additional pressures, which rather than redress its low status, served to reinforce it, and additionally, reveal its increasingly ambiguous position within the academy. The shift from colleges to university settings in the USA and Canada brought with it significant changes in expectations of teacher education faculty. Clarke (2001) reports that prior to the 1950's those involved in the preparation of teachers (teacher educators) had limited involvement in research and scholarship. Their work focused on introducing student teachers to the practice of teaching and supervision of students during school-based practica. With the shift to faculties of education within university settings, teacher educators, along with colleagues from other disciplines, became subject to the race for institutional legitimacy, accessible not through good teaching practice, but through rigorous research and scholarly publications. Entry into the academy brought with it an expectation of research and scholarship that kept pace with the achievements of colleagues in other disciplines. Teacher educators moving from colleges to universities were thrust into the 'publish or perish' culture of higher education, alongside new appointments to the faculties of education who brought with them PhD qualifications and typically a commitment to research that was grounded in the legacy of the natural sciences.

The desire for legitimacy within the university, coupled with the increasing tendency of education faculties to appoint researchers and research methodologists as teacher educators, "resulted in members of education faculties (both new and existing) spending considerable time becoming highly skilled in methods of scientific inquiry at the expense of their pedagogical work with beginning and practising teachers" (Clarke, 2001, p. 602). The shift to university settings resulted in erosion of the status and institutional regard for the role of teacher educator (practitioner), and a rise in institutional regard for the scholar (concerned with research and theory). The predominant pressure to engage in research and publication gave rise to an inverse relationship between professional prestige and status earned within the university and the degree to which one was involved with teachers and schools in formal teacher education (Lanier & Little, 1986, p. 530). The more one worked with teachers and schools, the less credibility one held as an academic and a scholar. The low status of those who engage in work with teachers and schools was reflected also in the low regard for practitioner research. Zeichner (1995) explains that in many research universities, the closer that one is associated with teachers and schools, the lower one's status, and the lower one's status, the fewer resources that are available to support one's research and practice (p. 169). It is little wonder that so few academics, including those who worked within teacher education, chose to identify themselves first and foremost as teacher educators.

It is also ironic that the shift from stand alone colleges of education to university settings in North America, rather than giving strength to the advancement of knowledge of the practice of teaching and learning, initially served to

devalue and undermine the role of scholarship in the *practice* of teaching. Some have suggested that the low status of teacher education research was contributed to by the variety of disciplinary backgrounds possessed by researchers in teacher education (Clarke, 2001; Lee & Yarger, 1997). Others argue that the status of teacher education and research in, and on, teaching and teacher education has been devalued as a consequence of teacher educators, "dual mandate to the university and professional community" (Cole, 2000, p. 34).

Is this a journey other countries are now to take? New Zealand, and to a lesser degree Australia, have a more recent experience of locating teacher education within traditional university settings. New Zealand may be unique among western democracies in its continued resistance to requiring teacher education to be a university-based field of study, and we must acknowledge that the culture that prevails in New Zealand may well have influenced the outcome of Ruth's story recounted at the beginning of this chapter. The University within which Ruth worked has a long tradition of teaching, studying and researching education as a discipline, but has only recently (1997) entered into offering full preservice teacher education programs. Thus teacher education, or as some others still insist on terming it, teacher training, is a very recent, and not necessarily popular (with the wider university community) addition to the university's undergraduate programs.

The location of teacher education within university settings, while typical in USA, Canada, UK and Australia, remains highly contested and the subject of continued debate in the authors' home country – New Zealand. Within New Zealand teacher training was, up until the 1990s, the responsibility of six colleges of education. To date only two of the original colleges have followed the international trend and amalgamated with universities. Hamilton Teachers College joined Waikato University in 1991 to form New Zealand's first university-based school of education. Palmerston North College of Education followed suit in 1997 to merge with Massey University. Although other mergers and alternative partnerships have been planned and discussed in recent years, none have reached fruition and there remain four stand alone colleges of education.

In a paper examining the history of one of these amalgamated colleges of education (Massey University College of Education), Openshaw (1999) argues that the traditional culture of the college of education, which includes allegiance to, and transmission of, government education policy, is increasingly incompatible with the goals of university-based education faculties who see their main role as being the critique of education policy, curriculum design and school practice, based on current research findings. Staff of the colleges of education were, and in most cases continue to be, recruited almost exclusively from primary and secondary schools, and were required to be broadly supportive of departmental and ministerial policies (Openshaw, 1999). In recent decades college staff have become more involved in the development and implementation of new curriculum for New Zealand schools. Openshaw (1996, 1999) has recorded the resistance of some college staff to university-based models of teacher education, which typically called for a more academic, research-based focus to preparing

teachers. In Openshaw's (1999) account it is not difficult to recognize the emergence of tensions similar to those prevalent in North American universities in the early decades of college/university amalgamations. It is not inappropriate to ask whether we in New Zealand will follow, or will we learn from the North American experience?

A further significant historical influence on the shape of teacher education in New Zealand was the Picot Report (Department of Education, 1988). The education reforms following the Picot Report (ibid, 1988) within New Zealand had significant impact on all levels of education from early childhood to tertiary (Alcorn, 1999). Codd (1999), a New Zealand educational researcher, has argued that the educational reforms brought about fundamental changes in the policies which governed the interactions of those involved in education giving rise to a "culture of distrust" (p. 45). The educational reforms of the late 1990s were grounded in a concept of economic rationalism that favors the goals of the economy over all areas of public policy. Goodlad (2002) acknowledges that researchers have cause to be concerned when the degree to which university activities are driven by the economic imperatives of the market place rather than the traditional university pursuit of independent research inquiry remains unclear (p. 216). Such is evident in one of the outcomes of The Picot Report – universities lost their monopoly as degree granting institutions, effectively opening the way for alternative providers to set up teacher education and teacher research programs in a very competitive market place. Currently, New Zealand, with a population just shy of four million, has a total of 17 institutions providing degree programs in preservice teacher education.

The internationally atypical nature of the New Zealand context, with its range of teacher education organizations including universities, teachers colleges (now known as Colleges of Education), wananga (Maori tertiary education institutions), polytechnics and private tertiary enterprises, raises interesting questions. Are New Zealand teacher educators destined to face an even greater struggle for credibility and acceptance as scholars than their colleagues in America since they are predominantly located outside of the traditional research universities and the majority of faculty do not yet hold doctorate qualifications? How can New Zealand teacher educators ensure that research in and on teaching and teacher education is given status within the academy when many are located outside the traditional university setting? What can New Zealand learn from the struggles of teacher educators and researchers in other countries?

Power and Politics in University Research

All higher education institutions, be they universities or colleges of education, have institutional structures and processes which present and support a particular understanding of what counts as legitimate knowledge, and how such knowledge originates. They each have their own hierarchies of epistemologies, where epistemology is understood to be the, "nature, scope and applicability of knowledge" (Walker & Evers, 1997, p. 22), or, "what counts as legitimate knowledge

and how you know what you claim to know" (Schön, 1995, p. 27). Schön (1995) argues that the prevailing epistemology built into research universities is one of technical rationality, where true scholarship contributes to fundamental scientific and systematic knowledge. It is not so much that the definition/s above are upheld by individual academics and applied to every research application, it is more systemic, some might say sinister, than that. The prevailing epistemology of an institution becomes built into the normal structures and processes of university operations, and as such acts to reinforce the hierarchy of epistemologies. Thus, calls to submit applications for competitive internal and external research grants are underpinned by positions of power and ideology. Those sitting on research funding committees have the power to act as institutional gatekeepers of prevailing epistemologies. Ruth's experience, and the experiences of others we are sure, signals the need for universities to examine critically the ways in which their procedures are serving to promote and extend the hegemony of traditional academic research. There is a need to examine assumptions made about research by the institution and the possible contribution of alternative, but perhaps less valued, epistemologies.

Extending the work of Ernest Boyer (1990) researchers at the Carnegie Foundation have argued for an end to the unhelpful separation of the researcher and the practitioner. Boyer extended the definition of Scholarship to include discovery (what is typically understood as research), integration, application and teaching, in an effort to reconcile the practice of research with the practice of teaching (Glassick, 2002). While the work of Boyer and others provides positive support in many ways to those of us engaged in the self-study of teaching practice in university and school settings, it is sobering to note that Hutchings and Shulman (1999) admit that the scholarship of teaching "runs against the grain in big ways", and that such research brings with it a risk with respect to promotion and tenure and in terms of impact on the wider intellectual and professional field (p. 13). The work of Boyer (1990), Glassick *et al.* (1997) and Hutchings and Shulman (1999) on promoting the scholarship of teaching is encouraging. Schön (1995) cautions, however, that in order for universities to pursue such "new forms of scholarship", we need to address first and foremost questions of epistemology (p. 27).

Schön (1995) suggests that we need to, "think about practice as a setting not only for the application of knowledge but for its generation" (1995, p. 29). Self-study offers one way in which teacher educators and teachers have sought to articulate and critique the ways of knowing that are embedded in practice. Cole (2000) argues that many teacher educators find themselves, "torn between survival as academics and their ability to flourish as creative and productive teachers, teacher educators and reformers" (p. 44). The preceding sections of this chapter demonstrate that self-study does meet the accepted criteria of research, the issue of credibility therefore is not one reliant on the authenticity of the epistemological base of self-study, but rather on the politics of how epistemologies are valued. Given academia's current practices in allocating research funds,

faculty who do embark on researching teaching practice, face the reality that their institutions are at best only beginning to become receptive to such work.

For Whom do we Research Teaching and Teacher Education?

The story at the beginning of this chapter refers to a research project that sought to improve teaching practice, the learning of the student teachers and, to contribute to the wider knowledge and understanding of how one learns to teach. Fairly lofty claims for something categorized by more knowledgeable, well, more senior, colleagues as "operational". What a university chooses to legitimize as research provides evidence of what it values as contributing to its collective intentions. Equally, what it fails to support also signals what is not valued within its current political, educational and cultural climate. It is acknowledged, and well documented elsewhere, that research and educational practice have undergone change since the beginning of the 20th century, yet Weinert (1997) proposes that the degree to which science, the dominant paradigm of the 20th century, can contribute to the solution of real educational problems continues to be a controversial question. After 100 years of systematic research in the fields of education and educational psychology, there is, in the early 1990s, still no agreement about whether, how, or under what conditions, research can improve educational practice (Weinert, 1997, p. 263). This would suggest that if we are to support research on teaching and teacher education that will make a difference to educational practice, we must address the issue of dominant and less dominant forms of scholarly inquiry within universities.

For those of us concerned with the study and practice of teaching and teacher education we are also caught within a wider socio-political context that exerts pressure from outside the academy. Teacher educators by definition are called to serve two masters – the academic demands of the university manifest as they are in the calls to publish or perish; and, the demands of the professional community i.e., schools, teachers, and students. These, often competing agendas, are framed within further questions of what counts as research for informing policy and practice in teaching and teacher education. With calls for teacher education reform becoming entangled with calls for accountability and compliance, at no other time in history has the interest in teaching and teacher education from outside the academy been so intense. The public investment in education, and therefore in the preparation of teachers, gives rise to intense scrutiny by policy makers and the general population. In the 1990s, calls for teacher education reform have been heard from both within and outside the academy as questions are asked about the relevance of research into teaching and teacher education.

Florio-Ruane (2002) suggests that what counts as educational research for informing policy and practice, "shifts with perception of the problems it might inform, the availability of resources to support it, and the particular interests and values of the powerful practitioners and policy makers who use it in their

decision making" (p. 206). This suggests that rather than research findings influencing educational policy, it is policy and practitioner imperatives that determine the value of educational research. Snow (2001) goes further to suggest that findings of educational research are given little credence in the reality of policy formation and that the triad of educational researchers, practitioners and policy makers are in effect operating on and within different, and somewhat disconnected, agendas, "we're talking past each other". Snow suggests that while educational researchers ponder questions of how we know and practitioners complain about the scope and relevance of what we know, "too many policy makers and members of the public are convinced that in fact we know very little" (p. 4). If, as suggested, the findings of research on teaching and teacher education have little impact on determining educational policy, can we also suspect a similar disconnection with practitioners? Are those of us engaged in research on teaching and teacher education striving for credibility within our institutions under the illusion that our research is valued by, and of use to, practitioners? It is critical that in seeking to address questions of the value of research into teaching and teacher education, we give serious attention to, and be critical of, the ways in which findings of such research are understood and perceived by teaching practitioners.

Is Research on Teaching and Teacher Education Valued by Practitioners?

> Teacher research is tolerated as an interesting and less oppressive form of professional development for teachers, but few treat the knowledge that teachers generate through their inquiries seriously as educational knowledge to be analyzed and discussed. (Zeichner, 1995, p. 160)

This may be even more problematic for teacher educators than for teachers. Husen (1997) suggests that the, "ultimate purpose of any knowledge arrived at in educational research is to provide a basis for action, be it policy action or methods of teaching in the classroom" (p. 20). Yet, it is often claimed, that research into teaching and teacher education has often had limited effect on either policy or practice. In fact Zeichner (1995) has suggested that educational research has been "strangely very uneducational" (p. 161) and it is commonly accepted that teachers (and for that matter teacher educators) have to date paid scant attention to research on teaching (or teacher education) practice.

> Despite some of the exciting breakthroughs that have occurred in recent years in both academic and teacher research in opening up possibilities for new forms of inquiry, teachers generally do not see much value in the scholarship of academics and academics do not see much value in the research of teachers – the worlds of teacher research and academic research rarely intersect. (Zeichner, 1995, p. 160)

Zeichner (1995) points to an apparent dislocation between research and scholarship and the practice of teachers in schools, when he acknowledges that although

he and his colleagues are heralded as outstanding scholars and researchers in the field of teaching and teacher education, for the most part, the knowledge generated by these scholarly activities seems to have had little impact on the reality of teachers and children in schools. School-based teachers and their students, he argues, have to date had limited voice in the conversations on education research, which has remained the privileged domain of the academic faculty. This is so even for the teachers in schools where some of this research was conducted.

> The Faculty of Education at my university has just been ranked No. 1 in the US again for scholarly production of its researchers … Inside the walls of the academy, it is easy to get carried away with the importance of our scholarly endeavors. We often fail to acknowledge, however, that it is we and our careers, and not the world beyond, that receives most of the benefit from this work. (Zeichner, 1995, p. 159)

Recent studies in Australia and New Zealand, however, have challenged the extent to which such assumptions can continue to be made. A large scale study into the impact of educational research commissioned by the Department of Education, Training and Youth Affairs (DETYA, 2000) in Australia revealed that there is increasing evidence of practitioner involvement in all aspects of educational research from design to its implementation (2000, p. 8). One phase of the research project examined teachers' practice through the use of interviews and stimulated recall for evidence of the impact of educational research. The researchers found that,

> In addition to direct research involvement, the teachers' decisions were strongly influenced by sources that are themselves directly impacted on by research, specifically initial teacher training, professional reading, advice of other teachers, professional development courses, and formal postgraduate studies. (DETYA, 2000, p. 8)

In New Zealand a study conducted by the New Zealand Council for Educational Research examined relationships between research and teaching by studying teachers' access to, and use of, research and theory (Boyd & Chalmers, 2001). The study found that teachers had varying levels of access to research findings and theory depending on their access to comprehensive libraries and their active participation in formal study, "Attending professional development courses was one of the main ways the educators accessed new educational theory and research findings" (Boyd & Chalmers, 2001, p. 72).

Which brings us back to the story at the introduction of the chapter where Ruth was so very indignant that the work that she considered worthy of recognition as research was marginalized by the funding process. She could indeed now ask herself, who was to benefit from that research? How was the research as proposed going to advance both knowledge and the practice of teaching and

teacher education? Was she indignant because it represented a missed opportunity for the improvement of teaching and teacher education that could have had the potential to be embraced by colleagues and teachers; or was her indignation the result of anticipating never ending difficulties with tenure? Graue and Grant (2002) suggest that research can be viewed either as a "window on the world" or as a "mirror to the researchers' intentions and commitments" (p. 271). Those of us within teaching and teacher education also clearly have a responsibility to examine critically what we count as research, what purposes it serves and whom it benefits.

Zeichner (1995) in an examination of the readings within his own graduate courses asks: "To what degree do we (or should we) challenge the hegemony of academic researchers over the production of educational knowledge?" (p. 165). To what extent are we, as teacher educators, teachers and researchers, contributing to promoting the hegemony of the traditional research university through the content, structure and focus of our own teaching programs? To what degree is teacher generated knowledge part of the work of teacher education? To what degree is teacher generated knowledge included in courses as course readings? While it is one thing for us as teacher educators to argue that self-study is a way of privileging teachers' voices, it is through our own courses that we may marginalize and undermine our own message. How many of us include in our readings for our preservice and graduate students the voices of teachers? Self-study seeks to advance knowledge about teaching and teacher education through examining and changing the frames of reference through which teaching is understood. Reframing our thinking, our practice and our scholarship in teacher education through intentional inquiry, critical review and examination of our own research and practice is one way of uncovering the ways of knowing that are embedded in practice.

Conclusion

The first two sections of this chapter discuss how those who do self-study in teaching and teacher education communities conceptualize and justify such studies as research. The first section locates self-study within a contemporary debate in the academy about the forms and purposes of research and the constitutive interests that it could, or should serve. Most, if not all, self-studies of educational practice which claim the status of 'research' do so in whole or in part because they involve the implementation of a set of peer legitimated modes of enquiry and representation and, largely in the belief that self-studies, as studies, could still somehow be accommodated within an established, if broadly defined, consensus on what constitutes the form and purpose of research within the academy.

Research is thus often conceptualized in self-studies largely as the processes or procedures of systematic enquiry and presentation. The key components of such modes of enquiry are a commitment to empirically derived evidence, an appeal to theory, broadly understood, or at least generalizable points of interest

or debate, and an enacted intent to make public. The first locates a knowledge claim in terms of specific, situated, contextualized social actions, the second locates it in terms of what may be of more general or public interest, beyond the instance given, and the third is an active invitation for public critique. The debate about research as a 'study' is a debate about *what* can be known and *how* it can be known, how it can be *presented* and how it can be *judged*.

The problem of self-research, however, is clearly not just about what can be known and how, but also raises particular issues about the role of the researcher as both the practitioner and the knower. Consequently, the second section of the chapter focuses on the epistemological import of the role of 'self' and the positioning of 'self' within such studies. In particular, it addresses the issue of what might constitute critical rigor in the conduct of research done on one's own practices, and how self-researchers of teaching and teacher education practices might deal with the critique that self-research is inherently flawed because of the extent of researcher self-involvement.

We present a counter rationale to that which questions the practicability, validity, comprehensiveness and significance of insider or self-research, in which we argue that the problem of researcher self-involvement is not unique to self-researchers. It is only one of the more obvious manifestations of a general post-modern reflexive dilemma facing all social researchers, especially in terms of the ways in which research might be re-presented in publication. In this respect the self-researcher approaches the same swamplands of research rigor with as much obligation as the outsider researcher, but perhaps from a different conceptual direction.

In the third section, we examine critically how teaching and teacher education have been positioned within the academy and the extent to which political, rather than educational discourses appear to have driven such positioning and associated decisions. This section focuses primarily on the context of teacher education, rather than that of teachers in schools, in an effort to demonstrate the forces that construct the nature and focus of researching *self* within the academy. Teacher education holds a unique, complex, and in some cases contested, position within universities not only due to its historical context, but also by virtue of the fact that that which is taught (teaching), is also that which is done (teaching), is also that which is researched (teaching). Self-research on the practice of teaching and teacher education strives to articulate and critique ways of knowing that are grounded in practice, yet it is far from clear the degree to which such enquiry is valued by, or informs the work of, teachers, policy makers or academics themselves. Those who work and write in the self-study of teaching and teacher education areas may wish to examine the degree to which we challenge or contribute to the status quo in the academy and the hegemony of academic researchers over the production of knowledge.

Reflexive Postscript

In this chapter we have tried to represent our own developing understandings and thoughts on the self-study of teaching and teacher education practices as

'research' – both as a matter of epistemological conception and as a matter of practical academic politics. We struggled to do this in a style or form which in some way itself represents and mirrors our evolving process of 'knowing' or 'thinking' about self-study as research, as it unfolded in our consciousness during reading and writing for this chapter, and the conflict between that and the completely detached style of a conventional literature review. Looking back on them, there is in our words a reasonable sense of our evolving thinking on the issue of self-study as research, and a fair presentation of our conclusions, insofar as we have come to them. But, like many in the self-study of teaching and teacher education community, we are still very conscious that such textual representation must necessarily fall short as any kind of realistic or even valid re-presentation of the intellectual journey by which we came to even such tentative conclusions. If we were to choose a metaphor to represent that mental journey it is still more likely to be something about trying to traverse a mangrove swamp than something about a trip on converging railway tracks. So we accept, as all researchers must, the fact that although we neither think nor know in logical straight lines, we are nevertheless obliged to write in them, and are thus content with evocation rather than reproduction as a goal.

We finish with another brief scenario and a recurring sense of the political and conceptual ironies involved in any discussion of the self-study of teaching and teacher education as research.

> *Vince's Story:*
> *In August of this year I submitted to our Ministry of Education a 104 page Research Report which was an Evaluation of a national program of teacher professional development in Information and Communications Technologies (ICT). The report outlines the findings of a longitudinal, multi-method study of the effectiveness of the professional development program, involving the analysis of empirical data from thousands of questionnaire responses, hundreds of teacher and stakeholder interviews and hundreds of direct observations of teachers and students using ICT in classrooms over a three year period. It was, in other words, a substantial but methodologically standard piece of conventional 'outsider' research.*
>
> *It is one of the ironies of academe, like those in the scenario at the opening of the chapter, that, as a piece of commissioned research with no ISSN number, the ICT Evaluation Report will not be listed in the College Calendar as one of my 'research outputs', and yet this chapter certainly will!*

Yet, how would we describe or characterize what we have done in the creation of this analysis of self-study as research? It is a 'reflection', certainly, in that it outlines our views on the issues of the status of self-study as research. It could also be a 'reflexion', in that we have commented critically on the processes by which we come to have such views. It could also be a form of 'self-study', at least in the sense of having focused on our own evolving views of an issue, as well as in the sense of having involved some consciously planned, formally

structured, and one would hope, intellectually rigorous, enquiry into what ourselves and others in the teacher – researcher community think. One might even stretch the notion of empirical data to include not only the extant writings of others but also our own journalized reflections and conversations on the topic as they were produced over time and reflected on in retrospect, and say it has some foundation as an account of what we currently 'know'. But would we call it a piece of 'research'? Ultimately, we think not.

Now why is that … ?

LEARNING THROUGH SELF-STUDY: THE INFLUENCE OF PURPOSE, PARTICIPANTS AND CONTEXT*

J. John Loughran
Monash University

Abstract

This chapter examines the nature of self-study in terms of teaching, learning and research and begins to build an understanding of the influence of purpose, participants and contexts in shaping learning of teaching and teaching about teaching. By exploring learning through contexts and approaches to self-study, the purpose and value for practitioners in these situations is highlighted. These contexts include the sites in which teacher education occurs (universities and schools) and the situations in which teachers and teacher educators place themselves to better understand the complex world of teaching and learning. It also involves understandings of approaches to teaching and teacher education that can only be examined by practitioners researching their own practice and making explicit the purpose for such study. The chapter concludes with a synthesis of the issues considered being illustrated in action through a case-study of learning through self-study. The case-study is designed to highlight how self-study can lead practitioners to develop insightful understandings of practice that also lead to meaningful changes in practice and, of illustrating how such learning might be conveyed and understood by others.

As has been noted in chapter one, self-study as a descriptor, like many other terms that abound in the literature, is not necessarily all that helpful for honing in on a specific type of, or approach to, research because its meaning has changed over time. Just as reflection has been used, interpreted and described in a variety of ways (Grimmett & Erickson, 1988; Richardson 1992), so too has self-study.

---

*Chapter Consultants: Fred Korthagen, University of Utrecht, The Netherlands and Clare Kosnick, OISE/University of Toronto, Ontario, Canada.

Smyth (1992) noted that reflection places an emphasis on learning through questioning and investigation in order to lead to a development of understanding, likewise, the same applies to self-study. Many aspects of the difficulty sometimes created by the use of the term, self-study can, however, be addressed by focusing on the complex interplay between teaching and learning that is central to the purpose of self-study.

Self-study of teaching and teacher education practices is not necessarily confined to one discrete field whereby all of the documented learning through self-study can be easily accessed, examined and evaluated. Rather, as self-study has grown out of the work of many other related fields (e.g., practical inquiry, reflective practice, action research, narrative inquiry, teaching about teaching, teacher thinking, learning to teach, beginning teachers, teacher as researcher, critical pedagogy and, teacher education research and practice), it has only been in the past decade that self-study has evolved to carry a specific understanding that is contextualized within the research of teaching and teacher education practices.

This refining of self-study and the links to its roots can be seen, for example, through examination of the Handbooks of Research on Teaching. In the Third Handbook of Research on Teaching (Wittrock, 1986) none of practitioner research, reflection or self-study was an individually indexed term for searching the text, while teacher as researcher had but one listing. However, by the Fourth Handbook of Research on Teaching (Richardson, 2001) all of these terms (as well as many others related to the field) populated the index. Throughout the actual text, reference to self-study was not as extensive as some of the aforementioned fields of research (practitioner research, reflection, teacher as researcher) but did illustrate its development and growth from other fields into a particular field in its own right.

> Although many of the reports of practitioner research have involved the work of elementary and secondary school teachers and other staff members who have studied their practice, there has also been a growing tradition of research in which college and university faculty members conduct research on their own practice. … There has been a growing acceptance of self-study research within colleges and universities, especially within the teacher education community … Although there have long been calls for this kind of research by teacher educators (e.g., Corey, 1955) and college and university faculty members who have conducted inquiries on their own teaching practice (e.g., Duckworth, 1987; Lampert, 1985), recently there has been a tremendous growth in the publication of self-study research. (Zeichner & Noffke, 2001, p. 304)

This growth in the publication of self-study research is best illustrated through the Self-study of Teacher Education Practices SIG (Special Interest Group) CASTLE conference proceedings (Richards & Russell, 1996; Cole & Finley, 1998; Loughran & Russell, 2000; Kosnik, Freese, & Samaras, 2002) and these,

in conjunction with the ever expanding books on self-study (e.g., Cole, Elijah, & Knowles, 1998; Hamilton *et al.*, 1998; Loughran & Russell, 1997, 2002; Mitchell & Weber, 1999; Russell & Korthagen, 1995; Samaras, 2002; Segall, 2002), chapters in books (e.g., Bullough, 1997; Clandinin, 1995; Heaton & Lampert, 1993; Nicol, 1997; Louie *et al.*, 2001; Munby & Russell, 1995; Tidwell, 2001; Zeichner, 1995) numerous published papers (e.g., Bullough & Pinnegar, 2001; Dinkleman, 1999a, 2000; Ethell & McMeniman, 2000; Guilfoyle, 1995; Hamilton, 1995; Lomax *et al.*, 1999; Munby & Russell, 1994; Pinnegar & Russell, 1995; Placier, 1995), conference papers and presentations (e.g., Crowe & Whitlock, 1999; Dinkleman, 1999b; Loughran, 1996; Loughran & Northfield, 1995; Myers, 1995; Segal, 1999) and dissertations (e.g., Austin, 2001; Baird, 2002; Berry, In Progress, Moguel, 2000; Mulholland, 1997; Schulte, 2001), illustrate the considerable growth in interest in self-study in teaching and teacher education practices.

Across the vast array of writings that comprise the self-study of teaching and teacher education practices, attempting to portray and categorize that which might be deemed as learning from self-study is a difficult task as the nature of the learning in these works is not generally limited to one single definable outcome. Rather, the learning is intertwined with, at least, the purpose of self-study, the participants (including the "self") in self-study, the context and the pedagogy in ways that inevitably offer insights into self-study itself, the methodology developed and/or employed as well as the more traditional research outcomes. This chapter then is organized in a way that is designed to make some of the learning from self-study accessible to others. Clearly, there are many ways of viewing such complex work and this chapter offers but one lens into the learning from self-study.

Structure of the Chapter

As a starting point, the chapter begins by considering the purpose for doing self-study as purpose represents an important driving force in learning from self-study. Building on the notion of purpose is then an exploration of the participants in self-study for it is through the participants that learning is both developed and enacted. The way in which participants come to learn through self-study is often contextually situated, hence an examination of the relationship between context and learning is also important. In building on these foundations, the chapter then focuses on learning through practice settings (university and school) as the development of wisdom is shaped by reflection on personal experience and the articulation of the nature of learning through self-study. The chapter concludes through a case-study which attempts to bring these issues to life through a real world example. A major purpose of the case-study is to illustrate how learning through self-study might be made accessible to the education community in meaningful ways.

Purpose in Self-study

> So often we, in teacher education, see ourselves as agents for our student teachers: motivating them, informing them, guiding them, preparing them. We do not think of it as a process that will also change and enrich us. However, we *must* be enriched by it if we are to prosper in this demanding profession. If we are to help our students develop we too must develop. (Kosnik, 2001, p. 65)

Kosnik, like some scholars in related fields, considers self-study as comprising an obligation that practitioners themselves should work in the very way they advocate for their students. For example:

> *Action Research:* … academics, who teach and write about action-research theory, should see themselves as under an obligation to undertake second-order action research into their own teacher education practices. (Elliott, 1993, p. 177)

> *Teacher Thinking:* Do teachers of teachers have the courage to think aloud as they themselves wrestle with troubling dilemmas … and the human mistakes that even experienced teacher educators make from time to time? (Clarke, 1988, p. 10)

> *Reflective Practice:* There was a general trend to emphasize the importance of reflective teaching for teachers … and to promote its development during teacher education [but] teacher educators did not seem to apply these ideas to themselves. (Korthagen & Russell, 1995, p. 187)

A major expectation then is that through self-study, both teaching and research will inform one another in ways that will lead to valuable learning outcomes for both the teacher and the students. Accompanying this expectation is that by doing that which one advocates for one's students, so it will offer insights into teaching and learning that might otherwise not be fully appreciated or understood if such learning was not genuinely experienced by oneself.

This recognition of a purpose for being involved in self-study is partly derived from the consistent calls throughout the literature for teacher educators to pay attention to their own experiences and to trust that learning through researching these experiences will help them to better understand how to approach teaching about teaching in order to enhance students' learning about teaching. Guilfoyle (1995) notes the inherent importance of "Walking the Talk", Schiller and Streitmatter (1994) and Loughran (1996) examine "Practicing what I Preach", while Adler (1993) implores teacher educators to become reflective practitioners, "an idea that has permeated teacher education" (p. 160). Further to this, Heaton and Lampert (1993) pay attention to "purpose" when they note that, "We also need to learn about how to teach teachers to put these practices into effect and how to prepare teacher educators to work in ways that are consonant with the kind of teaching envisioned in reforms" (p. 43).

Therefore this central purpose of focussing on experience in order that teaching and research might inform one another is clearly a strong attractive force for many practitioners. However, the purpose for self-study is not all at an individual level. It is also clear from the literature that beyond individuals' desire to be better informed about how they think and act (to purposefully reframe their practice), is an expectation that their learning through self-study might also help to positively challenge and change teaching and teacher education practices more generally. As Wilkes (1998) makes clear through her exploration of paradoxes in teaching, she is constantly driven to make her learning move beyond herself and to be available and helpful to others (students and colleagues). Changing practices and programs is a 'big picture' purpose that engages and sustains many involved in the self-study of teaching and teacher education practices.

> Research on teaching practice by teachers holds invaluable promise for developing new understandings and producing new knowledge about teaching and learning. Formalizing such study of practice through self-study is imperative ... The value of self-study depends on the researcher/teacher providing convincing evidence that they know what they claim to know. (Hamilton & Pinnegar, 1998, p. 243)

Without formalizing self-study, without illustrating the evidence that informs approaches to practice, without pushing the boundaries of knowledge about teaching and learning, change is not likely to be enacted beyond the individual. In order to see how the purposes for accepting the challenge to conduct self-studies are played out in different spheres of the work of practitioners, I turn first to the participants of self-study to develop an understanding of how their learning is developed and refined.

Participants in Self-study

To understand what is learnt through self-study, it is important to know who is involved in and how that involvement shapes learning. There is little doubt that the term self-study itself conjures up strong images of individuals researching their own practice. However, this can also be misleading for the participants of self-study are not always single isolated teachers, working alone to better understand their own practice. In fact, the participants in self-study often seek to move way beyond themselves in order to better examine their practice and to interrogate the subsequent learning so that what they come to know, although initially perhaps personal, might be shaped by, and impact on, those with whom they work.

Learning about "Self" through Self-study

> Even though my own self-study has afforded me the opportunity to resituate my understanding of myself along a range of professional, ethical, and

epistemological issues, I am wary. ... My research is certainly connected to the teachers with whom I work, but I did not initiate or conduct this project for them. And yet, in the ways I have come to see myself differently, it is through them that I own these understandings. ... Self-study can not only be about me and my work as a teacher educator ... [it] has to be done in a way that honors their voices [pre-service and in-service teachers] and integrates them more fully into both the process and the product of self-study, in a way that both recognizes and challenges our privileged and their marginizalied voices. (Kuzmic, 2002, pp. 232–233)

Kuzmic (2002) explains how the close links between self-study and teacher research cause him to challenge and rethink the ways in which he understands inquiry and research. Importantly, he also notes how investigating the self in self-study also involves (somewhat paradoxically), going beyond the self. As a consequence, one outcome is that that which one seeks to learn about is also a foundation for change and, such change is at both an individual and institutional level (more attention is paid to the institutional level in a later section: The context of teaching and learning through self-study).

This intertwining of individual and institutional change is not confined to teacher educators. More so, it is inherent in the problematic nature of teaching for understanding – as opposed to "teaching as telling" and the transmission of information.

Yet although the self-study literature abounds with examples of the exploration of self (see for example, Bass, 2002; Chin, 1997; Elijah, 1998; Freidus, 2002; Hamilton, 2002; Kaplan, 2000; Knowles, 1998; Munby, 1996; Nicol, 1997; Pereira, 2000; Wilkes, 1996), there is little doubt that learning about "self" is not the singular feature of self-study. However, despite this, it is still clear that the individual self is an important starting point for researching practice and that the individual gains in understanding and changes in practice are crucial in encouraging further refinement and application of self-study to new and different situations. This therefore means that self-study, and the subsequent growth in understanding for participants, is enhanced when self-study involves others.

Bullough (1997) uses autobiography as a way of studying his "self" in order to come to differentiate between Private and Public theory and to use this differentiation as a way of constructing his approach to teacher education. It is an important way for him to come to explain how he teaches the way he does and through this approach he articulates a number of principles that direct his pedagogy. However, it is his response to questioning whether his teaching approach makes a difference that appears to be an impetus for, "the ongoing study of my practice" (p. 26). He illustrates how through the use of student-teacher data his self-study is indeed ongoing and how it has caused him to believe that, "the future of teacher education is dependent on the willingness of teacher educators to practice theory and to theorize our practice and to put the results of our efforts before a frequently hostile public" (pp. 29–30).

In a similar vein, Clarke's (1997) study of his work with student-teachers and

their practicum advisors is informed by his own experiences as a student-teacher. Through reflection on his own practicum experiences, he comes to conceptualize that which he sees as crucial to his own teaching practice when he is the supervisor responsible for others during their practicum. Again, his "self" is a crucial initial focus of his research, but the implications for others emerges as he examines in detail his beliefs and practices in "Coaching Mathew"; an at risk student-teacher. Clarke's (1997) inquiry leads him to believe that the relationship between schools and universities in the education and preparation of beginning teachers needs to be understood in terms of professional development of all involved and, that practicum advisors' work is the work of teacher education. Hence, he begins to ask school teachers and university teacher educators to reconsider the role of the practicum advisor and to recognize and respond to the pedagogical needs and practices inherent in performing the role appropriately.

Responding to pedagogical needs and confronting one's own practices is well illustrated in the work of Dusting (2002) as she explores how she came to perceive a need for change in her pedagogy as she, "investigated how closely my perceptions of my teaching practice matched those of the students I was teaching … [and, in so doing] I hope to illuminate for others something of the interface between what a teacher perceives he or she needs to do in order to carry out the rhetoric of teaching for understanding, and what the students perceive is happening in the classroom" (p. 173).

In pursuing her self-study, Dusting (2002) was confronted by her own practices and beliefs in ways that challenged her understanding of herself as a teacher. As the "self" in her self-study, she does not appear to shy away from highlighting the important learning that caused her to reconstruct her conceptualization of teaching. Yet, despite the fact that it is her "self" that is the initial focus of her study, she is, "reminded about how important it is to not only attend to my agenda as the teacher, but to focus similar attention on the students' agenda as well" (p. 194). And, by taking her study a further step (publishing her work as a teacher researcher), she anticipates that making her research public might also cause others to consider their practice in similar ways. Hence, she hopes her self-study might also move beyond herself as an individual, and impact upon the self that is other teachers and the institution of teaching – and perhaps that of teacher education.

Learning With and Through Critical Friends

The self-study literature is replete with accounts of teaching, learning and research that focus on collaboration. Such collaboration is initially most apparent through the large number of publications that are jointly authored (particularly in the CASTLE proceedings), however, an extension of this is through the number of collaborative enterprises that have been maintained by co-researchers over considerable periods of time (e.g., Cole & Knowles, 1995, 1996, 1998; Flack, Osler, & Mitchell 1995; Flack & Osler, 2000; Osler & Flack, 2002; Guilfoyle,

Hamilton, Pinnegar & Placier 1994, 1995, 1996, 2000; Loughran & Berry, 1999; Loughran, Berry, & Corrigan, 2001; Berry & Loughran 2000, 2002; Weber & Mitchell, 1995; Mitchell & Weber, 1998, 1999, 2000).

The learning as a result of collaboration in self-study appears to be linked to the opportunity to access alternative perspectives on situations. In many cases, self-study reports illustrate how through working together and sharing ideas, issues and concerns with critical friends has helped practitioners to see beyond their own 'world views' and to broaden their perspective on situations in meaningful ways. A strong example of this is in the work of Austin *et al.* (1999) whereby their ten year collaboration through the Alaska Teacher Research Network (ATRN) illustrated not only what they had learnt as a group (and as individuals) but also what they had to offer other teachers, as well as what they had learnt about doing research on practice and how the two were closely tied.

They (the ATRN) came to see that problems in practice were opportunities that could lead them to learning and that barriers to progress needed to be examined and studied, not to be end points or inhibitors of progress. More so, they noted a shift in their thinking about research whereby, "In the beginning, we viewed our research as a way to look outward upon classroom happenings. Now we see it as a way to be reflective and to look inwards ... our research changes us as people, which in turn changes our practice ... [research on practice] is not a thing to do, but a way to be" (p. 130). This is in accord with Hamilton and Pinnegar's (1998) belief that collaboration in self-study, "leads one to think and act differently in teacher education practice [and] is a formalization of reframing" (p. 1).

Through working collaboratively with others, the likelihood that reframing will be encouraged is then an opportunity for learning that is valued by those engaged in self-study. Bass, Anderson-Patton and Allender (2002) explored the value of reframing as they linked it to the notion of transformative learning. In their self-study, they stressed the role of critical friends as an avenue to alternative views. Alternative views therefore begin to challenge one's privileged position, for, as they suggest, without such challenge, others' agency and ability to learn are diminished.

Reframing through accessing a critical friend is also strong in the work of Osler and Flack (2002) who through team-teaching together began to interpret responses to students' learning in new and different ways. It became apparent to them that their view of student learning from their "privileged position" as classroom teachers was a barrier to active learning. Through their collaboration they began to reconceptualize the possibilities for students' learning and began to examine new approaches to practice that better linked their concerns about students' passive learning behaviours. As their students' learning was transformed through their PEEL type approach to pedagogy (see Baird & Mitchell, 1986; Baird & Northfield, 1992 for a full explanation of PEEL – the Project for the Enhancement of Effective Learning), their learning about practice was substantially enhanced through the constant questions, challenges and innovations to practice encouraged through their critical friendship. Importantly, as they

researched the relationship between their practice and their students' learning, they developed a new *shared vocabulary of pedagogy* that allowed them to begin to better articulate their developing knowledge of practice. They also highlighted the links between the development of their knowledge of teaching and research.

> We learnt much about how to develop metacognitive awareness in our students and became more metacognitive ourselves. We developed a strong sense of commitment to supporting the developing skills of others by sharing our experiences of the research process. We became more aware of our professional growth, about how threatening growth can be and how hard it can be to manage. (Osler & Flack, 2002, pp. 245–245)

In working with teachers in an ongoing professional development project, Dalmau & Gudjónsdóttir (2002) also showed how collaboration through self-study was crucial in their learning about practice. The development of their Professional Working Theory was a way of accessing and then articulating the professional knowledge of teachers as they examined the dynamic interaction between practice, theory and ethics and came to create a shared discourse. Cross disciplinary collaboration (education, nursing and business administration) through self-study had a similar learning outcome for Louie, Stackman, Drevdahl and Purdy (2002). In their examination of their teaching they came to see that their self-study was a powerful way of encouraging change – even though that was not the initial intention of their study. Through their ongoing analysis, discussions and explorations of their beliefs and practices, they learnt how to recognise what they were *really doing* in their teaching as opposed to what they thought they were doing. Working with critical friends was, "simultaneously humorous, blunt, supportive, and confrontational, as well as educational and motivating ... [and] the learning that has taken place motivates us ... [and] we fully expect to be transformed as teachers once again" (p. 205). Hence, through working with critical friends, self-study has been a valuable way of learning about aspects of practice that may not have been so apparent if the work had been conducted alone.

Learning by Seeing Practice from the Students' Perspective

In order to look into the complex relationships of teaching, learning and research, one important set of eyes that are used by many involved in self-study are those of their students. Many authors have written about the ways in which students often see teaching and learning differently to their teachers and, how accessing these differing perspectives offers new insights about particular situations (Hoban, 1997; Nicol, 1997; Ojanen, 1995; Russell & Bullock, 1999; Schuck & Segal, 2002; Senese, 2002). Through students' eyes, a number of different learning outcomes have been reported and some of these, at first glance, might seem quite simple and obvious, yet many self-study reports highlight how insightful even the apparently superficial can be. For example, consider Dinkleman's

(1999b) learning through connecting two different events. Dinkleman was teaching a social studies methods course whilst also conducting research for his dissertation, hence some of the students he was teaching were also participants in his research.

> … as the class moved away from a discussion of the appointed topic, multicultural education, and toward a forum for airing grievances with the course, one class member began her contribution by saying, "I don't feel safe in this classroom. … " and burst into tears. I was taken aback … That our classroom had become a less than welcoming environment for some was an unsettling sentiment I had detected in the prior weeks, but try as I might to figure out what was so threatening about our class, I had few answers. (p. 1)

Dinkleman then goes on to explain how two months later, during a research interview, he asked the interviewee why some students did not feel safe to speak their mind in the class. With an extensive, honest and chilling quote, he shows how some students interpreted his 'look' as being judgmental and therefore a major inhibitor to honesty in class discussion. "I was stunned. This response was truly a revelation to me. Promotion of open discourse was, and is, one of the most valued objectives of my teaching, one that I was unknowingly squelching" (p. 2). He then sought further validation of this information and found that the problem truly did reside with him.

Through this experience, Dinkleman was 'shocked' into action because his beliefs about practice and his actions in practice were in some cases incongruous. The personal vulnerability he displays in his paper highlights how, for him, his teaching and his research informed one another. His use of self-study and the input from a different set of eyes helped him to see, and respond to, issues and concerns that he could not see on his own – or perhaps could not see from his personal teacher perspective.

The value in learning to see from a student's perspective is commonly highlighted in the self-study literature, where, as opposed to the somewhat accidental eye-opener of Dinkleman, the search for a student perspective is fully intended at the outset. Schuck (1999) found that by purposefully pursuing students' understandings of her teaching in a mathematics methods course, that she, "became aware that [she] needed to make the subject matter more explicitly linked to the content of the school curriculum" (p. 8). This in itself was not necessarily a substantial breakthrough for her, but it was the subsequent impact drawn from the emerging issues associated with this point that shed new light on the theoretical underpinnings of her teaching and the way in which she was inadvertently shaping, and/or misinterpreting, her student teachers' conceptions of teaching and learning in mathematics that became much more evident and important to her. "By persevering with ways of increasing student autonomy and by continuing to assess my practice, not merely from student evaluations, but also from examinations of students' learning and teaching of mathematics,

I will gain valuable insights into how to be a more effective teacher educator" (p. 14).

Just as Schuck (1999) came to pay more attention to student learning through self-study, so too did Segal (1999). However, in this case, she placed herself in the learner's position as she struggled to come to understand how to teach in a three-part learning and teaching model (co-operative groups, learners' questions and a techno-science context). By shifting between being a learner of teaching and a learner of learning in her work with her students, Segal experienced for herself the dilemmas of practice that were important and necessary to recognize and feel in order to be able to create situations through which the teaching approach would work with her students.

> Simone, Mary and I [Segal] put forward our ideas as equals … because I was puzzled too … in spite of my extensive preparation … I did not realise until I was a full participant in their explorations that my own understanding was tenuous. … In genuinely seeking to understand how they were learning, I was involved in the appropriation process myself … Thus for me, appropri-ation – the Vygotskian term for collaborative understanding becoming individual understanding has an emotional component … After a positive boost to my confidence, I was probably keen that students should experience this type of inner satisfaction through the learners' questions part of the learning model. (pp. 17–18)

In purposefully attempting to gain students' perspectives on his teaching, Russell (1986, 1997) draws on Schön's (1983) notion of 'backtalk' – the unexpected consequences of actions talking back to us (Munby & Russell, 1995, p. 182) – as a more formalized way of accessing his students' perspectives on his practice.

The use of backtalk is designed to invite students to offer feedback on the teaching and learning situations and for this feedback to be both a point of open and honest discussion as well as an explicit tool for encouraging pedagogical responsiveness. However, describing backtalk as feedback is also rather simplis-tic, for from a self-study perspective – rather than evaluative perspective – Russell's (1997) explanation of the evolution and use of backtalk focuses atten-tion on the value of students writing about their reactions to situations and episodes that are not usually vocalized in class. Through his backtalk papers, Russell compiles lists of strengths, weaknesses and suggestions (about his teach-ing) and prints these out to return to the class. This process, he believes, is a powerful way of showing his students how many features of teaching are interpre-ted and appreciated, or not, by different people. Backtalk also creates an agenda whereby new issues, ideas, needs and concerns can be introduced and responded to in a respectful way, but, ultimately, impact on the teaching in ways that may never have occurred but for the students' perspective being sought.

Instances through which backtalk is accessed with a similar intent include Senese's (2002) study of his evolving English curriculum and his work (as Deputy Principal) with the Action Research Laboratory at Highland Park School,

Illinois. In this case, Senese responds to his students' needs and concerns as a result of viewing the teaching and learning environment from their perspective based on his developing understanding of himself and his teaching role being redefined through directing action research projects with his staff. Similarly, Fernandez and Mitchell (2002), Walsh and Smith (2002) and Jeppesen (2002) illustrate well how they begin to question their pedagogy as they learn more about teaching and learning by seeking to view their classrooms from a student's perspective.

Participants and Purposes: Catalysts for Self-study

Overall then, participants in self-study appear to be driven by a learning purpose whereby an important starting point for examining the learning through self-study is based on confronting the dilemmas of practice that are typically, too easily ignored, or explained away, because of the pressure of the work of teaching. Self-study participants seek not to ignore these pressures but to respond in ways that will help them learn about practice for it is too easy to accept that one's intentions and practices are always closely aligned. Brookfield (1995) encapsulates this view well when he notes that,

> What we think are democratic, respectful ways of treating people can be experienced by them as oppressive and constraining. One of the hardest things teachers have to learn is that the sincerity of their intentions does not guarantee the purity of their practice ... Teaching innocently means assuming that the meanings and significance we place on our actions are the ones that students take from them ... we never have full awareness of our motives and intentions, and ... frequently misread how others perceive our actions ... (Brookfield, 1995, p. 1)

Self-study in teaching and teacher education practices then is driven by an underlying purpose that is embedded in a need to link teaching and research in meaningful ways and to view the practices associated with both from differing perspectives. In so doing, the aim is to seek alternative interpretations of situations (to frame and reframe) in order to better understand the complexity of the situation. Guilfoyle, Hamilton and Pinnegar (1997) describe this purpose and its interplay with their understanding of their practice in teacher education by focussing on the students that will eventually be taught by their pre-service teachers. They aptly capture the meaning of this intent through the phrase "Obligations to Unseen Children" and offer reasoned and honest insights into why this is important to them, their students and their students' students.

Zeichner (1995) encapsulates the inherent intricacy of these ideas and illustrates the value in genuinely examining the differences between one's own practice and beliefs when he reconsiders his own teaching in teacher education in a chapter that he described as, "a different kind of writing ... [that was] difficult [but] more rewarding than the more distanced academic perspective that I usually assume" (p. 14). Zeichner describes a tension he experienced in

his teaching that caused him to do much soul-searching. Although he strongly espoused the need to use action research as a vehicle for student teacher reflection, he came to see that despite his intentions to challenge the:

> hegemony of those who sought to impose change in schools from the outside, the voices in these papers and books [that were his major texts] were mainly academic voices. Despite my commitment to the role of teachers as knowledge producers and to the practice of teacher research, my actual practice undermined my intended message to students. Were my students really learning about the role of teachers as knowledge producers and reformers if they never were given the opportunity to read anything written by a teacher or another student teacher? (p. 20)

From this perspective, it is clear then that learning through self-study is dramatically influenced by the dilemmas, issues, concerns, problems or tensions that draw practitioners to see their practice with new eyes and to begin to question the degree of alignment between beliefs and practice and/or student needs and program goals. Within the literature, the ways in which these dilemmas, issues, concerns, problems or tensions are recognized by the "self" and therefore catalyze self-study are numerous. However, it is these different "ways in" to self-study that lead to learning through self-study. The next section of this chapter considers learning through self-study based on the impetus described above, whereby the context for the self-study has created opportunities for learning that have been important to teachers and teacher educators.

Contexts of Teaching and Learning Through Self-Study

Teaching is inevitably shaped by the context in which it occurs. The socio-economic situation, the physical nature of the setting, the age, disposition and ability of the students being taught, the content under consideration, and a host of other factors influence what might be described as the context of a teaching and learning environment. One way of re-focusing on the problematic nature of teaching is to change one's 'normal' teaching context. In many teacher education programs, the teacher educator's normal teaching context is a university classroom which brings with it different demands and expectations to those of a school classroom.

As such, teacher educators then work within an institution and institutional structures can inhibit learning about teaching. Therefore, in an effort to learn more concerning teaching about teaching through self-study and to address some of the institutional constraints inherent in a university teaching situation, some teacher educators have taken what might be described as the bold step of re-entering school classrooms to teach. Teacher educators generally embark on this change in the context of their teaching with the expectation that it will do more than offer recent and relevant experience. They make the change in order to help reconceptualize their pedagogical practices in their teacher preparation

programs and to be reminded of, and better understand, that which their student-teachers experience when they move into schools to teach – whether it be on their practicum or as they embark on their teaching careers.

Three instances of re-engagement with school teaching stand out in the literature. The first is that of attempting to access the student-teacher practicum experience; the second is the teacher educator accepting a limited school experience attachment; and, the third is teacher educator as school teacher.

Accessing Student-Teaching Experiences

There are many texts that introduce student-teachers to the world of teaching and that attempt to offer guidance and support in the development from student-teacher to teacher. For example, Groundwater-Smith, Ewing and Le Cornu (2002) set out one section of their text in a way that is designed to help student-teachers work through their experiences by paying particular attention to the complexity of student-teacher learning during the school practicum. They ask student-teachers to consider their own personal history and to bring their own school experiences to bear on their understanding of their field experiences. In this way, they are attempting to help student-teachers see the value of learning through experience by reflecting on how their experiences shape their views of practice.

For many teacher educators, their own school practicum may well be a vague and distant memory, hence, although they may genuinely desire to be supportive and empathetic toward student-teachers during their practicum, the feelings and practices that influence student-teachers' actions and, the difficulties that arise for them during their practicum, may not be all that well apprehended by teacher educators. In order to address this difficulty, some self-study practitioners have attempted to learn more about the student teaching experience at a personal level in order to enhance their ability to create more meaningful teaching and learning opportunities for their student-teachers through the practicum.

An extensive example of this is through the work of Featherstone, Munby and Russell (1997) in which a consistent focus on student-teachers' practicum experiences becomes the basis for shaping their thinking about learning to teach. Through their work, themes emerge that influence approaches to practice (of both student-teachers and teacher educators alike) that explicitly illustrate how important valuing the knowledge of the practicum is in learning to teach.

> I have been reminded just how important it is that one does not underestimate the value of creating a forum for listening to students' voices. I found messages from my students at two different levels. … For example, the student who said, 'You don't think that the only way we learn is if we are taking notes' caused me to think critically about what made the discussion so powerful and useful to the students in terms of their learning. … Thus I decided to develop a discussion summary sheet. I am certainly not the first to think about this, but there is something special about being able to say

that my decision is based on what I have learned from my students. (Featherstone, 1997, p. 136)

In this quote, Featherstone illustrates how personally using a teaching procedure in his own practice leads him to better understand and value the procedure. His response was initiated as a result of an incident that arose in his own class. His student's statement reminded him of the value of listening, something that he would certainly have been aware of as a 'piece of propositional knowledge', but something that he has come to appreciate in a much more meaningful way through this particular experience. This situation (quote above) is similar to the learning about teaching reflected in Russell's backtalk and was something that Featherstone had experienced in his teacher education classes, yet it could well be argued that the real meaning did not emerge for him until he was acting in the role of teacher. The value of the learning was clearly embedded in the experience, and, in this particular case, made possible through the practicum.

Russell and Bullock (1999) extend this exploration of learning about the practicum experience through their self-study. Like Featherstone before him, Bullock was also a student-teacher – in Russell's physics method course at Queen's University. As a teacher educator Russell wanted to get closer to the practicum experience from the student-teacher's perspective, and through working intensively with Bullock (as one documented example amongst his classes generally) uncovered ways of further developing the professional knowledge of teaching embedded within the practicum experience. The learning through this experience for both participants is made clear through their explanations of the value of framing and reframing, the development of metacognition and more meaningful questions about practice, and the rich interplay between learning to teach at university and learning to teach in school.

Russell's interest in student-teachers' experiences during the practicum and the value to teacher educators of learning to teach about teaching through greater emphasis on these experiences continued in his later individual self-study (Russell, 2002). In this case, Russell (2002) researched the intricacies and skills associated with focusing on student teaching during the practicum as he purposefully built on his previous work from his personal perspective. His purpose was to examine how he as a teacher educator could teach in ways that would help to bridge the gap between the worlds of theory and practice. As he had come to know from his previous work, this involved placing himself in the learning as best he could, and in so doing he came to see that,

over a five year period [this self-study] has been productive both practically and conceptually ... I have made specific changes to how I spend my time in schools. ... At the same time, studying my learning ... has refocused my attention on the multiple and challenging tasks that the role permits and invites. ... [a] compelling insight is that teacher candidates, experienced teachers, and Faculty Liaisons can be expected to approach supervisory interactions with "default" assumptions driven by unexamined personal

experiences … self-study is a way to bring such assumptions to the surface; over time, self-study is a way to keep one's focus on the goal of extending our professional understanding of what it means to learn from experience in the classroom and school settings. (Russell, 2002, pp. 85–86)

Attempting to get closer to the practicum experience has also been explored in terms of teacher educators' supervisory roles. For example, Kwo (1998) examined issues associated with the supervision of student-teachers during the practicum from both the student-teacher's and teacher educator's perspective. This led to an articulation of practice that was characterized in two ways: the first as "learning with student teachers to promote positive change" (see Adamson, 1998; Taplin, 1998; Lo & Lee, 1998; Cheung & Yung, 1998); and, the second as an examination of dilemmas in supervision such as pre-lesson discussion, assessing student-teaching and competing expectations (see Lopez-Real, 1998; Lo, 1998; Bunton, 1998; Tse, 1998).

These explorations of the practicum experience show one approach that teacher educators might use to learn more about their role in supervision. These studies also illustrate how the possibilities for collaboration and development with student-teachers lead to learning outcomes that impact on the participants' approach to practice. All of these self-studies highlight the degree of risk and vulnerability associated with examining these aspects of teacher education. However, Pinnegar (1995) increased the degree of personal risk substantially in the way she came to a better understanding of the practicum experience.

Teacher Educator as Student-Teacher

In her vivid and open self-study of re-entering the classroom, in effect as a student-teacher, Pinnegar became increasingly aware of issues and experiences that dramatically shaped her views of teaching about teaching. She began to question what the practicum really does to student-teachers and how easily it can be misinterpreted by student-teachers, teacher educators and supervising teachers alike as each one's purposes and practices collide. As she re-experienced what it was like to be a student-teacher (again) she began to look differently at the theories and practices that she considered important in shaping her views of learning to teach and teaching about teaching. She began to identify with her student-teachers' concerns and issues in new ways because she experienced them herself. Through this self-study she learnt about teaching in ways that would not have been possible except through again being a student-teacher.

Pinnegar entered the experience openly questioning whether, "any of the things I had learnt or taught students actually applied in teaching in public schools" (p. 58). She came to see that what she saw as problematic in the classroom did not always accord with what her "supervising teacher" perceived as problematic and this could cause discomfort, disagreement and various "power plays" that had real outcomes. She also experienced first hand, and in ongoing ways, how teaching procedures that she advocated in her teacher education

classes "played out" in public school classrooms. Her account of being a student-teacher illustrates again a common thread in the literature. It illustrates how being in the experience is so important for learning through the experience and this is substantially extended through self-study.

> I was able to identify the ways in which theory guided, framed, and emerged in my thinking about practice. As teacher educators. … We should go beyond the question of whether theories, ideas, and research taught in teacher education programs are evident in the practice of teachers, to focus instead on *how such learning is evident*. Perhaps some of the problems of practice might be more clearly explained by examining *how* theories emerge rather than discussing *whether* they do or do not. [emphasis in original text] (Pinnegar, 1995, p. 67)

Pinnegar's approach to learning to teach about teaching by re-experiencing student-teaching is obviously personally challenging. Perhaps less extreme, but no doubt still risky and demanding, is seeking out and accepting a teaching allotment through a school attachment.

Teacher Educator on School Attachment

There have been a range of responses by teacher educators to the call for 'recent and relevant' teaching experience. However, few responses match the large scale approach documented by He *et al.* (2000) in the Lecturer Attachment Scheme initiated at the Hong Kong Institute of Education in the late 1990s.

He *et al.* (2000) explained that the teacher educators involved in the Lecturer Attachment Scheme (LAS) were enacting the assertion by Knowles and Cole (1998) that, "teacher educators should put themselves at the heart of the teacher education reform agendas. [Therefore] learning and renewal of knowledge must start first with teacher educators [and the] Hong Kong Institute of Education … has made clear attempts to encourage staff to strengthen and update their professional knowledge" (p. 3) through initiating the LAS.

Through the LAS, the teacher educators involved began to question and reconceptualize many of their teacher education practices as they attempted to teach in schools in the ways they had been advocating with their student-teachers. The research that each conducted into these practices highlights an array of learning outcomes but central to all was the realization that through their LAS experience they were developing their professional knowledge of teaching about teaching in new ways.

> While researching for a true picture of reality, triangulation is often apparent as a means of validating what is discovered. Through a different channel of data collection, that is, as a classroom teacher … and from dynamic school classrooms … teacher educators are making inquiries about their own beliefs and assumptions regarding teacher education. Knowledge obtained from such an inquiry enjoys more validity … because the picture obtained … is

more congruent with the reality of local schools. Teacher educators can be accused of living in ivory towers if they separate themselves from that reality. (He & Heron, 2000, p. 24)

He and Heron (2000) explained in detail the value of collaboration and the resultant professional development that they achieved through the LAS because they maintained a professional dialogue throughout the process that encouraged them to frame and reframe their experiences in ways that would not have been possible without the LAS. Chow and Mok (2000) found that the experience led them to enrich and enhance their teacher education practices while Walker's (2000) study uncovered the value, for her, of being able to access students' perspectives in ways that are not possible in a university setting.

Wheeler's (2000) experience is reminiscent of Pinnegar (1995) where she strongly identified with student-teachers' practicum situations. Wheeler's learning was therefore very personal and no doubt impacted in new ways on her subsequent teacher education practices.

I was in the students' position, having someone else in my classroom observing me all the time … the teacher did not expect me to fail in achieving my objectives, much as we do not expect our trainee teachers to fail when we observe them … This process reminded me of that strong urge you have to defend yourself against "criticism" however much you want to learn from and share your experiences. (Wheeler, 2000, pp. 95–96)

He *et al.* (2000) explained how the learning from experience through the LAS was crucial to their ongoing roles as teacher educators but, that such learning could not be drawn from experience alone; there was a need for reflection on experience. This reflection on experience was clearly facilitated through the self-study approaches adopted through their research. The growth in personal knowledge through these teacher educators' experiences of conducting the LAS and then collaborating in writing up their experiences showed how, "the issues, ideas and view-points … became more explicit, focused, and sharpened … and how [they have] grown through the articulation of personal experiences" (p. 139). This aspect of self-study (documenting and sharing) is a key element for facilitating learning when shared experiences such as the LAS are undertaken.

In their conclusion, He *et al.* (2000) group their findings from these LAS studies under four major headings. The first was the learning as a result of closely monitoring their own personal teaching behaviors in systematic ways (journals, observations, videos etc.) and collaborating in "unpacking" the problematic situations that arose in action. Through this process, their perceptions as teacher educators were genuinely challenged as they reconsidered what was realistic and appropriate in real classrooms with real learners. The second was how the LAS opened up possibilities for, "an equal collaboration and cooperative relationship between school teachers and educators" (p. 140) whereby mutual respect and trust were able to be developed between teacher educators and teachers. This was certainly one learning outcome that positively addressed the

ever present theory practice gap. The third was how the LAS had benefited both the teacher educators and the school teachers as, "seeing what was going on in the classroom provided insights for the teachers as well as for the [teacher] educators themselves, regarding the feasibility and effectiveness of theories in action" (p. 141). They felt that this was important as it highlighted the different roles of teacher educators and teachers in developing student-teachers' procedural and declarative knowledge and the importance of both coming together in a cohesive and meaningful way. Finally, the LAS proved a rich source of learning for teacher educators in providing them, through their self-studies, with real evidence of problems and dilemmas which they might further encounter in their own teaching of student-teachers when attempting to practice what they preach and also in helping students to make, "informed pedagogical choices in a particular context" (p. 142).

For these teacher educators, helping student-teachers make more informed pedagogical choices is a valuable learning outcome of the LAS related self-studies because it directly links to a constant teacher education concern about context. The predominant site for teacher education is commonly the university, yet the literature illustrates time and again that it is the school context that student-teachers (and in some instances, teacher educators too) see as the important learning about teaching site. Hence, ways of attempting to address this contextual barrier in learning about teaching and acknowledging the value of the different learning that occurs in each is important as attempts to develop more holistic views of learning across contexts emerge.

At the extreme end of this linking of contexts is the work of those teacher educators who have returned to school teaching for extensive periods of time to examine their understanding of their teaching in the context (school) in which their student-teachers will teach. In many ways, this shift in teaching context is one way of becoming better informed about the pedagogical reasoning of teaching about teaching when self-study is confronted by the demands of teaching that are different in school to university. Some of the learning through such experience is outlined in the following section.

Teacher Educator as School Teacher

The path from school teacher to teacher educator varies across the world's different tertiary education systems. Yet generally, for many, it is this move from school to university that marks a transition in their understanding of their role as a teacher. For some teacher educators, their need to be continually reminded of how an understanding of school teaching shapes their pedagogy in teacher education has led to ongoing substantive links with schools as sites for their teaching. However, one outcome of this purposeful link is that it can create questions about practice that might only emerge through a sustained school teaching allotment. For example, consider the work of Berry and Milroy (2002) who, through combined efforts as teacher researchers and involvement in teacher education science method teaching, attempted to do with their high school

students what they believed was a natural consequence of the research knowledge about science teaching and learning they had come to know at university.

> Our Monash University experiences had been significant in influencing our views and we saw value in accessing the possibilities that a conceptual change approach might have on students' learning … To be able to implement a conceptual change approach requires expertise in both subject matter knowledge and in the construction of learning experiences. We found it frustrating and very time consuming trying to devise a sequence of lessons to address alternative conceptions and to lead students towards a concept of the atom. (Berry & Milroy, 2002, pp. 200–201)

Interestingly through their work, they come to understand anew what it means to teach a unit of work in ways commensurate with the findings of the research literature. Although they acknowledge the value of so doing, they also make clear that it is no simple task. Their research illustrates that many aspects of their approach could not genuinely be apprehended by student-teachers through the construction of a unit of work as a vicarious experience of unit construction in a university assignment. Understanding the daily struggles, the demands of teaching, the need for support, the lack of resources and the ongoing tensions only emerge through a sustained commitment at the school level.

Russell (1995) purposefully embedded a reconceptualization of his teaching about teaching (in this case as a physics method lecturer) in a school context by returning to teach senior high school physics. His decision was initially based on the desire to, "see how the experiences of daily high school teaching would affect [my] ways of thinking about my regular work with people learning to teach physics" (p. 95). Through this approach, he was also examining whether his overt involvement in school teaching (recent and relevant experience) influenced his student-teachers' learning about teaching in different ways from that which he commonly noted from physics method classes at university. Interestingly he concluded that, "My teaching in a school and encouraging them [student-teachers] to analyze personal experience were useful for some but 'a waste of time' to others" (p. 105). This finding is not a ringing endorsement for recent and relevant experience for teacher educators. However, it is not this outcome that is of prime importance to Russell. It is actually his new learning about teaching that is the valuable outcome for him as a teacher educator.

The return to the classroom taught Russell about the significance of personal experience in dealing with science textbook problems, the structure of the curriculum, challenging learning and the use of resources in classrooms that could not be garnered for him, or his student-teachers, in a university setting. Importantly, when Russell reflected on his experiences as a high school science teacher and teacher educator, the two major learning outcomes, although in one sense may be seen as contradictory, were in fact complimentary. He learnt about the need to create through his teaching about teaching, ways that encouraged student-teachers to have confidence in the development of the authority of their experience (Munby & Russell, 1994). He recognized, in ways similar to Berry and

Milroy (2002), that the daily demands of science teaching can not be replicated in a university setting, but, he came to refashion the purpose of his physics method teaching so that his student-teachers' experiences of learning *and* teaching of physics became the central focus. Through this new recognition of purpose came a new understanding of what was possible in learning to teach physics so that his student-teachers, like he himself had experienced, would be confronted by a need to extend their questioning and practice of their teaching as they moved beyond simply covering the curriculum. It could well be argued that he was learning how to professionalize not socialize his student-teachers into the world of science teaching.

   The work of Russell was also, in part, a catalyst for Northfield's return to school teaching. Hence, one of the important outcomes of self-study, making the experiences, practices and subsequent knowledge and learning public, is immediately apparent. Northfield's experiences (see Loughran & Northfield, 1996) were not dissimilar to Russell's (1995) but he formally challenged some of the existing educational rhetoric through his "Implications for Teacher Education". For example, he stated that his understanding of educational theories were of little value to him in dealing with everyday classroom situations. Also, that quality learning more often than not emerged from unplanned events and listening to students and, that students' perspectives on schooling and learning were crucial for interpreting their classroom behavior. These are not issues that can easily be 'dealt with' in teacher preparation programs based around lectures, the transmission of knowledge and the separation of practice and theory. In many ways, Northfield is suggesting that teacher preparation should be viewed as problematic, composed of dilemmas that need to be managed, rather than being seen as a range of selections between dichotomous alternatives. It is this view that is also apparent in the work of Lampert (1985) when she states that,

> … it would seem appropriate that help from outsiders appear in the form of arguments to teachers about why they should pay more attention either to classroom order or to student commitment. Much preservice and inservice education today takes this form. Professors and staff developers use evidence from research, rationales drawn from educational philosophy, or personal charisma to convince teachers that one approach is better than its opposite (pp. 190–191) … [but] our understanding of the work of teaching might be enhanced if we explored what teachers do when they choose to endure and make use of conflict. Such understanding will be difficult to acquire if we approach all of the problems in teaching as if they are solvable, and if we assume that what is needed to solve them is knowledge that can be produced outside the classroom … we shall need to adopt an image of teaching which takes account of the possibility that the teacher herself is a resource in managing the problems of educational practice. (p. 194)

Lampert's insights create a challenge for teacher education that can not easily be tackled from the outside, nor from teacher educators that advocate solutions

that do not include the teacher as a resource. The work of Lampert raises interesting new ways of considering the interface between teacher educator and school teacher. Lampert's professional role includes both teaching and research in teacher education and mathematics teaching in school. She notes in much of her work that this interplay between the two sites of her work informs her practice in ways that are not common and, that are not necessarily well understood by other teacher educators or school teachers. The underlying purpose for her involvement in teaching and teacher education in this manner was to begin to develop new relationships between teaching, research and teacher education, "As a researcher, she used her classroom as a site for inquiry into the practices of teaching and learning authentic mathematics for understanding in school. ... These practices are unfamiliar not only to many experienced elementary school teachers ... but also to most teacher educators" (Heaton & Lampert, 1993, p. 44).

Heaton (as an elementary school teacher and beginning teacher educator) worked in partnership with Lampert in ways that offered insights into teaching and teacher education, that were (in their view) not necessarily uniquely innovative – as elements of their practice exist wherever teachers and teacher educators work together on new ways of approaching teaching and learning – but in terms of a major purpose of self-study, are "little examined and rarely written about" (Lampert & Heaton, 1993, p. 48).

Through their collaboration, they came to see many parallels between the issues that arise in the teaching of mathematics and those that arise in teaching about teaching. The need to pay careful attention to encouraging learners to analyze and solve problems with others is a foundation to their understanding of learning (be it mathematics or teaching). Hence, their recognition of the importance of valuing teaching that focuses on, "... watching and listening to the learner, helping the learner to identify and articulate assumptions, and bringing new perspectives to bear on the interpretation and solution to the problem" (pp. 47–48) becomes an important principle of practice that shapes their understanding of teaching about teaching – something that is very different to what Myers (2002) describes as the teaching as telling model that is so dominant in many teacher education programs.

The interplay between school teacher and teacher educator that is illustrated through the work of Heaton and Lampert offers insights into teaching and teacher education that could not be articulated if it were not for the collaboration across sites and roles.

> Hearing the multiple, oftentimes conflicting voices within Heaton and Lampert is a way to begin to understand the challenges faced by teachers and teacher educators who have an interest in changing traditional ways of teaching mathematics and teaching teachers. It also provides insight into the multiple layers of teaching and learning involved in inventing a new pedagogy of teacher education. Heaton, an experienced teacher, entered a doctoral program in teacher education never expecting that her studies to

become a teacher educator would include an examination of her own teaching practice. It became necessary for her to do such an examination when she realized that the pedagogy of mathematics she wanted to teach teachers differed from her own practice of teaching mathematics. She could not live with the dissonance. (Heaton & Lampert, 1993, pp. 76–77)

Accepting the challenge to respond to the dissonance, as Heaton did, is an important aspect of self-study. Ignoring the dissonance is not acceptable to those teachers and teacher educators who seek to learn about practice through intense examination of their own practice. Self-study of teacher education practices is an important way of developing and articulating a pedagogy of teacher education (Loughran, 2002).

Learning about teaching and a pedagogy of teacher education

A common theme throughout this chapter has been the importance of learning from self-study to extend beyond the individual who has conducted the self-study. The need for this extension is based partly in the academic expectation that research should lead to the development of new knowledge and, that such knowledge should be made publicly available to others. But, it is also based on a concern for improvement in the learning outcomes of participants that might also reflect a valuing of teaching and teacher education in ways that are not necessarily (presently) apparent in the educational community. To make such learning and valuing apparent requires an ability for teachers and teacher educators to make aspects of teaching and learning that are often taken-for-granted (within and outside the profession), or implicit in practice, explicit.

Making the Tacit Explicit

Mitchell (1999) describes how he came to better understand and articulate his teaching when he was inadvertently confronted by his own inability to explain to another teacher important aspects of a particular teaching procedure. In the case[1] he wrote to share that experience with others, he outlines how, when passing on information for another teacher who was to take a class for him, crucial aspects of the teaching procedure were overlooked. However, this was not because he, "forgot to mention these things … rather they were still tacit knowledge" (p. 60).

Mitchell goes on to explain how he was astounded at how he had omitted important information, but that through the later discussion about the lesson with the teacher, the notion of "maintaining a sense of progress" emerged as a frame for his teaching. In his case, Mitchell illustrates well how, despite what he thought he knew about his teaching, his ability to both recognize and articulate his practice for others was inhibited by the tacit nature of such knowledge. Therefore, what he genuinely understood and could make explicit to others was not fully unmasked until he was confronted by 'hearing anew' that which he

thought he had already fully and appropriately explained to a colleague. By being confronted by the gaps in his explanation about "what to do when teaching his class" on this particular occasion, his comprehension of the tacit nature of teachers' knowledge personally confronted him in ways that he could not avoid. Even as an experienced teacher, he was amazed at how this had emerged in his own practice.

Mitchell's case is a powerful example of learning through self-study, which, although it was not planned and organized as a foray into researching his understanding of his pedagogy, led to a re-examination of practice and, ultimately, of ways of articulating and sharing knowledge of practice with others. The subsequent reflection on practice and the case writing helped him to reframe the situation so that he could see into his teaching (and the knowledge about his teaching) in new and illuminating ways.

Self-studies of teachers' and teacher educators' taken-for-granted assumptions about practice highlight further this issue of learning about one's own teaching and the articulation of the knowledge, principles and/or philosophy underpinning practice. For example, Boyle (2002) illustrates how important it is for teachers to withhold judgment about their use of teaching procedures. She describes how her lack of understanding of a teaching procedure was only realized when she decided to revisit a less than successful classroom episode. In so doing, she began to better see what she needed to know and be able to do to genuinely enhance her students' learning in the ways she had originally anticipated – but not achieved. Her initial inclination was to dismiss the teaching procedure as not helpful, yet by withholding judgment and revisiting the situation, she learnt a great deal more than she had ever initially envisaged possible.

Framing and Naming

Senese (2002) as a high school English teacher, Deputy Principal and initiator of the Action Research Laboratory (ARL) at Highland Park High School, Chicago, conducted an extensive self-study into his teaching that led him to understand important issues about his teaching in terms of axioms. Senese describes the development of these axioms as illustrating that each is, "counterintuitive, and the tension inherent in each rises from the opposing forces at play. Understanding and employing these opposing forces in the proper perspective is key to helping teachers grow professionally and also to helping students grow academically" (pp. 47–48). The axioms are: go slow to go fast; be tight to be loose; and, relinquish control in order to gain influence.

These axioms become interesting ways by which Senese begins to better understand his practice and ways of improving the relationship between teaching and learning. He highlights how the counter-intuitive aspect of the axioms helps him to pay attention to situations in different ways to that which he would normally automatically respond. Hence he has begun to learn through self-study how to interpret his actions and how to better shape his pedagogy to, as an English teacher, influence student learning, but more so, as an academic leader

and research initiator in his school, "to embrace the whole, and to view the horizon" (p. 54).

Fitzgerald, Farstad and Deemer (2002) learned about their teaching through the use of learning circles. Their self-study involved an investigation into their teaching in an attempt to understand their practice and to try to measure how it impacted on students' learning. Not surprisingly, they found that such an examination continually highlighted for them how such an investigation could be thwarted by the nature of course evaluations. They noted how traditional course evaluations, so often used by institutions to measure "good teaching", tended to create problems because such evaluations sought measures that tended to value telling as teaching; the antithesis of professional practice. Their use of learning circles was designed to gather data through which they could interrogate their practice and their students' learning that was not possible through the 'standard measures' of course evaluation. In so doing, they came to confront and challenge their own beliefs in ways that shaped their practice. Further to this though, they pursued their self-study with two learning objectives in mind. One was for improvements in their pedagogy of teacher education and the other was for the value of this for their students' teaching practice. Importantly, they also pursued this approach to researching their teaching in order to make public their learning, their measures and, their accountability in their roles as teachers of teachers.

Confronting Myths about Teaching

In a similar way Louie, Stackman, Drevdahl and Purdy (2002) also conducted a collaborative self-study into their teaching. They described their results by exploring myths about teaching and the university professor. Their first category of myths was based around the view that professors control all teaching and learning. The second categorization, almost a subsequence of the first, is that one can not teach well unless one is fully ready and prepared – leading to the situation whereby the professor needs to know *everything*; the infallible knower. Their third category of myths was based around the idea that excellent teaching is based on certain approaches or techniques and, that good teachers act on all student feedback. Not unlike Senese (2002), Louie *et al*'s examination of myths about teaching offered them new ways of seeing their own teaching and of how these myths actually played out in their practice.

> Our own experience illustrates that many of the attitudes and behaviors that are central to teaching in higher education are based on taken-for-granted assumptions learned from our experiences as students. Until coming together as a research team, we, like so many university professors, failed to use our skills of critical analysis for the purpose of improving teaching and learning. Only now can we acknowledge that our failure to examine our teaching beliefs has resulted in distorted assumptions about teaching. Furthermore, we can only guess at how these distorted assumptions have

possibly impeded our professional growth and ability to be effective teachers.
(Louie *et al.*, 2002, p. 205)

Finding ways to both understand and articulate knowledge of practice through self-study has been shown to take many forms. Beyond those noted above, there is the use of assertions (Loughran & Northfield, 1996), tensions (Berry, in press), thematic representations of students' critical feedback (Hoban, 1997), principles of practice (Loughran, 1997), articulating and critiquing beliefs (Chin, 1997), analogy (Clarke, 1997) and conversation (Guilfoyle, Hamilton, & Pinnegar, 1997; MacKinnon, Cummings, & Alexander, 1997) to mention but a few. However, perhaps one of the most influential approaches to articulating learning about practice is through the conceptualization developed by Korthagen (see Korthagen & Kessels, 1999; Korthagen *et al.*, 2001).

Realistic Teacher Education

Korthagen has been at the centre of what he describes as Realistic Teacher Education which developed because he felt it was important to build a coherent and meaningful way of challenging the traditional approach to teacher education whereby:

A teacher educator – an expert in a certain area – is in front of the classroom and lectures on recent theories in the field of learning psychology or general education. At best, the student teachers get some assignment to try out something in practice, but very often this practice is in time far away from the lecture (even as far as months later) or the person in charge of the supervision during teaching practice does not have the slightest idea of the assignment or the theory behind it … [inevitably then] many research studies demonstrate the failure of teacher education to fundamentally influence teachers and improve education. (Korthagen *et al.*, 2001, pp. x–xi)

Korthagen goes on to examine the relationship between theory and practice and outlines three basic assumptions that appear to underpin traditional teacher education programs. They are that: theories help teachers to perform their role; these theories are based on scientific research; and, teacher educators should make a choice concerning the theories to be included in teacher education programs. He explains how these assumptions are at the heart of the technical-rationality model and that it not only has serious flaws but that it creates and/or exacerbates the well documented theory and practice gap. His Realistic Teacher Education program then is developed by paying careful attention to the nature of theory and practice with regard to both its value and place in learning to teach and thus develops the ideas of the applicability of Theory with a big T (episteme) and theory with a small t (phronesis).

Through a conceptualization of teacher education whereby moderating the way that theory is appropriate and useable, Korthagen illustrates how the Realistic Teacher Education program helps participants (teacher educators and

student-teachers) develop their understanding of professional practice. One way in which this moderation occurs is through the ALACT model (Korthagen, 1985) and it is the underpinnings of practice such as this that lead to his call for others to similarly challenge teacher education through thoughtful and informed teaching and learning approaches. Korthagen *et al.*'s (2001) extensive description of Realistic Teacher Education, the imbedded research that shapes the approach and the importance of understanding the value and use of episteme and phronesis is an outstanding example of how teacher educators researching their own teaching about teaching might lead to a pedagogy of teacher education. Korthagen's approach is a valuable lens for examining and better understanding how episteme and phronesis can be useful tools for interpreting and directing learning through experience. An example of how learning through experience and the importance of episteme and phronesis might influence understanding of this learning is explained through the following case-study.

A Case-study of Linking Teaching, Learning and Research through Self-study

The following case-study is drawn from the year long study of Jeff Northfield's return to high school teaching documented in the book *Opening the Classroom Door: Teacher, Researcher, Learner* (Loughran & Northfield, 1996). An exploration of this work is designed to offer an extensive example of how self-study has been used as a methodology for learning from, and developing knowledge of, teaching practice.

As a well respected teacher educator, Jeff Northfield had long been advocating the need for teachers to teach in ways that explicitly addressed students' passive learning styles. As a teacher educator with a commitment to self-study, he could not help but also attempt to address this issue in his own teaching in his teacher education classes. The impetus for his desire to challenge passive student learning styles was partly derived from his long involvement in the PEEL project (Project for the Enhancement of Effective Learning, Baird & Mitchell, 1986; Baird & Northfield, 1992; Loughran, 1999, a teacher led initiative designed to develop teaching procedures that encouraged students to develop their metacognitive skills) and, partly in response to his challenging of the traditional approach to, and teaching in, pre-service teacher education programs (Gunstone, Slattery, Baird & Northfield, 1993; Gunstone & Northfield, 1992; Northfield & Gunstone, 1997).

Returning to School Teaching

Because many of the issues (above) became central to his own learning about teaching, Northfield chose to return to high school teaching for a year in an effort to better understand teaching using a PEEL approach in 'a real school setting' and to better inform his own teaching about teaching at University.

> If we [teacher educators] are concerned with educating teachers and under-
> standing teaching and learning we must have first-hand contact with schools
> and classrooms in a sustained way ... How can we be advocates of a
> profession we are not willing to work alongside? How can we expect
> education issues to be part of policy and management decisions when we
> do not understand and appreciate what happens in schools? It is comfortable
> for many responsible for education to keep the detail of schooling at a
> distance – maintaining simple stereotyped views of what happens ... The
> closer we get to what happens in school the more we get close to people
> and the more difficult and complex are the decisions that have to be made.
> (Loughran & Northfield, 1996, p. 5)

As an academic researcher, this move back to the classroom also brought with
it an opportunity to be personally embedded in a research project to document
the experience in new ways; hence his purposeful construction of a self-study.
Northfield's documentation of his self-study was based on data drawn from: a
methodical and consistent maintenance of a journal of his teaching experiences
and reflections on these events; collaboration with two colleagues (one a research
assistant who would be a classroom observer and another 'set of eyes' on
classroom practice, the other an academic colleague to question and probe the
meaning of the experiences); his students (through individual and focus group
interviews, classroom observations and documented responses of their views of
the teaching and learning processes from their perspective); and, collaboration
with his teaching colleagues to, in some ways, question and challenge his develop-
ing views of his learning through 'tests' of naturalistic generalisability (Stake &
Trumbull, 1982) over the course of the year.

Episteme and Phronesis

For Northfield, the adoption of a self-study approach was initiated in response
to the personal issues and concerns which were increasingly problematic in his
work as a teacher educator. This feature of self-study (being problematic) can
be framed in terms of Korthagen *et al.*'s (2001) articulation of episteme and
phronesis. Episteme is described as expert knowledge on the particular problem
that is connected to a scientific understanding of the problem. Episteme is
therefore propositional (consists of a set of assertions) that apply generally to
many different situations and are frequently formulated in abstract terms.
Phronesis is practical wisdom which is primarily concerned with, "... the under-
standing of specific concrete cases and complex and ambiguous situations"
(p. 24).

   This differentiation between episteme and phronesis becomes increasingly clear
in situations where problems from practical experience do not seem to be able
to be resolved through solutions available from theoretical research knowledge,
and for many teacher educators, is an ongoing feature of their teaching context
with student-teachers. For example, "It [problem] can stimulate a student to

look for instructional ideas in handbooks or even in research studies. But sometimes – more often than we wish – it does not seem to help. What seems obvious to the teacher educator is not so to the student teacher … there is an unbridgeable gap between our words and the student's experiences" (Korthagen *et al.*, 2001, p. 22).

Indeed Northfield recognized this episteme versus phronesis dilemma himself when he attempted to relate his existing research knowledge (episteme) to the practical problems he was confronted by in his daily teaching as he began to feel and see how the practical setting shaped his wisdom of practice (phronesis).

> Do those who try to influence practice (e.g., researchers, policy makers) really understand (or remember) the practice? The theories and the 'recommendations' seem to neglect the routine and contextual complexity of the classroom setting. Many of the 'theories' seem less useful from a teaching perspective. How do they apply to 7D on Monday last period? Unpredictability is a factor … The best research in the world will have little impact until the conditions of teaching allow teachers time and opportunities to consider ideas in relation to the classroom contexts they experience. (Loughran & Northfield, 1996, pp. 22–23)

In embarking on his extended self-study, Northfield's intention was to learn more about the nature of teaching and learning (using a PEEL type approach) through appropriately researching his experiences and enhancing his understanding of his particular situation. However, perhaps influenced and shaped by his extensive experience as an educational researcher, he could also see the possibilities that what he learnt through the experience might also be informative for others. Therefore, in essence, the documentation of his self-study was one way of attempting to bridge Korthagen's "unbridgeable gap" by embedding learning in experience, and attempting to share that knowledge through rich descriptions of such experiences, despite acknowledging its problematic nature.

To illustrate how (and to a lesser extent what) Northfield learnt through self-study, I draw on two of the perspectives (teacher's and learner's) that he paid careful and systematic attention to in his research. In considering these perspectives, it is important to note the central role of framing and reframing (Schön, 1983) in self-study and the need for the practitioner (in this case, Northfield) to be open-minded (Dewey, 1933) to the possibilities and new understandings that emerge through valuing alternative perspectives on the same experience.

Breaking Set

The move from university teaching to high school teaching and the desire to teach in a PEEL like manner, brought with it new demands related to pedagogical planning and reasoning as enhanced metacognition was the main focus of the teaching and learning situations. Therefore, Northfield had an explicit need to conceptualise and organise his teaching so that it consistently pushed his students to be active learners. This approach to teaching then brought with it a

need to ensure that his taken for granted assumptions of practice were continually questioned and that teaching for understanding needed to be a dominant purpose. This meant that he needed to be vigilant in avoiding routine teaching and learning tasks and procedures that allowed (or inadvertently encouraged) passive learning. Doing this carried a responsibility to think and act differently as a high school teacher, this he described as "breaking set". Breaking set then was used to,

> … describe the acceptance of the adjustments and changes he needed to make as a teacher as he learned to teach in a different context. Breaking set was part of his need to accept responsibility for what the class did and how they did it … [and his] concern was to find the right time and level of trust to introduce activities which required thinking and encouraged [students'] acceptance of responsibility for their own learning … 'breaking set' placed him in a less certain classroom environment, yet one that he was in fact seeking. (Loughran & Northfield, 1996, p. 32)

As he became more and more conscious of the demands that breaking set imposed on him as he attempted to teach in a PEEL type manner, he inadvertently overlooked the implications that breaking set concurrently had on his students. From his teacher perspective, he had become much more aware of his practice, his pedagogical reasoning and the learning that his teaching was attempting to foster. He illustrated well how the teaching procedures he used and his general attitude to teaching were in many ways contrary to the stereotypical approach of the transmission model (Barnes, 1976) so familiar to many teaching situations. Therefore, his breaking set as a challenge to 'normal teaching practice and expectations' stood out starkly for him as he struggled with the demands of constantly trying to teach for understanding rather than the simple acquisition of information.

In one documented episode, his use of the POE (Predict, Observe, Explain, see White & Gunstone, 1992 for a full explanation) teaching procedure highlighted the manner in which the POE challenges and changes the student's role in learning through a science demonstration. However, when he attempted to pick up on the episode and extend it with a further POE in the following lesson, the students' responses illustrate how, even with the best intentions, teaching procedures that are designed to encourage active learning and student responsibility for learning, can be less than successful when the underlying purpose for the use of the teaching procedure is overlooked. Hence, his concentration on the influence of breaking set caused him to see that in some circumstances, breaking set can lead students to revert to routine responses and lack of engagement. In this case, the desire to extend his students' engagement in a task and the continued use of an engaging teaching procedure (POE) over took the pedagogical reasoning that normally informed his practice and shaped his thinking about the reasons for using particular teaching procedures.

> … I can now appreciate that it takes a major focused effort for teachers to

spend time interacting about teaching-learning matters. The job and time it can take up makes it unlikely that time would be available … They [teachers] will go backwards before seeing any benefits. I greatly admire the PEEL effort. (Loughran & Northfield, 1996, p. 24)

Framing and Reframing

As Northfield was conscious of his breaking set, he was gaining new insights into practice, but it was not until he reframed the situation and considered the students' learning rather than his teaching that he recognized a hitherto unforeseen aspect of his practice. Just as he had to think carefully about breaking set; what it meant for him personally, how it influenced his practice, the value of so doing, so his students were challenged by the different learning demands resulting from this change in practice. In effect, they were also breaking set – or being expected to because of the changed nature of the expectations inherent in the teaching – but in their case it was in terms of their taken for granted expectations of school learning.

> The idea of wishing to understand does not seem to be relevant [to students]. This is not what one [students] does at school. The maths class was an example of how quickly they will complete routine activities but when asked to show evidence of understanding, they demonstrate resistance to thinking. Thinking appears to be something I [teacher] am concerned about – not part of what is and should be done at school. (Loughran & Northfield, 1996, p. 37)

In reframing the situation, taking the focus away from himself and placing it on the learners, he realized that breaking set was as equally demanding and problematic for his students as it was for him as their teacher. In fact, it could well be argued that it was even more demanding for the students for breaking set did not necessarily accord with their view of their student role. As Northfield came to see, students' views of their role as learners had been shaped by years of schooling through which their learning was largely dependent on their teachers' directions and instructions. Independent learning and thinking about thinking (i.e., metacognition, Flavell, 1976) were not generally viewed as aspects of successful school learning. Hence shifting the emphasis of learning from the teacher to the students carried another aspect of breaking set that needed to be carefully thought through and explicitly addressed.

Learning through Experience

As an academic with extensive experience of teaching, learning and teacher education this knowledge (about different perspectives and demands in breaking set) would no doubt have been more than accessible and known to him. However, such knowledge was perhaps configured 'epistemically' such that it did not necessarily inform his practice in this new context (high school). Teaching in a

PEEL type manner in teacher education may well have led to a 'phronetic' understanding but his learning as a result of the changed context was such that his practical wisdom was only substantially (re)informed through the changing demands of practice in a new and different practice setting. Therefore, Northfield's self-study illustrates one way of attempting to bridge the 'unbridge-able gap' between episteme and phronesis. Through his return to school teaching and the purposeful self-study he adopted to examine his experience, he was personally situated in the experience as a learner. He had a personal commitment and need to function in ways that could inform his practice – he was not simply adapting his practice. However, this approach to learning through self-study clearly requires a view of practice as problematic whereby framing and reframing of the teaching-learning context is crucial to enhancing understanding of both.

Because Northfield's professional learning occurred through insights into practice driven by his personal concerns/needs, it is clear that his phronesis is intertwined with his specific experiences and the personal concerns/needs elicited in those situations. Phronesis then is not only of a cognitive nature but closely connected to encounters with specific situations (and the emotions, failures, personal convictions etc. bound up with these) and this is what makes it difficult to convey to others.

At the end of his teaching year when the constancy of classroom demands had subsided and the dailiness of school was no longer an ever present aspect of work, Northfield reflected on and reviewed his experiences. In a similar manner to the framing and reframing associated with breaking set, he found that through reconsidering different perspectives on his experiences and through discussion with many and varied others, he had developed a substantial understanding of his practical wisdom that he believed informed his understanding of teaching and learning in ways that were different to that which he had previously understood.

As phronesis is more perceptual knowledge than conceptual knowledge, and as Northfield was an experienced researcher, he felt a need to both understand and communicate his learning in ways that might be accessible to others. Hence, he framed a shift in the articulation of his perceptual knowledge through conceptual knowledge (although it is not necessarily so distinct and exclusive). Therefore, in a more epistemic form, these new learnings were stated as assertions, and as such, perhaps carry less meaning for a reader than the extensive form of explication outlined above. However, as a brief insight into the manner in which the bridging of episteme and phronesis might be conceptualized through new forms of knowledge, one grouping of his "Learning from a Teaching Experience" is offered in Table 5.1 (below).

Each of these assertions carries meaning for Northfield in ways that are most likely not as apparent to a reader – especially in the absence of the rich descriptions that accompany their formation and explanation in the book. Yet through the documenting of his self-study it could well be argued that it offers an opportunity for others to begin to learn from his experience and to begin to reframe their own practice in light of the understanding that might accompany,

Table 5.1: Learning from a Teaching Experience

Nature of Learning

1 Quality learning requires learner consent.
2 Learning is done by rather than to students.
3 Student prior experiences are crucial and often do not fit the learning demands expected [when responsibility for learning is overtly being encouraged].
4 Effort and risk taking are critical for learning.
5 Understanding is rarely experienced, and not expected, by many students.

Extract from Loughran & Northfield, 1996, p. 124.

or begin to be derived from, these learnings of practice. The challenge for self-study is in many ways little different to that of other research. If the knowledge is portrayed as being solely 'epistematic' then the 'phronetical' demands that initiated the self-study may well diminish the practical value of the work. And this is an inherent difficulty when self-studies are documented and portrayed for others. Hence, conducting a self-study may well require skills and abilities that have been outlined in various ways throughout this chapter (and many others in this Handbook), but disseminating the results through meaningful portrayals and reports may call for another set of equally complex and demanding skills and abilities.

Conclusion

In reviewing the self-study literature that is at the heart of this chapter, a common theme continually emerged: *when seriously adopted, self-study of teaching and teacher education practices supports meaningful learning about practice.* More so, self-study appears to support learning in a variety of ways for all involved, not just the researcher. How this learning occurs varies with the manner in which the self-study is conducted, the participant(s) and, the context. Yet there are limitations to the possibilities for self-study and the subsequent learning due to external constraints (e.g., institutional and traditional expectations on teachers and teacher educators; structures of, and demands in, teaching and teacher education) and personal perspectives (e.g., taken-for-granted assumptions about teaching; the tacit nature of much of the knowledge of teaching) which can result in difficulties in easily defining the learning that might occur through self-study. There is also a clear purpose for pursuing self-study that is closely tied to the problematic nature of teaching and the desire by many teachers and teacher educators to work towards better aligning their practices and beliefs. Hence, examining their practice through self-study is inevitably an invitation to learning and one way of becoming better informed about teaching and learning about teaching.

This chapter then has attempted to document the learning from self-study that is readily accessible and apparent in the research literature. As has been

made clear, this learning is influenced by the nature of the self-study (who the "self" is and the purpose of the work) and the context and conditions under which the self-study is conducted. An important facet of learning through self-study is that it impacts the individual but that that impact is also regarded as a starting point for influencing practice. It is also clear that there is a need for the results of self-study to have a sphere of influence that moves beyond the individual to colleagues, institutions and the teaching and teacher education professions generally. However, for this learning to have real meaning it must carry understanding in ways that allow it to carry features/characteristics of applicability that are, in many ways, in accord with the issues pertaining to episteme and phronesis (as outlined by Korthagen *et al.*, 1999, 2001).

The case-study of Northfield was included as one way of attempting to illustrate how all of these aspects of learning through self-study might be understood through the practice and research of a practitioner involved in serious, ongoing self-study. Important to self-study is that the real learning (personal and public) needs to be articulable and accessible to others if it is to inform one's practice. Therefore, despite the different forms this knowledge might take (assertions, principles, tensions, etc.), there is a clear requirement that self-study practitioners provide and/or utilize data that is appropriate for the given situation, that offers new ways of seeing the taken-for-granted aspects of practice and, that helps to offer genuine opportunities for framing and reframing so that data (and subsequent analysis) can (and will) be acted upon. In so doing, responses to Korthagen's (2001) demand that a pedagogy of teacher education be pursued is finding currency in the work of many involved in the self-study of teaching and teacher education.

This chapter, I trust, illustrates the importance of the challenge that teacher educators face in attempting to look into their own practice with 'new eyes' in order to find ways of creating learning about teaching opportunities for student-teachers that will be meaningful for them in their own professional development and growth. Clearly, this is not a simple task, but such work is crucial to an articulation that might be valuable for the education community to learn from and build upon.

Notes

1. Case: as in the form of exploration of pedagogical situations described by Shulman (1992). Mitchell also edited a book of Cases written by PEEL teachers (see Mitchell & Mitchell, 1997).

FUNDAMENTAL FEATURES AND APPROACHES OF THE s-step ENTERPRISE*

Frederick F. Lighthall
University of Chicago

Abstract

The story here is in three parts. Part 1 discusses what is gained from a systematic analysis of the s-step enterprise's basic features or "commonplaces." In the present case, it provides readers not only with an organized view of the forest, but also a view of exemplars of each species of tree. Part 2 presents what Part 1 promises. After presenting criteria for selecting representative studies, it describes fourteen basic features of the field extracted from analysis of 125 representative studies. After examining in detail the six most prominent features, Part 2 proceeds to detail various approaches within each feature. Part 3 offers reflections on how the field might be enriched and advanced, and positions the s-step enterprise within the academy.

In this chapter I take a number of steps toward understanding and assessing the underlying structure of the s-step enterprise[1] as a whole, the field's fundamental conceptual-practical features or "commonplaces" (Schwab, 1978). Part 1 considers the intellectual and practical gains provided by an account of a field's basic features. Part 2, the centerpiece of the chapter, begins by considering criteria for including s-step studies as *representative*. I settle on criteria based on the activities of scholars who have been most active in producing and communicating studies with each other at the site where that activity is most extensive and intense, the S-STEP-sponsored international conferences at Herstmonceux Castle. By these criteria I consider 125 writings of the most active participants as the representative corpus of work to be analyzed for the s-step enterprise's basic features.

Following an explicit definition of "feature," I examine the benefits of discovering the basic features of the s-step field. I then describe and illustrate my procedures of identifying features and finding patterns within treatments of features so that readers have as clear a sense as possible of how I arrived at these judgments. I find 14 features treated in the whole corpus, noting that the 14 account for the basic features of all 125 of the studies in the corpus, and that the most prominent six of the features account for 75% of the studies (see Table 6.1).

After interpreting the composition and relative degrees of prominence of the most prominent features, my next step is to examine the different patterns in the ways s-step scholars treated each of the prominent features, providing brief descriptions of studies exemplifying each pattern. S-step scholars have treated each feature in at least three different ways, which I summarize for each feature. I then examine three of the most integrative studies in the corpus, to illustrate both what an integrative study looks like and the benefits to be derived from integrating the field's features into one's study. I show that of the 28 possible combinations of any two features among eight of the most prominent features, only one combination, Values and Collaboration, failed to be addressed together in any of the 125 studies, a fact on which I comment.

Having examined some basic dimensions of the s-step field in Part 2, Part 3 begins by positioning the s-step enterprise with respect to the norms, methods, and goals of academic research and writing. I argue that while the s-step enterprise is in important respects in conflict with the academic culture (as represented in the established academic disciplines) and, as such, is a reformist movement within academia, s-step and the traditional disciplines can find common ground in the transcendent norms, values, procedures, and habits of mind that are the mark of scholarship. I then comment on a number of possibilities for enriching the enterprise. I conclude the chapter by characterizing the enterprise in more general terms.

Part 1: Why Explore s-step's Basic Features?

Why study or read about fundamental features of a field of scholarship? While the gains for theory and for scholarly understanding are fairly obvious, the practical uses of such a study may need more explanation. Consider two readers. The first knows little or nothing about what the s-step enterprise is all about, and is curious to know something about its basic concerns and what it most regularly attends to, thinks, and writes about. The second reader is involved in the s-step enterprise, having carried out and presented one or more self-studies. This second reader implicitly believes he or she knows what s-step is all about, or surely, what it ought to be about.

The trouble with the view of the s-step enterprise held by those already involved, and I consider myself one, is that each of us sees the enterprise pretty much from our own position – from our own conceptions, methods of study, our own practices. Yes, we have read and heard presentations of our colleagues'

studies, but we generally see their studies in comparison with our own, which we know in detail. So each of us thinks we know the "field," but that does not mean that we have sat down and defined what we mean by "the field," much less studied it systematically. That is what I have tried to do, and this chapter presents my results. To mitigate my own biases, I have been as explicit and transparent as possible in my method of approach, which I spell out below.

So, why might either of these two readers want to read this chapter's analysis of the s-step field as a whole? If the person new to the s-step enterprise wanted a framework with which to read any article purporting to be a "self study" she or he would find one here, a framework that would stand up as useful across the wide variety of studies he or she would encounter. It would enable this person to "see" in what particular ways – ways defined by study of the field itself – that any two studies were similar and were different, and yet keep both studies in mind as part of the same intellectual-practical enterprise.

The reader already immersed in the s-step enterprise could compare his or her own framework of thinking about the field (we all have one) with the explicit and grounded framework provided here. My own original frame as an active participant has changed dramatically as a result of the far more systematic reading of the field I have done for this project. But my benefits as one involved in s-step go way beyond simply having that more systematic, more generic frame. The frame becomes a set of binoculars, the better to see the whole landscape, but also up close.

Contributing Knowledge to the s-step Field

Part of scholarly evaluation of any piece of scholarship is whether it makes a new contribution, or whether it merely goes over old ground. One purpose of this chapter's analysis of features, providing intellectual and practical themes already established in the s-step literature, is to provide a basis for assessing the ways in which one might make a contribution that was new and relevant to the field's fundamental features.

In this field of study and practice, however, judging whether a self-study of one's practices makes a new contribution is complicated by two factors. First, the s-step's ethos, as developed so far at Castle Conferences and for this Handbook, is for referees who evaluate self-studies of practices to comment in a way designed to improve the scholarly writing in question but not to judge whether it should be accepted or rejected.

This accepting stance is due in large measure, I think, to a second factor. Each self-study of practices that intends to contribute to the s-step enterprise as a whole, through publication in some form, has in mind two fundamental audiences or users. The primary users of a self-study are its authors. Self-studies of practices have as their prime purpose the improvement of the professional practices of those who plan and carry out the study. As a consequence, a study that might conceivably repeat most aspects of a self-study already conducted and reported, and hence contribute not much that is new to the field at large, could still convey

knowledge for the author that provided a strikingly surprising discovery about that person's practice.

Such a "repeating" or "replicating" study could also be an important contribution to the s-step enterprise as a whole as showing that a given set of methods and analyses can lead to similar discoveries by different professionals in different settings is indeed valuable.

But while the s-step community at large is an important yet secondary audience, potential readers or participants at conferences who are confronted with the choice of reading a given self-study report, or attending a discussion of it, will indeed judge its usefulness. One of the grounds for such judgment will be the promise of learning something new and useful by reading or hearing about that other person's study. Whether a study will be new and useful to more than a few in this field will be reflected, I would argue, in the degree to which it incorporates new combinations of the already established features of the kind I describe in this chapter.

For example, a study that combined *topic-focused autobiography* – like a narrative of the author's experiences, with a given subject matter (e.g., Muchmore, 2000; Pereira, 2000) – together with study of one or more *pedagogical practices* of the author (e.g., Tidwell, 1998; Trumbull & Cobb, 2000; Watson, 1998; Wilcox, 1998) would integrate in a single study basic features not combined before, would provide rich insights for the author and, would be of interest to two fairly large groups of s-step scholars.

Planning Studies Consciously:

Strategic Choices of Features and Approaches

As I contemplate conducting a study of my own practices, having in mind s-step's intellectual and practical commonplaces, I can be more deliberate in taking into account and addressing this field's basic features and approaches. Whereas before I constructed studies of my own practices from merely my own experience and perspective, I can now choose consciously among, and play with combinations of basic features of self-study inquiry, features that reflect the cumulative intellectual structure of the whole enterprise – the "whole" enterprise, at least, as I have been able to examine it. Playfully considering alternative combinations of the field's features and of different patterned ways of treating those features, I can contribute a self-study more likely to speak to the field as a whole and to be relevant to the work of more of its members.

For example, suppose a reader of this chapter decides to use, as orienting ideas about how "self studies" are carried out, the three approaches to self study presented below. As the reader starts to read a new study purporting to be a "self study," the reader will be on the look-out for one or a combination of those three approaches: (1) the author of the study examines his or her own teaching practices; (2) the author examines the author's teaching effects on his or her students; and, (3) the author examines processes or outcomes of his or her program or organization. With these three approaches in mind, the reader can

more actively and clearly interrogate a new study as to whether the study takes one or some combination of these three approaches to "self study."

If the new study does not feature any of these three patterns, does it incorporate other features basic to s-step – autobiography, for example? And if it is autobiographical, are the life experiences that are narrated those reflecting the author's life and struggles as teacher educator, or are they topic-focused, conveying experiences in learning mathematics, for example, or do they take some new autobiographical approach?

In general, knowledge of commonplaces and of treatment of commonplaces of the s-step field, that is, knowledge of the kind I have tried to develop in this chapter, should allow its possessor to place any study that seems or purports to be a "self study" in one of two informative intellectual landscapes. Any s-step study will be locatable either on the map drawn by these commonplaces and approaches, or outside this map. If on the map, then it addresses some basic feature of the field already established by s-step scholarship to date. If off the map, then it addresses some new feature or takes some new approach to an established feature. In either case, the mapping is informative.

Further, for those interested in carrying out a "self study," a reading of this chapter will allow them to be more explicit in discerning and articulating to themselves their own particular interests, in relation to the patterns of exploration revealed in this chapter. Since this review of s-step's features examines representative studies, it allows readers to pursue those particular studies that represent the features, and those particular treatments of features, that they find of particular interest. Therefore, having a grasp of how one systematic examination of the field's representative studies parses the field into its basic elements, illustrating the parsing with particular studies, presents not only a view of the forest but also close-up views of its various species of tree.

Readers who decided to use the features and approaches I describe below could also become what we might call *strategic contrarians*. They could now be more conscious about studies that would be really different, studies that attempted to add entirely new features, or that emphasized features only weakly addressed by the enterprise so far, or included combinations of features not yet included in a study.

In short, readers either familiar or unfamiliar with the s-step field who read this chapter can see a view based on systematic sampling of studies and systematic reading of them, of the basic conceptual structure of the field, the field's primary foci of attention and how it has addressed those foci.

A Scholarly Purpose

I must also add a word about why an active participant in the s-step enterprise, as I have been, might try to discover in some systematic way what this whole enterprise is about as a scholarly and practical enterprise. As I will argue below, the s-step enterprise is in some important regards a movement within academia to expand and change some important norms and conceptions, especially some

norms and conceptions that characterize the established disciplines in the social sciences. But as I shall also argue, this enterprise shares with all scholars of all disciplines the norms and values of scholarship. In the end, the s-step venture will endure or fail as it meets, or fails to meet, the dual demands of scholarship and practicality.

My own commitment to pursue this study came as a response to the scholarly challenge of contributing to this field as a whole by studying systematically its underlying intellectual structure, its guiding conceptions – or as the philosopher of education, J. J. Schwab (Schwab, 1978) would say, its "commonplaces."

> … commonplaces represent, in effect, the whole subject matter of the whole plurality of enquiries of which each member-theory [or member-study] reveals only one façade at best, and usually only one façade seen in one aspect. An adequate set of commonplaces, then, provides a map on which each member of a plurality can be located relative to its fellow members. (Schwab, 1978, p. 339)

This study of s-step's basic features was my attempt to extend Schwab's idea and method into this very practical field of teacher education. Knitter, Pereira, Roby and I made a first attempt to look at the whole field a few years back (Lighthall *et al.*, 1999), and this chapter takes that effort one step further.

As this present study of the field at large will attest, the study of a *field* is atypical among this field's studies, and certainly does not appear as a fundamental feature of this field or, I dare say, any field outside of philosophy. I hope I have made clear, nonetheless, that such a study has both practical and scholarly value.

Part 2: Basic Features, and Approaches within Features

Criteria for Determining a Representative Corpus of s-step Writings

How does one find out the underlying dimensions of an intellectual enterprise like a field of research? Before we can look at a field, however, a prior question is, how do we determine what is *in* the field, that is, how does one define the landscape's boundaries that circumscribe the field's *representative* intellectual-practical work? Let me address that question first, then move to the question of how to find the field's underlying dimensions.

In the present case, this field of endeavor not only has a widely accepted title, Self-Study of Teacher Education Practices, but also it is rooted in an organization with an active membership, the Special Interest Group of the American Educational Research Association (AERA) – see chapter one for historical roots of the S-STEP SIG. The SIG's name is the name of the field of scholarship in question. So I presume that some of the field's basic dimensions are pre-figured in its title. I was therefore on the lookout for "self" or "self-study", "teacher," "education," and "practices" to appear as fundamental dimensions. Some did, some did not, but I did have those clues to begin with.

I began also by assuming that somehow this field would be defined by its most active sites, by whatever was happening (and available to scholarly view) at the most prominent locations where those who participated regularly gathered under official sponsorship of the S-STEP group. One immediate candidate was the annual meeting of the parent group, the AERA. Another candidate was the S-STEP-sponsored biennial conferences at Herstmonceux Castle in East Sussex, England (the "Castle Conferences"), of which at the time of writing there have been four.

I selected the activities at the Castle Conferences over AERA annual meetings. I have attended all, and presented and participated at many, AERA conferences since the founding of the S-STEP group and have presented and participated at all four Castle Conferences. Hence my comparisons are grounded in direct participant-observer experience. Between these two, I judged the Castle Conferences richer in content for this project than the AERA presentations.[2]

One disadvantage of the papers published in the Proceedings of the Castle Conference, as compared to papers written for presentation at AERA meetings (in those cases where AERA papers actually are written), is the word limit on the Proceedings papers, a limit reflecting the fact that these papers constitute a special genre. The Proceedings papers are designed as the first part of a two-part communication, the second part of which is the 50-minute presentation each presenting author makes at the Castle Conference itself. The Proceedings papers provide space enough for authors to describe the major facets of their studies, but not for really detailed descriptions of more than one or two facets. However, the Proceedings papers offer both drawbacks and benefits. While detail is in some cases sacrificed, authors provide more than enough to judge the features prominent in their work, making the project of reading many authors' work much more manageable. Yet readers interested in pursuing many details of method or theory or procedure, etc., must either attend the author's 50-minute presentation at Herstmonceux Castle or communicate with the author him- or herself. The Proceedings papers ordinarily provide sufficient detail, however, to convey a sense of what the author(s) did, why and how they did it, and the effects on themselves and/or their students – often enough detail for me, at least, to feel that I, too, could use their methods.

With the Castle Conference Proceedings as the focus, would a reading of all the papers presented there be the way to find the field's fundamental features? Seeking greater saturation and durability of authors' involvement in the s-step enterprise, I eliminated as representing fundamental features of the field the writings of any author who presented only once at the four Castle Conferences. Included in my purview, then, were the s-step writings published anywhere I could find them that were authored by anyone who had published a study in two or more Proceedings of the four Castle Conferences. (All four conferences have published Proceedings that included all presentations made at the conference.) Those authors were the most active participants at the richest venue representing and discussing the intellectual-practical work identified with the enterprise publicly labeled "s-step."

Using this criterion, I have found 125 articles, chapters, or books written by these authors in which they represent their study as a "self-study." What this group means by "self -study" (or by virtually any other repeated set of terms) varies, variations I will address later.

Method of Identifying a "Feature"

My project for this chapter is not to summarize the "findings" of the 125 studies most representative of the field, but rather to identify the most prominent, recurrent, and therefore basic features of s-step studies – commonly addressed topics that Schwab (1978) would call the field's "commonplaces." How did I go about finding the most prominent feature of a piece of writing? First, I followed this definition of "feature":

*Any aspect of a study that is very prominent in the frequency or intensity or importance of its mention in the study, as prominent as, or more prominent than, any other aspect of the study, is an aspect which that study **features**.*

To find an article's most prominent feature, or features, I looked for some obvious cues – terms featured in the article's title or repeated in the article itself. For example, in D'Arcy's paper, "Tracking the ups and downs in my educative relationship with Jack Whitehead," (D'Arcy, 1998) I note: 1) educative relationship; 2) ups and downs; 3) between a student who is a teacher, teacher educator, and administrator (D'Arcy) and her doctoral studies mentor – Whitehead; 4) tracking – a study of the relationship over time; and, 5) a study carried out by the student member.

Next, I asked myself my recurrent question: "What is this writing most clearly, focally, and substantively *about?* D'Arcy makes recurrent reference to a conflict between what Whitehead seems to want more of in D'Arcy's writing, and what D'Arcy is trying to communicate about what her writing already contains, what it already has encompassed. It is a quality of interaction that D'Arcy sums up as an "educative relationship." The most generic of the two terms, educative and relationship, seems to me to be relationship, since D'Arcy is clearly questioning whether her interaction with Whitehead has been completely, or at least satisfactorily, "educative."

While D'Arcy speaks of her collaboration with Whitehead, it is the collaborative relationship that she focuses on most prominently. Clearly, most prominent, encompassing, and generic as a recurrent concern in the paper is "relationship." Relationship, then, becomes one of the field's intellectual dimensions. D'Arcy's study may turn out, eventually, to be the only study featuring relationship, but since she is one of the repeating authors, that feature gets listed.

Once I found the single most prominent feature of a study, I tested whether another feature was integrally central to the article's focus. Almost hidden from view and given no explicit attention by D'Arcy herself, is the fact that this article presents a *study.* The relationship was "tracked" over time, by review of e-mail exchanges between the two parties. Data were assembled, analyzed in an undefined way, and reflected upon. So some *method*, however loose, was entailed.

However, since neither study nor method was featured for focal attention, argument, or comment, I held off raising them to the level of fundamental dimensions. Because all 125 articles in the corpus constituted a "study," that term differentiated no aspect of the field. "Method," however, did come in for focal attention in other studies, appearing in several variations, so it turns up as a fundamental dimension of this field.

Once I had examined an article for its most salient features (the modal number of features per article was three, ranging from one to six), I moved to the next article. I remind the reader that I was collecting features of the field, not findings or particular methods of individual studies. Only later, once I had identified a set of features that could encompass virtually 100% of the 125 studies would I look for patterns among these features, combinations that recurred.

The Field's Elemental Conceptual Structure: Its Features

A search for the writings of all authors (or co-authors) who had presented more than once at the four Castle Conferences identified 125 writings. While I am sure other writings of these repeating presenters can be found, I took these 125 texts as representing the enterprise, representing in the sense that they would include all major features of "self-study of teacher education practices," whatever that phrase turned out to encompass in those studies.

Searching that corpus of 125 studies for features, I followed three steps: reading each text first for its features, writing brief summaries of each study's distinct characteristics and, searching these for patterns of approaches within features (adding, subtracting, and clarifying coding during this process). I eventually identified the 14 features in Table 6.1. These 14 features account for the major thrusts of work of all 125 texts. While the brief definitions of each feature in Table 6.1 are only the bare bones of the inquiry, they do tell their own small stories.

First, the s-step enterprise has some coherence, as indicated by the fact that 6 of the 14 features account for the major dimensions of 118 of the 125 texts and, 247 of the 329 codings, or three fourths of all codings. Second, collaboration matches the self-study of practices in prominence as a defining characteristic of the field. Third, methods of studying one's own practices and pedagogical methods of intervening with students come in for prominent attention. Fourth, the lives and lived experiences of s-step authors often appear prominently in their studies, in contrast to the prevailing research literature which, except for ethnography, tends to exclude such experiences. Fifth, important in defining this field is a concern for reform – the improvement and transformation of educational practice, or theory, or method of study, or of institutional norms and structures, or of all of these. Finally, the sixth major feature of the field's writings, conceptual-theoretical treatment of its subject matter, informs us that while the field is heavily engaged in, and saturated by teacher education *practices*, it also gives priority to perspectival thought about its relationships, content of study, processes of action, and methods of study and of communicating its discoveries.

Table 6.1:   Basic Dimensions or *Features** of the Intellectual-Practical Enterprise, s-step

6 Most Frequent Features (247 coded features = 75%)

1. *Collaboration* – Features collaboration between author(s) or author and others, collaboration in the study, in some professional practice, or both. ($62 - 62/125 = 50\%$ of the 125 studies; $62/329 = 19\%$ of coded features.)

2. *Self-Study of Practices* – Features the author(s) study of his/her/their own specific practices, or their students' reflections on *their* teaching, or of programmatic or institutional practices. ($59 - 59/125 = 47\%$ of the studies; $59/329 = 18\%$ of all features coded)

3. *Method* – Features some definite, explicit method of carrying out or improving s-step studies, or of improving professional practices. (41 studies = 33%)

4. *Autobiography* – Features references to or narrative of author's own life experiences. (35 studies = 28%)

5. *Reform of program, profession, or institution* – Features an explicit reform purpose and motivation – e.g., reform of teacher education, of education, or of teaching. (29 studies = 23%)

6. *Theory/Conceptualization* – Features explicit evidence of conceptualization, theory about, or framing of some aspect of its chosen subject matter (21 studies = 7%)

8 Less Frequent Features (82 coded features = 25%)

Contribution from Other Disciplines – Features a point of view or discipline established outside of the s-step field (e.g., semiotics, psychology, anthropology) in which the intent is to convey its important substantive or methodological contribution to s-step studies. (17 studies = 14%)

Values – Features some explicit, focal advocacy for some value or set of values. (16 studies = 13%)

Teacher Education Curriculum – Features specific curricular materials or content used, or proposed to be used, in a teacher education program. (14 studies = 11%)

Students' Self Study – Features a focus on how the author (s) supported self-reflection or self-study by their students or clients, with or without studying their own practice(s). (12 studies)

Relationship – Features a focus on some interpersonal relationship, relationship of person to group, or type of relationship. (12 studies)

Performing Art(s) – Features one or more performing arts as a communicative mode. (6 studies)

Other features: Biography and Outside Audience – Features study of life experiences of persons other than author(s), or an argument directed to scholars in other disciplines. (6 studies).

*"*Feature*" – Any aspect of a study that is very prominent in the frequency or intensity or importance of its mention in the study, as prominent as, or more prominent than, any other aspect of the study, is an aspect which that study *features*.

The eight less prominent features also tell several stories about concern for bringing to the enterprise the distinctions, outlooks, and theory from other disciplines; about the practical matter of effective curriculum for promoting reflection in students; about concern for values and for relationships; and even use of the performing arts as vehicles for conveying insights about one's teaching and reflective practice.

Different Patterns of Addressing Each Basic Feature

These individual features, described in this rather static way in a list, do not convey the more interesting ways or patterns in which scholars have treated the features. One can study one's own teaching practices (a single feature) in a number of ways. And as I will suggest further on, one can combine different features and different modes of treating features in very interesting and productive ways. Let me start by describing some patterns for each of the six most prominent features, citing specific studies. I introduce the patterns with a comment on my method.

Method of Finding Patterns

To be able to notice similarities and differences among the studies featuring a given dimension, I found it useful to move from the full texts of the studies themselves to my own summaries that focused on how the study treated the dimension in question.

Preparing each summary required a more detailed re-reading of each article, looking for particular ways of addressing the feature then in focus. I was now reading, not for features to code, but for ways authors treated a feature, for patterns in which they might employ methods or treat autobiography or approach self-study.[3] With summaries for a given dimension (collaboration, self study of practices, autobiography, etc.) I now could look for similarities in the studies emphasizing that feature. My method was to re-read a summary of a study within a given feature – a tentative exemplar study for matching with other studies – and then, with this exemplar study's modes of addressing that feature in mind, read each study summary for that same basic feature, looking for modes of addressing that feature that were similar in other studies. Similarity between an exemplar and other studies might be on the basis of other features shared with the exemplar study or on the basis of similar major intent, focus, or method. Using this method of discovering patterns within features, what did I find? With respect to collaboration, I could distinguish four patterns.

1. Collaboration

Pattern 1: Colleagues, face-to-face

Here are four examples from 29 studies showing this pattern, collaborations among colleagues within teacher education, working together on some project – conceptual, curricular, pedagogical, studying their respective teaching practices

or experiences, and the like. Fitzgerald and colleagues (Fitzgerald *et al.*, 2002; Fitzgerald *et al.*, 2000; Heston *et al.*, 1998) collaborated not only to study their own respective teaching, but also to bring about and to clarify conceptually a particular kind of "conversation community" within their own institution, one in which supportive listening would be promoted.

Lomax, Evans, and Parker (1998) narrated their interactions and experiences "exploring the meaning of their support for a group of special needs teachers," in which the theme became "liberation not just love." Through intense use of stories, "memory work" by the teachers in narrating and deconstructing "specific events" experienced, and the authors' own autobiographical narratives, they bring into the classroom direct experience of handicaps and prejudices against the disabled. Transcripts of their own discussions reveal the authors' quandaries and reflections.

Cole and McIntyre (Cole & McIntyre, 1998; McIntyre, 1998) collaborated as teacher educator (Cole) and therapeutically trained assistant (McIntyre) to draw out Cole's autobiography of learning and to transform it into a dance performance. McIntyre (1998) then commented on her experience and conceptualization as assistant, throwing light on one particularly effective form of collaboration.

A final example highlights different roles in collaboration. Loughran and Northfield's (1996) book, *Opening the classroom door*, portrays Northfield, a teacher educator returning to teach science and mathematics in a secondary school in order to better inform his teacher education practice. Collaborating with Jones (an experienced teacher) who interviews Northfield's students about their experiences of his teaching and, with Loughran (as teacher educator) who takes the lead in writing, together they draw on Northfield's journals and Jones' interviews and discussions among the three collaborators to construct an account of the self-study.

In this pattern, then, colleagues collaborate with each other in their practices, often commenting on the process, difficulties, and benefits of the collegial interaction they describe.

Pattern 2: Collaborating with one's students

A second mode of collaboration is between one or more teacher educators and their students, where students provide commentary on the teacher educator's teaching practices. This pattern of collaboration with students moves collaboration closer to those directly affected by teaching.

Tidwell (2002) had her students each week write curricular focused comments about what made sense to them and their confusions, and discussed these with a graduate student. Lighthall (2000, 2002) reported on his daily post-class reviews with his students about their responses to the discussion class just taught where they discussed (and he recorded and then analyzed) their responses to stems like, "I wish we had more (less) of …," "I liked it when …," and, "I was uneasy when. …" Hutchinson (1998) created a student advisory committee to provide occasional commentary from her students about her teaching. Johnston and

colleagues (Johnston, 2000; Johnston *et al.*, 2002) described an unusual collaboration with students of color in which they accept her invitation to become "cultural consultants," commenting on how they experienced her and her colleagues' teaching and program.

A novel form of collaboration with students is Allender's (2001) study in which both he and his students write their own "stories" about their experiences in particular teaching episodes, providing the reader with Roshomon-like stories[4] of the "same" classroom episodes or assignments. In this pattern of collaboration, students become collaborators with their educators, providing some form of commentary on the educator's teaching or on their experience of learning or being taught.

Pattern 3: Collaboration across disciplines

A third mode of collaboration brings together colleagues from distinctly different disciplines to create a project that draws on all the disciplines. Samaras and Reed (2000) and Cockrell *et al.* (2002), integrating Theater and Drama with teacher education, report how they involved their students (and themselves) in different forms of participative drama.

Harris and Pinnegar (2000) brought a teacher educator and a video-ethnographer together to produce a CD-ROM that captured teaching methods of the teacher, video graphic method of the videographer, and pedagogical methods of the CD-ROM designer. Cross-discipline collaborations like these (and like the Cole–McIntyre project above) provide perspectives and methods familiar, even tried and true in their own domains, but starkly new for these teacher educators.

Pattern 4: Overcoming geographical distance

A fourth mode of collaboration transcends geographical distance, joining colleagues at separate and distant institutions – the e-mail and internet collaboration. Guilfoyle, Hamilton, Pinnegar, and Placier (1996, 2000, 2002) have continued to interact from their respective institutions, writing as "the Arizona Group" (their alma mater) about their respective individual but related autobiographies of their pre- and post-tenure years in four academic institutions – years of struggling with sexism and other conservative forces. Kosnik and Freese and colleagues (Freese *et al.*, 2000; Kosnik *et al.*, 2002) were able to share both moral and technical support via e-mail conversations regarding their respective action research projects.

That these widely separated scholars could collaborate well and durably across distance and time is due in important measure to two crucial communicative mechanisms, e-mail, and face-to-face meetings at two venues, the annual meetings of AERA, and the biennial Castle Conferences. E-mail also enabled Dalmau and Gudjonsdottir (2000), collaborating initially at the University of Oregon, to continue to develop their Professional Working Theory when Gudjonsdottir returned to The Iceland University of Education.

LaBoskey, Davies-Samway and Garcia (1998) organized their own collegial

group of eight teacher educators from six institutions in the Bay Area of San Francisco, meeting bi-monthly. Within the collegiality of this group, LaBoskey and her two colleagues collaborated in a "cross-institutional action research project," reporting three separate studies by these authors in their own settings, but combined in a cross-case analysis drawing implications for collaboration in professional development.

DeMeulle, Anderson and Johnston (1996) and Johnston, Anderson, and DeMeulle (1998) reported studies of colleagues exchanging face-to-face but also exchanging e-mails on their teaching and then, with a third colleague who had received all copies of those e-mails, conversing through an on-line method about their reflections on the week's teaching and exchanges. Part of their method was the addition of the on-line "friendly prober" (my term not theirs) who read and commented/questioned on-line about her colleagues' e-mail exchanges. While these three collaborators were on the same faculty, their method of exchange, and of data gathering, was primarily via the internet, thus directly applicable to distant collaboration.

Griffiths' work on collaboration, fitting none of these patterns, treats collaboration conceptually and morally as a complex phenomenon (Griffiths, 1998), and then autobiographically, as she tries to revivify a disbanded collaboration on social justice (Griffiths, 2000).

A Related Feature: Relationship

Although explicit focus on relationships is relatively infrequent, it relates closely to collaboration, and collaborators have occasionally probed their own relationships. Manke (2000) explored her own power relationships, and Manke and Allender (1998) collaborated in examining four different kinds of relationship, using Allender's autobiographical or "archeological" notes and a poem by Manke as texts to interpret. D'Arcy's exploration (1998) of her relationship as student with her professor, Whitehead, already commented on above, focuses on particular aspects of the course of one relationship, as does the collaborative autobiographical study of husband and wife, Muchmore and Sayre (2002). An extended and collaborative study of the relationship between an "initially skeptical" faculty member and his new dean of faculty, drawing on face-to-face meetings and an extended e-mail record, is reported by Upitis and Russell (1998), in which the growing trust and authenticity of the collaborative relationship is apparent. Finally, as I show in the section on theory below, a number of studies featured theoretical-conceptual treatments of the nature of relationships.

Summary: Modes of Collaborating, and Relationships

Scholars engaged in this field collaborate often not only in their research and writing, but also in creating collegial niches for themselves and in the practical work of educating teachers together. Some take the next step, reaching beyond colleagues to engage students in the educator's own learning through a variety of mechanisms. Others extend themselves beyond their own circle of colleagues

to work with colleagues in other disciplines. Collaboration extends across space as well, sometimes vast expanses of space, with regular use of e-mail for on-going mutual consultation and occasional use of internet forums.

What would studies of teacher education practices look like that combined collaboration with one's "own" colleagues, collaboration with colleagues from different disciplines, use of the space-shrinking media of e-mail and internet forums, and collaboration with students, where one focus became a study of collaborative relationships? What gains in insights and effective practices might result if, in planning our studies, we consciously played with combinatorial possibilities among the ways of collaborating that we collectively have developed?

2. Self-Study: Professional Practices, Effects, Programs

Three patterns of self study emerged. The most prominent pattern was the study of one's own teaching practice, in general, or of one's specific teaching practices. The second type of self-study, about a fifth as frequent as the first, were studies in which teacher educators studied how they promoted skills or habits of reflection about teaching *on the part of their students*. The third pattern, about half as frequent at the second, was the study of the effects of one's program, organization, profession, or institution on reflective practice. Some examples of each follow.

Pattern 1: Studying one's own teaching practices

Gipe (1998) developed her own portfolio of teaching a course that included six types of documentation (e.g., copies of key assignments and learning activities, summaries of students' performances on assignments, self-assessment of the extent to which students gained course objectives). She learned that developing her portfolio was itself a self-study of her practices, that the portfolio captured her actual educational theory, and that it provided a basis for a more authentic evaluation of her teaching practices. Tidwell (1998) gathered data about three aspects of distance-closeness in her relationship with students: personal knowledge of her students; personal contacts with her students; and, student-centered instruction. Discovery of mismatches between her values and her relationships led her to confront questions about professional closeness and disclosure, which she distinguished from personal closeness and disclosure.

Russell (2000) gathered mid- and end-of-course free comments from 13 teaching candidates, discovering that what they thought they needed and wanted was at odds with his value commitments to action research, commitments emphasizing students' own discoveries from their teaching experiences. His research and experience left him in doubt about when and under what conditions teacher candidates can become ready to learn from examining their own experience rather than relying on expert telling and guiding.

Trumbull and Cobb (2000) examined the kinds of comments Trumbull made in returning students' written work and, with Cobb as critical friend, discovered aspects of this practice that had escaped her notice, leading to specific plans for

change. Holt-Reynolds and Johnson (2002) studied important assignments they regularly set in their respective teacher education courses, along with students' approaches to those assignments. Each discovered unnoticed weaknesses or flaws in those assignments, in assumptions about student skills or outlooks, or in students' preparation for the assignments. Each was left searching for ways to modify their assignments or preparatory instruction, or both.

Finally, Lighthall (2002) reported studying his attempts to implement changes in his teaching, as a result of students' comments and suggestions about his daily teaching, believing that the implementation phase of self-study was both under-studied and crucial to the success of any self study. He discovered that implementing his planned changes turned out to be anything but straightforward – hampered most not by a weakness in his researcher self but by an underdeveloped sense of being a disciplined agent of self-change.

Pattern 2: Studying responses of one's students/clients

One way to examine one's own teaching is to study students' responses to one's efforts. Anderson-Patton and Bass (2000) write separate accounts of their experience and process of, and their reflections about, "imposing self-studies" on their student teachers, by requiring them to construct portfolios of their own teaching. LaBoskey and Henderson (2000), at different institutions, studied the effects of assigning their student teachers to study how they, and experienced teachers, "set the tone" of their class. The authors followed the study into their students' first year of teaching. Both quantitative and qualitative analyses of students' responses to questions about the students' experiences in writing their stories about their "setting the tone" showed differences in students' reflective skills and attitudes between the authors' two programs. They also reflect on the effects on themselves of their collaborative teaching assignment.

Schuck, Brown and Schiller (2002), specialists in information and communication technologies (ICT) at widely separated universities, studied their collaborative attempt to assist teacher educators and other professionals responsible for promoting ICT literacy, who were also at different institutions, to help each other solve problems of extending ICT literacy by creating an on-line forum for discussing problems and possible solutions. While a number of professional development people "signed up," few could find the time to participate. The authors reflect on their collaborative experience.

Finally, Richert (1992) examined experimentally how the presence/absence of a reflective partner and the use/absence of a portfolio affected student teachers' reflections on their teaching, finding that portfolios focused reflection on content-specific and general pedagogy, that the absence of both portfolio and partner led to much higher reflection on personal emotions, and that both a partner and portfolio led to the most concentrated focus on content-specific pedagogy.

Pattern 3: Studying one's program's practices/policies

Freidus (2002) studied the Bank Street College Reading/Literacy Program in which intensive supervisory contact with student teachers by advisors is important. With data from questionnaires to alumni, four years of student feed-back

forms, field notes from monthly student-advisor conferences, alumni field notes and videotapes of their classroom work, Freidus identified the program's strengths and specific weaknesses. Important were two qualities of teaching, systematic (in planning, content knowledge, and curricular materials) and learner-centered, and that while effective teaching required a balance of these two qualities, concentrated development of a teacher's systematic qualities can undermine those reflective attitudes and habits necessary to being learner-centered.

Ross and Upitis (1998), the latter dean of faculty and the former the first incumbent in a new position combining university communications and development, collaborated in the development of Ross' new role, specifying criteria for "successes" and "false starts," and tracing the collaboration by examining e-mail exchanges. They reflected on the difficulties of evaluating performance in a new role, and on what each had learned in the first two years.

Summary: Patterns in "Self-Study"

"Self-Study of Teacher Education Practices" means at least three different things in these writings. While its chief "meaning" in this s-step enterprise is one's own study, with or without collaborators, of one's own teacher education practices, it can also mean study not of specific practices but rather of extended data about students' responses to one or many practices. And sometimes it means study of the process or outcomes of some aspect of one's program or organization. At present, all three forms are part of the enterprise.

3. Autobiography

Autobiographical studies reflect a distinctly different definition of "self," one that focuses much more on subjective experiences shaping one's life and much less on "self's" practices that structure interaction with students or clients. Autobiographical studies comprise three distinct groups and some related approaches. The first group is the modal group, with 18 studies, the second is suggested by three studies, the third with seven studies, leaving two unique forms.

Pattern 1: Autobiographical accounts of experiences entailed in being a teacher educator

Bailey and Russell (1998) describe their gratifying experiences as change agents in teacher-education reforms they participated in at their respective universities. They comment on the change process and conclude that the idea and the process of "in-flight correction" are crucial if innovation is to succeed. Hamilton (2000) described her contrasting "experience as a secret (change) agent," a "white woman in a position of authority" confronting the difficulties and disappointments of guiding reform at her institution to address issues of diversity and equity.

Donna Allender (2002) reported an autobiographical experience extending over many years, an experience brought into recent focus by returning to the school she and others had founded to explore the extent to which one of the

school's basic values (each person takes responsibility for his or her own learning) was still evident. Re-entering a living, institutionalized part of her autobiography, Allender found a basic value being short-changed, and formed plans to consult in ways to strengthen the enactment of that value.

Bass (2002) relates her autobiography of experiencing ethnic, religious, and racial diversity, of forming an identity deeply inscribed by that experience, and coming to value and to work for diversity as fundamental to education. Feldman's (2002) autobiographical inquiry, including a parallel narrative of his readings in philosophy to help him make sense of his life, was precipitated by a difficult choice recently experienced between his identity as a science educator and his identity as a teacher educator. He traces life events that brought him to the choice point precipitated by a sense of overload in his work and commitments, a choice resolved by his settling on an identity as teacher educator.

Russell (2002) also searched for coherence as a teacher educator in struggling to reconcile his deep commitment to teaching teachers and equally deep commitment to research. He traced his activities over a single year, examining the forces that distracted and overloaded, discovering some coherence in a research project that also yielded a satisfying curriculum product that helped him teach students ideas and methods of learning from experience, one of his core values.

A final autobiographical exemplar of experience is Griffiths' study (2000) reporting her "chats" with 11 former colleagues on a social justice project that had ended some years earlier, trying to see whether they might re-form the group to advance the project. She traces her gradual, unwitting discovery of the importance of "small tales," tales not of the big issues and events of social justice and injustice in the large ("tall tales"), but tales rather of the small daily experiences members had together in the closeness of their collaborative activities.

Pattern 2: The topic-focused autobiography

This second mode of autobiography treats it as a vehicle for setting forth and exploring one's own experiences related to some specific focus. One form is to assign autobiography as an instructional method for engaging student teachers in their own examination of their experiences, beliefs, fears, attitudes and outlooks in connection with their learning of mathematics or literacy. Teacher educators use this specific form of autobiographical study as a practice of their teaching, a method to induce students to confront their preconceptions and hidden fears about their specific subject matter. But the method also has produced unanticipated side effects on the teacher educator.

Muchmore (2000) describes how his students uncover more clearly their beliefs about literacy and about teaching literacy by writing their literacy autobiographies. Having students take this approach brought Muchmore to an epiphany in his own development as a teacher educator, realizing a whole new way of thinking about teaching teachers of literacy.

Pereira (2000) describes how his elementary teachers come to grips with their fears of learning mathematics, and find encouragement, by writing and discussing their own mathematics autobiographies. He also finds, in writing his own math

autobiography, that he discovers new aspects of his own orientation to math and to teaching math.

Parker (1998) assigns herself the focus of "one significant moment" in learning to become an action researcher, narrating an experience of trying to learn, providing details of her experience of arriving late at a seminar on action research in which she struggled to find some sense in the on-going discussion. The moment is examined for its wider significance.

Pattern 3: Autobiography via the performing arts

Austin, Gaborik, Keep-Barnes, McCracken, and Smith (1996) collaborated in writing and then presenting a drama depicting the development and struggles of their working group in carrying out action research studies. Cole and McIntyre (1998) collaborated in a study where McIntyre was Cole's self-study assistant. McIntyre, a therapist and former student of Cole's, drew Cole out and challenged Cole to render her understanding of herself as teacher and herself as learner by representing memories of her learning and teaching in movement ("Patty-cake") and dance.

McIntyre (1998) narrated her role as self-study assistant to Cole, drawing on her own autobiography and experience as a therapist to illuminate her relationship with Cole. McIntyre's chief theoretical and practical focus is the relationship to be formed with Cole, promoting a trusting and safe relationship as a "relational space" in which creativity can flourish.

Weber and Mitchell (1998, 2000, 2002) explored their own autobiographical experiences in school involving body image, clothing choice, and self presentation, communicating these by creating dramas and enacting autobiographical episodes of self presentation dramatically on stage.

4. Other autobiographical modes

Knowles and Thomas (2000) explore, through autobiography, poetry, and painting, their experiences of geographical "place" as forming their sense of who they are and as shaping their orientation to, and practice of, teaching. Muchmore and Sayre (2002), husband and wife, report their respective autobiographic experiences leading to, and centering on a conflict within them and between them about home schooling their daughter. Sharing their respective life experiences of their own schooling led to their wider mutual awarenesses and sensitivities and to a more collaborative management of their conflict.

Summary: Modes of Discovering Self in Autobiography

The experience of being a teacher educator in the academy or elsewhere in Western society is one of coping with contradictory values and competing demands, an experience that has been explored in a number of autobiographies – studies of self in relation to self's development in the past and self situated at the vortex of opposing forces, forces of reform in conflicting directions, and of academic survival amidst commitments to teaching, supervision, and research.

Autobiographical writing has proved to be a particularly appropriate medium and method for capturing that experience and those forces. But autobiography also serves students and teachers who are not caught in the forces of teacher education, serving them as a way of re-living their own learning in this or that respect, and, for students writing and discussing their subject-matter autobiographies, exposing richly painted pictures of the actual, lived complexities of learning and varied construals of their supposedly common subject matter. Assigning autobiographies of learning math (or learning to read, write, become literate – or learning any other school subject), becomes a method of sharing and confronting preconceptions and fears which if left unexamined can impede one's teaching.

As subject matter for dance or theater, autobiographies of school learning and school experiences can express in particularly evocative and penetrating ways what teaching and being taught, learning and failing to learn, being in school, being an adolescent, and other facets of school life can be like from very different perspectives. Clearly, autobiography has been exploited creatively and in many directions by s-step scholars.

4. Methods

Three approaches to methods were apparent, dividing up along lines similar to the patterns of self study. The first set of methods was designed to foster new behaviors or sensitivities in *teacher educators themselves*, those studying their own practices. The second grouping of methods was designed to foster new behaviors or sensitivities in teacher educators' *students*. The third pattern, combining methods promoting change in teacher educators and their students, divided into two parts. One set of studies employed separate methods, one aimed at changing the teacher educators themselves, the other aimed at changing their students. The other variant of this third pattern employed methods that simultaneously impacted the teacher educators and their students. Some examples of each pattern follow.

Pattern 1: Methods to promote change in teacher educators themselves
Gipe's (1998) study, where she assigned herself the task of developing a portfolio capturing her teaching of a course, and the Johnston (2000) study, of having students of color become cultural consultants to comment on her teaching, both exemplify this pattern. Johnston, Summers-Eskridge, Thomas and Lee (2002) not only engaged students of color as cultural consultants to increase their sensitivities to diversity, but they also used a method of explicit vantage points, perspectival "re-readings" of their conversations and multi-cultural experience, through use of diverse texts (e.g., from Bakhtin, critical theory, post-structural feminism) whose viewpoints provided them with different lenses to see different dimensions of their experience.

Watson (1998) illustrated a method that combined "close reading" of a narrative of one's teaching with reflection on the close reading. Feldman (2000) illustrated a method of studying one's real, as distinct from assumed, priorities

by collecting data on how he had allocated his hour-by-hour time for a week. He discovered that while he knew he had spent time on his research, nowhere did that effort appear in his record, leading him to conclude that he could only be fitting research in, unnoticed in its own right, amidst his other crowding commitments. A final exemplar is Wilcox's (1998) method of focusing, "more on recurring educator practices than on single classroom incidents," in which she specified in three moves the "personal conventions" of her teaching, then assembled artifacts of her work (handouts, abstracts, letters, proposals, workshop outlines) that reflected these personal conventions. Wilcox described how she then annotated each artifact, and illustrated her process of reflecting on the annotating experience.

Pattern 2: Methods to promote change in one's students

Austin (1998) described her process of having her student teachers write and revise their own "assessment plans" by which they would themselves evaluate their own teaching. She reflected on the "flowers" and "thorns" of this method of promoting her teachers' professional development. Holt-Reynolds (1998) described five activities comprising her method of eliciting her students' "just-out-of-conscious" beliefs and outlooks about particular aspects of teaching and their subject matter, specifying four qualities all of the activities have in common.

Cockrell, Placier, Burgoyne, Welch and Cockrell (2002) described their use of Theater of the Oppressed drama forms, engaging students not only in enacting dramatic scenes of classroom life, but also, as audience, entering the "stage" to enact their own solutions to the problems being portrayed, gaining multiple perspectives from watching and enacting different roles and different scenes. Cockrell *et al.* also differentiated their roles, some focused on dramatic activities, others carrying out research on students' on-going and cumulative responses to the drama experiences.

Kaplan (2002) describes a "contract system" by which his students contract for a particular grade for doing a certain amount of journal writing about their own learning and development during the course, which focuses on students' personal reactions to issues Kaplan and his readings raise. Already cited are the studies by Pereira (2000) and Muchmore (2000), using a method of focus-specific autobiography in which students write and share their own autobiographies of learning math or literacy. Teachers in the workshops of Korthagen and Verkuyl (2002) are drawn into contexts in which they ask, "Who am I and how do I reflect who I am?" Details of the process and steps of a workshop are described, including a process that reveals for each participant six levels, from peripheral environment to core self, at which the participant's revealed dilemmas might lie.

A final example of efforts designed primarily to promote reflection in students is the collaboration of Dalmau and Gudjonsdottir (Dalmau & Gudjonsdottir, 2000; Gudjonsdottir & Dalmau, 2002). They described and illustrated how they worked with their Professional Working Theory (PWT). The PWT spells out three basic contents of effective reflection and self-study of one's teaching: practice (what one does), theory (how one understands what one does) and, ethics (the

values that show why one does what one does). Students write about these three foci at three levels: daily work; work context; and, societal context, discussing their reflections in various group arrangements and procedures, which the authors describe (Gudjonsdottir & Dalmau, 2002).

Studies of this type, then, feature methods designed to engage students in examining their own beliefs, assumptions, emotional reactions, attitudes, outlooks and teaching. They may have side-effect reactions on the educators employing them, but they are aimed primarily at promoting their students' reflective skills, attitudes, and habits.

Pattern 3a: Separate methods promoting change in teacher educators and their students

Richards (1998) described four explicit steps she took to create a self-portrait of her teaching, followed by a sketch incorporating the results of each step, followed by reflective examination of this sketch, which uncovered previously hidden aspects of herself as teacher. She also taught this method to her students whose self-portraits of their own teaching are illustrated. Lighthall (2002) describes two different methods, one designed for students' reflection and one for his own. Students narrate their own teaching experiences in class and write for each class about connections they see between their current practice teaching experiences and the texts they are reading. The separate method aimed at expanding his own awareness of his teaching is the post-class "laboratory" where students and he share comments on the class ended minutes before.

Fitzgerald, Farsted and Deemer (2000) report a study also with separate methods for student and educator. To gain richer and more authentic disclosures from students of their beliefs and assumptions about various teaching situations, "Socratic-based learning circles" promoted "focused, noncompetitive discussion" in which students were prepared to consider evidence, viewpoint, and assumptions. Fitzgerald also engaged a doctoral student to carry out separately "an ethnographic evaluation as participant observer" in a course co-taught with a colleague, including "debriefing immediately after class."

Pattern 3b: Methods simultaneously promoting change in teacher educator and students

Richards and Richards (1998) describe ways in which they invite their respective clients (students and patients) to use metaphors to capture their experiences, their selves, their situations. They illustrate exercises in metaphor use, and argue for the explicit and regular use of metaphors as a part of self-study methods. Berry and Loughran (2000) devised a method of "unpacking" their unfolding teaching for their student teachers, a method designed to help the students "see" the thinking and choices that lay behind the pedagogy unfolding before their eyes. In their co-teaching, one teaches and the other, taking the role of collegial questioner, interrupts when they feel explanation of the teaching would be useful, and asks the teaching partner to annotate, as it were, their purposes and thoughts

about what they are doing. The students also, in their mini-teaching exercises, are asked to take this role with each other – with, the authors note, some difficulties.

Watson (2002) uses but moves beyond narratives dealing with what students do, focusing instead on what they *notice and wonder about* from their teaching experiences. She has students write and exchange with each other what they notice and wonder about in their teaching, and she responds with what she notices and wonders about in their writings. She analyzes her noticings and wonderings by noticing and wondering about what she has written. The method applies as well to students and to educator, and, while grounded in specific "things" noticed, incorporates also the person's implicit criteria for focusing on this or that, and his or her speculations. Watson illustrates how this framing of one's "observation" affected both herself and a student.

A final example of methods whose effect is to engage simultaneously the educator's and student teacher's reflection is Hamilton's (2002) use of art works of Winslow Homer, depicting scenes of rich and poor people, old and young, white and black, alone and with others in their everyday lives, pictures with content she notices, interprets, and wonders about in relation to issues of justice and equity important in education and salient in her and her students' attitudes.

Methods that do not fit these patterns are Griffiths' multi-vocal mode of *communicating* her study (Griffiths, 1998) and Pinnegar, Lay, and Dulude's (2000) collaborative method of *experientially grounded conceptualization*, where teachers narrate and then write responses to, stories of their recent experiences of teaching, then repeat cycles of probing stories and responses for common qualities necessary to developing effective teacher-student relationships.

Summary: Types of Methods

S-step scholars have developed impressively varied methods for promoting changed sensitivities and teaching skills both in themselves and in their students. Some studies focus on methods to change only the scholar's reflection and teaching, others focus on methods to change students' reflection and teaching. Still other studies report separate methods aimed at changing both the teacher educator and the students, and some methods reported effect changes in both students and teacher educators simultaneously.

Methods range from the micro-level (e.g., Watson's (1998, 2002) close reading of narratives, Johnston and colleagues' (2002) perspectival re-readings of their conversations, Richards' (1998) four-step self portrait of her teaching), to the more macro-interactional level (e.g., Hamilton's (2002) use of Winslow Homer's paintings as stimuli for reflecting on matters of equity, diversity, and power, Lighthall's (2002) daily reflective laboratories, Korthagen and Verkuyl's (2002) interactive workshops and so on). The fact is that this micro and macro listing is but a sample of methods for promoting and studying reflection on teaching developed by the s-step enterprise. It also suggests that a reading of the s-step literature for methods alone promises rich rewards for anyone contemplating self-study of their practices. However, there are still gaps.

In the 125 writings I have found only one offering guidance on autobiographical writing (Bullough & Pinnegar, 2001) and no description of methods of writing or having students write journals (a frequent practice and source of data in these studies), or of writing narratives. There may be methodological writings on all three of these modes of study, but the s-step enterprise has paid little attention to the question of method in these three respects. It is as if s-step scholars believe that one autobiography or journal or narrative is as good as another, and that the only methods necessary are those we all, students and teachers, already possess by virtue of our ability to write anything. Since it is likely that most who study their own teaching by using narratives, journals, and autobiographical content have in fact thought about more and less effective ways to do so, I must wonder what keeps us from writing about methods in these three areas when we are so creative in using, and explicitly describing, methods in the other forms I have cited above.

5. Reform of Practice(s), Profession, Institutional Culture

The s-step enterprise is deeply reformist in character. It promotes and widely exhibits reflective research that delves into the researcher's own self, practices, and programs. It therefore is revisionist on the very matter of research itself. It seeks reform of teacher education locally, in practices, and more widely with respect to professional norms. It has established a niche as a Special Interest Group of considerable size within the AERA, and has established a history of biennial international conferences devoted to reporting and reflecting on its own intellectual, social, and political activities.

In the published corpus I have reviewed I find three major reform or revisionist themes within the feature I have called the reform of practice, profession, or culture. Some examples of each follow.

Pattern 1: Reforming teacher education as a process and a profession

Members of the Arizona group, Guilfoyle, Hamilton, Pinnegar, and Placier (Guilfoyle *et al.*, 1996, 2000; Hamilton & Guilfoyle, 1998) have described their experiences in the reform of teacher education as a profession, and of reflective teacher education practices. Myers (1996) reviews studies of teacher education reform and of school restructuring and argues that nearly all of the weaknesses of those efforts "can be tied directly to an absence of self-study" (Myers, 2000), and argues that traditional teaching modes – of telling, showing, and guiding – used by his colleagues in teacher education both near and far, have resisted the kinds of change he has effected in his own teaching through self-study.

Korthagen (2000) and Korthagen and Verkuyl (2002) describe workshop and teaching methods that clearly offer antidotes for the telling-showing-guiding modes of teaching lamented by Myers. Kosnik (1998) narrated how a restructured teacher education program emphasizing action research changed her own outlook, practices, and professional self-concept. Bailey and Russell (1998) narrate their respective experiences in furthering the change process in their separate

teacher education programs. Finally, Donna Allender (2002) describes her return to an innovative school she helped found to discover, and her plan to reverse, some unraveling of the school's reformed agenda of placing responsibility for learning on learners.

Pattern 2: Reforming norms, practices, and culture of the Academy

Collier and Wilcox (1998) review experiences in forming and continuing a teacher-scholar network of ten diverse university faculty, whose regular discussions of teaching over three years mitigated the absence at their university of "a teaching subculture." Fitzgerald and colleagues (Fitzgerald *et al.*, 2002; Fitzgerald *et al.*, 2000; Heston *et al.*, 1998) describe various phases of their efforts to create and sustain "communities of conversation" at their university, including efforts to replace outmoded checklist types of evaluating teaching with more complex forms. Gipe (1998) shows in detail her answer to inadequate modes of evaluating teaching through construction of her own portfolio for a course.

Whitehead (1996) proposes two paths of reform, direct political action (which he illustrates in his own case) and promoting "academic legitimation" by developing an "epistemology of practice" and the development of "new kinds of educational standards of judgment." In line with this theme of setting standards for evaluating teaching, Lighthall (2000) outlined five basic components of any system of accountability, contrasting traditional forms of accountability with the new forms of *empirical* accountability developed by the s-step enterprise. Cole and Knowles (1996) outlined the need for, and path to, a political dimension of the s-step enterprise, arguing the need for organized efforts to legitimize within the academy self-study of practices as a recognized form of scholarship. Finally, in an effort that Whitehead, and Cole and Knowles, would applaud, Bullough and Pinnegar (2001) set forth guidelines for effective "autobiographical forms of self-study research," providing the beginnings of a shared basis for constructing and evaluating autobiographical studies.

Pattern 3: Attitudinal reform: diversity and equity

Johnston and colleagues (Johnston, 2000; Johnston *et al.*, 2002) collaborated in a novel process of "cultural consultation" to inform themselves and their teacher education program of the reactions and outlooks of students of color. Bass (2002) provides an autobiographical picture of her development as a white person whose experiences sensitized her to ethnic and racial diversity. Hamilton (2002) hit upon the art of Winslow Homer, depicting everyday people, high and low in station, powerful and weak, male and female, in school and out, alone and together, pictures capable of eliciting rather deep emotional responses of Hamilton, and of her students, thus assisting in the collective task of confronting and purging stereotypes of self and other.

Summary: Patterns of Reform

Clearly, the s-step enterprise is intent upon cultural change in pursuit of cultural enlargement – changing the norms and practices of not only teacher education

but also of the academy in which teacher education almost always takes place, all to the end that the s-step enterprise may find a more legitimate place in the academy. The autobiographical writings of the Arizona group show the struggles that one who does and values self-study of practices must go through in the academy. The telling-showing-guiding mode of teaching, which often becomes lecturing, is the object of a number of reform efforts reported, efforts emphasizing the new form of reflecting on practice that is unique among action researchers and this self-study group, namely, *reflection based on empirical data.* The academy's standard checklist and end-of-course modes of evaluating teaching are also objects of s-step reform efforts, which often turn to the portfolio as a corrective measure. Carving out a stable cultural space for the norms, procedures, and values of the s-step enterprise is one of its features.

Part of that cultural reform goes mostly unsaid in the 125 studies I have taken as representative of the field. Beyond being "said," reform is instead simply enacted. The s-step enterprise is starkly reformist by its practice of empirical self-study of teaching practices. It is counter-normative in the academic culture to act as if one's professional role or self-esteem required one to collect data about one's teaching practices, to analyze the data, to act on discoveries resulting from it, and to communicate one's studies of one's own practices with other professionals.

Another dimension of s-step's reformist orientation, one evident in many fewer studies, but still notable, is the effort to reform our own or our students' attitudes toward social, economic, and racial inequities and toward ethnic differences. One study that stands out as directly addressing issues of diversity, by consciously organizing, and studying, an on-going multi-racial consultation of students and faculty, is the study by Johnston *et al.* (2002).

6. Theory: Concepts, Frames, Contents, Distinctions

I was surprised to find so much theory featured in these writings. I counted as theoretical any statement that featured a concept, a way of framing, a distinction, or an explicit theory that was central to a piece of writing. Five patterns of theoretical thinking were featured in these writings.

Pattern 1: Conceptualizations of relationships

McIntyre (1998) articulated a concept of the assisting person in an assisted self-study, in this case, an autobiographical study of a friend and former teacher, Ardra Cole (Cole & McIntyre, 1998). McIntyre drew on her experience and training as a professional therapist, focusing on the "relational space" between her and Cole, tracing its development, a kind of biography of a relationship. Griffiths (1998) conceptualized important power and ethical dimensions of collaboration, including the conflict between conveying observations truthfully and continuing an important collaboration. Conceiving of collaboration as complex, with autobiographical, passionate, social, intellectual, and rhetorical dimensions, each requiring its own voice, she carried that realization forward using different type fonts to express the different voices.

Pinnegar *et al.* (2000) spell out necessary conditions for an effective teacher-student relationship to develop, extracting these conditions from cycles of commentary of each others' narratives of teaching episodes remembered, and from commentaries on their commentaries. Heston *et al.* (1998) and Fitzgerald *et al.* (2002) provide a frame for thinking about the process of assisted or collective self-studies, namely, the quality of "professional intimacy," a special kind of relationship among participants in which a few central ground rules are explicated and held to, conversations in which there is, "no jousting, arguing for the argument's sake, one-upmanship, or proving your point by defeating another" (Fitzgerald *et al.*, 2002, p. 78).

In a similar vein, Guilfoyle *et al.* (2002) conceptualize, "professional dialogue as a conversation or verbal interchange between two or more persons ... contrasted with monologue ... [which includes] our assumptions, beliefs, and theories ... [in which] two different positions or claims are posed and the point of dialogue is reconciling, synthesizing, or integrating the opposites ... [and in which] we can reveal our minds without holding back and with a willingness to be challenged" (pp. 97–98). Finally, Allender and Allender (in Allender, 2001, pp. 127–144) drew on Gestalt Theory to articulate self-in-relation as reflected in feelings, feelings that ought to be part of the contents examined in a self-study of teaching.

Pattern 2: Conceptualizations of personal, public, or professional self or identity

Trumbull (1998) finds it useful to view new teachers as developing a new self, that teacher education must be conceptualized, at least in part, as promoting the transformation of self from unexamined to examined, and draws on Kagan's (1982, 1994) "conception of the evolving self." Weber and Mitchell (1998) see the teacher's self-presentation – body image, clothing, conception of embodied and public self – as a shaping and constraining force in "how we think about who we are and could be," shaping teachers' conceptions of teaching, emotional responses during teaching, and teaching practices.

Feldman (2002) draws on Existentialist writings to propose a concept of teacher as *being*, a synthetic idea incorporating ideas, skills, knowledge, and experience with identity and sense of self as a being ineluctably making consequential choices. Finally, Korthagen and Verkuyl (2002) focus their students' attention on the students' "own professional identity" and "social-psychological goals and responsibility" as a means of helping them to "develop a moral view of the aspects of the teaching profession and their own social-psychological task." They position "identity" as close to a "core self," as distinct from more variable environmental forces that might shape one's teaching.

Pattern 3: Conceptualizations of the process of carrying out a self-study of practices

Here I grouped studies together that featured particular concepts or ways to frame or to reflect on experience and practices. Wilkes (1998), takes the idea of

paradox as her organizing principle, addressing several paradoxes in teaching in relation to her own autobiographical experiences, illustrating how paradox can be employed as a conceptual frame for doing and reflecting on one's own practices, a focus on content to be examined. Allender and Manke (2002) present a conceptual frame – where artifacts of one's practices are considered as "shards," to be interpreted as reflecting the world from which they came – and a theory of knowledge where an additional category of knowledge, neither practical nor theoretical, is sought, namely, knowledge that lies at the "inter-face" of the practical and theoretical. This synthetic idea is that self-knowledge "used at the moment of application" and "general knowledge" can exist simultaneously.

Johnston *et al.* (2002) develop a conception of the reflective process that calls for "multiple theoretical re-readings," examinations of teaching practices or experience from specific theoretical texts (e.g., Bakhtin's writing on dialogue, Clandinin's (1995) and Polkinghorne's (1998) writings on narrative, critical theory) used as lenses through which to see into the practice or experience under examination. Finally, Dalmau and Gudjonsdottir (Dalmau & Gudjonsdottir, 2000; Gudjonsdottir & Dalmau, 2002) present a "professional working theory," which calls for reflection on practice, theory, and ethics, a theory that lays out these three basic foci of reflection to be included in any effective self-study of educational practices.

Pattern 4: Self-studies of practices in relation to educational accountability

Whitehead (2000) distinguished between two kinds of standards of professional practice: "linguistic standards" and "living standards," where the former are identified in written or spoken statements and the latter are identified only in "embodied" form in on-going professional action observed or captured on video-tape or CD-ROM. This conceptual distinction brings into focus the kinds of data necessary to substantiate or disconfirm whether standards were or were not being met. I identified five basic components of accountability, and viewed the s-step enterprise as a special and unique case of professional accountability, comparing its forms of unassisted, colleague-assisted, and client-assisted empirical self-studies of practice to other types of accountability (Lighthall, 2000).

Pattern 5: Political conceptualizations of the s-step enterprise

Cole and Knowles (1996) place the s-step enterprise in a larger frame of "the politics of epistemology," conceptualizing the entire enterprise as a "reform mechanism" in a "struggle for legitimacy in the academy" for which "collective will and action are required" in which "organization and solidarity are key" (Cole & Knowles, 1996, p. 72). Whitehead (1996) argues for political action to "take forward our self-studies of teacher education practices" by urging his colleagues to "create a legitimate space for our work" by developing "an epistemology of practice" which focuses attention on "living educational theories" in which "living contradictions" constitute motivating force and in which evidence is sought to answer questions like, "How do I improve what I am doing?"

Finally, Hamilton and LaBoskey (2002) compared and contrasted three domains of inquiry – self-study, teacher researcher, and scholarship of teaching – across 15 dimensions, to begin to delineate self-study territory; a project at once political, conceptual, and professional.

Summary: Theory

S-step scholars wrote theoretically about relationships, underlining the enterprise's strong collaborative feature. The teacher's personal and professional self or identity came in for theoretical attention, as did the process and important foci of the self-study of practices. Some attention was given to aspects and types of accountability, and the s-step enterprise was conceptualized in political terms.

I found McIntyre's (1998) reflections on her role of self-study assistant in the Cole–McIntyre collaboration (Cole & McIntyre, 1998), drawing on McIntyre's experience as a therapist, particularly enlightening and relevant to the many forms of collaboration in which s-step scholars engage. The autobiographical method of Pinnegar *et al.* (2000), generating data for conceptualizing relationships, struck me as creative and as having wider applications, for example, focusing on memories of teaching that illuminate "self," "teaching," "support" (and its opposite), "engagement" – all commonly entailed in our professional activities. Trumbull's account (1998) of finding particularly useful Kagan's (1982, 1994) theory of levels of self-concept caused me to want to read Kagan's work. Feldman's (2002) autobiographical and philosophically informed account of his identity crystallization, and Korthagen and Verkuyl's (2002) conceptualization of professional identity, contributed an added dimension and depth to theorizing about self and identity.

Framing self-study of practices as an archeological exercise of examining and interpreting "shards" (Allender & Manke, 2002) casts the reflective process in a new light, as does Wilkes' (1998) focus on paradox as an organizing principle of reflection. The process of examining one's experience through the lenses provided by theoretical writings of Bakhtin and others (Johnston *et al.*, 2002) provided a model of "multiple theoretical re-readings" that has wide application as a method adapted to the complexity of teaching and teacher education.

Particularly useful in spelling out *generic contents* of reflection is the Professional Working Theory of Dalmau and Gudjonsdottir (Dalmau & Gudjonsdottir, 2000; Gudjonsdottir & Dalmau, 2002), calling for reflective practitioners to reflect on their practices, their theory guiding their practices, and their ethics. Whitehead's (2000) distinction between linguistic standards of professional practice and living standards of professional practice, and Lighthall's (2000) taxonomy of types of accountability, focus attention on evaluative considerations, while the focus on "s-step's recurrent end game" (Lighthall, 2002) draws attention to the several stages of any self-study of practice, emphasizing the last phase, implementation, which is not much studied.

The s-step enterprise as a whole was conceptualized in political terms (Cole & Knowles, 1996; Whitehead, 1996), particularly the politics of legitimation, and the "self-study territory" was examined conceptually in relation to two other

research enterprises, teacher research, and the published literature on teaching drawing on traditional research methods (Hamilton & LaBoskey, 2002). On the whole, then, while theoretical writings were sixth among the six major features of the field, they were rich in varied dimensions, creative, practical.

Part 3: Reflections: Enriching and Advancing the Field

The s-step Enterprise in Relation to the Academy

To enrich or advance the s-step field it is important to see how the field is situated in its larger institutional context. It is important to address the question of how s-step relates to the methods, goals, and norms of academic research and writing. My other fields of knowledge are educational psychology and social and organizational psychology. From the standpoint of the forms of research and of knowledge that characterize these academic disciplines, it is not too difficult for me to say how the s-step enterprise relates to them. My view is that it does partly, but in many ways it simply does not. The forms of research, the methods, and the kind of knowledge these other academic fields seek, use, and honor have the goal of accumulating generalizable knowledge with respect to stable domains of action. Empirical findings are sought which quantify differences between *variables*, measured under repeatable conditions. Academic research in these fields has its eye on knowledge established, codified, and known. Its eyes are blind to questions of applying knowledge, of improving anything. A sharp distinction is made between psychological knowledge as established by research, on one hand, and applying that knowledge to specific cases, on the other. While educational psychologists often speak of improving education, even improving schooling, as the goal of their research, no educational psychological journal would publish their account, were they to write one, of the process of applying that general knowledge to a specific school, classroom, or child.

In striking contrast, the s-step enterprise is oriented to the *improvement* of teaching, and teaching is oriented to the *improvement* of mind, being, and living. The s-step enterprise is concerned with particulars. Its eyes are blinded to establishing de-contextualized or narrowly contextualized knowledge of the sort the academy seeks and thrives on. The nature of teaching and of teacher education is that we are ineluctably caught in particulars – in particular contexts of particular places and cultures taking particular actions with particular people who, in turn, are coping with their own particular situations, skills, capacities, priorities. If anything is stable in our contexts it is a stability we must discover by particular inquiries amidst shifting situations.

But if that stance vis a vis the academic disciplines is counter-normative, all the more so is the proposition that such empirical self-studies of teaching be considered serious, legitimate, informative scholarship. While the academy seeks generalizable knowledge, knowledge which others may or may not "apply" to specific situations, teachers and teacher educators seek knowledge about their practices, their role enactment, their relationships – *all stable phenomena within*

each teacher's or teacher educator's own orbit of professional activity. The focus of self-studies of practices is too minute, too fleeting, too changeable, and too contingent on too many simultaneously operating forces to be suitable for study from the point of view of variable-centered, generalization-seeking research.

Further, the methods of the more traditional, generalization-seeking studies – analysis of variance, factor analysis, non-parametric analysis of categorical data – require repeated observations within categories of data, holding the conditions of observation constant (or sampling randomly across them). In contrast, practitioners in the teaching fields encounter – observe, interpret, and react to – unique combinations of events in complex and shifting contexts, all in real time, without opportunity to re-sample events before interpretation and response is required. As a result, teaching practices, even if regularly employed, must be responsive to unique combinations of events. Study of those practices, then, must develop methods sensitive to that peculiar context.

Metaphors and Methods

In light of these differences between the aims and tools of traditional quantitative research, on one hand, and the aims and tools of those of us who link our inquiries closely to the improvement of teaching practices, on the other hand, we are forced to develop our own scholarly tools, since our aims are starkly different. The rich variety of methods so far reflected in s-step writings represent an accomplishment in that direction. I view our situation regarding the traditional disciplinary methods and aims of research as being like the person who is looking for a penny buried somewhere in the sand nearby, and being offered by traditional searchers the use of bulldozers to find it. The academy's bulldozers are ill suited to our task. We need to develop the equivalent of our own metal detectors, sifting screens, and trowels, and we need to get down on our knees to make careful and close observations. That metaphor of looking for a penny in the sand while being offered bulldozers emphasizes the fine-grained character of the phenomena we have to deal with.

A second metaphor is needed to emphasize the changeable character of our teaching situation, requiring us to be, like Jack and the candlestick, quick and nimble. For me, it often happens in a class session with student teachers, for example, that events of their teaching day trigger emotionally intense interactions in our class discussion. For me this has required, not only immediate and serious reflection on the events of that class, but also detailed review of the interactions in the class with some of the students in the class who: a) have witnessed the interactions first hand; b) have more intimate knowledge of the ways of the student group than I do; and, c) expect to take part in such post-class reviews as part of their teacher-education curriculum. The clarification I have needed about those intense interactions cannot come from applying the bulldozers of traditional quantitative methods, not only because they can unearth only coarse-grained phenomena but also because they take so long to be deployed and enacted.

Time frame is crucial when it comes to looking at teaching acts and practices. And many of our inquiries cannot be served by waiting until a semester-end global evaluation, even with the assistance of students. We are engaged in a constantly moving, often shifting, dance, a dance in which our partner is often not one student, but a dynamic relation among 12–30 students interacting with the day's curriculum and tasks. In this dance we need to interpret and respond to events moving much faster than traditional research methods can capture.

So teachers and teacher educators need to learn a far more nimble set of dance steps for our craft than are illuminated by the established research methods of the academic disciplines. I view the s-step enterprise as arising out of a widely shared but still rather unconscious awareness of these special requirements of teaching and teacher education, requirements by virtue of a necessary focus on the interactive and rapidly shifting nature of teaching acts and practices.

That our teaching practices, professional role as teacher or teacher educator, and our relationships, however, are stable phenomena, about which generalization is possible, is attested to by the fact that none of these is easily changed. All of them are changed only slowly, only with persistence, and only with difficulty. Yet to be able to generalize about my practice – for example, of discussing with my students after each class about the events and episodes that captured their attention – such generalizations would hold only within my own teaching practices and situation. Most of the academy and most of its refereed journals would find little of interest in such a microscopic focus. Yet for me, as for s-step colleagues generally, it is only that kind of context and time-specific focus that can show us our actual practices and effects.

The s-step enterprise is at odds with the academy, then, on the range of phenomena over which generalizations can be made or ought to be made. Implicit in the low regard accorded the "lack" of generalization provided by self-studies of practice, I think, is that low value accorded in and by the academy to schools, teaching, and teachers at any specific site or in any particular person. Yet improvements in teaching (at any level) happen only at specific sites and in particular persons, in given time frames.

s-step's Contradictory Situation

Yet in some regards our position with respect to the academic establishment is one of internal contradiction. With respect to research – the "study" of s-step – we are at present in something of a conflict with much of academia. We pursue knowledge about improvement of our own practices within an institution which virtually ignores action, putting first the establishment of knowledge, derived from particular, and often contrived contexts, knowledge that is in any case, almost never geared to the improvement of the researcher or of the conveyor of research knowledge, the professor. Yet teacher education is situated at, and receives its economic support and no small legitimation from, colleges and universities. So teacher educators work within the culture of academia, a culture that values research over teaching almost universally. Since most of us teacher

educators must spend most of our time teaching and supervising teaching, we are all struggling, like Feldman (Feldman, 2000, 2002), to fit our research into our day and, like Russell (2002), to find some coherence between the conflicting demands of our teacher education and research activities. That experience of conflict is exacerbated by the research requirements of tenure criteria, especially when those criteria reflect the forms of research, methods, and goals of the traditional academic disciplines.

Thus, the s-step enterprise is not only at odds with, but is in conflict with, much of the academic culture and institutions, and thus, as Whitehead (1996) and Cole and Knowles (1996) imply, the s-step enterprise is in part a counter-culture movement, or at least an independent cultural movement, working toward legitimation of its own goals, methods, priorities, and forms of study and knowledge, suited to its own different situation, values, aims, and constraints. It is no accident that reform is one of s-step's major features, or that one patterned treatment of that feature in our studies is the reform of the norms and culture of the academic disciplines.

Common Ground: Scholarship

Notwithstanding all of these considerations, the s-step enterprise shares with the academic disciplines certain overarching values and criteria of work. We share the values, criteria of excellence, and self-critical habits of mind that are the mark of *scholarship*. The norms and methods of scholarship transcend all the disciplines and all particular forms of research. It is by those values and criteria that we form an intellectual community with scholars in the disciplines. And it is on that basis, I think, that we can contribute to, and draw from, the wider enterprise of scholarship. While we may be in conflict with some sub-cultures within the culture of scholarship, we can ensure ourselves of all the rights and privileges of that wider community if we fulfill the responsibilities of scholarship. Whatever else we do, for ourselves, for our students and scholarly community, and for those who follow us, we must infuse our work with scholarly qualities of thought, inquiry, and writing.

Part of s-step's position with respect to the traditional academic disciplines, particularly the social sciences, depends on which features within s-step we take as our focus. To the extent that one focuses on the "self" of s-step, for example, the s-step enterprise as developed so far is in a position of dependency in relation to those fields – psychology, sociology, anthropology in particular – whose scholars have explored the nature of "self" and "identity." We are, or ought to consider ourselves, in the position of learners from those scholars who have taken "self" and "identity" as major foci of inquiry – s-step has not sought that learning, at least so far.

So, while the quantitative methods of the disciplines are not suitable for our inquiries, the *ideas* and *distinctions* that disciplinary scholars develop can be immensely useful. In any case, the general norms of scholarship demand that we inform ourselves of the domains of inquiry of those disciplines that overlap with

our inquiries. "Self" is surely one of those overlapping domains, and the social sciences offer voluminous writings, empirical and theoretical, that can sharpen our own studies and actions. I offer two examples to illustrate this point.

My student teachers have found the concept of "possible selves" (Markus & Nurius, 1986) extremely useful, not only as they examine their own teaching experience but also to help them understand the outlooks and motivations of their own adolescent students. Markus and Nurius differentiate a "hoped-for" self from a "feared" self and from a "current" self, arguing that hoped-for and feared selves constitute centers of motivation and templates for evaluating our current selves. Student teachers readily recognize the aptness of these distinctions regarding their own selves as they carry out their teaching, writing and relating vivid images of their feared teaching selves and of their expected and ideal teacher selves. The discrepancies they discover between their current teaching selves and their hoped-for teaching selves are often the painful subject of their reflective papers.

It is precisely the discrepancy between possible selves that Higgins (1987) explored, finding that certain kinds of discrepancy between certain self-representations led to distinctive types of emotional reaction. Higgins distinguished three domains of self-concept – actual, ideal, and ought. He further distinguished two standpoints from which each person considers these three aspects of self – the person's own conception of his or her actual, ideal, and "ought" self, and his or her image of an important other person's conception of those selves. For example, I have my own view of my current, actual self as a writer, my view of my ideal self as a writer, and my view of the writer self I ought to be. From my wife's standpoint, as a veteran teacher of English and as a writer, I have a clear image of *her* view of my actual self as writer, *her* view of my ideal self, and *her* view of the writer self I ought to be. In Higgins' terms, I hold all six of these representations of myself, or selves, with respect to any activity in which I might engage.

Important for Higgins are the discrepancies among these various conceptions of self that I may have. For example, is the teacher self I *ought* to be, from my own standpoint, discrepant from how I perceive my *actual* teacher self? If so, I will experience a certain degree of emotional discomfort that will motivate removing the discrepancy. And what if my ideal or hoped-for self as a teacher is discrepant from my supervisor's view of the teacher I ought to be?

The differentiated terms of self provided by Higgins and by Markus and Nurius provide tools useful for examining the complexities of experience that we encounter in teaching and teacher education. These two social psychologists are only two social scientists among scores whose empirical or theoretical work explores the dimensions of self-related forces and experiences. Available to expand our presently vague and rather undifferentiated conceptions of self are explorations from psychology (Byrne, 2002; Markus & Wurf, 1987; Suls, 1993), sociology (Goffman, 1959; Goffman, 1963; Goffman, 1967; Holstein & Gubrium, 2000; Perinbanayagam, 2000), and anthropology (Crapanzano, 1990; Ogbu, 1990).

Since "self" is inescapably implicated in all s-step inquiries to some degree, if

we are to advance the s-step field as a scholarly enterprise, we must be much more informed than we have been about the wider scholarship of self within the social sciences. The ideas and distinctions in the disciplinary literatures – about "self," "identity," "attitude change," and other aspects of teaching and teacher education – are tools we can use to sharpen and enrich our own studies. Such ideas and distinctions can be useful to the s-step enterprise quite independently of the excessively coarse-grained methods some disciplinary scholars may use to collect or analyze empirical evidence.

Integrative Studies

Another strategy of scholarship – indeed, one criterion of an effective study – is to integrate fundamental dimensions of one's subject matter into one's studies (another criterion, of course, is the extent to which it integrates new ideas, methods, and forms of knowledge). I now examine three articles, from the 125 writings of repeating presenters at the Castle Conferences, which have integrated more than the usual number of the s-step field's basic features. By integrating more of the field's features, these studies and others like them fulfill three important scholarly goals. First, they make potential contributions in more of the field's basic dimensions, advancing the field's base of knowledge. Second, they speak relevantly to more scholars in the field, offering them more to think about that the enterprise as a whole has repeatedly attended to. And third, they explore, or open up for exploration, more combinations of the field's basic features. So let us see how that looks in the flesh, so to speak, with three studies already completed.

The study by Lomax *et al.* (1998), described earlier, examined the authors' own collaborative practices of supporting teachers of special needs (handicapped) students by using their teachers' stories and their own stories from autobiographical experiences they associated with their teaching. The study integrates seven features: 1) a highly interactive and disclosing collaboration; 2) reform of their own attitudes regarding handicapped persons; 3) use of a topic-specific form of autobiography; 4) a method, "memory work"; 5) feminist theory; 6) autobiographical stories associated with their teaching; and, 7) a self-study of their joint practice of helping their teachers.

This kind of study, integrating so many of the field's basic features, provides in a single study provocative thought for the design, execution, and communication of other studies. Not captured in my categories of features and of approaches within features is the extraordinary depth and authenticity of autobiographical disclosures by Lomax and colleagues – disclosures in their stories and in quotes from transcripts of their discussions together – something of a model of one effective way to communicate a richly layered self-study of practices.

The Cockrell *et al.* (2002) study features collaboration of a different kind, but no less intense – a collaboration across disciplines. Teacher educators joined with Theater and Drama faculty to bring two forms of interactive theater into five sessions of a course devoted to issues of diversity, a course attended almost

entirely by middle-class, Caucasian-American students. Not only was the collaboration inter-disciplinary, but the collaborators created a division of labor among themselves whereby a Theater faculty member (Burgoyne), with a research grant to study college teaching, would pair her class in Theater of the Oppressed (ToO) with five sessions of a teacher educator's (Placier's) class devoted to issues of diversity, where Placier would capture her experience in journals, and where the other collaborators would contribute in various ways in instruction and participant-observer research.

Two drama forms were taken from ToO: Image Theater in which participants portray situations or ideas nonverbally; and, Forum Theater where a protagonist confronts a problem and audience members, "spect-actors," enter the stage to enact their own solutions. Situations related to classroom difficulties in teaching were enacted.

The whole study was explicitly conceptualized as carrying out four of the five phases of an action research study, and included two contrasting types of data, autobiographical and participant-observations. Placier's running micro-autobiographical account of the experience (written in parallel with students' own journals) touches on her assessment of and reaction to some students' strongly and repeatedly voiced resistance to the Image Theater forms, on her own self doubts about "imposing" drama preparation and performance on her students (some of whom voiced strong preference for her advising them instead how to teach), and on her fear that if she "scrapped" the plan she would "sabotage" her colleague's research project. Findings of the observing researchers in the study, in contrast, showed many students to be positive about the experience, especially the Forum Theater, where they moved from audience to stage, enacting their own teaching solutions.

The combined evidence, from the researchers' data and Placier's journal, drawing on students' regular journals and videotapes of the Forum Theater, captured not only a teacher educator's (Placier's) unfolding interpretations and emotional experience, and not only the contrast between Placier's interpretations of student resistance and the researchers' more differentiated data showing many students' positive responses, but also a cultural conflict. Conflict was revealed between the Theater students and teacher education students reflected in, for example, their respective expectations about rehearsal time out of class, and in the views of theater students, who tended to see teacher education students as closed to anything innovative or challenging.

Here we have a study that integrates two forms of collaboration – across disciplines and with a division of labor; a focused mini-autobiographical account of a teacher educator's experience (none from students' journals); a new method of teaching and of raising issues of diversity and oppression; a self-study examining both the educator's practice and the students' responses to it; and an explicit framing of the research as unfolding in phases of action research. We can find both comparisons and contrasts between this study and that of Lomax, Evans, and Parker.

Lomax and her collaborators were members not only of the same profession

but of a close-knit group all serving the same kind of teacher population, while the Cockrell *et al.* collaboration brought together faculty from different disciplines who brought with them students of different departments, socialized into different cultures. While Lomax and colleagues took the same roles as teacher educator and researcher, Cockrell and colleagues divided their functions, giving depth to their specializations. Lomax and colleagues examined their personal stories mutually, touching on very personal issues in intimate collaboration, whereas Cockrell and colleagues examined the research data from students' experiences, working instrumentally in different functions rather than empathetically in mutual self disclosure and clarification. Yet both collaborations integrate many features of the s-step enterprise, both examine specific aspects of teacher education practices, both draw on autobiographical accounts of experience and both study practices designed to change attitudes. If we can imagine these two groups of collaborators reading each other's work and meeting to exchange views, what might members of each group suggest to the others about methods they have found stimulating, useful, impactful?

A final example of integration of features is that of Johnston *et al.*, following up Johnston's (2000) earlier report. As noted earlier, Johnston and Thomas, co-directors of a teacher education program, addressed their own racial biases by enlisting the aid of students of color as cultural consultants to discuss with them the shortcomings of their teaching and teacher education program that earlier cohorts of students of color had commented on despite their efforts to modify teaching and curriculum. Two completed years of this consultation were studied, bringing them to the point where their students of color not only had offered critical commentary and had joined them in analyzing the data into seven broad categories, but where the new cohorts of students of color had become less critical. This collaborative method of collecting and analyzing information about shortcomings in one's attitudes, practices, and program was accompanied by a second methodological innovation.

A second part of the report by Johnston *et al.* described a method of carrying out reflection on one's experience by "multiple theoretical re-readings" of their consultation experience. Johnston chose to use the idea of dialogue as conceptualized by Bakhtin as one lens through which to re-examine her experience, explaining that for Bakhtin, understanding comes from the dialogue itself, "in the space between persons." Johnston poses a question retrospectively, asking, "What if we had understood our words to belong to the dialogue, not to us as individuals, that understandings are created in the space where the words interact?" Having that new framing of where understanding is created, not within self or mind but rather in the interaction of minds, Johnston no doubt looked forward to deploying that perspective in her further conversations with the third group of cultural consultants. Johnston's second re-reading was through the lens of narrative, examining the stories consultants told by drawing on the writings of other scholars.

Lee re-read her experience through the lens of critical theory, asking, "How does 'inequity' survive and unnoticeably move around in our lives and in our

classrooms?", using critical theory as "a tool to re-think our teacher education practices." Lee and Johnston both re-read their respective experiences through the perspective of "post-structural feminisms," leading them to "call into question our uninterrogated use of language, our assumptions about transparency" of language as directly conveying meaning. They also understood from this perspective that they had not raised the issues of power important in post-structural feminist writing.

Thomas re-read his experience through the concept of "communities of practice," examining the consultant-consultee group for degrees of cohesiveness through concepts like "mutual engagement," "joint enterprise," and "shared repertoire."

In this study we again see collaboration, but in this case students are enlisted in a consultative group, to comment and participate in data analysis, bringing their perspectives not as faculty colleagues or as representing different disciplines, but as students experiencing and willing to comment on racial bias and discrimination in their teaching and program. This consultative group constituted a new organizational structure, then, for informing Johnston about teaching shortcomings and thus was a new method of self-intervention. The study is reformist regarding both attitudes and practices, features theory and the contribution of ideas from literatures outside teacher education, providing a theory-based method for reflecting on experience – and by extension, for reflecting on self, on other, on collaboration, on practices.

Integrative Possibilities

Having now reviewed three completed studies that show how several different features have been integrated into studies, I now proceed to consider how future studies might integrate features or approaches in fruitful combinations not yet included. Publishing deadline limits me to review combinations of two features among the first eight features of Table 6.1. Examining each of those eight against each other, I am astonished to find that of the twenty-eight combinations of these eight (taken two at a time), every single one of these combinations has been treated in at least one of the 125 studies reviewed – with a single exception. No study of the 125 featured both an explicit advocacy of a value and featured collaboration. Since collaboration is such a prominent feature of this field, it may be that all the active participants believe it simply goes without saying that collaboration is valuable. And indeed, individual collaborative studies may have said so in so many words without advocating a value or taking a value stance. Yet it does seem that the field would be enriched by both: (a) collaborative studies examining values of, or assumed in, the enterprise; and, (b) collaborative studies examining and evaluating the values (and drawbacks, limitations, pitfalls?) of collaboration itself.

A second discovery about collaboration that I find striking from this analysis is that while collaboration is a prime feature, with respect to both joint teaching efforts and collaborative writing, so little direct, *featured* examination has been

made of actual interpersonal relationships, as distinct from theories about relationships. D'Arcy's early study of the ups and downs of her educative relationship with Whitehead stands alone in this respect. The collaborative group from the University of Northern Iowa (Fitzgerald, Heston and colleagues) have studied their attempts to develop a culture of mutual reciprocity, a conversation community marked by "professional intimacy," but a close study of the relationships that actually enacted professional intimacy would inform us more concretely about the nature of productive collaboration in practice.

Extending Collaborations

The single most prominent feature of the s-step enterprise is collaboration. We can build on that strength. Some of the most intriguing studies involved collaborations *across disciplines*. The studies of Cole and McIntyre (Cole & McIntyre, 1998; McIntyre, 1998), Samaras and Reed (2000) and Cockrell *et al.* (2002) spring to mind. Such collaborations bring the thinking of other disciplines directly into the actions being studied in ways more dynamic than we can achieve by *our* reading of *their* literatures. What if some S-STEP members could arrange collaboration with a colleague in social psychology or anthropology or sociology who was interested in professional self, adult self development, group dynamics, attitude change, or issues of ethnicity or sex discrimination? Ordinarily, disciplinary scholars are uninterested in examining their own teaching, but it is also true that *ordinarily* (a) they are never asked to do so, and (b) cross-disciplinary collaborations like those of Samaras and Reed, Cockrell *et al.* and of Cole and McIntyre do not take place either – but they did. So perhaps we could expand our base of experience and knowledge and methods by more frequent approaches to colleagues in other disciplines. Perhaps a hint about where collaborations for self-study of teaching might be most congenial is given by McIntyre, who draws on her professional training as a psychotherapist. Teachers who teach students in clinical settings, professors of clinical psychology, of psychiatry, and of social work, might be disposed – more disposed than those who teach mostly by lecturing – to examine their own modes of teaching, mentoring, and supervising their students.

Another direction of collaboration might be even closer to home, with teachers in schools. Our understanding of the realities of classroom teaching – or teaching in any venue – would surely be enhanced by collaborative self-studies with teachers in classrooms and other settings. While teachers are not from "other disciplines," they can bring into view, as we alone cannot, the realities of teaching with which our student teachers must eventually deal. Such collaborations might place the teacher educator in the role of supportive observer, data collector, friendly critic, and supportive challenger.

The difficulties of arranging such collaborations, which would require all parties to find value and practical use in self-studies of practices (including collaboration), might be mitigated by approaching teachers already engaged in one form or another of action research, for example, members of the AERA

Special Interest Group, Teacher as Researcher. Such collaborations could also begin to build a bridge between the two organizations, S-STEP and TAR, with stimulating benefits to both.

S-step's Distinctive Expertise:

The Study of Practices by Their Practitioners

Matters from the traditional disciplines for scholarly inquiries about self, identity and attitude change, are entirely different when viewed through the study of teacher education *practices*. On this ground we are at home and the disciplines are strangers. It is our practices, that last word in the s-step phrase, where this enterprise can most easily and immediately create its own distinctive intellectual niche; exercise its own scholarly muscle in its own distinctive game on its own turf.

Not only are practices one of s-step's focal investigatory concerns, and not only is s-step's examination of practices empirical, but also the purpose for exploring practices ties that exploration intimately to educational *improvement*. Those studies of the s-step enterprise that explored practices – many more, of course, than the 47% that *featured* practices – did so to improve the practices of teachers, teacher educators, or programs of teacher education. Might this scholarly community now, after four biennial conferences and a richly developing literature, take stock of what its collective practices are?

Suppose we define a "practice" provisionally as any recurrent activity that professionals rely on to exercise their professional knowledge and judgment in action designed to improve a client's condition and functioning. A teacher education practice, then is some activity teacher educators engage in recurrently, or regularly, and rely on to enact their knowledge and judgment in the service of improving teachers', or student teachers' conditions and functioning. What practices do s-step practitioners rely on to enact their teaching of teachers? Would that not be a revealing catalogue or inventory if we undertook it seriously?

One practice of s-step participants is abundantly clear from my review of these writings. The practice in question is a kind of meta-practice, a practice that is about practices. I refer, of course, to the empirical study by practitioners of their own practices. That is one of the defining characteristics of the members of this community and of its shared enterprise. Surely a signal contribution of this enterprise to the literatures on teacher education and on educational improvement is its modeling in so many ways the single fact that teaching teachers can itself, in its details and through an array of methods, be subjected by its very practitioners to *critical empirical study*, study designed to reveal both strengths and weaknesses and thus to provide immediate and informed impetus to improved practices.

Such improvement is never guaranteed, even when explicitly planned and attempted (Lighthall, 2002). But it is often, as I read the s-step literature to date, deliciously prepared.

Accountability

On the matter of the s-step enterprise's core commitment to improved education, it behooves us to confront the ubiquitous assumptions that improved teaching and intellectual-moral development comes from experts setting state and national standards and officials imposing a system of rewards and punishments regarding their fulfillment. The s-step enterprise itself constitutes a particular mode of accountability. A teacher educator who collects data about his or her teaching practices is holding him or herself accountable – accountable to a set of standards: a) internalized by the teacher educator; b) centrally valuing continuous systematic observation of teaching self and practices; and, c) attuned to local resources and conditions. That is a form of professional accountability in evidence nowhere else – not in medicine, law, the academy, business life, or teacher education generally. Its distinctive feature as accountability is its systematic collection and reflective analysis of empirical data by its professionals about their own actions and practices. This kind of professional examination of self and practice is both courageous and unique.

To the extent that the S-STEP group can support the s-step enterprise's strengthening of the empirical components of this new form of accountability, it can challenge the prevailing assumptions about top-down and outside-in attempts to force educational changes. Humans do not like to be forced. They resist whenever and wherever the force comes from those who take little account of local complexities, local values, local resources, local situation, denying or ignoring the realities that make up the situation in which any and all improvements will or will not take place, the situation of this teacher, this student, this set of resources, in this school, with this administration, these students, and this community. The s-step enterprise stands in stark contrast to imposed forms of accountability, starting as it does with individuals who are intent on improving their own actions and practices, and who have empirical methods to further that commitment.

So, in the language of Russell and Munby (1992), one important way to "reframe" the s-step enterprise is as a new form of professional accountability. With that frame, as I have argued (Lighthall, 2000), the s-step enterprise stands as a challenge to all professionals: Dare you examine your own professional selves and practices by collecting and analyzing empirical observations of your own conduct with your own clients? Dare you hold your own selves accountable to your own professional values, and regularly share your struggles to improve with others in your profession?

Assumptions and Theory

Theory is often advanced by detecting differences in the phenomena under study, differences that should be explicitly distinguished. I distinguish two aspects of self in the s-step enterprise, and two aspects of actions. When self is treated autobiographically, a life is depicted in its unfolding, as a narrative over a span of time. By examining oneself as a learner of mathematics (Pereira, 2000) or as

one whose choices have led a tortuous path to becoming a teacher educator (Feldman, 2002), one becomes clearer about who one is, where one's central values lie, about defining moments. The self in question becomes, thus, framed as a more clearly articulated and developed person, mathematics educator, etc.

In contrast, other treatments of self emphasize on-going experiences, or one might say experiencing, in the short run – examining situated perceptions, interpretations, feelings (e.g., Allender, 2001; Dalmau & Gudjonsdottir, 2000; Gudjonsdottir & Dalmau, 2002) – focus on emergent subjective responses in particular situations. How these two aspects of self, the autobiographical and the experiencing, relate to each other has not been explored in the s-step literature to date. That is, how one's accumulated life experiences have shaped one's immediate perceptions, interpretations, and emotions in a particular situation has not been explored. But clearly, these two aspects of self are different, and ought to be explicitly distinguished in further treatments of both autobiography and immediate self experience.

Both of these aspects of self hold a relationship to teacher education *practices* that has been assumed and needs explicit examination. If a basic issue in teacher education is how teacher education pedagogy and curriculum actually affects student teachers' thinking, attitudes, and teaching behaviors, then theoretical issues arise about causality, issues of what shapes what. Many s-step researchers tacitly assume that their teaching *practices* are the chief and immediate means of shaping their student teachers' attitudes, thinking, and teaching. In that view, practices mediate, that is, stand between, the teacher educator's self, on one hand, and on the other, student teachers' thinking, attitudes, self concepts as teacher, and teaching behaviors. The teacher educator's self – both as situated interpretation and as autobiographical development – is in this view more remote than are the teacher educator's practices in shaping student teachers' teaching.

In contrast, those s-step scholars who emphasize the experiencing self and the autobiographical self assume one of two quite different cause-effect dynamics. One of these self-focused assumptions is that the teacher educator's self (either autobiographical or immediately experiencing, or both) shapes the teacher educator's practices, which in turn shape student teachers' orientations and behavior. The other self-focused assumption is that the teacher educator's self (in any view) directly affects student teachers' orientations, and that it is not practices that affect student teachers but the distinctive, self-shaped *ways* in which practices are enacted that shapes student teachers' orientations and teaching behaviors.

Neither the practice-focused assumption nor the self-focused assumption excludes the other, necessarily. Rather, each view (as represented in writings to date) places its favored focus center stage, as a lone actor in one scene of a longer play – or as one major factor to be looked at closely in one particular study.

Still another theoretical view among authors is that neither practices nor self are as important as *relationship*. This view holds that the relationship between teacher educator and student teachers mediates the effects of both practices and self. In this view, whatever the teacher educator's self or practices produces by

way of effects goes into constructing the relationship between teacher educator and student teacher, a relationship that in the end shapes the student teacher's orientation and teaching behaviors.

One way to enrich the enterprise theoretically would be for future studies to make explicit how all three of these shaping forces figure in the phenomena under study. However, each of these sets of assumptions – centered on practices, self, or relationship – is based on still another assumption, a common assumption that the s-step enterprise will have to confront explicitly at some point. That is the assumption that one or some combination of these three shaping forces remains important and powerful in the face of the student teacher's *environment* when he or she moves into full-time teaching. That full-time teaching environment includes such powerful shaping forces as the students being taught, student and school culture, curricular resources, school administration policies and demeanor, parental attitudes, the economy, and state and national policies and priorities.

While I am doubtful that the s-step enterprise alone could mount empirical explorations that would throw much light on the shaping forces of environment, we are all assuming tacitly that what we clarify in our studies, no matter our major focus, will in some form stand up to the student teachers' eventual teaching environments in an important way. Given that those environmental forces, together, do constitute powerful shaping forces on our student teachers' full-time teaching, does it not behoove us to address explicitly how we think the relationships, the selves, and the practices that we study will persevere in their effects on our students' orientations and teaching in their full time environments? It is a question of the "half-life" of our teaching effects beyond our students' presence at university.

Investigating the actual effects we have on our student teachers is precisely the task Whitehead (1998, 2000) has urged the s-step enterprise to address. One of the effects a teacher educator who studies his or her own self, relationships, or practices might expect to have on his or her student teachers in their full-time settings would be that they, too, would begin to study their own teaching self, relationships, or practices. But such an expectation must be tempered by the knowledge that the environments that have fostered the emergence and growth of self-studies are very different from the environments offered by schools. Further, even in the academic environment, where empirical studies and writing are encouraged, the supportive role of collaboration among s-step scholars in doing their studies is clear. Doing a self-study without assistance of a "critical friend" is not nearly as fruitful as with that kind of assistance. Further still, the s-step enterprise would not have emerged in anything like its present form without the formation of the S-STEP group, without AERA as a parent organization fostering such groups, and without the Castle Conferences. Clearly, conducting studies of one's own professional self, relationships, or practices depends greatly on a social and organizational infrastructure absent in school settings – absent unless teachers and administrators have made special efforts to form collaborative groups.

To the extent that forming professional relationships with others who share s-step values is important to the undertaking of self-studies, to that extent do our student teachers need to learn from us the skills and attitudes that prompt them to form and nurture such relationships. That is, to that extent they must learn ways to be proactive in building their own supportive environments, within schools, to support their own professional self-studies. I found no evidence in the corpus of studies analyzed for this project, or indeed, anywhere else, of teacher educators' even discussing with their students the need for collaboration, much less any effort to develop the motivation and skills of collaborative outreach. Perhaps that kind of skill development would be one way the s-step enterprise could influence the capacities of student teachers to introduce and sustain in their full-time teaching some forms of empirically examining their own professional selves, relationships, or practices.

Conclusion

Examining this corpus of writings has extended and deepened my sense of respect for this collective intellectual and practical effort. One can only be astonished at its energy and creative diversity, at the breadth of its dimensions, at the multiplicity of its methods – to say nothing of its four international conferences in the ten years of S-STEP's existence. As to its intellectual output, any putative group of studies can be reviewed and put in some kind of order. But this field has stood up well under examination and analysis of its basic features. I find coherence, yet great diversity of scholarship, diversity of focus, of integrative scope, of method, of writing – even diversity of scholarly quality. All of this bespeaks a spirit of community that supports and encourages and thus fosters release of enormous individual and collective energy. It is an energy that indicates deep professional commitment to the joint values of improving education and critically examining one's self, one's teaching, one's ideas, and one's self-examining process.

Notes

1. In the title of this chapter and throughout I use the lower case s-step to refer to the activities, processes, and products associated with the special interest group within AERA known as "Self-Study of Teacher Education Practices" or S-STEP. I use the upper case S-STEP to refer to that special interest group as an organization. In this chapter I focus on the enterprise, not the organization. It is also important to emphasize that "the s-step enterprise" I refer to consists of the studies, practices, and writings completed as of September, 2002.
2. I had six grounds for choosing the Proceedings of the four Castle Conferences as providing studies representative of the s-step field. First, the Castle Conferences are far more inclusive in their admission of papers for presentation than are the programs at AERA. Second, the number of papers at the Castle Conferences far exceeds the number of S-STEP papers at any two AERA conferences. Third, the length of presentation and discussion at the Castle Conferences much exceeds the time allotted to presentations and discussion at AERA. This marks the activities at the Castle as being more serious as intellectual confrontations and elaborations than is the case of the AERA meetings. Fourth, participants in discussions of papers and presentations at the

Castle Conference are active members of S-STEP more frequently than participants at S-STEP presentations of AERA meetings. Fifth, all Castle conferees eat all meals together and thus share more deeply the ethos of the s-step enterprise. Sixth, virtually all of the presentations at the Castle Conference are represented in printed form, while AERA presentations are frequently not. It is clear that, at the time of writing, the Castle Conferences are the flagship venue for representing the s-step enterprise.

3. This reading for patterns caused me to change my codings in several cases, sometimes seeing the article as emphasizing a feature I had not coded, but more often seeing that the article emphasized fewer features than I had earlier included. Most often I would discover that the codes I noted in my summary were identical with those I had earlier coded in my initial search for features

4. The "Roshomon" reference is to the 1951 film of that title, directed by Akira Kurosawa, in which the events leading up to a murder trial are told by those involved, each from their own perspective, highlighting the distinctive points of view and interpretations of each.

VOICE IN SELF-STUDY*

Rosebud Elijah
Hofstra University

Abstract

I argue in this chapter that the voices in self-study research are integral to creating and exploring a new landscape in teacher education that is able to bridge long-standing gaps. These voices are heterophonic and polyphonous, authoritative and authentic. They highlight dissonance and living contradictions within teacher education contexts. In doing so, they are creating a discourse that is responsive to the contexts teachers and teacher educators find themselves in. This is the new discourse of the new landscape in teacher education.

Any piece of writing has voice (Ivanic & Camps, 2001), but how that voice is defined, the characteristics embedded within it, and that which it constitutes has long been the subject of inquiry and debate among scholars in composition, rhetoric, and writing. The issue of voice has also been raised both explicitly and implicitly in the comparatively new body of work on self-study. In both bodies of literature, voice is interpreted as being integrally related to epistemology, ideology, and politics. Some frequent questions about voice that relate to self-study are: "Who has voice?", "Who should have voice?", "What kind of voice?", "Is voice personal?", "Is voice social?", "Does voice need to be authentic?" and, "Does voice need to have authority?"

In this chapter, I show that the voices in self-studies are integral to defining the work of self-study. Drawing on the literature on voice and on the work of self-study, I argue that the voices in self-study are simultaneously personal and social (Prior, 2001) and explain why they have to be so. I show how the voices in self-study are necessarily authoritative and authentic (two defining features of voice in the literature). Finally, I use a self-study that explores the issue of choice and voice (Fernandez & Mitchell, 2002) as an example of voice in self-study. Based on my arguments, the body of self-study work, and the example I

---

use, I conclude that the voices of self-study have begun to construct a new landscape in teacher education (Russell, 2002) by explicitly recognizing dissonance within the contexts in which they work (e.g., universities and schools), and in the context of their work (e.g., teaching and research). This new landscape is inclusive of both teacher educators and teachers (an infrequent phenomenon in other genres of educational research). Indeed, it is constructed by the voices of teachers and teacher educators, who bring 'living contradictions' (Whitehead, 1993) of their practice to their scholarship. This new landscape is not problematized by the theory-practice gap that has been historically characteristic of both teacher education and schools.

Voice: Defined

Much of the research in the areas of college writing, freshman composition, and second language acquisition overtly focuses on voice. Researchers discuss and debate the very definition of voice (see Elbow, 1994; Falmer, 1995; Hashimoto, 1987; Keithley, 1992; Macroire, 1985; Murray, 1986; Nakayama, 1997; Rose, 1989; Stewart, 1972; Wershoven, 1991), the applicability of voice especially in second language acquisition (Ivanic & Camps, 2001; Matsuda, 1999), and the hegemony of voice in western cultures (Ivanic & Camps, 2001; Matsuda, 1999, see also Goodson, 1997). Most all agree that voice is distinguished by authority and authenticity. If literacy is a hallmark of being educated, then it seems that having authority and authenticity in one's writing is ambitiously associated with it.

Voice is variously defined as expressions of authenticity (Stewart, 1992), authority (Rose, 1989), and identity (Ivanic & Camps, 2001; McElroy-Johnson, 1993). The personal element in voice (Elbow, 1973; Macroire, 1985; Murray, 1986; Stewart, 1972) suggests a presence (Bowden, 1996) or 'juice' (Hashimoto, 1987) in writing. Personal writing, or writing using the personal voice, has increasingly been encouraged in writing and composition classes since the late sixties and seventies under the persuasion of the expressionists – Macrorie, Elbow, Murray, and Stewart, for example. The emphasis on the personal in voice is an attempt to free student writers, "from restrictions that had traditionally been imposed on them," and to encourage them, "to reveal themselves in an honest, authentic voice" in an attempt to validate student voice and redistribute power (Wershoven, 1991 drawing on Harris, 1989, p. 22), and to emphasize freshness, creativity, and authenticity (Wershoven, 1991 citing Harris, 1989).

Efforts have been made to analyze the issue of ownership of voice. Drawing on sociohistoric theory (e.g., Voloshinov and Bakhtin) and sometimes the developmental theory of Vygotsky, some researchers of voice argue that, "voice is simultaneously personal and social (instead of either/or) because discourse is understood as fundamentally historical, situated, and indexical" (Prior, 2001, p. 55; see, also Bowden, 1996; Dickerson, 1989; Fleckenstein, 1997; Greenhalgh, 1992; Hashimoto, 1987; Yancey, 1994). Fleckenstein (1997) speaks of, "the heterophonic third voice which is neither culture nor psyche, but both" (p. 475).

Theorists from this sociohistoric perspective write about the false dichotomies of the personal and social, and form and content (e.g., Falmer, 1995 citing Welch, 1993). They also postulate the concept of multivoicedness (drawing on Bakhtin) evoking the notion of multiple selves. Further, the notion that, "language is neither inside nor outside, but *between* people ... [and] formed in a sociohistoric chain of situated utterances" (Prior, 2001, p. 59), underscores the *relationships* between people: the reader, the writer, and the text (Bowden, 1996) contributing to the notion of multiple voices.

Voice: Range

In academic contexts, distinctions are made between academic voice and personal voice, and there is an increasing recognition that students and faculty develop and use academic voices (distant, third person, with a pretense at objectivity), at great expense to their personal voices (intimate, first person, with no pretense at objectivity), (e.g., Wyche-Smith & Rose, 1990; Yancey, 1994). The argument here is that since academic discourse distances itself from experiential knowledge and from the emotions that inform intellect and experience, it alienates the self. Further, since academic discourse is valued over other types of discourse (at least in academic contexts), faculty become practiced at, and ask students to become practiced at valuing this alienation. Interestingly (but understandably in a patriarchal society), the dissatisfaction about the alienation is most often voiced by women. This is substantiated by work on women's voices (e.g., Belenky, Clinchy, Goldberger, & Tarule, 1986; Brown & Gilligan, 1992; Nugent, 1990).

Voice: Problematized

Even though most scholars of voice recognize that voice is simultaneously personal and social, there has been some concern that the expressionists' emphasis on personal voice results in discourse, which fails to adequately situate and locate voice in the social context. The critique of the politics of personal writing is valuable in terms of locating and connecting the self in context; courses in personal writing encourage egocentrism, "reduc[ing] the socially contextualized to the isolated" (Wershoven, 1991, p. 33). Personal writing that ignores the social, cultural, and historical norms of literacy, and writing in particular, may empower students to be themselves, but may not empower them within the academic context. While making this point, Wershoven (1991) argues that the politics are larger and more important than that of access to the academy:

> Making the step beyond "I," to the general, the abstract, the complex, is moving towards analysis and assessment of a whole world. ... Encouraging the students to consider the impersonal and abstract enables them to see, and even criticize the cluster of social, technological, economic, political and historical forces that form and deform the "I." Such thinking is true political empowerment because it frees the isolate from the limiting focus

on the self and proposes a linking of self and other, an integration of individual and society. (p. 34)

In the end, those who argue against the personal voice, argue that it is the quality of voice that matters, not simply having a voice. The personal voice that is isolated and decontextualized, may be, "the voice of those who have learned to be happy with little, to accept what is, and never to question" (Wershoven, 1991, p. 37).

Voices of Self-Study

I now turn from the literature on voice to the context of teacher education to show how the sociohistoric perspective on voice fits with the general notion of voice in self-study. I situate the heterophonic, multivoiced text, distinguished by authority and authenticity in the context of self-study in teacher education.

Dissonance in Teacher Education

Teacher educators and teacher education have always occupied an interesting place in the context of the university and in the context of schools. Much has been written about the low status of teacher educators within the university hierarchy and the clash between their obligations within school and university contexts (e.g., Judge, 1982; Lanier & Little, 1986; Schwebel, 1985). Teacher educators' preference for teaching in university contexts that mostly privilege research has also been well documented (e.g., American Association of Colleges for Teacher Education, 1989; Cruickshank, 1990). Teacher educators are criticized for not meeting university expectations of research and scholarship (e.g., Joyce, Howey, Harbeck, & Kluwin, 1977; Clark & Guba, 1977), while at the same time their research has been criticized as not being relevant to teachers and schools, teaching and learning (e.g., Loughran & Russell, 2002). Further, some teacher educators are dissatisfied when their research is separate and distant from their teaching, and with the way in which their research has often had no impact on their own teaching. In fact, the idea of dissonance so strongly reverberates through the teacher education community (given the differences in contexts it tries to straddle and the differences in research needs it attempts to meet), that in self-study research, the term 'living contradiction' (Whitehead, 1993) has come to symbolize the various dissonances that teacher educators live with and embody.

Self-study of teacher education practices attempts to bridge some of these discrepancies by explicitly recognizing the dissonance. As Russell (2002) explains:

In the teacher education classroom, most teacher educators are aware that their students can read every teaching move we make for an implicit message about how to teach. Those of us who are acutely aware of the potential for contradiction between the content and the process of our teaching and who

wish to minimize such contradictions seem to be drawn to the self-study of teacher education practices. (p. 3)

Self-study of teacher education practices attempts to bridge artificially distinct spheres (personal versus academic, emotional versus intellectual, schools versus universities, teaching versus research), in order to create personally and contextually relevant ways of knowing in the teacher-ly world (see Keith Miller's comment in Wyche-Smith & Rose, 1990, p. 46). It recognizes, for example, that traditionally, academic voices and personal voices belong to two different communities, and that, "language has no real existence outside of a community of discourse" (see Ed Lotto's comment in Wyche-Smith & Rose, 1990, p. 46). Yet, in recognizing the somewhat strange contexts it straddles, the voices of self-study are in the process of creating a discourse that is responsive to the contexts teacher educators find themselves in. In doing so, self-study merges the artificial barriers between genres that are supposed to describe certain voices. It recognizes the distinction between "scholarly voice" and the "scholar's own voice" (Wyche-Smith & Rose, 1990, p. 50). Self-study research serves as a means of exploring dissonance and bridging gaps.

> In teaching generally, and in teacher education particularly, there has been a long history of research that has had little influence on practice. One reason often cited by teachers themselves is that much of the research has little to say to them as the end users of such research. S-STEP [Self-Study of Teacher Education Practices] is largely driven by teacher educators' questions. Thus it is inevitable that the focus of inquiry is most commonly of immediate value to the practitioner, for it is in the manner of those inquiries that the results matter. Researchers intend to learn through their inquiries in ways that will inform their practice. (Loughran, 2002, pp. 241–242)

Characteristics of Self-Study: Reframing, Collaboration, and Openness

The concepts of reframing, collaboration, and openness (Barnes, 1998) have been postulated as a way to situate and locate the self in context, to capture the diversity of voices, and to support the potential of self-study to provide cohesiveness to the fragmented world of teacher education. These notions frame self-study primarily in relationship with the other (e.g., Griffiths, 2002). I describe these notions briefly so that readers may contextualize the heterophonic and multivoiced nature of self-study work.

Reframing

The notion of reframing (Schon, 1983) is central to self-study. It allows the researchers to explore living contradictions by considering multiple perspectives and thereby situating the self and all the other players in context. As Loughran (2002) explains:

> It is not sufficient to simply view a situation from one perspective. Reframing is seeing a situation through others' eyes. For the teacher educator, a given dilemma, contradiction, or sense of discomfort may actually be associated with being the student rather than being the teacher. Hence there is an ongoing need to be able to view the teaching and learning situation from different perspectives. If all of the problems to be investigated are solely from the teacher educator's perspective, then a myriad of teaching and learning perspectives would, sadly, be ignored. (p. 243)

This reframing is made starkly evident in, for example, Loughran and Northfield's (1996) *Opening the Classroom Door: Teacher, Researcher, Learner*, where the book accounts for the teacher's perspective and the students' perspectives of critical events before considering the implications for teaching and teacher education.

Collaboration

In what Loughran and Northfield (1998, p. 7) call, "a significant paradox" within the term 'self-study,' they argue that while the experience of an individual may be the focus of the self-study, the work of self-study is a collaborative task. Collaboration in self-study enhances learning and understanding, and supports more and better reframing. While Jeff Northfield provided the teacher's perspective (Loughran & Northfield, 1996), Carol Jones collected data around students' perspectives, and John Loughran was the, "colleague who was able to remain at a distance from the experience and see the trends developing over the year" (Loughran & Northfield, 1996, p. xi).

While collaboration occurs in many self-studies (e.g., Conle, Louden, & Mildon, 1998; LaBoskey, Davies-Samway, & Garcia, 1998; Lomax, Evans, & Parker, 1998), there are also considerable individual self-studies (e.g., Gipe, 1998; Hutchinson, 1998; Oda, 1998). Hamilton (1998), describes these individual self-studies as:

> Systematically bring[ing] to bear all of their past experiences, understandings, scholarly perspectives, and theoretical frames to make sense of the experiences within which they are engaged. Critical reflection becomes an essential tool in this [individual] form of study. (p. 111)

In all of this work, authors have systematically collected data around student perspectives in order to enhance reframing, and of course, finally these studies are shared with an audience who potentially provide other perspectives or frames.

Openness

Since self-study entails vulnerability by exposing pedagogical approaches, curriculum challenges and reform 'failures', the nature of relationships between colleagues becomes critical (Barnes, 1998). One's living contradictions are exposed as well as contradictions of the self-study. Authority has to be debated and

negotiated so that vulnerabilities may be exposed (Barnes, 1998). The quality of openness is crucial to self-study in order for reframing and collaboration to occur in successful ways.

The characteristics of reframing, collaboration, and openness support the notion of heterophonic and multivoiced texts in self-study research.

Heterophonic Voice in Self-Study

Voice in self-study is heterophonic, "a third voice which is neither culture nor psyche, but both" (Fleckenstein, 1997, p. 475); it is simultaneously personal and social (Prior, 2001). Even as the *self* in self-study is prominent at first glance, and self-study is inaccurately critiqued as 'navel-gazing' (e.g., Hamilton, 1998), or as overly personal, self-study researchers have from the very beginning, grappled with notions of self. This is evident, for example, in Whitehead's (1996) question, "Who is the 'we' in self-study research?" and in the question, "How and why is self-study research?", raised by Munby (1996) and pursued by Cole and Knowles (1996).

Self-Study as Multivoiced Texts

Sociohistorical perspectives (Bakhtin and Vygotsky) suggest that texts are always multivoiced because it is not only the voice of the writer but also the voice of the reader that needs to be considered in the negotiation of meaning. Authors of work in self-study suggest that audience is critical to the work of self-study, contributing multiple perspectives and understandings. Loughran and Northfield (1998), for example, suggest:

> Just as self-study is not an individual task but is best seen as a collaborative enterprise, so too the reporting of self-study is influenced by the intended audience of the report. If self-study is to move beyond the individual, it needs to resonate with others in similar situations. Therefore, the way self-study is reported is important in helping to make the findings clear and meaningful to others. Obviously, then, the form of reporting is shaped by the audience and an understanding of the relevant needs and concerns of this audience. (pp. 15–16)

Yet the voices of the authors and audience are only one layer of the multivoiced text. Many (e.g., Majors, 1998; Matsuda, 1999; Yancey 1994) suggest (drawing on similar theory) that within a so-called single voice are many voices – "multiple ways of representing reality" (Wertsch, 1991, p. 13 cited in Majors, 1998, p. 81), that come, in part, from having experienced dissonance (Majors, 1998).

In a postmodern world the idea of a coherent, autonomous self has given way to the idea of multiple selves that reflect a plurality of voices. "The 'I' writing is not singular, but plural, a fluid composite of cultural voices and individual selves within the writer" (Yancey, 1994, p. xi). In addition, the Bakhtinian notion of multivoicedness also exposes the false dichotomies of academic and personal

discourse, form and content, intellect and emotion, etc., (Falmer, 1995), suggesting that these may be present simultaneously.

Especially in its formative years self-study work was concerned with the investigation of the self. In a sense, the self had to be deconstructed in order to be reconstructed and many self-studies explored the possibilities of the self. For example, deconstructing the self in self-study work provided the opportunity to discuss the, *negotiated and shared self* (Rasberry, 1996), and the uncovering of the *hidden selves* (Campbell Williams, 1996). Able to give voice to living contradictions (e.g., Upitis, 1996), the coherence of selves came undone and the plurality of selves became evident (Griffiths, 1996). By examining the contradictions and paradoxes in teaching and self (Wilkes, 1996), and taking on roles of teacher educator and researcher (Holt-Reynolds, 1998), librarian and teacher (Casey, 1998), the unity of self came to be questioned (Griffiths, 1996) in self-study research. Through the work of self-study it became evident that voice in self-study, "is not singular, but multiple, a medium created through the weaving of different strands of self – or selves – into the fabric that at best only pretends to be whole" (Yancey, 1994, p. xi).

Other researchers (e.g., Jones Royster, 1996; Nakayama, 1997; Ono, 1997) draw on cultural and postcolonial studies (e.g., Anzuldua & Keating, 2002; Spivak (see Landry & MacLean, 1996); Mohanty, 2003; Bhaba, 1994) to show how multiple selves and multiple voices have evolved as a consequence of dissonance experienced by 'hybrid people'. These 'hybrid people' are those who, "move with dexterity across cultural boundaries, to make themselves comfortable, and to make sense amid the chaos of difference" (Jones Royster, 1996, p. 37).

The dissonance in the field of teacher education, experienced by teacher educators as they attempt to work with at least two landscapes (university and school), multiple populations and voices (e.g., students in the university and school, teachers in the university and school, administrations in the university and school), and demands for different kinds of research (in the university and school) may be likened to the 'hybrid people' in cultural and postcolonial studies. Loughran (2002) observes:

> Self-study offers some teacher educators a way of being liberated in their practice in a system that is often far too restrictive. Thus self-study creates opportunities to develop the relationships and understandings in teaching and learning that tend to characterize much of the work of teachers, but have largely been ignored in the past by academia. (p. 245)

Voices in self-study are heterophonic and polyphonous, together constructing a new landscape in teacher education by explicitly recognizing and dealing with contextual dissonances and living contradictions in practice. I now turn to the idea of authority and authenticity in voice, and examine whether voices in self-study research are authoritative and authentic.

Authority of Voice in Self-Study

Exploring reasons why many students lack 'authentic voice' (Stewart, 1986), Rose (1989, p. 111) defines, "a writer's voice [as] an expression of her authority."

She suggests that, "students do not convey their authority in texts because students have no authority" (p. 116). Establishing that it is the teachers in the classroom who have the expertise and the power, she argues that students need to practice "claiming the power" (p. 118), because authority of voice is not simply about meeting complex cognitive demands in writing.

Reflecting on her experiences as a young African-American student from her current position as a teacher, McElroy-Johnson (1993) underscores the idea of power:

> Voice is identity, a sense of self, a sense of relationship to others, and a sense of purpose. Voice is power – power to express ideas and convictions, power to direct and shape an individual life, towards a productive and positive fulfillment for self, family, community, nation, and the world. (pp. 85–86)

In fact she argues that there is a direct relationship between teacher voice and student voice:

> In order for students to develop their voice, the teacher's voice must be clear, distinct, and above-board ... I'd venture to say that many students ... need to hear a teacher's strong voice in order to feel secure in developing their own voices. (p. 102)

In spite of teacher power over students, there has been ongoing concern that teachers in schools do not have enough authority in the daily happenings in schools, and little power over the curriculum they teach and the way they teach it (Hargraves, 1996). While teacher educators in general have authority in their classrooms and in their curriculum and pedagogy, they too suggest that their authority is curtailed in the conflicts between the university and school structures, between the structure of the tenure system and needs of schools, and because of their continually marginalized status in university and school contexts (e.g., The Arizona Group, 1996; Knowles & Cole, 1998).

Educational reform movements, especially in the last quarter of the twentieth century have tried to support teacher authority and voice through narrative research. Yet representing teachers through narrative research has revealed concerns that teachers are still left with very little or no voice. One concern is that the teachers' voices are not situated within the sociohistoric context; they remain narrated voices instead of located and contextualized voices (Carter, 1993; Goodson, 1997). Further, in the narrative genre, teachers may only be represented if they speak in a voice that is congruent with that of the researcher, or worse, their voice may be interpreted as being congruent with the voice of the researcher, when it actually is not (Carter, 1993; Goodson, 1997; Hargraves, 1996).

For example, Goodson (1997) warns that, "stories and narratives can form an unintended coalition with those forces which would divorce the teacher from knowledge of political and micropolitical perspectives from theory, from broader

cognitive maps of influence and power" (p. 111). In effect, Goodson suggests that teachers might end up with less rather than more power, reinforcing Wershoven's (1991) critique about personal voice. He emphasizes that stories, "should not only be *narrated* but *located*" (p. 113; see also Carter 1993). Drawing on Denzin (1993), he suggests that narration of teacher stories is "academic colonialization" because, "the other [i.e., the teacher] becomes an extension of the author's voice. The authority of their 'original' voice is now subsumed within the larger text and its double-agency" (Goodson, 1997, p. 17).

Hargreaves (1996) points to another authority related problem with the genre of narrative – the problem of representing some teachers' voices over others. He notes that, "these teachers' voices are not randomly representative voices. They are selectively appropriated ones" (p. 13). Often only teachers with a particular voice and/or orientation to teaching are represented.

> Instead of searching for and listening appreciatively to voices that differ, voices that jar, voices that might even offend, we are perhaps too ready to hear only those voices that broadly echo our own. (Hargreaves, 1996, p. 13)

Hargreaves reminds researchers engaged in representing teachers' voices that contextual comparisons are essential to appropriate understanding and representation, "so that claims regarding the teacher's voice can be built through cumulative generalization, not moral assertion!" (1996, p. 17).

Self-study, I argue here, is able to eliminate in large part, the problem of academic colonialization and the problem of selective representation. Underlying both of these problems in narrative research is the idea that the teacher's voice is not located and contextualized enough. Representing teachers' voices through narrative in these ways then may result in less power for teachers rather than more power, despite our best intentions.

Self-study work eliminates the problem of academic colonialization because teachers and teacher educators represent their own voices in the research. Teachers and teacher educators may work together, and this allows for reframing and multiple perspectives rather than simply a re-presentation of voice. Further, anybody interested in self-study can do self-study research. However, since one is drawn to self-study research because one wants to engage in examining the "living contradictions in their practice" (Russell, 2002), there is an inherent selection bias in those who engage in self-study. In sum, self-study research fosters an authority of voice by being inclusive of teachers and teacher-educators, by reframing for multiple perspectives rather than re-presenting, and by collaborating rather than colonizing. Since voice in self-study strives to be simultaneously personal and social, it attempts to locate voice in the social, cultural, and political contexts of education.

Authenticity of Voice in Self-Study

In the research and dialogue on voice, the expressionists (e.g., Elbow, Macrorie, Murray, and Stewart) have made an integral connection between voice and

authenticity, the same kind of inextricability that voice and authority seem to have. Stewart (1992) writes of authenticity in this way:

> That a writer may adopt a number of superficially different surface voices I do not deny, but I will strenuously continue to affirm that any good writer has a single identifiable voice running beneath all his or her work, regardless of context or genre. (p. 288)

How one portrays and communicates this authenticity is important as it relates to voice, especially since voice almost always connotes communication through language. Consider Prior's (2001) assessment of voice:

> There is one deep flaw in the notion of voice, the way it continues to privilege language at the expense of the full semiotic toolkit (e.g., see Kress 1997; Wertsch, 1998; Witte, 1992). However, for nonverbal, visual, and material signs, there is not a term that so clearly connects the person to the semiotic means. ... A dialogic, sociohistoric notion of "voice" may not be perfect, but it does offer resources for getting beyond the binary of the personal and the social, for taking a complex view of agency as distributed across persons, practices, artifacts, and cultural activity systems. (p. 79)

In a wonderful play on languages as systems, Nakayama, drawing on Roland Barthes, writes of the challenges he faced as he tried to make sense as a hybrid person of *the strangeness that exists between our voices and ourselves.*

> I once thought that escaping into another language would always be the answer to these challenges. From between languages – or more accurately – between social systems imbedded in languages, I could find new voices, voices of the other. Les voix de l'autre. The problems in moving from one language to another, in translating, seem less like "problems" and more like ways of empowerment. The incompatibility and never perfect fit between languages gives us different ways of speaking, of living, of identity. (Nakayama, 1997, p. 235)

Nakayama suggests here, that communicating in different ways is empowering, the spaces and the seeming disconnectedness provides other ways of knowing and being, and the opportunity to hear other voices.

Denzin (1995) and Eisner (1991) argue that, "a new form of looking, hearing, and feeling must be cultivated; a form that goes beyond the masculine way of seeing" (Denzin, 1995, p. 17), in understanding and representing educational research. As an example of how mainstream ways of methodology and representation may constrain ways of knowing, Brown and Gilligan (1992) in their research on the development of girls' voices confess:

> We had come to the school to understand more about girls' responses to a dominant culture that is out of tune with girls' voices ... and yet unwittingly we set into motion a method of psychological inquiry appropriated from

> this very system. Constrained by our own design, we found ourselves losing voice and losing relationships in our own research project. (p. 10)

Building on Prior and Nakayama's work on voice, and the work of Denzin (1995) and Eisner (1991), I argue that the curious experiences of dissonance and the complex nature of the spaces they inhabit, encourage self-study researchers to push the boundaries of traditional forms of representation in order to represent themselves in authentic ways.

While the dominant form of representing self-study is still written narrative (both because it is familiar, and because refereed journal articles and books are still the dominant criteria for obtaining tenure), self-study researchers have experimented with different ways of knowing such as art and drama (portraits, painting, readers theater, photography, mime, etc.) in order to portray themselves and their work in authentic ways. Because self-study research seeks to preserve complexity and because these researchers often emphasize process rather than product, alternative forms of representation seem to respond well to both methodology in, and findings of, self-study (e.g., Allender & Manke, 2002; Childs, 2002; Cockrell, Placier, Burgoyne, Welch, & Cockrell, 2002; Derry 2002; Cole & McIntyre, 2001; Hamilton, 2002; Perselli, 2002; Tidwell, 2002; Weber & Mitchell, 2002). It becomes obvious that in trying to create and explore new landscapes, new methodology may be required, and new methodology may require new forms of representation and communication. Researchers of self-study seem to be engaged in that work.

I now turn to examine the heterophonic and multivoiced text of one self-study (Fernandez & Mitchell, 2002) and the notions of authority and authenticity within it.

An Example of Self-Study

Choices and voices: Students take control of their writing

Kerry Fernandez and Judie Mitchell (2002)

This self-study represents one of many topics of interest in self-study, just one way of going about self-study, and one way of representing and reporting self-study. I have chosen to use it to explore voice in self-study because not only does it present itself as an example of voice in self-study, but the authors also explore the issue of voice as part of the self-study, bringing to the forefront the authority of voice. The authors are teachers in schools, not teacher educators, and I have chosen this study because it symbolizes the inclusion of teachers (with teacher educators) in self-study research, something that has not frequently characterized other genres of educational research.

Methodologically, the authors use reframing, collaboration, and openness to report and represent in written narrative (still the predominant form of reporting and dissemination in self-study), a multi-vocal text. Yet, it suggests other forms of representation through its findings, allowing us to consider the authenticity

of voice in a variety of forms. While I need to describe the study in order to provide a context, my own comments are italicized to differentiate them from the description of the study. I show, through a description and elaboration of this study, that voice in self-study is heterophonic and multivoiced. I also show how the voices in this self-study are authoritative and authentic.

This study is based in PAVOT (Perspective and Voice of the Teacher), which in turn had its roots in PEEL (Project for the Enhancement of Effective Learning; Baird & Mitchell, 1986; Baird & Northfield, 1992; Loughran, 1999). The PEEL project, initiated in 1985, "included a group of teachers meeting together on a regular basis to discuss their attempts to improve the quality of students' classroom learning" (Loughran, 2002, p. 5). PAVOT evolved in order to:

> Assist teachers to research aspects of their practice. It is a natural extension of PEEL in that it aims to support teachers in documenting and communicating the kind of teaching and learning that occurs with active involvement in PEEL, and to further explore issues which are important to teachers in their daily work. (Loughran, 2002, p. 9, citing Mitchell & Mitchell, 1997, p. 3)

Situated in the context of PAVOT and PEEL, it suggests that Kerry Fernandez and Judie Mitchell were both interested in exploring classroom practices and student learning, (specifically, teaching and learning writing). It seems that Kerry was open to exploring "living contradictions" in her practice and was open to (and sought) Judie's collaboration. I set the context of Fernandez and Mitchell's self-study by quoting extensively to give the reader a sense of the voices involved, and a sense of how the authors view voice:

> This story has a number of characters. The characters in this multivocal text are the 25 students of 7B; the English teacher/observer, Kerry Fernandez; and Judie Mitchell, a colleague and observer. It is the combination of the voices that produces the narrative and the story is incomplete and inconclusive if any one voice is dominant or omitted. We have chosen to tell this story as a narrative, in our own voices. A complexity of perspectives is evident in the different individual experiences of the 25 students of 7B (Year 7 being the first year of high school). These students had been together as a class for approximately six months when this series of writing lessons began. They came from various primary schools, both government and Catholic, within the local area. (p. 21)

This opening paragraph suggests that Kerry and Judie considered voice an important issue, and that they perceived voice from a sociohistoric and dialogic perspective. They intended the study to be a multivocal text (25 students and 2 teachers). They also intended that the study would be inclusive in a democratic manner, suggesting that the different backgrounds of the students would be important considerations.

The text as multivocal is highlighted at the start of the study. Through their

collaboration, the text consists of at least two voices (Kerry and Judie's), voices that are clearly identified. Even though Kerry and Judie report the self-study in their own voices, their voices are informed by the voices of the 25 students. In addition, they also represent the voices of the students in the text.

Kerry was interested in creating an atmosphere that would encourage students to engage enjoyably in the process of writing or "the construction of their own texts" (p. 22). Intrigued by metacognition, she wanted to, "alter students' perceptions of school writing by creating a positive episode, or succession of episodes" (p. 22). So together with Judie, she asked students how they felt about writing, and then, what would make writing more enjoyable. Kerry then developed, "a unit of loosely constructed lesson plans that incorporated the students' ideas" (pp. 26–27) for writing sessions, once a week the following semester. Data collected included, "student surveys, student texts, audio taped interviews and the field notes made by Judie as she viewed and interacted with the students. There were also observations and notes made by [Kerry] as 7B's English teacher. … A video was also made of a discussion session conducted twelve months after … data collection began" (pp. 21–22).

It seems that Kerry was interested in getting her students to develop their personal voices in their writing. She wanted them to have ownership in constructing texts. To do this, she gave them opportunities to voice their views on writing. Kerry (and Judie) seemed to have an understanding of the inextricable relationship between spoken and written voice (Keithley, 1992; Rose, 1989), and realized that one way of exploring voice in writing was through spoken voice. This suggests that Kerry valued both the spoken and written voice in the classroom. Written, audio, and visual texts were all sought as appropriate data. The text consists of written, verbal, and visual (transcribed) voices.

There were only four students who claimed to like writing in response to the first statement: "Put your hand up if you like writing" (p. 23). When asked to raise their hands if they did not like writing, "a cacophony of voices rose round the classroom" (p. 23). The most common response was that writing was "boring:"

> Last year in Grade 6 we had to do an hour and a half every day and we got sick of it. (p. 23)

> If I need help, I have to wait for the teacher. I had to keep my hand up and my arm got sore. (p. 23)

> The pen runs out. It's also a waste of paper when you have to do drafts. (p. 24)

> Maybe stories are boring because the writer wants them to be boring. (p. 24)

The first three of the four comments I have selected from the Fernandez and Mitchell (2002) text suggest that the students found writing boring because of the context – forced writing for long periods, waiting interminably for the teacher, having to draft and redraft and refill pens, etc. (I have tried to select comments

that represent the range of comments). Yet, these are also the kind of comments that are frequently dismissed by teachers (if they do solicit students' input) as irrelevant to the topic of writing. Teacher responses such as: "practice makes perfect," "put your hand down and put it up again when I look up," and "refill your pen," dismiss the students' comments, not because the teacher necessarily intends to be rude, but because the teacher may see these comments as separate from the writing process and as an essential part of the schooling process. Kerry and Judie seem to take all student responses seriously because of their intention to reframe the writing process (both for themselves and their students). They understand, and make evident in the study that the writing process is contextualized by the schooling process.

The last comment, as Kerry points out, is interesting. She asks: "When there is little or no incentive to write, is there a lack of intrinsic motivation?" (p. 24), pointing to the incentive to communicate. Kerry has framed the writing process in the larger context of communication and begins to see the contradictions between writing within the context of schools and writing within the context of communicating.

Here, Kerry (and Judie's) voices are heterophonic. Writing about the problem at hand, they are careful to situate it in the context of school processes and communication processes. Because they do this, they are able to take students' comments seriously and not dismiss them.

Asked "what would make writing more enjoyable?" they discussed, wrote comments, and shared them with "great enthusiasm" (p. 24). Kerry and Judie present the wide range of their recommendations; I present a (representative) few of those:

> More action, more Spice Girls, less drafts. (p. 24)

> Write stories in a group. Do just one copy. It helps knowing it will get somewhere. Make it into a play, a film or a book. (p. 25)

> Include real people. Make it something that you would want to read. (p. 25)

> Write any words or things you want. Write a story with your friends so that it has different ideas in it. (p. 25)

> Make it into a video, a play or a book. Talk about it instead of writing about it. (p. 25)

Reflecting on the students' comments, Judie emphasizes that a salient characteristic of the students' suggestions is that "language is communication",

> I saw three main areas of student complaint. The first was the individualistic nature of the writing they had to do. Secondly, they felt they had to write too much and too often. Thirdly, they wanted more control over their texts – what form they would take, the language they used and who and what could be included. (p. 26)

The students' comments and Judie's interpretations of their comments could fall into two categories based in the literature on voice: a) authority; and, b) authenticity. Students suggested that they should write in order to communicate what they wanted to communicate and in ways that they wanted to communicate, rather than write in order to practice writing.

Further, most of the comments suggested less actual writing (through group work, less drafting, and talking), and more "real" ways of communication (film, book, play, video, etc.). Teachers might, in general, be suspicious of suggestions from students that discourage writing when the purpose of soliciting feedback is to encourage writing! Yet, Kerry and Judie were able to frame these comments in the larger context of communication. This in particular, seems to require trust in the students and an openness to the situation.

Following the students' suggestions, Kerry developed a unit for writing and explained to the students that apart from genre and censorship of language, "students had total control over what kinds of texts they wrote and how they wrote them". She writes: "I was prepared to take the risk of following the direction of the students. This proved to be a decisive turning point in my own appreciation of the way in which texts are constructed" (p. 27).

Having set the guidelines, students proceeded to work in groups formed mostly around "lines of gender and issues of social development" (p. 27). Kerry writes:

> Having selected their own groupings, the following lessons were highly productive. They wrote practically nothing! However, what was achieved was a total immersion in communication. Essentially what they were being asked to do was to solve a problem. The problem was to construct an adventure text. They used problem solving communicative techniques to achieve this end. … Prior to writing, they discussed, they play-acted, they debated and argued, until a resolution was achieved by the group. (p. 27)

Kerry uses Vygotsky's (1986) social interactionist theory to explain student dynamics – "individuals relate mutually to produce an effective communication, by voice, gesture and facial expression" (p. 28). About the context, she writes:

> The writing sessions took place during one period per week over the second semester and culminated in the videotaping of the performance pieces, the reading of the stories and the displaying of the cartoons. This time frame allowed other areas of the English curriculum to be addressed. (p. 28)

Kerry not only responded to the students' ideas, but she showed an openness that finally allowed her own understanding of writing in the classroom to grow. Imagine – students wrote practically nothing! When they wrote "practically nothing", Kerry did not demand that they write. Instead, because she saw writing primarily as a form of communication, she realized that they were communicating in alternative ways. But of course, the nagging question, for me, the reader is: "Did they write at all?," and, "If so, what was the quality of their writing?" Judie responds:

> The task overcame all three of the students' objections to writing. They

worked in social groups as a community of speakers and writers, sharing their voices and ideas. The resulting student texts were rich and vibrant – illustrating vividly the extensive textual histories these students already possessed, at the ages of 12 and 13. Their texts were full of, but not derivative of, the adventure films they had seen, the TV shows they had watched and the video games they played. (p. 28)

Based on her field notes, Judie observes that she was surprised that, "given the opportunity, the majority of students began immediately to think of their writing in terms of much more than simply words on a page" (p. 29). She writes that they were engaged in Discourse rather than simply discourse, citing Gee (1996), who wrote that, "Discourses are ways of being in the world, or forms of life which integrate words, acts, values, beliefs and social identities, as well as gestures, glances, body positions, and clothes" (p. 127).

Kerry observed that the process caused the students to see her as a "reference point" rather than the English teacher (p. 31). She writes: "What I observed was groups of young people using speech and other ways of communicating to organize their collective ideas. In their groups, they were transferring their ideas into written language in a very personally meaningful way" (p. 31).

The students wrote richly and vividly, co-constructing their texts. They engaged in discourse to communicate, and writing was simply part of the act of communication. The students reframed Kerry's role from English teacher to "reference point." They were engaged in communicating with each other, and did not need a teacher telling them what to do.

Moving to the findings of the study, Kerry and Judie ask: "Was an episode created? Did it change their views?" Twelve months after the writing episode, a class discussion was videotaped. During that class discussion students were invited to discuss what they remembered about the episode. Kerry and Judie conclude that though an episode was created, it did not change students' views about writing. They suggest that one writing episode, even though over a twelve week period, was not powerful enough, "to impact on these students' memories of years of boring school writing tasks" (p. 31). Yet they record:

> [Students] remembered vividly many aspects of the writing episode. The context of the discussion was interesting too – when Kerry asked them to move into the groups they had been in for the writing, they did so immediately and animatedly, even though there had been a number of changes in the class; some students were no longer present, and some had not been there in 1998. (p. 31)

They also remembered a number of details – that they were able to "use language" (or negotiated swear words) and significant lines from their texts (e.g., "You are an un*imag*inable bastard"). They recalled that they loved working in groups, having choices, not having to do individual drafts, and working with their friends because,

'We knew what each other was like.' One student stated that it was the 'first *real* story that we've been writing'. They remembered who had what parts in the plays, being able to play with their props, act out their roles, and 'use our voices.' (p. 33)

One group, however, had negative memories of the episode because they felt that one student controlled the process of writing. The mixed-sex group also had had disagreements over the content of their play.

The students who had positive experiences were authentically engaged in the process and claimed authority over it. They wrote "real" stories, and got to use their "voices". The two groups who had negative experiences claimed not to have authority over the process and their work. An episode was definitely created: students remembered significant positive and negative aspects about the process.

When asked if they had changed their ideas about writing, Kerry and Judie write about the students' responses:

Their comments were a depressing repetition of the comments from twelve months earlier. In trying to probe why this might be, it seemed that they regarded this episode as too different from their usual school writing.

'It wasn't just like writing, it was drama too.'

'It was a different sort of writing – that's why it was fun.' (pp. 33–34)

Trying to find meaning in the findings, Judie turns to a structural analysis in schools that puts school writing, and the findings in context:

Much of the individualisation of writing in schools is driven by assessment – as teachers, we don't always want the hassles of dealing with group problems and ascertaining which student has contributed what to a group project. The outcomes-driven nature of the state's [Victoria's] curriculum documents force us into these positions as well – we are forced into reporting on whether Cindy in Year 8 can individually measure up to a certain standard. We are forced to put into the background other important skills that Cindy may have, such as being willing to collaborate and share ideas with her peers, and mentoring a less able friend in the art of spelling. In the final two years of secondary schooling, we are constrained by the apparent necessity of 'authentication' – the need to be 'certain' it is the student's own work. (p. 34)

Judie makes the case that school writing is very different than any other writing, because in general, writing beyond school has consequences, is collaborative, has a defined purpose, and an audience.

Judie's writing is heterophonic – it is simultaneously personal and social. Trying to find meaning in students' attitudes towards writing despite the significant episode, she narrates students' responses and then locates them within the context of assessment. It is not that the students did not "get it;" that explanation is too

simplistic. Importantly, what Judie and Kerry learned through this self-study is that over the years, students have made clear distinctions between writing in school contexts and writing to communicate. Judie locates the reasons for this partly in teachers' responsibilities of assessment given the rigid curriculum. In doing so, she is able to locate the narrative and the problem in the larger context of education.

She also puts Kerry's role as a teacher and facilitator in context. Regarding Kerry's vulnerability and openness, Judie writes:

> The episode Kerry provided for the students of 7B involved considerable risks. It would have been much easier for her and her mental health to have forced the students to write individual stories seated at their desks in silence. They would have hated it but they would have done it (without much of a murmur, because they are rarely asked for their opinions). Instead, Kerry found herself with a bunch of noisy, active Year 7 students who repeatedly tested the boundaries of what was and was not 'allowed'. She needed to be flexible in her timing; she could not put arbitrary time frames on this task – as she says, it was a problem-solving exercise and any artificial time frame would destroy the 'scientific method'. The fact that they chose to write plays meant organising and stage managing a dramatic space and a major performance. (p. 35)

The students appreciated Kerry's efforts. They noted, for example, the relationship between rigid boundaries and learning:

> You learn more if there is [sic] not so many boundaries. If you've got so many boundaries, like you can't do this and you can't do that, then you can't experience more things so you don't learn more things. (p. 35)

Here Judie returns back to the situation at hand – and the personal. She explains the considerable risks that Kerry undertook – the giving up of traditional authority in the classroom to take on a new form of authority. But even here, in accounting for the immediate situation, Judie locates Kerry in the larger context of schooling. While her intention is to applaud Kerry on her risk-taking and openness, she also clearly suggests that school contexts are not necessarily conducive to these types of attitudes and behaviors, for teachers or for students.

While this self-study is a heterophonic, multivoiced text, are the voices in this text also authoritative and authentic? I suggest that much like the students in the self-study who engaged in the episode because they were attempting to communicate in authoritative and authentic ways, Kerry and Judie's voices in this text are authoritative and authentic. They were able to reframe the problem situation rather than simply represent themselves, and they were able to reframe the situation by taking into consideration multiple perspectives. In short, they have established voices of authority in their self-study. Just as the students experimented with multiple ways of communication (e.g., drama, video, etc.) to present their solutions to the problem in authentic ways, so Kerry and Judie engage with the self-study and the text in authentic ways. The manner in which

I, the reader, engage in their text, is just one perspective on the authenticity of their voice.

Potential Problems and Possibilities: Constructing a New Landscape Through Voices in Self-Study Research

Voice in self-study may be one effective way to determine whether teachers and teacher educators believe they have an authority and authenticity in the work that they do. Self-study research may serve to empower teachers and teacher educators in their work. Yet, with a single-minded focus on voice in self-study research, we may lose sight of the most important goal: providing contexts in which students may develop and use their own voices and feel empowered (as Kerry and Judie did). Even as we continue to encourage and track the development of voices of teachers and teacher educators, it is imperative that we remember that our success may only be measured by the success of our students.

The biggest challenge for self-study research as it emerges into mainstream teacher education is its ability to preserve its many voices while making those voices heard. Historically and traditionally, movements and grassroots organizations (e.g., the woman's movement in the U.S.A.), have had to be exclusionary in order to provide a unified front to gain power and access. For example, the woman's movement in the U.S. excluded diverse voices (of women of color) in order to provide a strong, unified stand and be considered more acceptable in mainstream society. When they fought for their rights they were fighting for the rights of certain women – women who represented that unified voice.

Currently, the voices in self-study research are diverse, vibrant voices that are authoritative and authentic. They represent a range of methods in self-study research and are presented in a multitude of forms. While focusing on the self, these voices say many important things about the contexts of teaching, learning, and teacher education. Because self-study research recognizes multiple contexts and multiple selves, the work and findings are complex. While principles of self-study research need to continue to be generated, generalizations must be cautious with an eye towards inclusion. In excluding some voices in self-study research, the work might possibly be presented as more coherent and unified, but it will be narrow and confined, much less rich and vibrant.

The impact of self-study research in the fields of teaching and teacher education will necessarily be slow as long as it preserves its many voices and does not seek one unified voice from many diverse voices. In considering the impact of ten years of self-study work, Russell (2002) observes:

> While self-study has not transformed teacher education in its first ten years, self-study of teacher education practices has rapidly generated a new landscape for professional dialogue among teacher educators and between teacher educators and both new and experienced teachers. On that new landscape, the self is the focal point for studying the intersection of theory and practice. Teacher education has long been criticized for its inability to

practice what it preaches. Self-study appears to be a powerful way to respond to such criticisms. (p. 9)

I have argued in this chapter that the voices in self-study research are integral to creating and exploring a new landscape in teacher education that is able to bridge long-standing gaps. These voices are heterophonic and polyphonous, authoritative and authentic. They highlight dissonance and living contradictions within teacher education contexts. In doing so, they are creating a discourse that is responsive to the contexts of teachers and teacher educators. This is the new discourse of the new landscape in teacher education.

SELF-STUDY IN PROFESSIONAL PRACTICE*

Susan Wilcox[a], Jinx Watson[b] and Margo Paterson[a]
[a] *Queen's University;* [b] *University of Tennessee*

Abstract

Professionals across fields claim to learn much from experience. Self-study as an approach to learning about one's work and theories in use offers explicit methodologies, including reflective reading, transformative professional development and inquiry to inform professional artistry. These three approaches look for patterns of beliefs and values that assist practitioners to know themselves more authentically within the dimensions of their work. Most professions set standards for individual growth and development that, in turn, affect organizational progress. Nevertheless, few, if any, consider self-study as an explicit means for reaching personal/professional goals or gaining insight into individuals' strengths and weaknesses. This chapter addresses the needs of both novice and seasoned practitioners who continue to learn about themselves within the context of their work. It offers both rationale and examples for learning how to examine personal motives and assumptions within the explicit technical and implicit human expectations of the helping professions, this chapter draws on three examples the: librarian, postsecondary teacher and, occupational therapist.

This chapter will demonstrate how self-study is applicable and useable in fields of professional practice beyond teacher education, and draw links between self-study and research with congruent purposes in other professional practice settings. In particular, it will pay attention to self-study as a form of reflective professional practice, self-directed and transformative professional development, and practitioner inquiry to inform professional artistry. Illustrations from three fields (library science, higher education, occupational therapy) will show how approaches to self-study can differ in focus and intent, and will also highlight strategies and themes common to self-study in different professional settings.

---

*Chapter consultants: Sandra Weber, McGill University, Canada, and John Baird, University of Melbourne, Australia.

One theme to be explored is the issue of novice vs. seasoned practitioner: are some approaches better suited to practitioners at different stages in their development? Another theme is the holistic nature of self-study: each of the three approaches looks for patterns of beliefs or values that help individual practitioners know themselves in an authentic manner. The chapter also affords a critical perspective on the current state of self-study in teacher education settings and concludes with suggestions for ways forward that will be meaningful across fields of professional practice.

The approaches to self-study research we review in this chapter illustrate practice – and practitioner – based alternatives to the scientific/positivistic paradigm (Fish, 1998). The purposes of practitioner research are to improve practice and/or develop the practitioner (though the goal is not entirely instrumental), and to engage in research through a research process that is itself a form of practice (i.e., not separate from practice). The first approach we present emphasizes the interpretive perspective; key features of interpretive self-study are reflection and reflective professional practice. The second perspective is critical or transformational and takes its cues from the self-directed and transformative adult learning tradition. The third approach to self-study is an emphasis on the artistic; the emphasis is on practical inquiry intended to enlighten the artistry of practice.

In writing this chapter, we have two different audiences in mind. The first audience comprises those in professions other than teaching who could benefit from knowledge of the self-study movement, especially in terms of strategies for self-study. Most professions expect their members to be self-aware and self-reflective, but may not provide them with educational strategies to achieve this outcome. In fact, many professions do not consider self-study (gaining a better understanding of self-motives, personal agendas, assumptions, goals, personal strengths/weaknesses, etc.) to be part of the professional education process per se, but rather something that individual professionals should engage in implicitly as a matter of course in the form of personal development. Our chapter may alter that perception. Further, self-study in professional practice is new and it is therefore difficult to direct readers to literature in our areas of practice. However, we are able to illustrate ways into self-study through descriptions of our own work; and that is what we do in this chapter. In so doing, we invite members of other professions to follow our lead and to take the ideas of self-study and adapt them to different practice settings. The second audience comprises teachers and teacher educators who advocate and practice self-study in teacher education. We believe members of this group could benefit from a description of approaches similar to self-study used in other professional fields of practice and so the rich descriptions we offer in this chapter, we trust, will create new opportunities for these readers.

Schön (1983) suggests that all "helping professions," including ministry, social work and other endeavors of caring work with people, defy standardized measures of success. Unlike successful "projects" of engineers, architects or technical medical work, evidence of success where the human being serves as the focus or

"project" can vary. Thus, measures of success come from the individual's own understanding within the standards and expectations of the profession as well as with the client's perceived satisfaction. Engaging in self-study assists those in all fields to appreciate their individual strengths within the competencies set by the profession.

Who We Are

Jinx Watson is a faculty member in the School of Information Sciences at the University of Tennessee, where she teaches pre-service courses designed to prepare students for careers as teacher-librarians and works with graduate students doing research degrees in library and information sciences. Jinx will present an interpretive perspective on self-study, illustrated with a case as an example of one self-study method she uses to help novice teacher-librarians become reflective practitioners.

Susan Wilcox is an adult educator and member of the faculty at Queen's University, where she works with university educators across the disciplines, helping them make changes in their teaching that will improve the quality of student learning. This process of learning to teach more effectively is called educational development, and Susan's role, as educational developer, is to foster that learning. Susan will present a critical perspective on self-study, illustrated with descriptions of the methods and strategies she uses to foster self-directed and transformational professional development among university educators.

Margo Paterson is a faculty member in the School of Rehabilitation Therapy at Queen's University where she works with undergraduate students learning to become occupational therapists (OT's) as well as graduate students doing research degrees in rehabilitation. Margo will present an artistic perspective on self-study, illustrated with descriptions of the varied tools she uses to enlighten and develop the artistry of practice in occupational therapy students.

In this chapter, we first provide an overview of issues relevant to self-study across varied professional practice settings. Then each of us offers insights into self-study drawn from our own different professional contexts. We do this to show how particular contexts have shaped the way we think about self-study and the approaches we adopt. We hope that it will offer openings for others to learn from our experiences and use what is relevant from these to their own practice contexts. Each of us, coming from different theoretical and professional backgrounds, has come to use self-study as a valuable way forward to understand and improve practice. We have elected to take turns using our own voices so that we can ground our overview of this important topic through a presentation of three related but unique theoretical perspectives and practice settings.

An Overview of Issues

The approaches to self-study research used in each of our practice settings all originate in a fundamental concept: we learn from experience. The 'experience'

is professional practice, and the 'we' is practitioners, both novices and experts. Learning is especially likely to be significant when we make the effort to reflect upon moments of disruption in our practice, disorienting dilemmas that have the power to highlight and call into question our usual ways of thinking and doing things. These situations hold the potential for transformative professional and personal learning. In responding reflectively to these unforeseen and problematic situations we initiate a process that can become professional artistry.

Active, engaged, self-directed reflection on our experiences is the key. Each of these three approaches to self-study is focused, methodologically, on strategies that help practitioners attend to the professional practice 'data' we routinely collect in our practice, yet typically ignore. We need records of our experiences, artifacts from practice that can serve as texts to be analyzed. The *how* of reflection begins with collecting information upon which we can reflect, and stories of practice create a wonderful material for this purpose. Our stories, written in journals, told in conversations with colleagues, shared in e-mails with mentors, can become an object of inquiry and reflection. Not surprisingly then, all three approaches include strategies designed to prompt story-telling concerning moments of practice. It is through reflective analysis of these moments that our understanding of self and practice begins (in novices) and deepens (in experts).

Stories of our practice, brought to light and shared with others through self-study, offer a bridge between theory and practice. But the only way to cross that bridge is to *question* the self and the story: our own stories of experience, our personal and professional selves, and the collective stories (or theories) that are told within each profession. When reflection takes the form of self-directed, critical questioning of our individual and communal stories, self-study enters the realm of critical theory and the potential for transformative learning arises. Transformative learning is manifest in practices that are deeply grounded in an authentic understanding of what is 'really' going on in our practice, and who we 'really' are as practitioners. When freed from the necessity to practice as we've always done before, and empowered to practice in the way that seems best in particular situations, we begin to develop the artistry of practice. Taken together, the three approaches to self-study described here allow us to uncover, critique and celebrate the less explicit, yet significant, aspects of professional practice.

Our different approaches to self-study have similar intended outcomes. First, self-studies help us create a body of personal and professional knowledge. Through our self-studies, we are able to contribute to what is known about practice in particular professions or disciplines (occupational therapy, higher education, and library science). Self-studies also have the potential to help us better understand aspects of practice that cut across professional boundaries. Through them, we come to know more about reflection, about transformative learning, and about artistry. Second, self-studies help practitioners create a stance toward their professional practice. Each of the approaches described in this chapter encourages practitioners to uncover patterns of personal beliefs and values, leading to greater self-awareness. Including our selves in our studies of

practice encourages a holistic understanding of what it means to be an effective professional. If there is such a thing as "finding one's essential story" in relation to a professional field of practice (and we suggest this implies that one develops an authentic approach to professional competence/expertise), self-study offers a method of inquiry very likely to help professionals meet that ideal. The third kind of outcome we can hope to attain through self-study is an enhanced capacity for professional reasoning. Through self-study we learn how to think/feel/sense/intuit our way through the complex situations we experience in our practice settings. Through experience and through training, we learn how to think like a teacher-librarian, or occupational therapist, or university professor. Through our self-studies we may develop professional artistry, becoming adept at handling situations of uncertainty, uniqueness or contradiction.

Our three stories illustrate a recurring theme in professional practice self-studies: collaborative relationships with others. Although the other is often a peer or colleague, it may well be a client or student. Mutuality is the goal, but may not be so readily negotiated given that relationships between professionals and clients, and between experts and learners, typically include a certain power dynamic. The nature of these relationships raises other important ethical concerns to be considered. For example, self-studies may implicate family, friends, partners and spouses in ways we do not fully appreciate until we find ourselves referring to them in our journals and conversations. When publishing our self-studies, how can we balance our interest in respecting the confidentiality of trusted colleagues and trusting clients with our interest in contributing to the professional knowledge base for practice?

The emphasis on mutuality in self-study extends to the relationship between experts and novices, and has interesting implications for professional development. We answer the question of whether some self-study strategies or tools are best suited to novices while others are better suited to seasoned practitioners through a small sidestep. We highlight how practitioners (including novices and experts) may share effective strategies for self-study and thereby develop, over time, their combined capacity for self-direction, for reflection, for artistry. When experts and novices share professional development interests and share ownership of the professional development process, their self-studies may converge, to the mutual benefit of individual practitioners and the profession.

To begin this exploration, Jinx offers an interpretive emphasis through the notion of self-study as reflective professional practice.

Self-Study as Reflective Professional Practice

Professional experience offers content worthy of exploration. As we inquire about our own assumptions, efforts, and trials, we raise questions about the essential meaning of our experience. For example, as faculty in a professional school, I ask myself, "What does it mean to my own practice when I place graduate students in school media centers for practica as teacher/librarians?" Regarding the students I teach, I ask them, "What does it mean to engage in

this assigned practicum?" Rather than technical analysis or measurements of skills and decisions, questions of meaning about one's work provide foci for understanding the interplay between the intent and results of one's own practice.

Inquiring about one's own practice lays the groundwork for self-study. And self-study offers one process of making personal meaning of one's professional life. Bruner (1994) suggests that we capture our experience in the form of narrative. The texts of such stories serve as data for analysis, for reflection, and for making sense of experience. Thus, in order to understand the range and nuances of motivation and behaviors, one may begin to recollect anecdotes, collect e-mail correspondence and review personal journal entries to locate central themes and theories of one's own work experience. One may engage in incidental conversations (Watson, 1998) or intentional *authentic conversations* (Clark, 2001) where no matter the focus of the experience, the heart of such conversational learning is about oneself (Ibid, p. 177).

In the pre-service setting, both faculty member and student may each locate themes from self-generated texts in order to examine questions of meaning. Thus, in the following case from my practice, one will read of both teacher (me, JW) and the graduate student (HC) in conversation via electronic mail, electronic journals, electronic text chat from online classes and telephone. Our teacher and student relationship in the self-study endeavor revolves around making sense of the excerpts from our written and oral reflections on the practicum experience for the students and upon my own engagement as teacher with them. Thus, my work as an educator of practitioners – for school and public libraries – and my graduate students' work as novice practitioners offer each of us a rich source for reflection and ultimately, for self-study.

Learning from Experience

Those in the helping professions have the distinct and messy business of making sense of their experience rather than assessing results against a standard measure (Schön, 1983). But the notion of learning from experience proves to be elusive and complex. Drawing from the research in teacher education, Lieberman's (1995) concept of *invented learning* suggests that the linkage of professional learning and work experience can be idiosyncratic, complex and not formalized. One finds that such learning is influenced by many sources: one's personal beliefs, needs and culture; the workplace milieu; pedagogy; and, the consideration of the subject matter (Elbaz, 1983). Russell and Munby (1993) add that teachers hold preconceptions about the nature of what they are teaching, preconceptions about learning and how it takes place and, preconceptions about students' limits and possibilities. Feiman-Nemser and Buchman (1986) agree, writing that sources of influence on teaching include, "the personal capacities, temperaments and … beliefs of teachers" (p. 3). Thus, the way each faculty and student perceives work relies on the intangibles of values, beliefs and former experiences.

Therefore, attempts to question and understand the complexities of one's own work offer the possibility of creating both a stance of reflective practice (Russell,

1993; Schön, 1983) and a body of personal and professional knowledge (Elbaz, 1990; Eraut, 1994). Practitioners who question their experience in order to understand may shape a professional identity (Connelly & Clandinin, 1997); come to know themselves (Jersild, 1959; Hunt, 1987) and 'find their voice' (Featherstone, Munby & Russell, 1997). Embracing reflection as a stance for professional growth has found its way from theory into practice.

Since 1997, The Tennessee State Department of Education has employed a *Comprehensive Assessment and Professional Growth* instrument for all supervisors to use with educators, including school media specialists and others. Standard # IIIC on page 29 questions whether or not the professional has engaged in 'reflecting' ["As you reflect over this lesson and previous lessons, what ideas or insights are you discovering about your teaching?"]. Such an important criterion of professional success assumes that all educators know how to go about the business of examining their practice through reflection. But my own experience with pre-service and novice practitioners suggests that this is not so. In fact, with the current drive for standardized measurement and scientific assessment of both teachers and students, notions of 'reflection,' [of 'insight' of personal 'ideas'] might come as a surprise to many. Indeed, one might worry that a standardized measure of reflection might ensue from the state department, thus extinguishing any spark of real thought. On the other hand, one might perceive this standard of reflecting for its potential. Thus, the pre-service practicum experience offers the opportunity to begin to learn and practice ways of reflecting.

Questions Associated with Reflective Practice

Certainly, the breadth and depth of professional experience assume varying *horizons of understanding* (Greene, 1988) or repertoire (Schön, 1983; Sternberg & Horvath, 1995). Claims from some (Snow, 2001; Fenstermacher, 1994) that novice practitioners cannot engage in reflective practice because of their lack of experience and knowledge, can be countered with Schön,'s (1983) argument that the concept of 'surprise' in work has both the possibility of driving new learning or offering disruption. In fact, the moments of disruption and unexpected results from 'best laid plans,' may provide substantive content for analysis and questioning. Bruner (1994) suggests that, "trouble is the engine of story." It is the complication or conflict in experience that drives our cognitive need to make sense and we do so through narrative. The number of critical incidents during the novice stage of practice provides the content for story-making and rich reflection.

Additionally, some practitioners have not learned how to reflect on their practice. That is, many know how to report on their activities, list their encounters or account for their time, but have not learned a process for gaining understanding of the dynamics of their work. Teachers, for example, may not know how to wonder about the way that they engage students; they may not ponder why a student succeeds or fails in a certain instance; they may not understand how to perceive the levels and nuances of an event. In order to seek

meaning, to appreciate the lived experience of the small moments that make up a working day, practitioners must invite themselves to contemplate their own work. Clark (2001) suggests that such inquiry about the professional arena reveals the personal realm. Examining my practice offers not only the portrait of what I do but also, of who I am.

Thus, reflection offers the possibility of unveiling essential assumptions embodied within one's practice. The interplay of subjectivity and objectivity throughout a self-study inspires coming to know not only *what* I do, but *why* I may act in particular ways. Therefore, insight gained from self-study may not easily be systematized into a universal knowledge base. Yet, another person, in hearing or reading another's story may resonate with themes or excerpts stunning to him or her alone. The power of sharing the results of self-study projects lies in offering a process and illustrating universal issues and themes. More powerful than knowing about specific skills and espousing current theory, reflecting on and sharing lived practice offers a way to grapple with the meaning of the choices we make and the results of our work. We may begin to recognize patterns, themes and central ideas that represent a particular stance, our worldview. Schön (1983) and others (e.g., van Manen, 1994) suggest that such reflection includes conscious and unconscious problem-setting and problem-solving to employ one's repertoire of strategies. Reflection may ultimately illuminate the theoretical basis for professional actions.

Sharing ways to engage in reflection and self-study has offered a touchstone for my work as an educator of teacher-librarians. I continue to learn about myself as a teacher of adult professionals. As I explicitly examine and model my own interactions with pre-service and novice teacher-librarians, they begin the process of learning how to examine their own work. Our self-studies often converge as we read and discuss the evidence of our work. The case that follows illustrates one way that a teacher and a student's self-study projects may intersect.

Noticing Practice through Language

Bleakeley (2000) suggests that practitioners and scholars alike have come to appreciate the multiple venues for reflecting on practice: through dialogue and conversation and through writing in various genres. He suggests that language itself offers the motor for assessing tacit knowledge (p. 13), which Schön (1983) maintains drives one kind of reflecting, 'reflection-in-action'. Merleau-Ponty (Langer, 1989) argues that to know something, then, means that we must say it or write it. And, by shaping our own experience, as the question for inquiry, it becomes the object and subject of an expression in language.

> Authentic speech is the presence of thought in the world – not its garment, but its body. Communication with others would be impossible if authentic expression were not identical with thinking; unless the listener can learn something from the speaker's words themselves, communication becomes an illusion ... speaker and listener are subjects inhabiting a shared linguistic world. (Langer, 1989, p. 59)

When one's personal experience becomes, in effect, detached from the self and shaped into language, it becomes the object of inquiry and reflection (Kwant, 1963, p. 159). Thus, both novices and seasoned practitioners seeking to reflect on their practice create ways to capture and attend to the linguistic expressions of their work, replete with meaning.

One way to study and understand the phenomena of the everyday world, including one's own work, is to embrace the text-based, interpretive tools of the hermeneutical-phenomenological research tradition. "The reader-interpreter of life texts enters a hermeneutic circle of witnessing, responding to, re-framing and re-languaging the object of experience" (Becker, 1992, p. 32). Reading one's own written texts or spoken texts suggests a dynamic, creative and open-ended process that continues to raise questions of meaning rather than predict or control behavior. Many students in the professions write in journals, attempting to capture critical incidents and events. But, journal writing is best inspired by fruitful prompts, such as, "Write about what you noticed and then wondered about today in your work setting." 'Wondering about' suggests a recursive rather than a linear train. Those of us who notice may begin to wonder, and then, return to noticing in order to determine patterns for further wondering and consideration. Asking ourselves to notice and wonder about (Watson, 2002) offers a focus for collecting excerpts of experience worthy of attending to. Instead of listing activities or the plan for the day, we ask questions regarding the activities of a mentor, the students in our charge and our selves, and begin to notice what 'really' happened. Regarding their practicum journals, I often write to students, "Begin to use phrases such as, 'I noticed and wondered about ...' or 'What really surprised me was ...' or 'Why does (or doesn't) ...' in order to show that you are questioning, inquiring about the multiple choices you and your mentor make each day." This explicit set of inquiry tools may be difficult for those who have rarely questioned, who feel so novice-like that they dare not question, or who feel they do not know what kinds of questions to raise.

The excerpts of the moments that catch our eye and appear important enough to document as a journal entry will often appear as a narrative. Crites (1989) argues that, "the formal quality of experience through time is inherently narrative" (p. 66). Bruner (1994) suggests that that cognitive response to an experience of disruption, aberration, or the unexpected shapes a small narrative. The moments in our experience that we notice appear as stunning anecdotes of one day's full narrative. The small narratives or anecdotes manifest the complications or inexplicable times in one's day that we notice because they continue to perplex us. We choose to come to know these stories by telling about or writing them.

But the writing of phenomena in our experience offers only one level of sense making (Dervin, 1992). The literary and philosophical traditions of phenomenology and hermeneutics not only offer ways of capturing and shaping experience, but ways of reading and re-reading our stories as well (Barthes, 1974; Carini, 1975; Ritscher, 1995). Elsewhere (Watson & Wilcox, 2000), we have written about annotating our stories of experience and conventions of practice. Briefly, the annotation presumes reading in multiple ways: a 'quick reading,' a 'close

reading' and a 'bird's eye reading.' This 'zooming into' text offers ways for readers to grasp and wrestle with the individual themes of a text; the 'zooming out' allows ways for an individual experience to be linked to and understood within universal practice and theory (Watson, 1998). The beginning professionals in my classes practice learning how to read through multiple lenses by sharing their own stories. Each brings a journal entry to the whole class, much as a doctor might share a patient's condition on her medical rounds. After the student comments on why she selected the entry, she engages in a close reading, to illustrate her own sense-making. She invites classmates to enter into the textual analysis by reading closely and interpreting. Many times students concur, but more often than not classmates may offer new insight into the particular use of a word, of a scene or theme. Then, the students 'zoom out' to connect the story's significance with what they have learned from practice and theory. They help to link the idiosyncratic and very particular story to a larger panorama of the workplace, both the human and the technical aspects of the profession. The writer of the story often leaves such a session with new insight and questions to ponder. Others may leave with their own new questions.

This particular model of a self-study process that examines one's text of experience is not solely classroom-bound. As students practice sharing their entries, they begin to appreciate the need for colleagues in professional learning. Many, though, have reported that although their workplace is a lonely one, they use their journals of reflection in order to make continued sense of their work. The journal entries, whether many or few, provide, over time, a resource for learning about themselves in the context of their work. Connelly and Clandinin (1990, 1995) help to confirm that reading others' and one's own stories of experience offers one way to go beyond learning the standard sets of skills and values that characterize the profession.

One Example

With the advent of the Internet, student writing becomes available to an audience of classmates as well as the teacher. The electronic texts of students' weekly "noticing and wondering" about their practicum experience mailed to classmates and me serve as one set of data. Additionally, the lesson models that students submit to the class entitled, "What I want to happen" and "What really happened" offer both intent and honest results with data for class discussion. And finally, in our online classes, the captured 'text chat' exchanges can be retrieved for close readings and responses. The online, synchronous teaching each week produces audio text ('playback') as well as the 'text chat' worthy of analysis. By sharing the texts as pre-service teacher-librarians, we model a way for future professional development. Lieberman (1995) reminds us that exchanging stories and sharing insights about practice offer content for professional development.

In the example I offer through the following case, my own text (JW) and a student's text (HC) illustrate how each of us furthers our professional self-studies. As a fairly new higher education professional, I continue to question my guidance

of adult graduate students. I am interested in how much I lead in a didactic way and how much I remain true to the Greek definition of education, *educare* (to bring forth). I struggle with when to intervene and when to support the student's own raising of questions. I share my story of *intervening too much* and trying to make sense of it. The student's text is one of many from the semester, but she selected it for examination with her peers on her own. I continue to wonder why this selection called her in ways that others did not. The complication in her story is classic: a 'wild' boy in her library program and her behavior management techniques.

HC submitted to me her plan and later musings on the picture book program she had prepared and offered to a kindergarten class of seventeen children:

Plan:

Read: _____
Talk about friends. Ask questions, letting kids answer by raising their hands. Ask who can be a friend. Pets? Who has a pet? Who likes cats?

Read: _____
Activity: _____
Say: I know you all are working on numbers, I need your help with this next story. This is a counting story.

Read: _____
Activity: _____
Read: _____
Hand out dog stickers

What really happened:

The class just came back from the computer resource lab where they had to sit still in front of a computer and do a lesson with the computer resource teacher that lasted 30 minutes. So, a couple of the boys were a little restless. I told the kids one of my story-rules, the one about having two ears and one mouth so they needed to do twice as much listening as _____ I always let them fill in the blank. They settled down for the first story. Surprisingly, the 'friend' talk did not run away with itself. I read them a poem and we did the first activity ... The little boy who was restless during the start decided to do his finger play at turbo speed. I invited the children to sit down on the carpet saying 'criss-cross applesauce, bottoms on the floor, hands in your lap, wiggle no more.' The next story went well, the kids shouted out the number of dogs from 1 to 10 then 10 to 1 as the story progressed. The little boy got really wild. So I did 'head, shoulders, knees and toes" instead of "Shimmy, Shimmy, Shake." Because there was no way, he was going to learn anything new. We did that three times. The kids asked to do it again really fast so we did. Then the wild boy fell down on the floor. I had to do the hands on your body game to get control of the situation ... Then I asked all the girls to form a line. The wild boy pushed a little girl aside and got in line first. I said to him, "Gosh, I

guess on your next birthday, you are going to get a girl doll and a pink dress with sparkles on it.'' The teacher came over to attend to him. Instead I asked her to hand out little doggie stickers to the girls. Then, I had the little boys get in line and did the same … (HC, 9/18/02)

The student first verbally reported the narrative to the class during class. The students noticed and wondered about HC's use of 'crowd control' techniques, lauding her for the swift transitions between activities, the ways she avoided chaos, her balance of reading books and doing activities. One commented that she had been sensitive to the fact that these very young kids had been sitting still in a computer lab and, "what was that all about for such young children?" But no one in class noticed or wondered aloud about her singular verbal comment to the 'wild boy.'

 Because I had perceived her statement about the boy getting a doll and dress as negative and detrimental to a child's self-concept, I struggled with myself to come to terms with addressing this question in public with the other students; I pretended to myself that she had not said her comment. I could not believe it and therefore, I accommodated myself with the thought that I had not heard her correctly. But the text then appeared as an electronic report that evening. I read this and noticed the 'hot spots' or theme of the 'wild boy' as a staccato interrupting her best laid-plans. I saw the text of her comment, just as she had reported it orally. I chose to wait until the following day to initiate a private electronic exchange with HC.

HC, your work on ancient Egypt will be a rich one, I'm sure. I like that you'll get both fiction and nonfiction … I think that the work up of a staff development session on graphic novels is important … I think that you might see some good references to read and quote in Sullivan's book on that chapter.

HC, on another matter: it occurs to me from reading your debriefing on the picture book program, that you might want to consider how you negotiate with the acting out kids. Once we accept that the kid who acts out is doing so for reasons way beyond our control and knowledge, then we must not try to aggravate his problems. Your suggestion to him about confusing the girl/boy line might be humiliating. In our culture, it's humiliating for little boys to be considered 'girls' or sissies. So, gently guide him to the right line without a word. That's 'punishment' enough. Hope all that makes sense re the situation – (JW, 9/19/02)

I noticed and wondered about my particular passion for this incident that did not seem to be noticed by anyone else. I noticed that I was not gently guiding in communicating my comment! I wondered why I was didactic rather than allowing the student to come to this herself. I convinced myself that the student had not 'heard' her own self in this instance. She had reported this incident verbally and then, written the incident. In neither instance did she self-correct or attend to it. I felt the need to attend to it. My own text to her is full of what

I've learned over the years. It's not what she knows yet. I am sure that this direct style from me is unfamiliar for one used to my 'wondering about' approach. I awaited her response with nervous anticipation.

> *Considering that I am raising two little boys – working daily to prevent my nine year old from participating in the stereotyping, bullying and sexist remarks and activities boys sometimes do and let both boys celebrate boyishness, I was just a little bit put off by your comments at first. I wanted to write back and debate the matter extensively with you, that since you were not there you did not really see it or understand it.*

> *But you'll notice four days have passed since your e-mail and I've contained myself. Thank you for your comments! (HC, 9/24/02)*

I was confused by such sophisticated language about cultural issues from one who made a comment I found offensive. I had to examine why it was so 'offensive' for me before I pursued this. Heidegger (1968) writes, "What is it that calls on us to think?" (p. 188). He claims that to learn the thinking of thinkers – this teacher-librarian – is to, "be attentive to things as they are, to let them be as they are, and to think them and ourselves together" (p. xii). I had to respond to the call from this student's text and engage her in the text as well. Gadamer (1975) would add that engaging in this way with a phenomenon represents a model of conversation concerned with the same object – the library experience – placed before the storyteller and the listener.

I am sensitive to notions of inclusivity as, for many reasons, I care for those left out and for those who struggle making sense of our culture. For me, the student's remark was not 'pedagogical' as defined by van Manen (1991) which presupposes the idea that teachers orient themselves intentionally to the way that the child experiences the world. Thus I felt a need to write back to HC and then, to offer to talk to her on the phone.

> *HC, it was a risk on my part to even mention it … anyway, your message here confuses me and I guess that's the way with electronic communication. I see that it was an upsetting remark that I made and you're absolutely right, I was not there to witness, to hear, to appreciate the fullness of the situation. Was I off the mark entirely then? … Thanks for getting back to me. I have been wondering how it hit. I hope we can both let it go, but I don't mind calling you so that you can talk to me a bit, if that would help straighten out this temporary haze. (JW, 9/24/02)*

In this text, I offer my own vulnerability as a 'confused' teacher. I agree with her rationale of my lack of context. But I challenge her thinking: "Was I off the mark entirely … ?" and because I am her teacher, a guide and mentor, I offer one more opportunity to explore her thinking, by phone call. And she accepts.

Our resulting phone call was not recorded. I called HC the next day, 9/25/02, and we continued the discussion about her remark to the child. HC gets rave

reviews from her colleagues and from me for selecting and reading books in her programming. She can maintain the level of disruption in her groups. Her classmates give her positive remarks. Given this, I perceive her as strong. But no one wants to be told about the meaning of her own thinking. I had not gently guided her to the question of how she had addressed the child. She sounded pleasant but still cautious of me. We chose to perform a 'close reading' of the text in front of us and noticed that this boy emerged as the theme of her narrative. We talked and concluded the conversation with mutual respect for discussing the delicate topic. The outcome of this exchange produces no immediate theory or hypothesis for what this teacher-librarian or all teacher-librarians say about their work and learning about their profession. The outcome produces a new sensitivity on my part as teacher of this novice that the arena of values and beliefs is so central to professional ego. The fact that we exchange these ideas privately, rather than with the entire class does not lessen her pain or my difficulty in discussing such personal issues. Indeed, other readers can be highly sensitive to the context or setting in which the phenomenon occurs. Thus, no generalizations may be made. But identification can occur for others: "What do I make of this story for my own situation?" The complexity and ambiguity of teaching and learning about professional practice can best be understood by noticing the small and ordinary moments within a teaching day. Such noticing continues to raise questions to wonder about. However, further to this, in terms of the development of my own learning through self-study, this instance raises other important issues that go way beyond the particular situation and my response to it.

The perceived gender stereotyping itself is also problematic for there are certainly other ways of reacting to this situation. However, even beyond that issue is a bigger one. The portrayal above illustrates how I struggled with the dilemma of when and how to help students think in ways similar to me, but this is also problematic and at a much more fundamental level than the intervention in practice. Clearly it is important that I question that which I was doing and consider whether I should be doing this at all. Hence, the fundamental issue is whether or not I should be trying to get my students to think like I do; assuming a recognition that such intent is apparent in practice. In this case, it can easily appear as though I have overlooked this issue as I examine the action rather than the underlying perspective that itself needs to be questioned. Moving beyond the particular situation and into the deeper issue of probing or discovering my own limitations and view with regard to the content of the issue in the process of intervention is a crucial aspect of self-study that can emerge through a re-examination of practice in a systematic way. In so doing, issues arise about how I would 'check' on these problematic perspectives and deal with the limitations of my own approach to the situation. This then further highlights the value of a 'critical friend' to aid in checking of alternative perceptions; some sort of "validity" check, or reframing. In this particular situation, I have not interrogated the situation in this way, however, if this situation were to be fully examined, these issues would need to be carefully considered. For this example I have

simply attempted to illustrate how apprehending situations in practice can lead to more fundamental questions, issues and concerns that further develop the value and purpose of self-study in terms of one's personal and professional development.

Summary

As this example shows, our online degree program offers many conveniences and possibilities, but lacks the human, face-to-face contact that such delicate guidance of novices requires. But the text-based data of one's own work provides the possibilities of rich self-study, distance or not. In this case, HC spent four days before she could respond to my explicit question. And we were able to re-read together, on the phone, in privacy, to make sense. This time I took a less didactic role to see if she made sense of her comment in new ways. And yet, again, I found myself sensitive to controlling her views and neglecting to assess my own worldview in this case. I wanted her to have her own 'ah-ha' – an embrace of my belief – and yet, she resisted. Real learning takes time; for both teachers and students. Roles of teacher and student are so ingrained with historical power: I saw that I did not openly reveal my self and my own self-study questions to her, but I asked her to reveal herself. Yet, we each left the phone conversation, perhaps, with more questions than answers and theories. We had bridged the social gap of being astounded with each other's behavior. My own self-study about guiding students and allowing them to grow in ways that are true to themselves continues, a lifelong process. Such self-study clearly involves questioning my perspectives and practices in ways that might highlight new ways of seeing that which I take for granted in teaching and learning episodes and experiences.

My own stance and model as practitioner of 'noticing and wondering about' often works for me but I did not create the conditions for this student to come to her own insight. I *told* her. She was affronted at first. It took time for us to negotiate. Precious time. And that slow process of capturing, reading, re-reading and negotiating the narrative of our professional lives now offers the possibility of continuous questioning and genuine self-study and growth. Because of her interaction with regard to this story, the calling forth for re-examination, one might suspect that, for HC, through reflection on her own practice she might begin to look more deeply into the ways in which she engages with children. Because of my interaction with regard to this story, I recognize a deeper need to assess my beliefs and my urge to impose them on novices. Because we both noticed and wondered about our own stories, we are invited to begin to shape new foci for our own continued professional development, and for me in particular, my self-study research.

In the next section, Susan offers a critical or transformative emphasis through an examination of self-study as directed professional development.

Self-Study as Self-Directed Professional Development

Professional development is an ongoing process of critical inquiry. As we engage in practice, we question how to improve and, the answers we formulate become the foundation for our continuing approach to practice. This notion of development as inquiry is highly relevant to my own field of professional practice: educational development (also known as faculty, instructional or staff development) in higher education.

Among those committed to the improvement of teaching in higher education settings, there is growing interest in encouraging the professional development of faculty members as teaching scholars. Boyer's *Scholarship Reconsidered* (1990) was a critical document in the development of the way we conceptualize efforts to engage academics in the improvement of teaching. Boyer chaired a Carnegie Commission that analyzed the nature of scholarship and redefined the role of academics to include a *scholarship of teaching*. This document provides a rallying point for a movement in the field of educational development towards a 'more intellectually engaging' approach to the improvement of teaching, in which teachers play an active role in research/scholarship concerning ways to bring about better student learning. Action research and classroom research are examples of proposed approaches to the improvement of teaching that reflect the idea that there is a scholarship of teaching that should be fostered (e.g., Zuber-Skerritt, 1992; Cross, 1990; Schratz, 1990).

Action research is a method of inquiry well suited to the development of teachers' practical knowledge, and the work of Bereiter and Scardamalia (1993) confirms that scholarly communities organized around the development of such knowledge can foster educational expertise. Another approach to teaching improvement through scholarship is practice-centred inquiry – a continuum of activities that begins with casual observations of practice, at the midpoint is characterized by sustained reflection, and at the far end becomes formal classroom research (Amundsen, Gryspeerdt, & Moxness; 1993). Schön (1995) has argued that Boyer's new scholarship implies, "a kind of action research with norms of its own, which will conflict with the norms of technical rationality – the prevailing epistemology built into the research universities" (p. 27). This kind of action research, according to Schön, will raise difficult epistemological, institutional, and political issues within universities. It is a form of critical social science, which may be broadly defined as research that, "combines participation in the process of critique with the political determination to act to overcome contradictions in the rationality of social actions" (Ewert, 1991, pp. 373–375). It is here, in this call for critical practice-based inquiry conducted by faculty members, that my interest in self-study as an approach to educational development arises.

At the same time, there is recognition that the improvement of university teaching is essentially a professional development process and, as such should be guided by theories of adult learning. Cranton (1994a, 1996) and Brookfield (1990) have each articulated quite sophisticated views of educational development as a form of adult learning. Brookfield (1990) used his experiences as an

adult educator and his knowledge of adult learning as the starting point for a book addressed to faculty members interested in learning to improve their teaching and in finding ways to encourage their colleagues to participate in improvement activities. Cranton (1994a) has provided a compelling argument for placing educational development practice in a framework that includes attention to university instructors as self-directed adult learners and, to educational development as a process of transformative adult learning. I have found that adult learning theory also offers a sound rationale and foundation for using self-study as an approach to educational development and that it is particularly well-suited to efforts at furthering the scholarship of teaching.

There are significant connections to be made between self-study and self-directed, transformative approaches to adult learning. I will begin by making conceptual connections then illustrate these connections through examples from my own educational development practice.

Connecting Self-Study with Self-Directed Learning

The concept of self-directed learning (Candy, 1991) is based on the idea that all persons are ultimately responsible for conducting their own search for personally meaningful knowledge. The origins of self-directed learning can be traced to Dewey (1916, 1938), who proposed that all persons are born with an unlimited potential for growth and development. Dewey defined education as the agency that facilitates this growth and cautioned that the teacher should guide but not interfere with or control the process of learning. The term self-directed learning emerged in the North American adult education literature in the mid 1970s. Tough's (1971) learning projects research had demonstrated that self-teaching was a natural process among many adults, and Knowles built his andragogical (i.e., adult education) model on the basic assumption that adult learners are self-directing (Knowles, 1975, 1980). Since that time, self-directed learning has become a prominent feature of adult education theory and practice – in fact, some educators suggest that adult education is synonymous with self-directed learning. Candy (1991), in a work that is widely regarded as the most comprehensive analysis and discussion of self-directed learning to date, has constructed a conceptual framework for understanding self-directed learning as both a goal and a process which embraces four distinct phenomena: personal autonomy; self management; learner control; and, autodidaxy. Brookfield (1986) has been one of the most articulate critics of self-directed learning, warning of the dangers of orthodoxy. Yet he continues to be one of its most ardent supporters, arguing that self-directed learning honours both humanistic and critical traditions in adult education, and allows adults to achieve autonomy in and through learning (Brookfield, 1993).

Although self-directed learning is often equated with independent inquiry, "knowledge … is socially constructed and … accordingly learning is a social process … Self-direction does not necessarily imply solitary learning" (Candy, 1991, p. 367). Connections with others through relationships and dialogue are a

crucially important and potentially quite powerful influence on the process of self-directed learning. Connection and autonomy, though apparently dichotomous, are equally important conditions for learning – in fact, each is essential to self-directed learning. While many adult education scholars and practitioners have concerned themselves with finding ways to help adults act autonomously to direct their own learning (i.e., planning, initiating, and evaluating their learning efforts), the relational component of self-directed learning is more commonly overlooked. Adult educators are only beginning to appreciate and understand the problem of how to foster, at the same time, autonomy through independence and connection through relation. One proposal has been that connection and autonomy interact dialectically and that this dialectic is made possible through caring relationships (Wilcox, 1996) in the learning environment.

In all educational contexts, decisions must be made about what will be learned and how that learning will be assessed. In the context of professional education and development, the question of what is worth learning is at the very heart of professional self-determination and, no notion of professional practice is complete without attention to how the professional is to be evaluated. Self-directed learning, as an approach to professional development, implies that practitioners should themselves define what knowledge of practice is to be learned, how it is to be learned, and how that learning is to be evaluated. If we view professionals as self-directed learners, we will ask them to consider what is worth knowing and expect them to participate in decisions about the design of professional development experiences and the assessment of their learning through these experiences. When practitioners define, through a collaborative and self-directed process of dialogue, what knowledge is needed for effective practice, they are constructing a personal standard, or *ideal*, against which they may assess their own professional knowledge.

The ideal is the learner's best image of his or her self in relation to the study of a discipline, or the practice of a profession. There are no shortcuts to the development of an ideal (Noddings, 1984). Enforcing an ideal through formalized principles and rules, for example, is a poor substitute for encouraging individuals to meet the standards provided by a personally constructed ideal. Noddings (1984) argues that the *caring* educator is in a good position to help learners with the critical process of constructing their own ideal – by showing learners what an ideal might look like in a particular discipline/profession, and modeling for learners how an ideal shapes further learning and development. However, if others (even well-meaning others) define for individuals what is worth learning, acting as external arbiters of what is intellectually and/or professionally valuable, this may be a powerful barrier to self-directed learning. Of course, this does not imply that 'anything goes'. For example, to construct a legitimate and useful standard for professional practice, practitioners will need to engage all stakeholders (including clients, the general public, institutions and governments) in discussion regarding their views of effective practice.

I believe that engaging practitioners in self-study is a powerful way to foster a self-directed approach to professional development.

Connecting Self-Study with Transformative Learning

When practitioners engage in self-study, they are in effect participating in a form of potentially transformative scholarship, or knowledge building, that, like critical social science, incorporates our emancipatory interest.

According to Mezirow (1981), engaging in critical thought and reflective action is the essence of adult learning. Mezirow recognizes that our perspectives on the world are shaped by our values, assumptions, and beliefs, which may be invalid. Although most of us tend not to be aware of nor question these values, beliefs, or basic assumptions, distorted assumptions about the world lead us to have invalid or distorted perspectives on the world.

Through a self-directed process of critical self-reflection on our 'meaning perspectives' (the assumptions that we use to interpret our experiences) we may reformulate these perspectives to allow a more inclusive, discriminating, and integrative understanding of our experience and then act on this reformulation; we then engage in the process Mezirow calls transformative learning i.e., "the activity of making an interpretation that subsequently guides decision and action" (1991, p. 375). The effort to facilitate transformative learning is called emancipatory education. Mezirow argues that individual transformation through emancipatory education enables societal transformation because, "if individuals discover that their assumptions are based on cultural distortions (women can't be mechanics; men don't know how to do laundry; all Germans are ruthless; the poor cannot go to university) and if those assumptions are revised and acted upon, social change will be the next step" (Cranton, 1992, p. 175).

Essentially, to say that an assumption is distorted means that it is invalid in terms of an individual's personal experiences. Individuals who have accepted cultural values, beliefs, and explanations without question may not notice the ways these societal perspectives are or are not confirmed by their own experiences. Through transformative learning, we correct errors in understanding and affirm sound understandings that arise through critical reflection on our experiences. In the normal course of events, people may not act upon their own understandings of situations (which sometimes are convictions) because their personal perspectives are not affirmed by societal values. Sometimes when we reflect on our experiences in relation to our perspectives we come to the conclusion that our perspectives are good ones – and then make a more concerted effort to act upon them. When individuals reflect upon and affirm knowing and use it to guide action, societal transformation can come about just as it does when individuals revise their perspectives and act upon them. While Mezirow's language of constraints and distortions is rather negative, one may choose to view transformative learning as a process of moving towards more inclusive understandings of the world, expanding one's sense of the ideal, sometimes through affirmation and sometimes through revision, and acting upon that.

The emancipatory knowledge gained through transformative learning is quite distinct from both technical knowledge and communicative understanding of practice (Cranton, 1994b). Reflection on meaning is an important aspect of both

communicative and transformative learning, but when our understandings are transformed as a result of critical reflection and we view the world from a new perspective, learning moves beyond the communicative domain and into the emancipatory arena that truly reflects our drive to grow and develop and our interest in self-knowledge and autonomous action. The need to act upon a revised perspective – for the professional, attention is always on the implications of learning for practice – then brings into play a requirement for technical knowledge. Thus, a self-study that engages a practitioner in transformative learning will likely also demand learning in the communicative and technical/instrumental domains.

Brookfield connects emancipatory learning with critical thinking, but is careful to clarify that critical thinking involves more than logical reasoning or, "scrutinizing arguments for assertions unsupported by empirical evidence" (Brookfield, 1987, p. 12 cited in Cranton, 1994b, p. 61). Cranton (1994b, p. 55) notes that although Mezirow describes critical self-reflection and transformation in language that emphasizes the conscious and the logical, others have suggested that the process is not entirely rational. Boyd and Myers (Boyd & Myers, 1988; Boyd, 1985; Boyd, 1989) describe a process of discernment in which symbols, images, and archetypes play a role in personal illumination. Cranton also cites the postmodern perspective of Stanage (1989), who has suggested that the transformation of meaning is not a linear, determinable, or predictable process.

The process of transformative learning can, nonetheless, be usefully portrayed in terms of general distinctions between typical stages in the process (Cranton, 1994b). There is usually a trigger event or disorienting dilemma, leading to a phase of appraisal or self-examination, then exploration of new ways of thinking or behaving that includes assessing the validity of various alternatives. This is followed by a process of developing alternative perspectives that may include developing a plan of action and acquiring necessary skills and knowledge and must include trying out new ways of thinking or acting. Finally, there is integration – which is likely to involve the transformation of beliefs and assumptions so that new ways of viewing and experiencing the world are accommodated. Knowing of these typical stages assists individuals (and this includes professionals conducting self-studies of their practice) in recognizing what stage they are at in their own transformative learning journey and thus in making decisions about their learning; it also assists educators in considering how they may facilitate learning at each of these stages.

Transformative learning, as a process of emancipatory education, is closely tied with the concept of 'autonomy':

> Any knowledge that inhibits a person's achievement of freedom and autonomy is ideological and therefore distorted … social systems that prevent a person from developing his or her full capacity for freedom and autonomy are repressive systems … the critique of knowledge is required to overcome the limitations to self-knowledge based on the internalization of social constraints. (Ewert, 1991, p. 355)

Cranton (1994b), based on a review of autonomy as characterized by Brookfield (1986), Candy (1991), and Jarvis (1992), concludes that becoming autonomous is, "becoming free of the constraints of unarticulated or distorted meaning perspectives" (p. 60), and is thus a transformative process; Mezirow's own words confirm this view:

> … dramatic personal and social change becomes possible by becoming aware of the way ideologies – sexual, racial, religious, educational, occupational, political, economic, and technological – have created or contributed to our dependency on reified powers. (Mezirow, 1981, pp. 5–6)

The concept of transformative learning calls upon us to trust in the ability of individuals to critique and then transform knowledge accepted within a community of scholar-practitioners. This belief in the socially transformative power of an individual's critically reflective learning lends credence to the value of self-studies that are conducted within professional practice communities.

Full autonomy is, of course, an unattainable ideal (Cranton, 1994b) – as is being completely conscious of the sources and consequences of meaning perspectives and being free from coercion, constraints, and distortions in these perspectives. The autonomy of the individual is desired in two senses: in knowing the culture, i.e., "to be reflective about the cultural context and traditions in which he or she is embedded" (Ewert, 1991, p. 354), and in knowing the self, i.e., "to become articulate about our own affective and emotional constitution" (Ewert, 1991, p. 354). Knowing the self and knowing the culture are accomplished simultaneously through dialogue/discourse. According to Mezirow, the purpose of education is to provide the conditions in which such discourse is possible. Through better knowledge of self and society, one is able to gain a new perspective that offers new possibilities for personal action in the world, thereby enabling societal transformation through individuals' emancipatory-knowledge-in-action.

Because self-study is potentially transformative, it comes with profound implications for individual practitioners and their professional fields of practice. I believe that an understanding of, and appreciation for, the process of transformative learning is essential for those who choose to engage in self-study as a means of professional development.

A Framework for Practice

In my own practice, I have elected to approach educational development from an adult learning perspective.

> *A personal philosophy of practice: My interests in: a) the teachers I work with as persons; and, b) the development of knowledge for teaching, shape my educational development practice. I fuse my commitment to the personal development of teachers (myself and others) and my commitment to the development of teaching knowledge (my own and others') through a commitment to teachers as scholars. I express my commitments through a particular*

> *form of scholarship: by constructing, engaging in, and reflecting on educative experiences (i.e., experiences that enable the growth of knowledge), on my own and with other educators. (S. Wilcox, Teaching Dossier, 2000)*

I have found that the best way for me to encourage and support the development of teaching in the university setting is to model a self-directed approach to the scholarship of teaching through self-study, to promote self-study strategies that invite self-directed and transformative learning and, to respond with care to the challenge of self-directed educators who choose to engage in the potentially transformative process of development through self-study.

I have found that a workplace devoted to self-study must provide an environment in which practitioners have the autonomy and support they need to engage in self-directed efforts to re-construct their sense of self as a teacher and their approach to teaching. I believe that educational development programs have an important part to play in the construction of the all-important ideal among university educators – they can provide the setting in which educational developers and developing teachers engage in dialogue, helping one another construct a personal ideal as educators. Students also play a crucial role in helping teachers construct a personal ideal, and thus, the quality of teacher-student relationships has a tremendous impact on an educator's capacity to develop (Wilcox, 1998).

I have established for myself a two-part framework, originating in Candy's (1991) model of self-directed learning, for promoting transformative professional development through self-study. I outline it here, and include examples of strategies I have developed and used to support the framework.

1. To prepare for engagement in self-study of practice, practitioners must first strengthen their capacity for self-directed learning. For a course focused on what is involved in becoming a more self-directed practitioner, I have put together a wide range of theoretical and practical readings (Wilcox, 2001) intended to be useful for educators interested in taking greater responsibility for their own professional development. I encourage activities that help practitioners:
   - *Establish a sense of self as a continuous learner in their chosen profession.* Useful approaches include:
   – identifying personal learning styles and preferences;
   – developing a deep and personal understanding of the adult/lifelong learning process, especially in terms of what it means to be *self*-directed (need to know/understand self and trust self), the ways in which self-directed learning may become transformational, and how this contributes to authentic practice (and how our views of self may inhibit learning);
   – assessing the conditions for learning in our practice settings and the impact of the working environment on our capacity for self-directedness;
   – considering the potential consequences (benefits and drawbacks) of seeing ourselves as learners while simultaneously playing the role of competent professional.

   Texts that I have found helpful in supporting these kinds of activities include

Brookfield (1995), Cranton (1992, 1996, 2001), Hunt (1987), and Wilcox (1996).

- *Learn how to structure and manage the process of professional development.* This includes:
- selecting personally-meaningful and contextually-appropriate approaches to improving professional practice through self-directed inquiry (e.g., allowing for evolutionary growth [Kugel, 1993; Pratt, 1989] problem-solving [Cross & Steadman, 1996; Schratz, 1990; Wilcox, 1992, 1993], setting strategic priorities [Wilcox, 1999], story-making [Connelly & Clandinin, 1990; Watson, 1998]);
- finding the resources we need to support our learning. This can range from setting aside time at the beginning of each day for journaling, or establishing access to theoretical literature, all the way to learning how to submit a proposal for funded research on practice.

Hammond and Collins (1991), Knowles (1975), and Wilcox (1992, 1993) are useful guides for professionals looking for assistance in structuring their self-directed inquiries.

2. Then, to facilitate the transformative development of professional practice, I recommend self-study, including:

- *Independent self-study.* I use and encourage, for example:
- strategies that allow professionals to take action towards development without being dependent on others to guide their learning, including ways such as journaling (Moon, 1999) of becoming one's own 'critical friend' through reflection on practices (see also Watson & Wilcox, 2000);
- strategies for monitoring and evaluating one's own practice, such as setting criteria for performance and describing core competencies (Hammond & Collins, 1991; Wilcox, 1998) and developing the essential professional skill of self-evaluation (Boud, 1995; Oberg, 1988);
- portfolio development, grounded in an explicit statement of professional philosophy (Redman, 1994).
- *Collaborative self-study.* I use and encourage, for example:
- strategies for establishing positive relationships with clients/students (Purkey & Schmidt, 1987) that foster our own development as a professional (e.g., identifying, with clients, the qualities of helpful practitioner-client relationships), as well as collecting and using feedback from our clients/students (Rando & Lenze, 1994; Weimer, 1988);
- strategies for learning with colleagues/peers, including action-learning, networks, discussion groups, peer feedback, and mentoring (McGill & Beaty, 1995; Collier & Wilcox, 1998; Hutchings, 1994, 1996; Zachary, 2000).

Summary

I have emphasized the theoretical foundations for my recommended use of self-study as a means of self-directed professional development, and have provided a framework, including examples, for the ways this approach shapes my practice.

Not surprisingly, I have learned most about the transformative power of self-study through self-studies of my own professional development (Wilcox, 1997, 1998). A self-study of my growth as a novice in the field of educational development in higher education allowed me to become an active agent in my own learning and development. Most significantly, I discovered that my transformative journey was facilitated through a collaborative relationship with a colleague/client (Strachan & Wilcox, 1996; Wilcox, 1997).

When Ian Strachan (geography professor) and I decided to write about the educational development process we were engaged in, our writing together was an excellent way to check assumptions, to clarify what we knew and what we believed and, to draw finer distinctions in the meanings of our respective explanations for practices. Being able to do educational development work and reflect on the process at the same time offered a holism that enabled me to be fully present and engaged, curiously and critically participating in professional practice. This collaborative self-study transformed my experience of educational development work. I also found that critical reflection on my experiences allowed me to make and defend explicit knowledge claims about the process of educational development and the nature of educational development work (Wilcox, 1998). These personal experiences have served to strengthen my commitment to engagement in self-study as a valuable form of professional development in higher education.

Margo now concludes this depiction of self-study through our three different professional contexts with her emphasis on professional artistry.

Self-study to Inform Professional Artistry

For many professionals, theory and practice often seem at odds when in fact there should be a dialogue between both realities to ensure effective practice. I have found that the concept of professional artistry offers one way to bridge the gap between theory and practice and that practitioners' self-studies encourage the development of professional artistry.

After almost 15 years in the field as an occupational therapy (OT) practitioner, in my first position at the university as Academic Fieldwork Coordinator, I was responsible for student fieldwork placements/practica. This position gave me regular contact with OT practitioners and I became aware that, although they were able to maintain their clinical currency and had developed 'theories in use', their 'espoused theories' (Argyris & Schön, 1974) did not necessarily reflect their clinical experience and practice-based knowledge. At the same time, many clinicians seemed alienated and intimidated by the formal theory that was being published within their own profession and could not relate to it. My observation was that this resulted in an unnecessary division between academia and the practice setting, which is worrying for a relatively new profession like OT, where theory development is crucial to the future success of the profession.

In the 21st century, all health professions are expected to demonstrate accountability through 'evidence-based practice'. Governments and other funding agencies, wanting to make best use of limited financial resources, demand evidence

that best practice is occurring through collaborations between researchers and practitioners. Therefore, it is necessary that the gap between theory and practice narrow rather than widen. Throughout my teaching career at the university, I have valued the reality orientation of hands-on clinical practice and have actively sought ways to bridge the gap between theory and practice.

A focus on the development of professional artistry informs and pervades my efforts to prepare occupational therapy students for practice. I will discuss why professional artistry makes sense and how I have incorporated artistry in occupational therapy professional education, including such self-study strategies as: fostering experiential learning; facilitating dialogue; encouraging self-assessment; promoting reflective practice; understanding clinical reasoning; and, supporting holistic professional practice.

What is Professional Artistry?

Professional artistry is defined by Schön (1983, 1987) as the, "competence by which practitioners actually handle indeterminate zones of practice" (1987, p. 13). He refers to the artist practitioner as, "unusually adept at handling situations of uncertainty, uniqueness and conflict" (1987, p. 16). He stresses the need for artistry in professional education and suggests that reflection-in and reflection-on action, are central aspects of professional artistry. Fish (1998) lists a number of characteristics of professional artists including intuition, imagination, improvisation, creativity, empathy, holism, and critical thinking. She encourages the concept of critical appreciation of the art of practice much like an art critic evaluates the meaning of a piece of art or music.

Although their backgrounds are physiotherapy, Beeston and Higgs (2001) propose that professional artistry can be viewed generically. They build upon the work of Eisner (1985) to suggest that artistry is comprised of both connoisseurship and criticism. Excellent professional practice involves an, "understanding of the nuances, subtleties, wordless being and interactions" (p. 116). Within the teaching profession, Goodfellow (2000) refers to artistry as acting with, "wisdom, integrity and understanding as they participate in the uncertainties of the living and experiencing that is cooperating teaching" (p. 26).

The *artistic paradigm* is a way of thinking and knowing that is an extension of the interpretive and critical paradigms described above through Jinx and Susan's cases. Eisner (1981) points out many differences between scientific and artistic approaches to qualitative research but his final point is that, "we must turn to the artistic not as a rejection of the scientific, but because with both we can achieve binocular vision" (p. 9). Fish (1998) has taken this view a step further and developed a paradigm of artistic practice, which goes beyond the critical paradigm and encourages the practitioner researcher to take an artistic approach; the opposite of a technico-rational research approach.

The purpose of the artistic paradigm is to inform practitioner judgment and to encourage an appreciation of practice. The artistic paradigm is characterized by holism; viewing theory and practice from a holistic perspective. Artistic

research methods involve creative arts processes, narrative and, critical commentary often on a small scale.

Why is Professional Artistry Important?

In the 21st century, an artistic paradigm is needed in both the academic and practice settings. The benefit of artistry is that it acknowledges that there are unique and valuable aspects of professional practice on an equal footing to the scientific world. Artistry has been essential to me as I relate my academic and practice worlds, which are often at odds when in fact there should be a dialogue between both realities. Despite the emphasis on scientific approaches and increasing professionalization there is still a need for the less explicit aspects of practice to be acknowledged and celebrated. As Eraut (1994) notes,

> Professional knowledge cannot be characterized in a manner that is independent of how it is learned and how it is used. It is through looking at the contexts of its acquisition and its use that its essential nature is revealed … professional knowledge is constructed through experience and its nature depends on the cumulative acquisition, selection and interpretation of that experience. (pp. 19–20)

The professions in general have moved from an earlier era (1950–80s) whereby the art and science of practice was accepted, to an increasingly scientific emphasis towards the end of the 20th century with a resultant skepticism towards artistry. In the health professions, medical practitioners first stressed the need for evidence-based medicine with the push for quantitative research approaches where the gold standard was randomized clinical drug trials. This is gradually being challenged. Allied health professionals have since followed suit with a push for evidence-based practice meaning that practitioners need to seek evidence in the literature to prove that they are providing best practice. Administrators jumped on the bandwagon with a demand that practitioners be able to demonstrate that they were providing effective and efficacious treatments (Taylor, 2000; Tickle-Degnen, 1999).

With the knowledge explosion of the past few decades it is apparent that new graduates quickly become out of date in their practice unless they incorporate various ways of keeping themselves clinically current. They must strive for excellence by combining evidence-based practice and professional artistry (Zimolag *et al.*, 2002). One solution to this dilemma is to promote the concept of self-study to students who will eventually become beginning practitioners and hopefully life long learners. At the same time there has been an upsurge in qualitative research methods and an increased understanding of the benefits of approaching research from alternative perspectives. This is in response to the realization that quantitative research is not applicable to all research questions. In occupational therapy, for example, controlled experiments that reduce movement or occupation to a simple cause-effect relationship lose sight of the persons involved (client and practitioner) and the reasons underlying movement or

engagement in occupation. Experimental approaches assume that: a) people with the same injury, disease or degree of disability will have the same rehabilitation outcome; and, b) there is a single best course of treatment, with no practitioner judgment involved – fallacies that few experienced clinicians would support (Hammell *et al.*, 2000).

The artistic paradigm and professional artistry, on the other hand, offer a positive perspective on the uncertainties of the real practice environment and self-study offers a more grounded approach to the improvement of professional practice. In a sense there is a symbiotic relationship between the two concepts, professional artistry is enhanced by self-study and those who access self-study opportunities and engage in reflective practice are more likely to become professional artists.

Strategies for Incorporating Artistry in Practice and Education

As background to the discussion of strategies I use to incorporate artistry in occupational therapy practice and education, for those readers who are not familiar with the profession, I offer this definition: *Occupational therapy* is a health discipline aimed at promoting, restoring and maintaining health through occupation. Occupation consists of a balance between the three spheres of self-care, productivity, and leisure. Occupational therapists work with people who are disabled by illness or injury, emotional disorder, congenital or developmental disorder or the aging process (CAOT, 1997; Kielhofner, 2002).

> Occupational therapy is concerned with the key elements of occupational performance: the individual and the roles, occupations, and relationships which that person has in the environment which he or she inhabits. [It] aims to enable and empower people to be competent and confident performers in their daily lives, and thereby to enhance well-being and minimize the effects of dysfunction or environmental barriers. (Hagedorn, 2001, p. 5)

Fostering Experiential Adult Learning

A useful starting point in promoting artistry is to acknowledge that beginning professionals, or students in the professions, are responsible adult learners who can access experiential learning and self-directed learning opportunities (Knowles, 1975; Wilcox, 1996). Models for promoting learning from one's experience (Boud, Keough & Walker, 1985) and acknowledging the importance of self-direction for life long learning (Candy, 1991) are very helpful in facilitating student learners to see experiential learning in a broader perspective that really impacts on their lives and their future as health professionals.

I encourage student learners to develop an awareness of their own *learning styles* and thus their strengths and weaknesses as they approach new learning situations. This emphasis on taking responsibility for their own learning and using it to their own advantage in the university as well as the clinical fieldwork setting has been a primary message in my teaching. Students complete learning

style inventories (Honey & Mumford, 1986; Kolb & Fry, 1981; Kolb, 1984) early in their OT educational program and are expected to communicate this to their preceptors/clinical educators in clinical fieldwork settings. I have been involved in situations where this has been crucial to sorting out communication problems students experience when adjusting to the real world of clinical practice in their fieldwork education.

I have used *learning contracts* to assist student learners to see that all four aspects of Kolb's (1984) experiential learning cycle are played out when learners move from the university to the fieldwork setting (Abstract conceptualization → Active experimentation → Concrete experience → Reflective observation). Learning contracts have been beneficial in both the academic setting and the fieldwork setting to facilitate self-directed learning (Gaiptman & Anthony, 1989; Tsang *et al.*, 2002).

A key example of experiential learning is *fieldwork* placements conducted in hospital and community settings by occupational therapy students. As the university liaison person with the fieldwork settings for 10 years, I observed many instances where the concrete experience of fieldwork education provided a foundation for understanding the theory learned in the classroom and a place for learners to reflect in and on their actions. Reciprocally, the practical fieldwork experience made the theoretical knowledge from the classroom experience real to the student learners (McAllister *et al.*, 1997; Alsop & Ryan, 1996). From my experience, I have come to see that students often return to the university from their fieldwork experience with a sense of wonder that finally the theoretical material learned in the classroom 'clicked' for them. They recount many 'ah-ha' experiences after six or eight weeks in a practicum, especially when their preceptors mentored them and encouraged self-direction in the learning situation. For example, a student encountering a child with a new diagnosis or disability would need to refer to anatomy and pediatric texts as well as OT practice texts while in placement in order to offer quality services to the child. Often these situations are life and career changing events that are transformative opportunities for the student learners, which ultimately impact on future career specialty choices (i.e., working in a children's outpatient centre versus adult psychiatry).

Facilitating Dialogue

Ongoing teacher-student dialogue assists the student learners in understanding the process of becoming a professional and one tool that I have used for this is the weekly dialogue that is *journal* communication (Ashbury *et al.*, 1993; Trysennaar, 1995). Journaling has offered a rich opportunity for students to explore their own reactions to their learning as well as a chance to engage in their own reflective discussion about more complex issues such as ethical dilemmas; awareness of personal/ professional boundaries etc. Through journaling, students are encouraged to express themselves verbally but also to use creative and artistic forms of expression if they wish. Examples of this are the addition of drawings, photographs, cartoons, newspaper clippings, magazine articles, in short, anything that is relevant in assisting the students' self-study and to

support/reinforce the dialogue between journal writers. As an example of the type of self-study that is possible with journal writing I will quote from a student journal:

*Self-awareness is key for developing effective therapist-client relationships. If you know yourself and are reflective, you will ideally be able to recognize what affects your effectiveness as a therapist, both positively and negatively. I like this idea because it recognizes that every person is different and there are no hard and fast rules. What is good for one therapist might be bad for another therapist. The key is acting on that self-knowledge. Some people in our class said that for them they would need to consciously **not** bring their work home with them so they have a life outside of work and are not excessively burdened down by other's problems. But I think for me that thinking outside of direct interaction is key for my effectiveness. When I am interacting with someone, I see them in a certain way and may be acting under assumptions. But when I am not with them and not under interactional demands and constraints, I am free to mull over the situation and perhaps think of the problems in other ways. I may miss the obvious, but later, in the middle of doing something else, an idea may pop into my mind or I may see or read something that will cause me to pursue other possibilities. (HV, personal communication, 22/11/00)*

This student used her journal writing to have a weekly dialogue with her teacher and also to track her own ideas as part of her own self-study and development.

To illustrate another example I have included the attached magazine picture Figure 8.1, which was submitted by a student in her journal.

Figure 8.1.   Magazine picture submitted in journal.
Artist: Sylvie Bourbonniere.

This picture was followed by the entry below:

> *I came across this picture which I could totally relate to. The picture illustrates a woman who seems to be juggling her work (the clock and buildings) with her health (the flower plant) all in a day (full moon). For me, I feel like I was juggling homework and preparation of the interview with my illness (stomach flu) all in one day. (RJ, personal communication, 22/11/00)*

When I approached this student 2 years later, requesting use of her journal entry in this chapter, she happily complied and added the following:

> *As I read my OT 240 interview entry specific to this picture I couldn't help feel a tinge of familiarity, maturity and satisfaction. As I looked over this picture, I realized that the ideas that I had written in my journal still stand, however I feel as though my experiences at Queens – both academic and social – have enabled me to grow and develop from a tiny seedling into a strong, mature individual. Just as the lush green leaves of the plant, I too feel as though I have been granted here the world; something that I can give back for the life I have been granted here and now. Being so close to graduation and having so many rich experiences to look back on, I can shed a new light to the meaning of the photo. As a woman, I believe the struggle between one's personal, social and productive lives will be ever evolving. Just as we think we have mastered and completed one task, another arises for us to conquer and the cycle continues though out our lives. When I first wrote about this picture, I was at the beginning of this cycle, having to take responsibilities and juggle my time between school, adjusting to living in a new city on my own, being away from loved ones, and carrying out tasks … I guess what I am trying to say is that I can now appreciate this photo on a broader level and I have no doubt in my mind that when I look at this picture 5 or even 10 years down the road I will have a new perspective on its meaning. Thanks for listening Margo. Sorry if I have rambled on; I just thought I would share these new feelings with you. (RJ, personal communication, 12/2/03)*

This comment strongly reinforces my sense that the dialogue that begins early in the occupational therapy education program continues between students and educators long after the course is completed. This type of interaction is both exciting and powerful. As an educator, I find it very gratifying to see these students recognizing the importance of self-study and growing personally and professionally.

Encouraging Self-Assessment

I believe that opportunities to engage in self-assessment allow students to learn a critical appreciation for the art of practice and thus are essential to the development of professional artistry. For example, students in the first year of the OT program engage in an intensive communication skills course whereby

they complete a weekly interview with a volunteer client and have the opportunity to *videotape* these interviews and receive immediate feedback from their classmates and their teachers. This *self-assessment technology* has not replaced the teacher but has provided real evidence for students of areas for self-improvement. Consider a student who interviews a volunteer client and makes an error in judgment by asking an inappropriate question, she then has the opportunity to see that error on the videotape review. The student is aided in self-critique by using a checklist of verbal and non-verbal cues. Students are amazed by the way that they come across to others and make corrections themselves for the follow-up interview. They are also encouraged to continue with their self-study, by reviewing their videotapes and making weekly journal entries.

This communications skills course has been greatly enhanced by the addition of a state of the art interdisciplinary building shared by medicine, nursing, physiotherapy and occupational therapy students whereby the students 'rub shoulders' with the peers whom they will encounter in the future in the real clinical world. They learn practical hands-on skills in a safe environment where it is acceptable to make mistakes and correct themselves; continuing their self-study journey. This setting and the advanced technology is unique and the envy of other health science programs nationally and internationally.

Promoting Reflective Practice

Schön's seminal work on reflective practice has encouraged many professionals to take a closer look at themselves and to consider the depth of their practice. Schön began the pursuit for alternative ways to think about practice by suggesting that:

> The question of the relationship between practice competence and professional knowledge needs to be turned upside down. We should start not by asking how to make better use of research-based knowledge but by asking what we can learn by careful examination of artistry. (Schön, 1987, p. 13)

All of the above strategies have been successful for encouraging beginning students to reflect upon and communicate their own progress in their professional development. In the upper years of the Queen's University occupational therapy program, reflection is encouraged through a final year independent study course where students complete a *professional portfolio* prior to graduation (Alsop 1995a & b; Bossers *et al.*, 1999; Crist *et al.*, 1998). One component of the portfolio is a five page personal statement, which encourages reflection on the theoretical and practical experiences in the educational program. It is designed to assist students to consolidate their learning from the occupational therapy curricula. My experience has been that the use of portfolios has facilitated reflective practice in these graduating students as they start their new lives as beginning practitioners. In the words of a member of the Queen's University occupational therapy graduating class of 2001,

> *In training to become an Occupational Therapist, there were many times when I wondered how the knowledge gained in the courses I was taking fit together and how it would help me to become an effective therapist. Completing the portfolio course, at the end of my training, helped me to reflect on all that I had learned and all that I still needed to learn. The course served not only as a reflective tool, but also as a springboard for future learning and professional growth. (NL, 04/03/03)*

On a practical level, when students become new graduates they take their portfolios to job interviews and use them to show potential employers that they have evidence of their development through their professional journey. In a less tangible way, they also refer to the process of preparing their portfolios as a way of organizing their learning and to link the various aspects of the curriculum (that often seems fragmented until the end of the degree when they see the linkages across their undergraduate OT program). This view is further supported by authors such as Kinsella (2000), who published a practitioner workbook to facilitate reflective practice. She advises:

> Reflective practice offers a fresh approach to professional development. It does not begin with an outside expert but rather with your own experience as a professional practitioner. It is a professional development strategy that calls upon you to be an active participant, rather than a passive recipient. You are the expert in terms of what you have learned from your professional experience. Continue to tap into your own expertise so that it can serve both you and your clients in the years to come. (Kinsella, 2000, p. 63)

A further indicator of the usefulness of portfolios in the real world came in 1995 with the Regulated Health Professions Act in Ontario and the establishment of the College of OT of Ontario. In response to public demand for ensuring quality care, the College instituted a process whereby practitioners were required to develop their own portfolios – which then must also be available for a random auditing process at any time. This type of reflective activity is designed to ensure that health care practitioners – who often struggle to keep current within the context of changing health care, globalization, etc., (Higgs & Edwards, 1999) – will be successful in continuing to develop a repertoire of professional behaviours (Fidler, 1996). Although this may seem to be a bureaucratic exercise in account-ability, my observation is that there has been an increase in clinician attendance at university sponsored continuing education opportunities that are documented in the College of OT portfolios. Further to this, clinicians have also taken more interest in suggesting topics that they would benefit from learning about at annual clinician-faculty professional development days.

Finally, clinicians have recently indicated a desire for upgrading from Bachelors to Masters level education with the introduction of a clinical masters degree at the university effective September 2003 (in addition to the research Masters degree which has been in place for over a decade). All of these examples suggest that clinically based OT practitioners are making efforts to maintain

currency and to direct their own destiny as life long learners. My belief is that keeping a portfolio is an activity that stimulates this process. The Deputy Registrar at the Ontario College of OT provides another perspective on the value of professional portfolios, highlighting the close relationship between self-assessment and reflective practice:

> *We worked with the Conscious Competent model … (from Edward Demming's work). Within this model the concept is that consciousness about practice ensures the highest level of performance, and reflective practice is one method that supports raising consciousness about one's practice. Of 21 health colleges, 15 have implemented some form of self-assessment and professional portfolio into their quality assurance programs for similar reasons as us: one, reflective practice is expected to lead to more appropriate learning/continuing education activities and two, portfolios serve as a good tool to demonstrate one's ongoing professional development activities. (SJ, personal communication, 24/02/03)*

Understanding Clinical Reasoning

In recent years there has been increasing interest in understanding clinical reasoning in the health care professions. Higgs and Jones (2000) defined clinical reasoning as, "a process in which the clinician interacting with significant others (client, caregivers, health care team members), structures meaning, goals and health management strategies based on clinical data, client choices, and professional judgment and knowledge" (p. 11). Rogers (1983) was one of the first occupational therapists to make the link between reasoning and artistry, defining professional artistry as, "the artistry of clinical reasoning … exhibited in the craftsmanship with which the therapist executes the series of steps that culminate in a clinical decision" (p. 615). She describes the artistic components of the OT decision-making process, including: inter-personal skills; adeptness in gathering cues; perceptual acuity; and, non- verbal aspects of professional practice. Further, the research work of Mattingly and Fleming (1994) articulated the various types of clinical reasoning used in occupational therapy (narrative, conditional, inter-active and procedural reasoning). A survey of occupational therapy educators in five countries (South Africa, New Zealand, United Kingdom, Canada and Australia) found that Mattingly and Fleming's work has had a huge impact on the occupational therapy curricula (Paterson & Adamson, 2001) as students learn to recognize the more artistic aspects of reasoning as opposed to only the traditional hypothetico-deductive types of reasoning.

According to an exploratory study of occupational therapy students, facilitating the development of self-directed learning and clinical reasoning involves supporting students as they construct their professional self-identity and competence (Paterson *et al.*, 2002). *Journal writing* and *portfolio development* are effective strategies to assist in this growth because the learner must actively take ownership and relate their learning to their own personal circumstances, applying

theoretical concepts to their everyday life experience. Ryan and McKay (1999) encourage the use of *narratives* to facilitate thinking and reasoning in occupational therapy, which are compatible with other self-study approaches.

Supporting Holistic Practice

Another aspect of artistry and the artistic paradigm is the importance of holism, which in the occupational therapy field is acknowledged through *client-centred practice* (Egan *et al.*, 1998; Sumsion, 1999). In my case this has been through involvement in a departmental initiative called the Community Partnership Project, which was implemented in 1999 as a trial project. Students are paired with a volunteer client with a disability living in the community and they meet with this one client for approximately 2 hours per week for 6 weeks. The objectives of this experiential education for students are to develop an awareness of disability; identify challenges that people with disabilities face; acknowledge the multiple factors which influence occupation; recognize the complexity of an individual's unique situation and environment as a pre-requisite for client-centred practice; develop a community orientation as a framework to study OT theory and practice; and, finally to initiate a process of self-reflection.

A complete description of the course and its perceived success have been published elsewhere (O'Riordan *et al.*, 2001; Paterson *et al.*, 2000). Importantly though, this holistic approach fits with the need to assess the whole picture of the client with a disability and their lifestyles rather than adopting a reductionist approach to practice. Regular journal writing with the course coordinator is a key component of this experience to promote ongoing reflective practice.

Summary

I have defined artistry and the artistic paradigm, described why they are important concepts, and illustrated my use of a number of strategies in my teaching and research to promote professional artistry. For me, artistry provides an overarching framework for the development of professional practice through self-study: an artistic paradigm clearly promotes self-study in professional practice and self-study encourages artistry. This can be seen as a cyclical or symbiotic relationship.

I have offered a number of experiential adult learning tools (e.g., learning style inventories, learning contracts) for students to become more self-aware. In addition, self-study tools (e.g., journals, videotape/self-assessment technology) that facilitate dialogue, promote reflective practice and foster the development of clinical reasoning, culminating in a holistic approach through client-centred practice.

As stated earlier, many OT practitioners develop 'theories in use' quite easily but do not readily connect this practice-based understanding with 'espoused theory' in the profession, which sets up a dangerous separation between academia and the practice setting. Professional artistry is one way that this artificial divide

can be minimized. Practitioners engaging in self-study can examine their unique insights and ultimately contribute to the knowledge base of the profession.

Conclusion

What then is self-study? Is it research? Is it development? Is it the action of participating in the multiple and varied processes of inquiry we have each described in our practice settings? Is it self-study only when the situation is examined further and written up to be communicated to others? Are the activities we have outlined bits of self-study or possibilities for self-study or are they full-fledged self-study? And when is that self-study valuable: when it results in observable transformations in our practice or when the knowledge gained is accepted as legitimate by our academic peers?

These are good questions for which we have not offered definitive answers. We simply propose, and have argued here, that self-study is vital to professional practice. Self-study allows practitioners to engage in inquiry that contributes to their own capacity for expert and caring professional practice while also contributing to the growth of their professions. Through active, engaged, self-directed reflection on practice experiences and ongoing, critical questioning of our individual and communal stories of practice, professionals establish an ever-deeper understanding of self and practice. Self-study suits the needs of both novice and seasoned practitioners, assisting them in knowing themselves more authentically within the context of their work, encouraging them to uncover, critique and celebrate the less explicit, yet significant, aspects of professional practice.

Practitioners are empowered, through their self-studies, to transform their practice to better suit particular settings and purposes. And self-study helps develop professional artistry, so that practitioners are more adept at handling situations of uncertainty, uniqueness, and contradiction. Self-study is a simple, yet grand, scheme for lifelong learning in the professions, and its time has come. We look forward to conversations concerning self-study within an ever-widening circle of professions.

THINKING ABOUT THE THINKING ABOUT SELF-STUDY: AN ANALYSIS OF EIGHT CHAPTERS

Robert V. Bullough, Jr. and Stefinee E. Pinnegar
Brigham Young University

Abstract

This chapter has specifically been written to offer the perspective of critical friends on the issues raised in the first section of this Handbook. As a crucial aspect of self-study, there is an ongoing need to move beyond oneself and to grasp alternative viewpoints on situations. Attending to alternative perspectives is important in self-study so that the development of ideas and actions and, the resultant learning, might be informed by careful consideration of perspectives beyond the self in line with the ideas of framing and reframing described by Schön (1983, 1987). However, framing and reframing is itself problematic and this chapter explores how, through a careful analysis of the first eight chapters of the Handbook, critical friends are able to question and critique the work of others in meaningful ways. This chapter is illustrative of the underlying approach to self-study whereby honest and professional critique is sought to enhance learning and to better inform the subsequent claims derived from such learning.

Ours is a daunting task, to critically review the eight chapters that comprise this section of the Handbook and to identify themes that cut across the chapters. Our hope is that what we write will be of value to the individual authors as they consider their future work, to readers interested in self-study research, and to self-study practitioners who see themselves as pioneering a new area of study, sometimes characterized a bit pretentiously as a movement and other times as an incipient field of inquiry.

Introduction

Our initial review of this section of the handbook led us to divide it into two parts for analysis (with Stefinee taking on the first and Bob the second). The

first part, comprised of four chapters, develops a functional definition of self-study holistically and then in terms of each of the three elements or purposes of self-study: inquiry, teaching, and research. The second part, also comprised of four chapters, attempts to establish the worth of self-study through examining what self-study has contributed to our understanding of teacher education, what it has not examined, how its voice is represented, and how it can serve other kinds of professional practice.

Explorations of the Boundaries

Loughran's introductory chapter explores the definitional boundaries of self-study. In the second chapter, Clarke and Erickson examine self-study from the standpoint of the underlying nature of inquiry. The third and fourth chapters take on self-study from each of the two worlds of teacher education. In chapter three, Tidwell and Fitzgerald examine self-study from the standpoint of teaching and in chapter four, Ham and Kane consider self-study from the standpoint of research.

Chapter 1: A History and Context of Self-Study of Teaching and Teacher Education Practices

In the first chapter Loughran attempts to contextualize self-study by establishing broad, holistic, boundaries for determining what is and is not self-study. He begins by noting that self-study originates in the recognition that teachers stand simultaneously in two worlds – the world of practice and the world of scientific research on education. The central aim of self-study practitioners is "to understand teaching from the inside out rather than the outside in and to simultaneously put what we learn into practice". Loughran sets definitional, functional, historical, and epistemological boundaries in his attempt to define self-study. Subsequent chapters in this section explore these boundaries in various ways.

The struggle for definition has been central at every gathering of self-study researchers. Even now a satisfying definition remains illusive. As we consider this quest for definition, we find ourselves wondering: Is a definition needed? Is the quest doomed from the beginning? Language is always metaphoric. When definitions are set the thing or practice named is altered – changed in subtle ways. Unwittingly a joyous and experimental practice slips into technique; and poetry turns to prose. When a term is completely nailed down it loses life and the living territory that once uniquely belonged to it is taken over by other words or lost altogether. Children learn to speak language and make meaning with it by using it. We learn new languages by using them. In using a language, we come to understand the nuances of meaning and structure. For my part (Stefinee), I have come to understand that when I act in certain ways in my research practice what I am doing is self-study. Functional boundaries are the ones that I employee when I seek to make sense of this form of action called self-study. Self-study is what self-study practitioners do. But it is also, as we will

suggest later, a moral stance, a matter of ontology more than or in addition to epistemology. Ultimately, no fixed definition is possible, nor is one desirable.

Loughran's boundaries help to distinguish self-study from traditional research and research methods and posit the topological features of the two forms of practice involved. Thus, those who want to understand self-study as a research movement but not necessarily conduct self-study research will find such maps helpful in understanding or accounting for self-study research. Similarly, those who conduct self-study research will find both the proposal of these categories and an exploration of them helpful for interrogating their own understanding of self-study research and moving their own work forward. As a self-study pioneer and theorist, Loughran is ideally positioned to set the terms for further discussion and debate. He is trustworthy.

Loughran begins this chapter with a historical exploration of the use of the term self-study as a descriptor in research studies before the emergence of the Self-study in Teacher Education Practices (S-STEP) research community. This exploration identifies three ways in which the term, "self-study," was conceptualized in past educational research. In one set, self-study describes individually paced learning by students. In a second, self-study is a term used in research where individual's views are measured in relation to their development of self-image or identity in a particular profession or field. A third and still prevalent use centers on institutional evaluation where current status is compared to underlying institutional purposes or against criteria of an outside accrediting agency.

Loughran suggests that the last type is possibly the most connected to current self-study work, although the psychological understandings of self and development of self are also critical. What work in the last area establishes is "the expectation that beliefs and practices should be closely aligned and that the self (however this might be understood as a person or program) carries a major responsibility in establishing this alignment." This feature is central in most current self-study work.

Loughran's discussion of these three uses of the term, "self-study," points to the importance for sense making of attending to how definitions of compound words are constructed. The meaning of compound English words is established by the meaning we assign to each term and the relation between the two words. For example, snowmen are figures made out of snow and dressed as humans. Mailmen are not, however, made out of mail, instead mail names their work – humans delivering the mail. In each of the three fields of self-study work reviewed by Loughran self and study employ a different sense of self and a different relationship to study. In the first, the term "self" refers to the fact that the learner is alone and working alone and "study" in this use means "learning". In other words, the study (learning) is done "by" the self in isolation. In the second use of the term, the self refers to a psychological construct representing an individual human held by that human, and "study" means to explore. Thus, self-study is a study of the development of the self. Interestingly, in this instance, the study of the self is actually conducted by someone other than the self, an external

agent. The final use of self-study points to the more functional definition that Loughran finds useful and proposes be embraced by the self-study of teaching and teacher education practices research community. In this instance self is understood reflexively. An individual or an institution or a program examines itself. In this use of self-study the study is done by the self on the action of the self for the purpose of examining the relationship between belief (or knowledge) and practice (that in turn define the self). The self is the person doing the work and the work is study. Thus, "self-study is used in relation to teaching and researching practice in order to better understand: oneself [in the various roles assumed]; teaching; learning; and the development of knowledge about these." What comes to be understood is teaching and learning and the relationships between them and the elements of practice in relation to preparing teachers (by a self – individual or institutional) in terms of the self. In this way, those who do autobiographical work and use that work to understand who they are as a teacher, or to understand schools as institutions, or the work of being a teacher educator are doing self-study. Those who begin with beliefs about their own practice as teachers in relationship with their students and then find ways to reveal themselves and their practice in order to determine if their practices embody those beliefs are also doing self-study. Those who want to understand what happens in the development of future teachers [and thus the practice of self as a teacher educator] in particular learning contexts in particular kinds of activity also could be engaged in self-study. As Loughran suggests, this is not research whereby the researcher distances self from what is to be studied and from that distance manipulates the subject being studied. Rather, the term acknowledges that the "self", the person, is at the center of all research. This position (the role of the self and the active changing nature of what is being studied) has implications for evaluating the worth and establishing the value of self-study research.

   In providing a functional definition of self-study, Loughran establishes purpose or researcher intent as the definitive boundary for self-study. He explores that boundary through an examination of the use of the term "modeling" within self-study in contrast with the use of "modeling" as a term in social learning theory. He establishes that since the purpose of self-study is to come to understand teaching and teacher education practice, self-study researchers are not attempting to promote a uni-dimensional transfer of their own teaching practice directly into the teaching practice of pre-service teachers. Instead, self-study practitioners expect that their explorations will support future teachers in establishing their own practice, their own voice as teachers, and their own moral stance in relationship to their students. Of course, the dilemma is what happens when students in their roles as teachers choose to instantiate teaching practices in opposition to those modeled and promoted by the teacher educator. The side-stepping of this dilemma in the reports of many self-studies through a focus on teacher or teacher educator learning more than the learning of students or teachers often makes self-study appear to be a "romantic" genre. For example, Loughran quotes Schulte (2001): "My students have said that many of the strategies and activities

I used were successful, at least in the short term in helping them to challenge their assumptions about teaching and themselves. Practice and my students' positive feedback have given me courage." Such a stance can promote the view of the teacher educator as "romantic hero". However, when we examine self-study work we find as well examples of researchers who freely reveal the difficulty of "student resistance" and the failure of certain preferred practices.

Loughran's exploration of the historical context from which self-study emerged articulates the complex interplay of the wider acceptance of alternative methodologies and research practices by the educational research community and the overlapping of particular research agendas within the larger research conversation and within the field of research on teaching and learning to teach. These overlapping and shifting research commitments included a move from a focus on the study of learning to the study of teaching, an exploration of the understanding that how teachers thought in their practice had a determining influence on their practice, a commitment to understanding the tacit theories of teachers in order to better understand teaching practices, and the reflective practice movement in teacher education.

As we considered the work reviewed by Loughran in this section, we noted a common underlying theme – a moral commitment to improving practice. From the beginning, even before the establishment of the self-study SIG, many of the teacher educators involved in self-study research felt that whatever we taught students about teaching should be evident not just in our statements about teaching but in our teaching practice. In order to do this we had to understand our practice better and determine how and when our action did not reflect our beliefs about teaching and teacher education. In fact, in retrospect I (Stefinee) think the reason why the Arizona Group began to explore their experiences in institutions of teacher education was that we believed we had been hired because the institution shared our beliefs about the education of teachers and wanted to develop programs sensitive them (Arizona Group, 2002). Instead, we found the opposite to be true. The collision of our idealism and the reality of the academy fed our efforts to understand what we were experiencing. Thus, the historical boundaries of self-study coalesce not just in understanding the thinking behind teaching, the dynamics of reflective practice, and the developmental path of learning to teach, but around issues of the collision of romantic ideals and institutional realities and moral commitment and obligation.

In exploring the epistemological boundary, Loughran revisits work done earlier by he and Northfield (Loughran & Northfield, 1998) whereby they proposed concepts for evaluating self-studies which could, they hoped, establish a foundation for making claims about teaching and teacher education. His list of features and characteristics helps members of the self-study research community determine what is and is not self-study research. Beginning in a section entitled, "Factors that influence the nature of self-study" and continuing to the chapter's end, he presents and examines evidence that the following features constitute the epistemological boundary of self-study research:

(1) "Self-study defines the focus of the study; not the way the study is carried

out." Loughran argues that the proper terrain of self-study work is the relationship between the self and the practice of teaching or preparing teachers. How someone engages in such research is actually a matter of academic choice. New technology and a widening acceptance of various research methodologies expand the tools available for those who want to examine practice as it happens. It allows for the study of self in the act of practicing. For example, videotapes of teaching, alternative descriptions of teaching practice (students, colleagues, self) and re-interpretation of initial responses to teaching situations each are promising research tools.

(2) Self-study researchers reveal evidence that they sought alternative perspectives from those they reached. In seeking alternative perspectives, self-study researchers attempt to establish a viable description of the reality of their teaching. Self-study researchers routinely explore alternative versions of the reality of a particular experience.

(3) Self-study and reflective practice are not the same thing since reflection largely resides within the individual whereas self-study "demands that knowledge and understanding derived be communicated" in order to be challenged, extended, transformed and translated by others. Loughran argues that like all research, self-study requires that researchers make public their descriptions of the reality of their practice in order that such descriptions might be challenged. Thus, new conceptions or constructions of reality can be further explored or the limits of the conception proposed can be revealed.

(4) Self-study data gathering is dominated by dilemmas, tensions, and disappointments. Loughran articulates the ways in which gathering data when you are yourself part of a study exists in a world of relationships, politics, and other tensions. Thus, data gathering provides the sharpest collision between ideal images of ourselves and our practice and the reality of how others experience our practice. Thus, personal humility is an important researcher attitude, one that must underpin data gathering.

(5) Self-studies recognize the importance of audience in shaping the nature of individual self-study reports. How we present our view of what is "real" in our teaching and what we come to "understand" as a result of our study is shaped by the arena in which we report. Loughran suggests here that establishing the veracity and "realness" of our claims from self-study is shaped by what we can assume about the audience and what counts as "real" to them. A self-study audience may want different information about a study than would a research journal.

As we review these features and Loughran's exploration of them, we discover that in attempting to establish an epistemological foundation for self-study, Loughran actually establishes an *ontological* one. Ultimately, self-study is best characterized as a way of being for and with others – by a moral commitment to better understand ourselves in relationship to the practices that mediate our human connections so that we can better care for others. It is, therefore, a reflection of a particular moral stance toward the world. When I (Stefinee) consider why concern with ontology is central to self-study, I am first reminded

of the romantic tone of much self-study work. The collision between the romantic (the ideal) and the real generates impetus, direction, and commitment to self-study. When self-study researchers follow Loughran's guidelines, they find themselves confronted with reality rather than the romantic ideas of their practice they may have originally hoped to express or thought they expressed.

Through exploring the definitional, historical, and epistemological boundaries of self-study work, Loughran creates a framework against which we can explore the role of teaching, learning, and researching in self-study. Loughran's framework exposes the topological features of self-study work. In introducing this section of the Handbook, he establishes function and purpose as the essence of self-study research. A critical element of such research is the recognition that the self is the one doing the studying. Loughran's examination of the historical context of self-study firmly establishes moral obligation to others as a key boundary. Through his exploration of the epistemological features of self-study, he points toward issues of ontology – establishing a particular way of looking at what is real in terms of self-study and what is real in terms of self-study accounts. The consideration of ontology, of one's being in and toward the world, should be a central feature of any discussion of the value of self-study research. Against these boundaries – definitional, historical, and epistemological – Loughran proposes that work in self-study can productively allow teacher educators to honestly and simultaneously develop research and practice as the twin commitments of teacher education researchers.

The next three chapters explore each of three standpoints from which self-study can be viewed definitionally: the nature of inquiry, the perspective of teaching, and as research.

Chapter 2: The Nature of Teaching and Learning in Self-Study

Clarke and Erickson invite us to explore further the functional, moral and ontological boundaries of self-study through an exploration of the nature of inquiry in self-study. Inquiry in self-study is played out against the roles of the researcher, the learner and the teacher. Focusing on learning, Clarke and Erickson pose two questions: What is learning? and who is the learner? This introduces one of the entanglements in the reality of a self-study: In self-study there is never just one learner.

However, Clarke and Erickson never completely explore the entanglements that a question like "who is the learner?" raises as a property of self-study. The Arizona Group (1997) articulates this complication when they speak of "obligations to unseen children." Teacher educators must be constantly aware that the student in front of them will one day be a teacher. As a result, commitment to pre-service teachers cannot blind us to the obligations we have for the learning of their potential students. A romantic tone emerges in self-studies when researchers focus too closely on their own learning. There are always, after all, at least three learners who must be considered. In examining what was learned about learning, self-study researchers ask of the study, "What do we learn about the

learning of the teacher educator that can inform other teacher educators?" "What do we learn about the learning of pre-service teachers?" "What are the implications of what we learned for the learning of public school students? This makes the discussion and understanding of learning and learners in self-study slippery and contested terrain.

As Clarke and Erickson pursue the learning question, they rightfully argue that the definition of learning evidenced is usually a social constructivist one – learning as "situated and contextually-bound". Yet, much of self-study rests on another long-held definition: learning as a change in behavior. Loughran argues that a constant theme in self-study is, "Have I changed my behavior to reflect my beliefs? This makes the exploration of what is learning as conflicted as the question of who is the learner. Yet, as Loughran's epistemological and implicit ontological criteria in the first chapter demonstrate, self-study researchers expect studies in this genre to provide evidence of the way the contradictions and complexity of learning and teaching play out in teacher education practices. Self-study research findings can have the power to reframe learning, yet cause us to question further the findings. We need only look at the Pereira (2000) example quoted. He says "... mathematics teachers must change the way they learn before they can change the way they teach." Reading this finding may feel like the explosion of a bomb in busy traffic. For we instantly realize that as teacher educators we are responsible for more than the subject matter competence of our students. We then begin to wonder, "Must we call into question preservice teachers' experience in learning subject matter?" We wonder about the increased responsibility our students must therefore take for the learning of their own students. "If schools have teachers who teach differently, are the schools prepared for that? Will this "different" teaching really have the impact on student learning we expect?" Finally, what implications does this position have for teaching in teacher education and for the evaluation of pre-service teachers?

When Clarke and Erickson turn to the question of teachers and teaching within self-study, their definition points to a moral distinction that sometimes seems to slip the notice of self-study researchers. Teacher/researchers who focus on their own learning can make us uneasy about whether or not they are acting responsibly in their role as teacher. As self-study researchers, do we consider seriously enough the ways in which taking risks and being vulnerable exposes our students, and possibly theirs, to unscrupulous or inappropriate teaching where students are asked to set aside concern for their own learning to support the learning of the teacher? More than the vulnerability of teacher educators in self-study, emotional strength and humility and the ability to respond in the heat of the moment in ways that are morally appropriate and supportive of students are bigger issues. In doing self-study research, we may create a new space and reality for teaching and learning. When we create new spaces and new realities, we create new terrain for moral obligation and responsibility.

In a section entitled, "What is inquiry? Who is the inquirer?," Clarke and Erickson place issues of teaching and learning raised in the chapter within the framework of self-study as research. Here the terrain becomes difficult, indeed.

For how do we simultaneously meet the requirements of research and the moral obligations we have as teachers and teacher educators? Our purpose in studying our own practice is to come to understand it and thereby, we hope, to improve it. Research in learning has often pointed to the fact that when new meaning emerges the automaticity of routines is disrupted and established practices and routines may actually disintegrate rather than become smoother until the new knowledge is integrated and new routines developed (Bereiter, 1993). This is the greatest vulnerability we face as self-study researchers. In studying our practice to understand it and create stronger practice, we will actually disrupt it. As a result, we actually may be less competent as teachers in the moment of self-study than we would be had we not been so engaged. We know that as we discover things in the moment of practice, we are going to want to alter our practice in that same moment. Yet, we also know that as teachers we have an obligation to be people who our students can trust. Negotiating this terrain during self-study is a difficult task that each must confront in her own way.

When we commit to doing self-study, part of the commitment is moving from critical reflection to creating and sharing an account of that reflection. The humaneness we should display as a teacher and the accuracy required of researchers may be irreconcilable fault lines in any self-study report. The research issues of confidentiality and informed consent loom large in such work. Simply being "good" or "moral" people may not be sufficient to meet these obligations. Teaching practice is always inconclusive. In any moment in a classroom, we bring into contact our past and present experience in classrooms and in teaching in order to promote a hopefully richer and more interesting present as well as future (Arizona Group, 2004). What emerges may be much like lumberjacks walking across logs as they float down a river. We know the danger. Yet, when we study our own practice (no matter how frequently we do so), we are immediately confronted by uncertainty; like lumberjacks we must negotiate a shifting reality. We need findings whose veracity will allow us to step onto the next log and the next, and thus move teacher education practice forward. This chapter raises pertinent issues in considering the ontology or basic nature and properties of learning and teaching in self-study inquiry. The age-old questions of teaching and learning and their interrelationships and community expectation are immediately complicated when both are also simultaneously sites for preparing teachers and doing research. These comments appropriately frame our consideration of the next two chapters. Chapter 3 explores self-study from the standpoint of teaching and chapter four from the standpoint of research.

Chapter 3: Self-Study as Teaching

The title of Tidwell and Fitzgerald's chapter, "self-study as teaching" suggests not that self-study is teaching but that a particular kind of self-study could be called teaching or that teaching in particular ways constitutes self-study. Thus, the title of the chapter reopens the dilemmas of definition, moral obligation, epistemology and once again ontology. In engaging in self-study of teaching or

teacher education practices, the teacher (or teacher educator) attempts to simulta-
neously fill the responsibilities inherent in the role of both teacher and inquirer
(or researcher).

In terms of the historical, Tidwell's autobiography provides a life-experience
of growing into self-study that is similar to the historical account of development
of self-study as a movement presented by Loughran. While her account is
autobiographical, there are interesting parallels: Beginning with research founded
in technical rationality, the introduction of research methods beyond the quanti-
tative, embracing a form of reflective practice (in this case Fenstermacher's (1986)
notion of practical arguments), understanding of the complexity of the relation-
ship between belief and practice, recognizing the need to practice and demon-
strate reflective practice elements to and with pre-service teachers, coming
together in community as self-study researchers and developing an understanding
of what self-study research is by doing it. As a case of the historical development of
a person who does research on teaching or learning into a researcher who
embraces self-study this chapter works. However, it is not as clear that this
chapter is a case of self-study as teaching. While the authors make clear how a
series of self-studies pushed forward the development of Tidwell as a teacher,
they do not really make the case that teaching and self-study are synonymous.

In her explorations of the role of the teacher and role of the learner, Tidwell
uses student data to provide evidence of her success as a teacher in much the
same way that champions of the effective teacher movement used student achieve-
ment data to establish and validate use of specific teaching strategies. I (Stefinee)
was reminded that quantitative studies of teachers produce lists for checking
teaching action. In such studies, variability is controlled by accounting for factors
or measuring and manipulating them. Thus, most accounts of teaching from a
quantitative perspective feel stilted, clinical, and a little forced. However, holistic
accounts told from the perspective of one of the main actors in the event, can
take on a romantic glow that in blithely acknowledging difficulty glosses over
it. What is missing in this exploration of the role of the teacher, perhaps because
Tidwell's self-studies and her account here are so clearly focused on self, is
concern with the conflicting nature of the teacher's responsibility and obligation
to others with Tidwell's role as researcher.

Having long been interested in understanding the complication of the
intertwining of personal history and belief in teaching action, she encounters the
problem of habit – of how difficult it is to alter beliefs embodied in teaching
practice. While we often speak of learning from experience, we seldom speak of
how it is "in experience" that our theories and our practices are revealed to us.

Tidwell and Fitzgerald cogently argue that understanding our practice and
accounting for it can lead us to be better teachers. Accordingly, they say self-
study is a tool that can help us develop as teachers. While I find myself in
agreement with this idea, I am also troubled by it. For in making self-study and
teaching synonymous, the political and public nature of research, where reflec-
tions are made public, is hidden from view. When such contradictory and

embedded obligations and responsibilities are embraced glibly, the teacher educator can easily assert a sentimental tone of moral superiority and of personal uniqueness. Such a tone in self-study usually results in research reports that romanticize and glamorize the role of the teacher educator and leave readers concerned about the moral tone of the teaching. Self-study researchers must demonstrate in their account that their behavior met the moral obligations of research rigor as well as the moral obligations of teaching. In making the case for self-study as synonymous with teaching, Tidwell and Fitzgerald do not necessarily fully articulate how research is balanced in the equation.

Early in their chapter, Tidwell and Ftzgerald argue that: "… *building* a plan of action over time using experience to inform the plan parallels for me the nature of teaching, where, for example, through experience with a group of learners a teacher's plan of action for instruction is shaped." Tidwell and Fitzgerald propose that the action research cycle is the basis of teaching action. When I think of the tacit knowledge of teaching, the artistic and aesthetic, or the intuitive quality that is characteristic of good teaching, I wonder, can research, even when the researcher and the researched are one and the same person, ever capture the ineffable nature of such action and knowing in practice? Are there not times when, as a self-study researcher, no matter how carefully we have video-taped, invited in collaborators, or taken notes, we decide to do what we do because we just have a "gut feeling" that's what needs to be done.

In attempting to make clear the nature of teaching and learning in an environment of self-study inquiry, Clarke and Erickson (2004) reveal instead the layered and entangled nature of teaching and learning in that context. Here, Tidwell and Fitzgerald trouble Clarke and Erickson's definition and actually enmesh their own definition of self-study as teaching into self-study as learning. Throughout this chapter, Tidwell and Fitzgerald represent Tidwell's growth as a teacher educator through self-study as *teaching*. This conception of teacher education work (the teaching of those who will be teachers) as identical to the work of teaching hides much of what makes teacher education problematic and worth exploring from the insider's perspective that self-study can provide. Identifying self-study of teacher education practices exclusively with the world of teaching, it could well be argued, diminishes much of its promise and may therefore reduce its moral force.

Chapter 4: Self-Study as Research

Ham and Kane's chapter explores the phenomenon of self-study as research through the use of the hermeneutic circle. They begin with the case of the rejection of funding for Kane's proposal of a self-study project because a committee said it was not research. After exploring the argument against self-study as research, the definitions of research, and the politics of research funding, they end with an assertion of how and why self-study is research. While this hermeneutic exploration of the definitional overlap between self-study and research reads like sword play, it relies heavily on exonerating self-study as research through a

consideration of research epistemologies: It could even be viewed as taking the form of an apology.

The basic purpose of modernist research is to establish belief as justified true belief. The basic purpose of self-study research is to explore what we learn about teacher education, learning to teach, teaching and learning when we explore the influence of beliefs in practice. Thus self-study research attempts to explore embodied belief in the hope of learning about teaching and teacher education, concerns beyond the reach of modernist research. Just as a definition of self-study research is best captured by the functional one offered by Loughran (2004a), establishing knowledge gained from self-study may be more an issue of ontology than it is of epistemology – the presentation of claims about how things "really" are – an appeal to the ontology of teacher education.

Ham and Kane artfully explore the political battle over who can claim to know something and how the claim must be established to have currency in the politics of scholarship and educational knowledge. One of the things that strikes me about this chapter is what it reveals about the fundamentally basic role that politics and power and authority claims play in any research endeavor. We label Tolman and Bandura behaviorists today. Tolman (1951) studied rats' ability to use cognitive maps. Bandura's (1977) conception of modeling, learning from observation, and being rewarded by watching others has much in common with Semiotics. However, in their era, psychologists were only funded, published, and promoted if they were somehow able to present themselves as card carrying behaviorists. Thus, the politics of the era more than the foundational beliefs behind their ideas determined their theoretical perspective and the possibilities for publication.

One of the difficulties of research on teaching and teacher education seems to be the battle between the disciplines of education involved in teacher preparation and teacher educators and teachers. Educational psychologists long claimed as theirs the territory of exploring both learning and teaching. A historical look at research on teaching demonstrates that as researchers became more interested in understanding the knowledge of teachers, they necessarily became more respectful of teachers. Researchers also recognized that in order to study the knowledge and beliefs of teachers in relationship to practice, they would need to have more intimate and respectful connections with them. The playing out of these factors resulted in the contested terrain of research on teaching and teacher education that currently exists. These struggles were the crucible from which self-study of teacher education practices emerged. Most of us who do self-study research are as concerned with our obligations to educating outstanding committed teachers as we are to studying our work in order to understand it and get better at it. In this way, our political engagement in the research and practice of teacher education is morally grounded. From this stance, self-study researchers can be as passionate about their work (both teaching and research) as Marie Curie was about her studies of Radiation. When we engage in the politics of research it is easy to be blindsided by narrow definitions of research and established epistemologies. So, for me, research as a social practice represents

a narrow, constrained, and repetitive work dictated by rigid rules and convention. In contrast, scholarship represents creative acts that draw on a wide range of research tools in order to understand ideas and then articulate and defend them. While scholarship completely inscribes research, research does not inscribe scholarship. Thus, the purposes of self-study research are, I believe, better represented as scholarship. In this way, work in self-study might be more aptly and powerfully established as scholarship rather than merely as research.

In proposing and exploring the definitional features of self-study holistically and from each of three standpoints – inquiry, teaching, and research, this set of chapters reveals that self-study is best distinguished from other research on teacher education and teaching at its boundaries. These boundaries are functional, historical, and ontological and moral. These boundaries mark off self-study as different from other forms of research because it proposes to create an educational theory that grows from both practice and scholarship and in doing so presents the ontology of teaching and research on teaching differently than does past research on teaching and teacher education. In addition, self-study demands a deep moral commitment to inquiry that connects the past in the present to imagine a new future in the concrete reality of a single teacher educator, as well as new possibilities for teacher education collectively.

Exploration of the Worth of Self-Study

Having established distinguishing features of a self-study stance toward teacher education, the next four chapters in this section of the Handbook attempt to explore its worth. Again, work by Loughran frames these four chapters – chapters five through eight – and highlights what self-study research contributes to conversations about teaching and teacher education. Lighthall's investigation turns inward attempting to establish the worth of self-study research to the self-study researcher community by analyzing a collection of self-studies in order to determine what aspects of self-study's potential remains unfulfilled. Next Elijah considers the "voice" of self-study research and researchers in the larger research conversation. Finally, Wilcox, Watson and Patterson consider what self-study offers professionals beyond teaching and teacher education.

Chapter 5: Learning through Self-study

In chapter five, Loughran seeks to "document the learning from self-study that is readily accessible and apparent in the research literature." At the conclusion of his review, he observes that learning from self-study "is influenced by the nature of the self-study … and the context and conditions under which the self-study is conducted. An important facet of learning through self-study is," he asserts, "that it impacts the individual but that that impact is also regarded as a starting point for the influence on practice."

The chapter begins with the problem of definition that runs across this entire Handbook section. Loughran notes that self-study "has grown out of the work

of many other related fields." He lists several of these, including action research, narrative inquiry, practical inquiry and "teacher as researcher." The thread that binds each of the areas of study listed is that they are one or another form of practitioner research. By implication, then, the learning outcomes that are promised by self-study are the same as those associated with practitioner research: To improve some aspect of *my* practice.

The first section of the chapter is entitled, "Purpose in self-study." In this section Loughran observes that many self-studies are grounded in a sense of "obligation that practitioners themselves should work in the very way they advocate for their students." More than modeling is implied here; the assumption is that teachers will do what students do and through this they will gain insight into, "teaching and learning that might otherwise not be fully appreciated or understood if such learning was not genuinely experienced by oneself." The assumption here is that teachers, educated and experienced adults, will, by doing what they ask students to do, learn what students learn. But this claim is not sustainable. Only rarely do adults and young people have similar problems or come to similar insights when engaging in similar activities. The justification for repetition of student activities has little to do with learning and much to do with questions of authority and justification. By saying, "see, I did it too," the teacher asserts to the students that an activity has value even if they question that value. In one of the examples presented, Loughan notes a self-study researcher's concern that modeling may offer students a "prototype" for their own work. This fear seems oddly off-point since modeling means to model, to offer a prototype to others for emulation. But, from the perspective of self-study, a more serious objection than this arises.

In this section, Loughran favorably quotes Schulte (2001): "If I truly wanted my students to be life-long learners of teaching, then it makes sense that I should demonstrate the same by exposing my process to them … I was insecure and doubtful, but this study also led to a certain confidence." This is modeling of a special kind. In this instance, one models a practice and in modeling reveals, or probably more accurately, discovers oneself. At its extreme, one becomes a kind of flasher who hopes what is revealed will be appreciated, even admired. When it is not appreciated, shame and disappointment follow. The danger here is that in exposing oneself in this way, one's own vulnerability is heightened and by becoming course content is moved center stage. Student vulnerability is swallowed up in instructor vulnerability and desire. The focus is on the teacher, not the learner, nor, as Parker Palmer (1998) would say, on the "great thing" that draws them together. To be sure, students may express appreciation for the revelation that their instructor also has worries and they may feel more than a bit empathetic, but it is their own vulnerability and the instructor's moral responsibility to help them productively manage such emotions that is of most concern.

The next section is entitled, "Participants in self-study," and begins by noting the importance of learning about self. As suggested in the analysis of chapter one, "self" is a term that needs careful explication. Kuzmic is quoted: "My

research is certainly connected to the teachers with whom I work, but I did not initiate or conduct this project for them." The point is a good one: Seldom do researchers admit the play of self-interest in research. This said, self-interests are inevitably tempered by context and by the moral demands of claiming to be a practitioner of one or another social good. In this section, it is asserted that to investigate the self "also involves (somewhat paradoxically), going beyond the self." Implicitly, what is recognized is that we are nothing without others, that we are because we are in relationship to others and through others we live and find our being; we are bound together, and in facing one another, as Levinas (1969) argues, are morally obligated. Yet, despite the student's ever present and threatening eye/I, such encounters are not inevitable. It is because of the teacher's superordinate position in the classroom that we can assume a subordinate position, temper the demands of our own desires, set aside our need for self-confirmation, and sustain the other as she confronts her own limitations and encounters her own shadows. Ironically, the ability to constrain the self confirms the self's worth and power. As Loughran implies, self-study that is driven by self without embracing the other can promise only scant fruit. Rich harvests require intense engagement, not mere reminders of the importance of attending to the "students' agenda as well."

Loughran (2004b) reminds us that self serves as an interpretative backdrop: Biography and history are projected onto the present and future. The self is ever-present. But, does self-study necessarily begin with self?: "it is still clear that the individual self is an important starting point for researching practice." On this view, what is the self that is the departure point for self-study? As noted above, since we exist in relationship, self-study might begin with an intense and scrutinizing stare at the other or perhaps at the self-and-other-shaping context called school or university. Given the human propensity for self-confirmation, gazing inward, toward the self, might not lead outward but looking outward must lead inward if improved practice is genuinely the heart's desire.

Next comes the section, "Learning with and through critical friends." In this section, collaboration is championed as an unqualified good. The value of working closely with others is that access is gained to "alternative perspectives on situations." The focus on collaboration suggests mutuality, that collaborators bring something of equal value to the study. The importance of wisely choosing self-study partners is self-evident, but unexplored. In this section the work of the Alaska Teacher Research Network (ATRN, Austin *et al.*, 1999) is quoted: "In the beginning, we viewed our research as a way to look outward upon classroom happenings. Now we see it as a way to be reflective and to look inwards … our research changes us as people, which in turn changes our practice … [it] is not a thing to do, but a way to be." The assumption is that a change in belief will lead to a change in practice; the converse, as Thomas Guskey (2002) has shown, is also true. Because teacher educators, in contrast to practicing teachers, largely have control over the conditions of their work, this causal chain-belief to practice-can be realized. But, there is a more important point here about the nature of self-study: The Alaska Teacher Research Network suggest that self-study is a

stance, an ontology, a way of being as an educator. By working within a network and in a school, it appears that these teachers have taken the power necessary to maintain the stance and to create the conditions whereby they can act upon their beliefs. They have learned that together they are powerful.

One of the claims for critical friends is not only that they provide alternative ways of understanding the world but enable access to truth: "they learnt how to recognize what they were *really doing* in their teaching as opposed to what they thought they were doing." Here and there throughout the chapter claims of this sort are made in the self-studies referenced. The claim is that there is a kind of truth to be had through collaboration specifically and through self-study generally. Ironically, while claims of this kind might deepen and widen our conceptual pockets, they keep us within them. What is missing is a lively sense of the interpretative nature of virtually all research in the human sciences and of the shifting nature (as well as the form) of truth claims. Drawing on William James (1907), rather than seeking truth the aim is to locate the *good* and express it in right action. The good takes multiple forms for educators from better questioning techniques to more empathetic relationships. Self-study, understood as a matter of ontology, a stance, rather than a settling on a truth, requires of its practitioners involvement in an ongoing quest for greater goods, more productive ideas, more interesting and enlivening relationships, better forms of communication, a purer sense of one's obligations and a richer sense of one's own and others' possibilities. And, there is a moral imperative – to become increasingly open to contrary data.

"Learning by seeing practice through students' eyes" is the next section. The point here is straightforward but not simple – that much can be learned through paying attention to students, how they learn and how they respond to our attempts to get them to learn. Educators need to listen to "back talk," the "unexpected consequences of actions talking back to us." Student experience of our practice may open "alternative interpretations of situations (to frame and reframe) in order to better understand the complexity of the situation." Students may help us to recognize differences between intentions (beliefs) and practice. Effective teachers recognize and resonate with this plea and often read tests and papers for just this purpose, as data sources useful for reconsidering instruction or curriculum. Systematically attending to students as sources of data is less common and a practice encouraged by self-study.

Next follows a section entitled, "The context of teaching and learning through self-study." This section is introduced in this way: "One way of re-focusing on the problematic nature of teaching is to change one's 'normal' teaching context. In many teacher education programs, the teacher educator's normal teaching context is a university classroom which brings with it different demands and expectations to those of a school classroom." The section is divided into three parts, each supposedly representing a shift in context. The first, representing a kind of imaginative contextual shift, suggests that there is value for teacher educators in "re-experiencing" their own student teaching. Thus, the teacher educator is invited to imaginatively step out of the university to re-enter the

classroom as a student teacher. The value of making this leap is that the experience of student teaching is presumed to linger and to influence how teacher educators work with their own students; and re-experiencing is a way to identify and reconsider deeply embedded assumptions. This suggestion is a specific example of a more general point: Educators need to explore how biographically born assumptions about teaching, learning, and students shape and sometimes distort practice. It is unclear how powerful an influence one's own student teaching experience is on one's practice as a teacher educator, but it is widely recognized that such experience informs cooperating teacher practice. The second and third parts touch on self-studies that involved teacher educators returning to the school classroom in one or another way, including, in the third part, as teacher.

   The second and third parts are tied to the commonly held assumption that teacher educators ought to be skilled school teachers in order to teach about teaching: Recent classroom experience is essential for teacher educator practice. Is this assumption true? Is it good? A close reading of this section suggests that an underlying reason for teacher educators to return to the classroom is to find a means for reasserting authority claims to their doubting teacher education students: authority of experience over expertise. Moreover, such a move brings with it a solidarity claim, that the teacher educator is part of the community of teachers and therefore a sympathetic interpreter of the experience of teaching. Motivation for returning to teach in a public school is crucially important to understanding the worth of self-studies of this kind. From a teacher educator's perspective, it is not necessary to return to the classroom as a teacher to be expert on teaching and teacher learning. Indeed, effective coaching in any form of human excellence does not require that the coach be an able practitioner. His is a different art form. What is required is that the coach understand the performance from the inside and the outside and then be able to simultaneously distance himself from his students and enter into their experience in such a way as to give just the right feedback and direction at just the right moment. Harry James, for example, was one of the most successful tennis coaches in the United States, and he coached from a wheel chair. If a teacher educator is interested in improving her practice, she should study her practice *as teacher educator*. But, if she is interested in her practice *as public school teacher*, then she ought to study that practice. The two are incommensurate. What is learned is different, although related, and not merely because the contexts are radically different. The authority of teacher educators ultimately can best be grounded in the systematic and consistent study of teaching with teachers in both contexts as they practice in one. To assume that because teacher educators are not also practicing public school teachers leads to ineffective teacher education practice, to the "separation of practice and theory," is simply to misrepresent the issue-it's bad etiology.

   Throughout this section and most of the chapter runs the belief that the central motivation to engage in self-study is to "respond to … dissonance." The bias is toward self-study as a form of problem solving. What is lacking is a

broader sense of the motivation that inspires teachers to teach and seek to improve. They not only work to overcome difficulties, they also build to strength and experiment for the sheer joy of it. Heretofore, remarkably few self-studies have been conducted for the joy of learning, as expressions of the pleasure many teachers and teacher educators find in wondering about their world and testing their wonder. The drive is less about discovering than responding to limitations than about pushing boundaries for the sake of understanding. Hopefully this will change. Perhaps it is a function of prejudice in publishing.

The next section is "Learning about teaching and a pedagogy of teacher education." Once again, the focus is on challenging one's own beliefs and a variety of studies are presented that pursue this aim. Loughran quotes Louie, Stackman, Drevedahl and Purdy (2002): "Only now [following completion of their study] can we acknowledge that our failure to examine our teaching beliefs has resulted in distorted assumptions about teaching. Furthermore, we can only guess at how these distorted assumptions have possibly impeded our professional growth and ability to be effective teachers." Once again the specter of false consciousness raises its ugly head. The assumption is that there is undistorted truth, and apparently a god's eye view is possible, but it's not quite clear who or where god is. Hints of an epistemology of positivism linger.

The chapter concludes with an extensive discussion of a study of Professor Jeff Northfield's return to public school teaching. The book (Loughran & Northfield, 1996) from which this section is drawn is a remarkable work. Jeff Northfield opened himself completely to study by others in a desire to better understand teaching and himself as a teacher. As a wise and experienced teacher educator, he reports that he ignored theory in his public school practice as he struggled to manage the day. This is a surprising claim, one that suggests the difficulty of getting out of pocket and of recognizing what's in pocket: "He stated that his understanding of educational theory was of little value to him in dealing with everyday classroom situations." Yet, there is something quite peculiar about this claim when seen in relationship to much that is reported in the chapter. Robert Coles (1989) has suggested that theory can best be understood as a form of beholding, as in "I behold." On this view, theory, like belief, shapes our beholding and better theory, then, brings with it a greater ability (and inclination) to behold, to see the world and see it richly, broadly, as fraught with difficulties and filled with possibilities. Northfield struggled to get his students to "break set," to get out of their comfortable student roles and engage in a kind of learning foreign to their experience. They resisted. He became troubled. However, he *beheld* the problem, and beheld it in rich and interesting ways that helped him to think through alternative responses. In effect, he *theorized* his practice. Jeff Northfield was filled with theory, it was part and parcel of his way of being in the world. Looking back over the chapter, it is obvious that much can be learned by exploring self-study from the perspective of learning.

Although Loughran argues strongly that action and reflection must go side by side in self-study, much of the work he quotes points toward an elevation of personal theory over public theory, perhaps to the denigration of public theory,

episteme. The value of episteme comes, as Coles notes, in how it informs our beholding. Through concepts, like Northfield's "breaking set," teachers and teacher educators can and do see differently. With each new concept, the world takes on a new name and with a new name inevitably comes new ways of being of and for others and self. The action as well as the reflection valued in self-study research are enriched by public theory. The result is overflowing pockets.

Chapter 6: Fundamental Features and Approaches of the s-step Enterprise

In this chapter Fred Lighthall takes on the daunting challenge of conducting a functional analysis of self-study as a "field." To this end, he identified 125 articles written by individuals who had presented more than one paper at the biennial Castle Conference (see Cole & Finly, 1998; Kosnick *et al.*, 2002; Loughran & Russell, 2000; Richards & Russell, 1996). As noted earlier, functional analyses allow a rough mapping of what is being done by individuals who, by their own actions and claims, define a practical domain. Thus, in established disciplines: sociology is what sociologists do and linguistics is what linguists do when claiming to behave as linguists. So, self-study is what self-study researchers do, or, in this case, what those people do who presented at least two papers at a conference in England. In emergent areas of inquiry, like self-study, functional analyses produce a mixed bag, a little of this, a little of that. What emerges from the mix may be a desire for orthodoxy, for one group or another to set a definition of what *proper* self-study entails. That so much of the time spent at Castle Conferences and AERA conferences has been devoted to discussion of just what is self-study and that early chapters in this Handbook focus on questions of definition indicate that this is no idle concern for many self-study practitioners.

Before moving to his analysis, Lighthall briefly explores the status of self-study as scholarship. This is an important topic especially for untenured professors. Lighthall asserts that "Part of scholarly evaluation of any piece of scholarship is whether it makes a new contribution, or whether it merely goes over old ground." One of the purposes of his analysis of the self-study literature is, then, "to provide a basis for assessing the ways in which one might make a contribution that was new and relevant to the field's fundamental features." Self-study, Lighthall notes, has two audiences: The author for whom the study has value regardless of whether or not it traverses old ground, and "potential readers or participants at conferences." Thus far, Lighthall argues, the "s-step's ethos" has been to support one another's work, to offer assistance to improve it, but not to be judgmental. Hence, criticism of some self-studies, those that reveal self in intimate ways, is difficult because of the potential to do harm or give offense. In any case, author interests dominate the studies reviewed.

Lighthall identifies six predominate features of self-study from his analysis. A feature, he states, is "Any aspect of a study that is very prominent in the frequency or intensity or importance of its mention in the study, as prominent as, or more prominent than, any other aspect of the study, is an aspect which that study

features." The six include: 1) Collaboration – which is understood loosely to capture a range of cooperative relationships from fully shared agendas and intense working relationships among teacher educators to what can best be described as focus-group feedback on a practice; 2) Professional practices, effects, and programs-when taken together the components of this category define the particular focus or concern of a study. Thus, a program may "count" for the self in self-study; 3) Autobiography – which includes descriptions of one's own development as a teacher educator as well as giving assignments to students to write narratives of learning a particular subject; 4) Methods – which centers on means for prompting change in self or others, including one's students; 5) Reform of practice, profession or culture – Lighthall argues that this category represents the "deeply reformist ... character" of self-study. Among the papers that fall within this category are those that seek to alter what are thought to be the academic norms that exclude self-study as legitimate research and those that speak of self-study as a form of scholarly practice; and, 6) Theory: Concepts, frames, contents, distinctions – studies that draw on public theory in some fashion.

Reading through Lighthall's discussion of the six features of self-study highlights the problems of conducting functional reviews to map a field, problems also evident in Loughran's review. Along the way I found myself periodically asking, "What makes this a self-study?" Several of the examples presented would comfortably fall within well-established forms of scholarly qualitative research practice. A few others seem to understand "self" in ways that seem distorting, a stretch beyond reason. Lighthall recognizes the problem, but chooses instead to highlight differences between self-study and quantitative approaches to research, what he characterizes as "generalization-seeking research," rather than to discuss self-study in relationship to qualitative approaches or consider ways of increasing rigor. The result is that readers revisit moments of the qualitative/quantitative wars and are encouraged to take sides when to do so unnecessarily restricts the range and type of promising data available even in self-study.

Apparently Lighthall disagrees. However, he finds value in disciplinary knowledge: "So, while the quantitative methods of the disciplines are not suitable for our inquires, the *ideas* and *distinctions* that disciplinary scholars develop can be immensely useful." One of the genuine virtues of self-study is that what counts as data has been significantly broadened and a great deal of creativity has been shown in developing clever means for data generation but discounting established research tools in favor of "develop[ing] our own scholarly tools," seems perhaps a little unwise. This is especially so if the second audience, potential readers and conference participants, noted above, is taken seriously. Will this position endanger the future of self-study in the academy, for, as Lighthall states, "In the end, the s-step venture will endure or fail as it meets, or fails to meet, the dual demands of scholarship and practicality." Both demands must be met.

As Lighthall reviews his review he notes a few, serious, omissions in the literature. There are not nearly enough studies of implementation. Morover, too few self-studies have been grounded in the results of traditional academic inquiry.

Lighthall's discussion of the place of "self" in self-study and of the richness of the research tradition associated with studies of self makes the point forcefully and well even as he offers a wise caveat that one must be wary of disciplinary knowledge dressed up in sheep's clothing: "Matters from the traditional disciplines for scholarly inquiries about self, identity, and attitude change, are entirely different when viewed through the study of teacher education *practices*." Lighthall further suggests that there is a need for integrative studies, self-studies that demonstrate more than one of the 14 features he identifies. Studies of this kind seem to hold promise for producing fresh insights into teaching and learning and being a teacher and teacher educator. His suggestion that self-study represents a particularly powerful form of accountability is provocative and compelling although risky. Studies of this kind inevitably would privilege the second over the first audience and may encourage the habit of looking outward rather than inward to the profession, to one's students, and to one's self for standards of quality practice.

Finally, Lighthall's analysis points him toward wondering about the kind and quality of the self-study community. His conclusions suggest that that community needs to be broadened not closed down into like-mindedness. He finds sufficient coherence in the work to recognize a self-study community and enough diversity of various kinds to be energizing and interesting.

Chapter 7: Voice in Self-Study

The purpose of this chapter, as Elijah states, is to "show that voices in self-studies are integral to defining the work of self-study." Put differently, she attempts to locate and define the voice of self-study in the larger conversation of self-study. The first half of the chapter explores the various aspects and meanings of voice, underscoring that authentic speech – which is the very definition of voice – always carries authority and is simultaneously personal and social. The second half of the chapter presents what she asserts is a self-study focused on "choice and voice."

The most interesting claims for self-study research in the first half of the chapter have to do with the "hegemony of voice in Western cultures," a claim which seems to run contrary to the power of image in post-modern societies and that we always speak with multiple voices, representing multiple selves. The later claim requires attention.

Elijah reiterates a point frequently made in the past: that academics speak with two voices, as "distant, third person, with a pretense at objectivity" and as a personal voice. The claim is made that the academic voice is a male voice, a voice of alienation for women (and not men) while the personal voice is somehow pure, and, apparently, female. The charge is that academics compel students to develop academic voices and drive them to value their own alienation. The author gives great power to academics to dominate personal voice, perhaps too much power. However, the clear difficulty is that if communication is the desired aim then all voices must speak through some sort of language, some symbol

system that parses and shapes experience. Academic and personal voices both inevitably embrace abstraction; with language there is no such thing as purity and perfection of meaning. To speak in an academic voice does not necessarily denigrate the personal voice. That there is tension between the two is a reminder that knowing the rules is a prerequisite for finding place within a conversation. This conclusion underscores a point Elijah makes, that all voices are simultaneously social and personal. But one does not lose the personal voice because in some contexts an academic voice is required. Moreover, one result of the growing dominance of qualitative approaches to the study of education has been a dramatic expansion of the forms of acceptable speech within the academy. Personal voice abounds. The question is no longer whether varieties of speech forms are acceptable, they are. The more pressing issue is the comprehensibility, richness, quality, beauty, and veracity of the voices spoken. Personal voices may be shrill and atonal and like some academic voices, they may be uninteresting, or even stupid. Yes, "it is the quality of the voice that matters, not simply having a voice."

Elijah turns directly to teacher education and self-study within a section entitled, "Dissonance in teacher education." In this section contradictions lived by teacher educators are noted. "Self-study," she asserts, "attempts to bridge artificially distinct spheres … in order to create personally and contextually relevant ways of knowing in the teacher-ly world." This is what it means to live mindfully. In this respect, self-study is a quest for purity of heart, as St. James said – to live with one mind and one heart and to serve one master. It is, then, a virtue-quest, a utopian – in the best sense – desire to be and to be oneself more fully. Yet, here we run into a difficulty, a contradiction. Elijah argues that self-study has the potential to "provide cohesiveness to the fragmented world of teacher education." The promise is that through self-study one can become whole, yet we are inevitably multiple selves, with multiple voices. How does this claim square with the promise of cohesiveness of self through self-study? Indeed, Elijah argues that one essential tool of self-study is reframing, exploring "living contradiction by considering multiple perspectives," which, it needs to be acknowledge, can also lead to greater incoherence.

The argument for reframing is that seeing a situation from different perspectives has inherent value. But not all perspectives are of equal worth, not all voices are of equal value to one's learning and development. Wisdom is required when choosing which voices to hear since not all can or should be heard, a point well understood by Jeff Northfield (see Loughran & Northfield, 1996) as he planned his study. Put differently, even in self-study, there is good data and there is bad; there is also noise.

Elijah, as with others in this section of the Handbook, observes that self-study inevitably involves increased vulnerability. "Exposure" or being "exposed" is the source of vulnerability. The implication is that self-study researchers are in some ways more courageous than other researchers. Is this claim warranted, or does it represent a kind of immodesty, a hint of perverse pride felt when revealing one's all to Jerry Springer. Like confessing sins, the act of revealing brings a

sense of well-being but true repentance requires action. It is here, as Lighthall (2004) noted in chapter six, where self-study often falls down: After revealing ourselves and our weaknesses we must take action on the world. If self-study ends when it really has only begun – a point not lost on Action Researchers who see their work as cyclical, and to be able to act requires coherence of self – then possibilities for learning as a result of action is lost.

In a section entitled, "Self-study as multivoiced texts," Elijah asserts that "within a so-called single voice are many voices. ... [That] in a postmodern world the idea of a coherent, autonomous self has given way to the idea of multiple selves that reflect a plurality of voices." Here, I take exception and somewhat ironically, so does Elijah in other places within the chapter. Certainly some writers, Kenneth Gergin (1991) prominent among them, argue for and then celebrate the notion that there is no self but selves, multiplicity over unity. In *Shattered Selves*, James Glass (1993) shows what happens when there is only multiplicity – one is committed to a mental health facility. My view is more akin to Jennifer Nias' (1989): There is a core self, which is an achievement and a historical creation, and there are situational selves, spin-offs of the core that call into expression different elements of the self. In healthy people, situational selves are grounded and disciplined, as Freud would suggest, by super-ego but also by our desires to be who we say we are. Trouble follows when situational selves spin out and disconnect. At such times we feel adrift, lost. Given radical multiplicity, what is the self in self study?

Elijah's views highlight the ongoing recognition of contradiction in self-study. Two quotes make the point: Stewart (1992) is quoted favorably: "That a writer may adopt a number of superficially different surface voices I do not deny, but I will strenuously continue to affirm that any good writer has a single identifiable voice running beneath all his or her work, regardless of context or genre" (p. 288) McElroy-Johnson (1993) is also quoted approvingly: "In order for students to develop their voice, the teacher's voice must be clear, distinct, and above-board ... I'd venture to say that many students ... need to hear a teacher's strong voice in order to feel secure in developing their own voices" (p. 102). Morally, the teacher and teacher educator must speak in a strong voice for the sake of their students. To do so, they must have a clear sense of self, of who they are, what they care for and how they care, and how and where they stand in the world. To teach, on this view, is to testify; a life is an argument. One aim of self-study, then, is to strengthen one's voice and to help us learn to speak more clearly. The result is authentic speech, the sort of speech Jurgen Habermas (1979) describes as right, truthful and true.

Just before presenting the self-study of Fernandez and Mitchell (2002), Elijah briefly explores different forms of representation of self-study research. She notes that written narrative remains the dominant form but that "self-study researchers have experimented with different ways of knowing such as art and drama." But are these different ways of knowing or are they different ways of representing self-as-data, of revealing self to others? Moreover, while self-study has the potential to preserve a measure of the complexities of teaching and learning and

learning about teaching and learning, complexity must be managed in order to communicate. Indeed, one of the greatest challenges facing self-study researchers is to gain an appropriate balance between complexity and simplicity, and to accomplish this it is necessary to tap disciplinary concepts, as noted previously.

In the second half of the chapter the Elijah presents what she sees as an "example of self-study: choices and voices: students take control of their writing." This part of the chapter forces the question, "In what ways and in what sense is this a self study?" Mostly, it appears to be a curriculum development study, a unit for writing was produced and evidence gathered on its effects. There is some talk in the study interspersed in the narrative about what the authors did and thought as they worked together. But, is self the focal point of the study, which the authors put forward as an essential characteristic of the "new landscape" of self-study? I think not. The central concern was whether or not students' attitudes toward writing changed, and they did not.

Chapter 8: Self-Study in Professional Practice

This is an ambitious chapter that has as its aim to show the use and value of self-study in three diverse fields: library science, adult education, and occupational therapy. The central idea underpinning Wilcox, Watson and Paterson's chapter is straightforward, almost a commonplace, that reflecting on and inquiring into one's practice is valuable in any human endeavor. But, the authors hope for something more: to reflect on their work in a way that can best be described as "artistry," to become "adept at handling situations of uncertainty, uniqueness or contradiction." Residing in their argument is a useful definition of professionalism: what distinguishes the professional from others is the commitment and refined ability to learn from experience in order to improve practice. The argument can be extended: To research practice is to engage in self-development.

The authors present their shared view of self-study and their desire as self-study researchers in these words: "The approaches to self-study research used in each of our practice settings all originate in a fundamental concept: we learn from experience." To learn from experience, the authors say, requires "active, engaged, self-directed reflection" on what they describe as "stories," or "artifacts of practice … texts to be analyzed." The result is useful knowledge that helps professionals, "think/feel/sense/intuit our way through the complex situations we experience." Finally, they assert in the penultimate sentence in the chapter, that, "Self-study is a simple, yet grand, scheme for life-long learning in the professions, and its time has come."

Each of the authors ground their studies in one or another body of literature: Watson in a conception of reflective practice; Wilcox in research on self-directed professional development; and Paterson in a conception of professional artistry. Drawing on Watson's approach to text of "noticing" and "wondering," I will notice and wonder about each of the three studies in turn. I approach the task

in the spirit suggested by the authors, that of giving each text (study) a close and critical reading that reveals assumptions. Such a reading is at the heart of self-study research as they conceive of it.

Watson describes her interaction with a pre-service "teacher-librarian" that centered on an incident with a "wild boy" described by the teacher-librarian. Despite various attempts to get the boy focused, he was reported to be out of control. Getting up after throwing himself to the floor, the boy "pushed a little girl aside and got in [the girls'] line first." "I said to him, "Gosh, I guess on your next birthday, you are going to get a girl doll and a pink dress with sparkles on it." Watson responds to this event with horror and a discussion follows of how she and the novice librarian were unable to come to an understanding, of how she (the librarian) failed to see the damage this remark may have caused this small boy. As Watson read the e-mail that contained a report of the event she wrote to the librarian and, "wondered about [her (Watson's)] particular passion for this incident that did not seem to be noticed by anyone else." The phrase, "that did not seem to get noticed by anyone else," is important. Watson was deeply troubled that the librarian did not "self-correct or attend" to the issue, so she decided to force her attention. Watson comments that her own e-mail to the librarian calling attention to the incident was "full of what I've learned over the years. It's not what she knows yet." This is perplexing for Watson seems to suggest that she knows just what the librarian had better come to know. Watson does not question her own stance, consider that perhaps she may have over-reacted or misinterpreted the situation herself or that the librarian might be a person who, knowing the boy, might have acted in a way appropriate to the context.

Echoing a concern that emerged in the analysis of Chapter 2, Watson writes that she offered her "own vulnerability as a 'confused' teacher" to her student as she [Watson] sought to challenge the student's thinking. Yet nothing other than Watson's status as the one who knows appears to be at stake. "I wanted her to have her own 'ah-ha' and yet, she resisted." Herein lies a dilemma common to those paid to profess – the "ah-ha" to be had was the "ah-ha" already had by Watson, an "ah-ha" she wanted her student-librarian to experience. Watson laments that she, "did not create the conditions for this student to come to the insight as I had." Wondering over Watson's text of her student's treatment of the "wild boy," I shared the story with an experienced and thoughtful urban 5th grade teacher who spends a good deal of time in the school library. Thinking about the story, this teacher laughed, spoke of her own "wild-boys" who she sometimes teases as a way of signaling to them that their behavior has crossed a line, underscored the importance of context and of quality of teacher-student relationships in knowing what is and is not appropriate and right to say to a child or to do to him, and then concluded, "sometimes, it's best to laugh and get a grip."

When reading Watson's story, I found myself noticing and wondering about her actions more than her student's action. I noticed that it took her sometime to arrive at the possibility that her interpretation may have been partial, or

perhaps in some respects, too focused on herself and not enough on her student. This episode illustrates the difficulty of confronting our own biases. It was only because of her student's persistent resistance that Watson came to recognize the possibility of her own blindness. What, if anything, would Watson have learned if H.C. had not been so stubborn? I also wonder, what, if anything, did H.C. learn from her encounter with Watson? The episode also highlights how teaching is always a form of invitation that is open to rejection, and how education, as Dewey argued, is always indirect, accomplished through the environments we create as teachers. Pursuit of right answers and conformity in our students is bound to result in disappointment. And so, Watson's study raises once again the question, "Whose interests do self-studies serve?"

Wilcox's study is grounded in a deep commitment to and understanding of self-directed learning in adult education. In this respect, her study is a response to Lighthall's (2004) call that researchers tie their work to the disciplines and to Loughran's (2004) concern that the results and practice of self-study be theorized. Wilcox observes that while, "self-directed learning is often equated with independent inquiry, 'knowledge (and now quoting Candy, 1991) is socially constructed and accordingly learning is a social process. Self direction does not necessarily imply solitary learning." This strikes me as an important point in self-study research. Throughout this section of the handbook, there is inconsistency in how self-studies are viewed: Some authors say that self-study must involve collaboration; others suggest self-study research can be done alone. Certainly in teaching autonomy and solitude both have a place; each interacts with the other in a circular relationship. So it is with self-study-quiet contemplation and dynamic interaction with interested others are both important to the quality of an analysis. If too much emphasis is placed on interaction, one may lose one's self; if contemplation is given too large a place, distorted vision and myopia may follow.

Wilcox's discussion of the importance of "best image" in self-directed learning is extremely important. Dewey (1916) wrote extensively about education as growth, but was criticized when he failed to articulate an especially clear sense of direction or outcome for growth. What Wilcox suggests is that the future plays a crucial place in learning, that a lively sense of what we might become profoundly shapes what we do and how we do it. So it is in self-study research. It is our sense of the ideal that enables identification of dissonance and contradiction that are so important to Fernandez and Mitchell's project reported in chapter seven. In effect, we work toward our dreams of self, and, for this work to be successful, as Wilcox reminds us, technical competence is necessary. This is a point too often neglected in self-study research when awareness becomes the sought after end result rather than action on the world.

Wilcox also reminds us that learning, or in this instance, the process of self-study, is "not entirely rational." Clearly, there are limits to the power of reason to shape understanding and belief. Recognizing the place of the irrational, of the emotions, in learning is to recognize the inherent limitations of the prosaic to

capture human development and the need for the poetic and artistic; other forms of representation are necessary. This recognition has led to the effort to broaden the norms of scholarship and to rework the traditions of scholarly reporting. There is a danger, here, however: Reason must not loose its place at the self-study table. This danger is embedded in Wilcox's celebration of the achievement of freedom from constraint and autonomy as twin aims of self-study research, a view that echoes an enlightenment myth of self-creation. What is lost is realization that freedom comes not inspite of but because of social embeddedness and history-too often autonomy masquerades as social disconnection and isolation and self-distortion and destruction follow.

Finally, Wilcox calls attention to the importance of social context to self-exploration and study. This is an important and too often neglected point. With her, I wonder: What are the qualities of educational environments most likely to invite engagement and encourage thoughtful self-consideration? The description of her program takes us a long way toward being able to create just such environments for our students, environments that invite rather than compel the good.

As an occupational therapist, it is the development of professional artistry that captures Paterson's imagination. Her assertion is that it is in artistry where theory and practice best meet. Through her work she hopes to encourage the, "critical appreciation of the art of practice much like an art critic evaluates the meaning of a piece of art or music." Like Wilcox, Paterson's study is of an approach to professional education she has developed and tested. Both engage in self-study as a form of program evaluation and the programs evaluated have as their aim to encourage self-study (or "assessment" for Paterson) *and* professional knowledge and technical competence. Both seek to institutionalize their specific forms of self-study.

Paterson points to a set of troubling issues that I have struggled with (see, *Becoming a Student of Teaching*, Bullough & Gitlin, 1995, 2001). Can reflection be forced? Is it ethically responsible to require students to "reveal" themselves? How do we create a learning environment that invites and inspires sharing without jeopardizing fragile selves or intruding unwanted into sacred personal space? These issues become especially salient as Paterson describes her use of portfolios which involves a "random auditing process." I suspect that wise students, those who anticipate the possibility of being audited, will avoid revealing too much about themself, too much about their self doubts, too much about their weaknesses. The ethics of self-study as student-required practice is a topic that needs greater and more systematic consideration than it has thus far received. Finally, the relationship between the development of artistry and the outcomes of Paterson's work with her students creates for me a sense that her students become increasingly skilled and empathetic practitioners and that this is what counts as artistry. It seems, then, as the research on teacher development and expertise would suggest, that artistry is most likely to be a distant aim of the program, a state longed for rather than necessarily achieved in initial training.

Conclusion: A Summation of our Thinking about Thinking about Self-Study

We conclude our analysis of the eight chapters in this section of the Handbook (which purport to explore and establish the boundaries of self-study research and then provide an assessment of the worth and potential of self-study work) with a set of propositions surrounding four perplexing clusters of problems for self-study. We write from the perspective that in order for self-study to prosper as an intellectual enterprise and practice that it must, at is heart, be oppositional.

The problem of definition: As the eight chapters in this section indicate, conversations about definitions have been lively and protracted. The discussion is centered in defining "self," "study," and the relationship between them and professional practice. As long as this conversation remains invigorating, the community of self-study practitioners is likely to remain vital and creative; however, once a definition is set and the conversation finalized, self-study will loose its metaphoric and seductive quality that gives it life and inspires engagement.

The problem of ontology: While self-study researchers have expended great effort in exploring warrant and validity issues, these are epistemological concerns. Explorations of process and agreement over method will not lead to stable truth claims. An essential quality of all self-study points toward a specific ontology, which includes a commitment to a quest for understanding and to a way of being with and for children, colleagues and our students. Philosophers like Buber (1970), Levinas (1969), and Noddings (1984), rather than psychologists, offer the most promising insights into the self of self-study, because the self is never merely psychological and individual but is formed and maintained in relationship to others. As a result, at its core, self-study embraces a moral imperative. Our being as teachers and teacher educators is wrapped up in the exploration of the point where, in practice, we meet and souls and selves touch. Thus, there is always a utopian moment in self-study, a point where the self is invited to be more than, or better than, itself.

The problem of form: The expressed form of self-study is always constructed in relation to the audience being addressed and is tempered by recognition of the deep moral obligation teachers have to students. It is here where vulnerability presents a genuine danger, but it is recognized as part of learning, which also involves unlearning. When unlearning, the vulnerability felt by the teacher educator must be managed so that in its expression in teaching and in the reporting of the research no harm is done. Finally, what we publicly reveal about our practice must further the cause of teacher education.

The problem of scholarship. Like any good research self-study must represent rigorous data gathering and analysis. Data sources should be stable and empirical. Methods must be transparent. Quantitative methods have a place. In making sense of the data, public theory is crucially important. Privileging private over public theory opens the door to romanticism and invites self-justification, two seductive outcomes that only stable data and rigorous analysis can constrain.

This is not merely an epistemological matter; it is a moral obligation that must be met if self-study is to impact in more than peripheral ways the academic conversation and scholarship of teaching and teacher education.

APPENDIX TO SECTION 1

Diane Holt-Reynolds
May 14, 1951 – February 28, 2003

The paper that follows "Personal History-Based Beliefs as Relevant Prior Knowledge in Course Work" by Diane Holt-Reynolds is an example of the type of work that was a precursor to the formalization of S-STEP. This paper (published in AERJ in 1992 and reprinted with permission of the publisher) highlights the types of issues, concerns and research in teaching and learning about teaching that were influential in shaping a growing understanding of the need for, and value of, self-study. Diane was a founding member of S-STEP whose work was particularly influential in the field of personal history, beliefs and practices in teaching about teaching.

Diane Holt-Reynolds was an associate professor of instructional leadership and academic curriculum in the College of Education at Oklahoma University. She was also the director of the Oklahoma Writing Project and the author and illustrator of "Cancer: An Introductory Course In Learning To Let Go." Diane was, "surrounded in love by many friends, former and current students, and colleagues from Oklahoma, Michigan, Indiana and Tennessee."

PERSONAL HISTORY-BASED BELIEFS AS RELEVANT PRIOR KNOWLEDGE IN COURSE WORK

Diane Holt-Reynolds
Michigan State University

Abstract

This study explores the relationship between the personal history-based beliefs preservice teachers brought to their study of teaching and the principles of reading, writing, and discussing to learn that one professor advocated. This analysis represents an effort to look closely at how preservice teachers use the knowledge they bring with them from their lives as students to make decisions while engaged in course work about the value of ideas they hear there. This study documents (a) the lay theories and beliefs that participants had developed out of their personal history-based experiences, (b) the decisions that participants made about the potential value of the principles of good instruction encountered as part of their course work, and (c) the relationship between their personal history-based beliefs and those decisions as explained by each preservice teacher.

The principles of professional practice that we as teachers of teachers study, value, and submit to our students have an annoying and unavoidable way of doubling back on us. Consider, for example, the notion of schema development (see Anderson, 1977; Rumeihart, 1980). This principle posits that, since some form of prior experience with the material is valuable – even essential – for learners who must come to understand a new poem or theorem or historical attitude, good teachers should work hard to help students access relevant prior knowledge and/or build it. I am keenly and often uncomfortably aware of the recursive nature of this argument as I approach it with those who would become teachers. Like a woman who stands between parallel mirrors and sees her reflection reflected back on itself in an infinity of progressively diminishing images, I ask myself whether I am reflecting accurately the principle I am advocating. For even as preservice teachers objectively study schema theory, they function simultaneously as subjective participants in an episode of teaching,

as students using their own schema as a resource for that study. They come to class carrying prior knowledge about the concept of prior knowledge. And so I ask myself, "Am I practicing what I am teaching? Do I know what these students already believe that might be relevant to our study of this particular principle? We are, after all, always a teacher and a group of students. Do not the very principles we are discussing apply to us while we are studying them?"

Students of teaching indeed come to their formal studies of teaching with powerful, personal history-based lay theories about good practice (Knowles & Holt-Reynolds, 1991). Lay theories are beliefs developed naturally over time without the influence of instruction (see Vygotsky, 1978). Preservice teachers do not consciously learn them at an announced, recognized moment from a formal teaching/learning episode. Rather, lay theories represent tacit knowledge lying dormant and unexamined by the student (see Barclay & Wellman, 1986). Developed over long years of participation in and observation of classrooms (Lortie, 1975) and teaching/learning incidents occurring in schools, homes, or the larger community (Measor, 1985; Sikes, 1987), lay theories are based on untutored interpretations of personal, lived experiences (see Bullough, Knowles, & Crow, 1989; Knowles, 1989).

Therefore, communicating the abstracted principles of professional practice to students of teaching is qualitatively unlike communicating the abstracted principles of any other profession (Feiman-Nemser & Buchmann, 1986; Zeichner, 1983, 1986). Preservice teachers enter programs of professional study with a quantity of knowledge about schools, classrooms, and pedagogical practices. They come with lay beliefs about what works with students and therefore constitutes "good" practice and with volumes of personal experiences in the form of narratives about teachers, teaching classrooms, and subject-matter specific pedagogies (see Clandinin, 1985; Connelly, 1986; Elbaz, 1981). They are, in effect, prepared to make sense out of the subject matter of teaching. They already possess quantities of experience-based information on virtually every topic or concept we plan to teach.

It is altogether possible that these personal history-based lay theories could indeed act as helpful schemata that preservice teachers can expand as they pursue their formal studies of teaching. There are, however, times when students' lay concepts are not quite contextualizing, illuminating, and helpful so much as they are powerful, potentially misleading, and unproductive as resources for learning the principles we hope to teach. Science in general (Roth & Anderson, 1988) and physics in particular (DiSessa, 1982; Holland, Holyoak, Nisbett, & Thagand, 1986) are areas where students' prior experiences of living and constructing meaning out of those experiences can lead to lay theories that are in error, tenacious, and highly resistant to instruction. These theories are often not even identified by the student as theories at all until, as part of the process of formal study, they appear as if in relief against the solid, explicit background of scientific knowledge or theory.

Comparing the personal history-based beliefs that preservice teachers bring to their formal studies of teaching to the lay beliefs that students bring to the

study of science or physics is, however, problematic. It is possible to demonstrate clearly that a lay belief about science is wrong or inferior to formal scientific theory. However, when preservice teachers' lay beliefs differ from those of teacher educators (see Ball, 1988; Hollingsworth, 1989; Holt-Reynolds, 1990a; Knowles, 1988,1990; McDiarmid, 1989), questions about the comparative value of the two sets of theories are more difficult to settle.

The study reported here was designed to explore the relationship between the personal history-based beliefs preservice teachers brought to their study of teaching and the principles of reading, writing, and discussing to learn that one professor advocated. It represents an effort to look closely at how preservice teachers use the knowledge they bring with them from their lives as students to make decisions while engaged in courses work about the value of ideas they hear there. (As such, this study leaves unexplored the question of whether the principles taught by this professor were appropriate, valuable, or well presented as well as the question of whether the beliefs expressed by these preservice teachers were valid, worthy, or equally adequate ways of thinking about classrooms.) Instead, this study documents (a) the lay theories and beliefs that participants had developed out of their personal history-based experiences, (b) the decisions that participants made about the potential value of the principles of good instruction encountered as part of their course work, and (c) the relationship between their personal history-based beliefs and those decisions as explained by each preservice teacher.

Study Design

In a concerted effort to understand more clearly the character and impact of the knowledge that the preservice teachers with whom I work bring to our formal study of teaching, I talked at length with 9 preservice teachers about the content area reading course work with which they were engaged. Content area reading for secondary majors is a course mandated for certification by more than 40 states. It provided an exciting context for looking at preservice teachers' beliefs because resistance to this course has already been well documented (Conley, 1990; O'Brien, 1988; Rafferty, 1990). At the midwestern university selected as the site for this study, it was a course taught to groups of preservice teachers representing the full spectrum of secondary subject matters. Of the 22 students enrolled the term I studied this course, 11 satisfied the only criteria for participation: they were preservice teachers with no field experience prior to enrolling in the course. Since the course itself had no field component, these 11 were ideal for this study of personal history-based beliefs as prior knowledge and the interactions of those beliefs with decisions these preservice teachers would make about the value of course ideas. Two declined participation due to excessive academic loads. The other 9 – 6 English majors and 3 math majors – talked with me six times in audio-recorded, loosely structured interview settings.

The first two interviews elicited information about participants' experiences

of community, school, and home. Three subsequent interviews focused on partici- pants' impressions of the purpose and value of course readings, statements made in class by the professor or by peers in discussion, and events – in-class writing or guest speakers – that formed the text of classes. Participants were also asked to generate a list of the main principles the professor had addressed and rank these in order of their importance and to point out and defend any principles from the course they had used in the lessons they developed as a final project in the course. The final interview invited participants to read 36 of Professor Barnett's statements drawn from recordings of class. Using a Likert scale, each rated the statements to show how much they agreed or disagreed and to show the statements' relevance to their future teaching. Participants talked about and gave rationales for each rating. They also rewrote any statement with which they disagreed so that it became a statement they could support and talked aloud about their reasons for making changes.

All data were completely transcribed and then read and coded for themes – repetitions in explanations and meanings ascribed to events – within any one participant's set of interviews. Based on this reading, I wrote a personal history that described these themes and tied them to personal stories of schooling or home for each participant. Participants read these histories, met with me to discuss errors, misrepresentations, or omissions, and approved the revised histor- ies. Transcripts were then read looking for thematic similarities and differences across all participants' responses to similar questions as well as across the coded categories previously identified. The resulting set of categories and the coding of individual transcripts were reviewed by a team of three researchers. Discrepancies were resolved through conversations between researchers until a consensus was achieved.

Care was taken to prevent this study from becoming one about the pedagogical strengths or weaknesses of the participating professor. Although he talked with me following each class session about which principles he had addressed in that session, we collected no data to document his rationales for selecting course principles. This professor's decision to allow the study of students' responses to the course he taught was predicated on the assurance that the study would focus on the rationales driving participants' decisions rather than on the effectiveness of his teaching. Consequently, although the study yielded rich data about the thinking of the preservice teachers who were involved, comparable data about the thinking of this professor were unavailable. The data for determining his logic for advocating course ideas are his actual statements in class as transcribed from recordings of course sessions.

Many of us, regardless of what course we teach, hope to encourage new teachers to develop expertise in process-oriented, student-centered modes of instruction. Barnett's content area reading course addressed these goals by advocating that teachers substitute directed reading activities, direct instruction in the reading process, and writing to learn activities for traditional, teacher-as- teller modes of instruction. Therefore, I have elected to report here preservice teachers' rationales for defending responses to these course principles. I explore

specific lay theories of subject matter, lay projections of high school students' abilities as readers, and lay beliefs about teachers' subject-matter specific roles as disseminators of information. The second part of this report provides an analysis of the character and quality of the interaction between these preservice teachers' lay beliefs and their decisions about student-centered, process-oriented instructional strategies. Based on that analysis, the final section of this report suggests five broad principles of pedagogy for preservice teacher education course work.

An Encounter: Lay Beliefs Meet Professional Theories

Content area reading courses are generally predicated on the principle that teachers need to mediate discrepancies between students' abilities as readers and the demands inherent to text in order to help students learn from texts and become independent learners in a content area. Jim Barnett (the pseudonym for the course instructor) devoted a major portion of class time to the development of this theory by defining and illustrating text demands, redefining "reading" as "understanding," challenging those enrolled about the value of teacher-led discussions/lectures, and inviting them to participate first hand in writing-to-learn activities both as in-class and as out-of-class assignments. He invited guest lecturers from a variety of content areas to speak about how they incorporated direct instruction in the reading process into their subject-matter curricula.

The Professional Argument for Change

Barnett's course in content area reading was, in essence, one extended campaign for the adoption of student-centered, process-focused, constructivist practices in subject-matter secondary classrooms. He repeatedly questioned the value of teacher-telling – of lectures – as instructional tools for fostering students' growth as independent learners. Presenting the premises of Barnett's position as if they were arguments in a debate that unfolded in rationale, linear fashion is useful for making his point of view accessible because it simplifies the task of explicating the course as a background against which these preservice teachers acted. However, this debate metaphor also casts preservice teachers' beliefs in the defensive role. The result is an implicit suggestion that research-based theories *should* act as measures by which preservice teachers will gauge the "correctness" of their beliefs. This debate metaphor mirrors an assumption often underlying course work. That assumption is an uneasy if not unfounded one and will be discussed in the conclusion of this report.

Barnett centered his argument around two premises. First, he argued that many, if not most, high school students have difficulty negotiating high school textbooks and therefore are not skilled at using reading as a way to learn. Second, he argued that, while presentational modes of instruction like lecturing effectively bypass texts for students and thus make the information contained in those texts accessible to them, teachers' telling of content actually does little to

help high school students become more skillful readers or independent learners. He argued that students are passive while teachers lecture or engage in other forms of teacher-telling and that this passive state is an undesirable one. Barnett maintained that teacher-telling does little to help students read difficult text. Rather, it allows at best and facilitates at worst high school students' tendencies to circumvent text. Throughout the course, Barnett recommended writing and small-group, peer-led discussions as activities teachers could substitute for more presentational modes. He advocated these alternatives using the rationale that they could invite students' active participation in their own learning.

Preservice Teachers' Defense of Current Practice

Barnett's arguments were not accepted by the nine preservice teachers with whom I talked. While most accepted writing-to-learn activities and small-group, peer-led discussions as occasional additions to traditional formats and some preservice teachers were in fact quite excited about these instructional tools, no one regarded them as appropriate substitute formats for traditional teacher-as-teller, lecture formats. Their personal history-based arguments for accepting these strategies on even a limited basis did not match or mirror Barnett's research-based arguments and rationales.

It is important to remember in reading these arguments that each is predicated on lay, personal history-based conceptualizations of "good" teaching, "good" subject-matter classrooms, and "good" student capabilities. Drawing on personal experiences of schooling, home, and community, these preservice teachers had developed attributional beliefs about what teacher behaviors were causal to the successes, failures, and memorable incidents in their previous histories as students (Holt-Reynolds, 1999b; Knowles & Holt-Reynolds, 1991) long before they arrived in Barnett's classroom. Reporting their rationales as arguments in defense of lecturing formats provides, therefore, a way to organize these lay beliefs and look at the interaction between their personal history-based beliefs and the professional theories of "good" teaching advocated by this particular course. An analysis of thematic issues, as represented in the content and character of these arguments, is reserved for the second section of this report.

Listening is active. All nine preservice teachers reacted quite positively to the idea that teachers should get students actively involved with subject matter. They absolutely, unequivocally agreed with Barnett on that point. No one tried to argue that passivity is desirable or even merely unavoidable. However, these preservice teachers did not share Barnett's definitions of the terms "active" and "passive." Consequently, no one accepted Barnett's argument that listening is a passive event for students. They countered by explaining the connections they saw between listening and thinking. Dave's argument is a good example: "If [students] are listening and thinking about [the math problem] while they are listening, then they are learning." As a group, these preservice teachers agreed with Dave. They argued that thinking is indeed active and that, therefore, listening will not be passive if students think while they listen:

"Passive" means not following a lecture, not trying to understand. "Active" means thinking about the topic. A lot of students do just sit there, but a lot of students may be thinking, trying to understand what the teacher is presenting. The active student is trying to learn more. (Will)

Will's comment underscores Dave's point but also suggests that the question of whether students are active or passive learners does not rest so much on the format a teacher employs as it does on qualities inherent to students – their motivations to be active. According to Will, lecturing itself does not determine students' passivity.

Interested students will listen actively. Several preservice teachers echoed Will's premise. They characterized students' responses to lectures as overt decisions that students make about whether they will be active or passive during a lecture. They attributed students' decisions to students interest in the topic. Jude's explanation was typical:

When teachers are lecturing, it doesn't necessarily mean that I shut off. I think [passive] means [students] are not engaged. Engagement can come in all forms, and one of them is sitting there daydreaming about what the teacher is talking about, something the students have an interest in.

According to Jude, students' interests will be the decisive element in a lecture/listen instructional format. He expressed the belief that interested students will think about what the teacher is saying during a lecture and thus will be "actively" involved with the subject matter.

Jude's belief was shared widely among preservice teachers in this study. Beth and Charlie both expressed similar beliefs connecting students' interest to students' engagement during a lecture: "Sometimes [students] are formulating questions about what they are thinking. But somebody who is not interested in math might not do that" (Beth). "If it's a good lecture, [students] aren't passive. They are involved and really interested in what's going on in the lecture, and it's stimulating something in their mind and making me think about a lot of things" (Charlie).

These preservice teachers did not accept Barnett's link between lecturing and passivity. Jane and Corinne went so far as to offer explicit examples of how active students could be when listening to lectures: "When teachers are lecturing, students can ask questions and participate" (Jane). "[When] students are taking notes or listening, that's not passive. Listening is active" (Corinne). They believed that listening can constitute active participation because listening can involve thinking, taking notes, asking questions, and working examples silently and privately but along with the teacher's oral explanation. They linked the degree of student participation to interest in the lecture's content, not to an inherent feature of the lecturing format. They believed that, if students are interested and/or the lecturer is interesting, students will be actively engaged with the material.

The belief that interest or excitement or having fun will be the key concern –

perhaps the only concern – when teachers hope to foster learning was a powerful one. All nine preservice teachers believed that "interestingness" would be the most important attribute of instruction (see Holt-Reynolds, 1990b). All nine talked about the positive correlation between students' interest in a subject or teacher and students' effort to learn. And all nine had developed that belief based on their interpretations of their experiences as students in classrooms: "You get more out of things that you're more excited about than something you dread doing" (Corinne). "You pay more attention to teachers that are doing what you are really interested in. [Students] may pick up [information] in my class because [they] are interested" (Jeneane). "I think the interest part goes with understanding. Some [students] can understand without being interested, but I think it does make it easier for a student to understand if they are interested in the topic" (Will). "If students are interested in a topic, they'll pay more attention to it. They'll get more out of it" (Beth).

Arguing that students' levels of engagement are tied to their levels of interest did not negate Barnett's premise about the importance of active engagement. These preservice teachers agreed with him there. They did not, however, accept the corollary that students' roles during lecture are inherently passive ones. They countered by offering definitions of active participation that included thinking, silent monitoring, following the talk, note-taking, and interrupting the lecture to ask questions. They defined "passive" as synonymous with "bored" or "not interested."

Lecturing is necessary given specific subject matter. With the issue of passivity comfortably resolved, these preservice teachers turned their attention to Barnett's premise about the importance of helping students become independent readers of texts. No one asserted that students' reading independence was not a goal. Instead, they raised arguments reflecting their beliefs about the likelihood of achieving this goal given the nature of the subject matter they intended to teach.

Jane talked about the importance of teacher-telling in a subject-matter specific context:

> In history, I'm sorry. it's just not going to come out of them. I'm going to have to lecture – I don't think that's bad. I don't like history books for high school. They're usually boring. I would be tempted to throw out the textbooks, have [students] read primary sources, and then have me tell them the rest.

Jane was concerned about whether, in history, students would be able to learn independently. She did not value textbooks as sources of information. Rather, she saw them as supplementary to teacher-telling. Consequently, Jane saw little reason to foster students' independent use of textbooks – a goal Barnett advocated. Since Barnett's premise of defending the replacement of lecturing formats with strategies to help students become independent learners hinged on his assumption that fostering independence is both valuable and possible, his entire argument was vulnerable to counterlogic like Jane's.

Dave believed it would be unlikely that students could learn his subject matter, math, independently since "math is sequential in nature." This belief formed the premise he used to build his argument for a link between good teaching and lecturing:

> You just have to tell [students] the next step. Some [steps] they are not going to discover on their own if you give them a lifetime. That's where you give it to them. I think it's better to teach slow and let them figure it out by themselves, but it's not practical at all. You do have to cover the material.

Beth and Will agreed with Dave on this point. All three math majors argued that learning math is easier if a teacher lectures rather than if a teacher requires students to learn math by reading the textbook. As Dave explained "The textbooks are so difficult that it's easier to [lecture]. The kids can't ask a book a question. [If] you are lecturing, they can raise their hand, and you can answer." In effect, they argued that learning math is more important than learning how to learn math:

> Lecturing can help students, especially in math class. You wouldn't want 100% lecture, but I still think it helps. I know I do a lot better in my math classes if I have somebody lecturing to me about what I've been reading. (Beth)

Will too connected the nature of learning from texts in math classrooms to a need for some form of teacher-telling: "Considering the texts [math classes] use, [lecturing] is almost needed – to talk the course. I'm not saying this is the best way to do it, but it is about the only way."

Reading and certainly writing and discussing are not traditional elements of math classes. When these math majors consulted their own experiences as students, they found memories of difficulty in learning independently from math textbooks. All three math majors realized the demands of math texts and, therefore, readily agreed with Barnett's prediction that their students would have great difficulty in reading math textbooks and learning math from that reading.

They disagreed, however, about how "good" teachers should mediate the difficulties of texts with students. All three insisted that it is in fact the very difficulty of math textbooks that has made math classes the way they are today. All came to their study of content area reading carrying positive pictures of classrooms where lecturing served a mediational role and dominated, classrooms where they had been quite successful as learners. On four occasions in three different interviews Beth explained:

> [Math] has been work on problems, work on problems, and work on the problems some more. The teacher says, "Read this section tonight, and we'll discuss it in class tomorrow." No one reads the section. They come to class, and then the teacher teaches them how to do it, and you go work on more problems.

Will agreed, explaining that "to get the best educational experience, you have to go through and work with a student by lecturing or just discussing the problems." Dave recalled: "We sat in class and got lectured at. [There was] a question period and then there was homework." Dave went on to say that he expected his own teaching to follow this pattern "with some added spices" to keep students "interested."

Since all three had been remarkably successful students in that context, it is little wonder that they interpreted their experiences positively. Lecturing had helped them learn math; therefore, they saw lecturing as an inherent, necessary feature of good instruction in math.

All three math majors believed that the classroom formats they had encountered as math students were somehow inherently connected to the nature of math as a discipline. While neither Beth nor Will was as forceful on this point as Dave, all three math majors shared the belief that math must be told to learners. No one believed that students could become self-directed learners able to read texts independently *in math*. Their beliefs about subject-matter specific pedagogy (see Shulman, 1986) complicated and to a large degree thwarted Barnett's campaign to offer strategies for making learners independent of teachers. Since these beliefs were not replaced by Barnett's arguments, lecturing remained the only mediation they saw as effective.

Lecturing motivates students' interest in literature. Barnett based the rationale for adopting reading support strategies instead of presentational lecturing strategies on the assumption of students' need for that support. All nine preservice teachers, however, were remarkably optimistic about students' abilities to read *literature* analytically and relate it to their lives: "English textbooks, I think, are fine without help. You could get something out of it" (Beth, math major). "You can get things out of [literature]. Plots are easy to read. You might miss all the symbols and themes" (Dave, math major). "Literature anthologies are intended for students to read on their own. I could handle reading an anthology when I was in high school" (Lauren, English major). "A novel is something you can pick up for pleasure. I don't think most authors intended for everyone to have a mentor with them while they read their book" (Jude, English major).

These preservice teachers differed from Barnett in their estimations of the potential difficulties that high school readers would have reading literature at even the literal level. The arguments given by Jeneane, Charlie, and Lauren – all English majors – subsumed the others' positions:

> Most kids know what's going on today. They read the paper, watch the news and talk shows. Now they just [need] to read [literature] and see how that knowledge applies. As difficult as that sounds, I really don't think it is. (Jeneane)

> [Students] can [analyze literature], but I'm not sure they know they can. I think once you read something, you have an opinion about it. I guess younger students don't realize that's analysis. (Charlie)

> I think [students] analyze [literature] on their own without really knowing they are doing it. If it's like *Catcher in the Rye* where the guy is really depressed, that's something they would be able to make a connection with. (Lauren)

The English majors held belief systems that were in direct opposition to Barnett's. They believed that students are actually quite competent as readers but that teachers do not give them credit for that competence. Therefore, not only could they see no need for supporting students' reading, but they also logically were uncomfortable even considering the possibility. They were operating under a belief system that said, "Good teachers believe that their students are competent," while Barnett based the use and study of reading strategies on the argument that students would require help. Minus the argument that students need reading support rather than additional, teacher-based information about texts, Barnett's rationale for eliminating the lecture as an instructional format was weakened.

Since the English majors in this study believed that students' difficulties with reading literature texts would be minimal, they argued in defense of the lecture as a motivational tool:

> Lectures help students learn because they infuse the teacher's personality and unique knowledge into the subject matter and make it possible for students to ask questions directly of the lecturer. They can't ask questions of their book … Lecturing *is* a way to mediate between readers and texts. … If [students] are reading a passage on Shakespeare and it tells some boring things, I could make it more interesting and more memorable if I told them or acted it out. (Jane)

Jane's revision of Barnett's argument reflected her dual beliefs that (a) teacher-telling personalizes the material or makes it interesting and (b) lecturing provides a more active response for students than reading. In her comment, we see once again that keeping students' interest was an important consideration. We see once again the belief that teachers can provide instructionally valuable "interestingness" via lectures: "Talking the course is a way. of making it come alive, of mediating for students" (Jude).

Lecturing demonstrates subject-matter expertise. These preservice English teachers used one additional argument to defend the practice of lecturing. They believed that lecturing would "prove" that they are subject-matter experts. Jane made this point explicitly:

> I don't think that lectures are [spoon feeding] – I mean, why am I going to school for 4 years and studying English if I can't tell them anything I've learned from it? I am a source of knowledge. I would think I would be at least as valuable as a textbook.

Jane apparently conceived of knowledge as a body of information and of teachers' roles as transmitters of that information. Barnett's arguments assumed that

knowledge is something constructed in the interactions of learners with texts, writing, and peers. Barnett assumed an epistemology that Jane did not share. Lauren was also concerned about appearing knowledgeable to her students: "They're going to think you're dumb if you don't know it off the top of your head." She believed that "good" teachers know their subject matter, and they "prove" their knowledge by lecturing.

  "Good" lectures vs. "bad" lectures. Just as the preservice teachers who spoke with me did not share a definition of "active" and "passive" with Barnett, neither did they share his definition of "lecture." Barnett used the term as synonymous with teacher-telling. He defined any teacher action as "lecturing" if its primary purpose was the direct transmission of previously constructed information. Barnett therefore considered question-answer-evaluation formats as "lecturing." While the nine preservice teachers agreed that when teachers talk to transmit information they are indeed giving a "lecture," they recognized formats where teachers ask questions, students volunteer answers, and teachers evaluate those answers as "discussions," not as "lectures."

  They also distinguished between types of lectures while Barnett did not. They considered some lectures or uses of lecturing "bad" while other types and reasons for lecturing might be "good":

> Discussion with the teacher is okay. If you talk to [students] while you're giving them information, and they feel free to ask questions if they don't understand, that makes things comfortable. (Lauren)

Lauren had interviewed high school students and been told with impressive regularity how much they disliked "straight" lectures. These sorts of lectures, Lauren believed, were therefore "bad." But "discussability lectures" were "comfortable," and Lauren planned to use them. Charlie saw lectures as useful formats to "pass out" and so transmit information: "I don't necessarily think [lectures] are the best techniques or ones that should be used 5 days a week, but I think they can be very helpful to pass out a lot of information in a short time."

  Many believed that lecturing could be valuable, but only if it is used in moderation: "It depends on how much you do" (Corinne). Corinne went on to explain why she believed that only limited amounts of lecturing would be valuable. Notice how she built her argument around her belief that holding students' interest is an important teacher behavior:

> If you *only* use [lecturing], then of course it's going to do little to help students learn because they're going to become bored . … [Lecturing and independent reading] are both fine if you don't overuse them because then students get bored.

In other words, either format was fine. It was the *variation* of formats that Corinne valued. She saw nothing inherently more valuable in student-centered activities or inherently more limiting in lecturing as Barnett had argued. But

sameness could cause boredom, and interest, she believed, would be the vital element to good teaching.

Several preservice teachers argued for only a limited use of lecturing based on a belief that sameness in and of itself would be undesirable. Like Corinne above, they believed in the inherent value of variation. Jeneane used this belief as part of her rationale for minimizing her use of lecturing: "[Students] go through 13 years of schooling, and a lot of it is lecturing. If there is one class where teachers do something out of the ordinary, I think that can really aid a student in learning." The full extent of Jeneane's argument is presented here. It was Barnett who linked learning with active engagement in the making of meaning. Jeneane's rationale tied learning to the state of being different. Others shared her belief that "differentness" would have inherent value in their class-rooms: "I got the feeling that [students] would like [my final project]. They would think it was different" (Corinne). "[Students] would enjoy [my final project] if they could get into it. It's better than just the same thing all the time. It's good to shake [students] up a little bit" (Jane).

The net effect of the arguments presented in defense of lecturing was to redefine this teacher behavior in a way that would leave many of its forms outside the debate. Lauren, Corinne, Jane, and Charlie carefully qualified their rejection of the lecture format, leaving many forms of teacher-telling available to themselves.

As did Charlie and Corinne, Lauren believed that quantity of use determined, at least in part, whether lecturing might be a "good" teacher thing to do. In our final interview, she revised one of Barnett's statements to read: Lecturing and other forms of teacher-telling do little to help students learn if that's all they do and the students have no input. Lauren believed that a lecture would "mediate" a Shakespeare text for students by "giving them the history and where Shakespeare was from," and she defended her planned use of this lecture in part by invoking Barnett's argument for text mediation with students. She redefined lecturing as a text mediation strategy; yet, telling students information about an author's life did not meet Barnett's definition of mediating a text by any stretch of imagination.

An Analysis: Thematic Issues in Preservice Teachers' Beliefs and Arguments

The specific arguments these nine preservice teachers shared for defending their decisions about the value and validity of the rationales their professor offered are important in their own right. Their arguments are coherent, cohesive, and clearly grounded in their personal histories. By exploring the specific arguments preservice teachers use for supporting their decisions about the potential value of specific principles, we stand to learn much about the effects of the rationales we use as we attempt to establish the importance of the principles we hope to teach. As in all well-argued debates, each side learns more about its own point of view by listening carefully to the strategic arguments of the opposition. Certainly it is possible to read the arguments here and, working inductively,

discover in them a different strategy for recommending student-centered, participatory, process-oriented teaching formats to preservice teachers.

However, since it is my intention to use this set of arguments as a sample out of which to begin to develop belief-sensitive principles for teaching preservice teachers, what follows here is not so much an analysis of these specific arguments as an analysis of what these arguments tell us about the character and content of the beliefs and lay concepts preservice teachers are likely to bring to their formal study of teaching.

The Character of Preservice Teachers' Lay Beliefs

Preservice teachers' beliefs are typically generalizations based on references to themselves in the role of students (Knowles & Holt-Reynolds, 1991). The preservice teachers cited here are certainly no exception. Over and over, they referenced themselves as prototypes upon which to build a generalized premise.

Charlie's statement cited earlier is perhaps the most dramatic example of how easily preservice teachers dip into their own experiences for data with which to support a belief and build an argument. Note the shift Charlie makes from the objective pronoun "they" to the personal, subjective pronoun "me" to prove his opening, generalized premise:

> If it's a good lecture, [students] aren't passive. [They aren't passive when] *they* are involved and really interested in what's going on in the lecture and it's stimulating something in *their* mind and making *me* think about a lot of things.

Charlie was not only talking about students in general or even his own future students; he was recalling his own experiences while teachers lectured. When he was interested in a lecture, his reactions to it seemed to him to be qualitatively different from his reactions to a lecture in which he was not so interested. Since this perception had the advantage of accounting rather nicely for his own experiences, Charlie linked passivity to boredom rather than to the relationship between learners and subject matter inherent to lecture modes. He treated this belief just as Barnett treated the research-based principles he advocated – as a generalizable premise out of which to build an argument for what "good" teachers ought to be doing.

While Charlie's statement above is especially easy to use as an illustration, he was in no way an isolated case. Each of these preservice teachers used their explanations of their own experiences as students in classrooms as data out of which to develop beliefs about how other students would react to particular teaching behaviors. These beliefs had been established long before these preservice teachers met Barnett. When Barnett's link between a teaching behavior and a student outcome failed to match the association each had already developed, each preservice teacher in this study questioned the validity of Barnett's argument, not the validity of their own previously constructed premises. The character of these preservice teachers' lay beliefs was such that they used their personal

histories to test Barnett's principles and arguments. They did not use Barnett's principles and arguments to test their lay beliefs. The ways that these nine preservice teachers used their personal history-based beliefs match and thus formally document the uses that I have observed more informally across 5 years of working with preservice teacher education.

The Content of Preservice Teachers' Lay Beliefs

These preservice teachers' arguments share some striking themes in terms of content. Each of the arguments presented above differs from Barnett's because it rested on (a) a lay definition that differed from Barnett's, (b) a lay value that differed from Barnett's, or (c) a lay belief that was, in turn, based on limited data.

Differing definitions. The most obvious debate about definitions centered on the differences between Barnett's definitions of "active" and passive" and the definitions that the preservice teachers held for those terms. Barnett's definitions were operationalized according to the formal, cognitive understanding of those terms. For Barnett, "active" meant participatory. It meant engaged in the creation or construction of knoweldge. These preservice teachers relied instead on a lay definition. They understood "active" to mean anything that was not clearly "passive." "Passive" they understood to mean "disengaged" or even "bored." Therefore, when these preservice teachers listened to Barnett devalue lecturing on the grounds that students would not be active while teachers lecture, they disagreed. They maintained that students could well be disengaged, "passive," but only if they were bored. Therefore, they saw little need to abandon the lecture format. Instead, they argued for modifying lectures to insure their levels of interestingness. This difference in definitions for critical terms cost Barnett his argument. Without confronting the differences between his research-based definitions and his students' lay definitions of terms, he had little chance of successfully defending his argument.

Barnett faced a similar problem with the term "lecture" itself. These preservice teachers simply rejected his definition of "lecture." They defined "lecture" quite narrowly and so, whether consciously or otherwise, they left forms of what Barnett would have labeled "lecturing" available to themselves. Therefore, when they expressed a reluctance to "lecture," these preservice teachers meant that they were reluctant to talk to students for 55 minutes without at least pausing to ask or answer questions. They defined formats that included questions as "discussions," not "lectures." Consequently, in their statements about the disadvantages of "lectures," they sometimes appeared to agree with Barnett even though they did not. The lack of agreement about the definitions of these critical terms served to mask the level of preservice teachers' rejection of Barnett's arguments.

In addition to these obvious differences in definitions of terms, other, more subtle distinctions also served to thwart the debate. Barnett and his students did not share a definition of "learning." The preservice teachers in this study talked about learning as if it were exclusively an issue of motivation. They

returned repeatedly to the question of "interestingness" as central to every decision they made about every principle they encountered in the course. They held no concept of learning that included the development and strategic use of cognitive skills. That was Barnett's definition – a definition they did not share. Consequently, when Barnett advocated teaching strategies that could foster students' development of independence as learners, these preservice teachers had no way to evaluate those strategies other than to anticipate their motivational potential. The criterion of "interestingness" which they applied was unproductive and not especially helpful for assessing the value of the strategies Barnett advocated. Defining "learning" as exclusively an issue of motivation led these preservice teachers to dismiss strategies they might otherwise have come to value and to value strategies for unproductive reasons. Several preservice teachers argued for the use of process-oriented strategies like writing-to-learn and peer group discussions, not because these formats would encourage the active construction of knowledge, but because they would be "a change of pace." They defended their potential use of alternatives to lecturing by arguing that, since variation itself is valuable as a way to elicit interest, these alternatives would therefore be valuable.

Finally, these preservice teachers operated under a very different definition of "knowledge" than did Barnett. Principles associated with course work in content area reading assume that knowledge is constructed by learners. With the exception of Charlie, these preservice teachers assumed that knowledge is a thing to be transmitted to students intact. They saw textbooks as one source of that knowledge. They saw themselves as another source. Only Charlie saw students themselves as sources. This difference between assumptions is critical since the strategies Barnett advocated were designed to help students become skillful producers of knowledge rather than skillful receivers of knowledge. Unfortunately, neither Barnett nor these preservice teachers ever discussed much less argued this central issue. Each acted as if there were no difference between what each understood "knowledge" to be.

Unrecognized differences between preservice teachers' definitions of critical terms and concepts and teacher educators' definitions means that each talks to the other as if there were no differences. In this case, exposure of the differences between these preservice teachers' lay definitions of knowledge and learning and the definitions Barnett used would have made genuine exploration of strategies for achieving those ends a possibility. Unrecognized and thus unexplored, these differences between lay definitions and conceptions and more formal professional definitions and conceptions in effect sabotaged the debate. Both sides argued their case; neither side dealt with the argument presented by the other.

Differing values. Since Barnett and these preservice teachers never explored these differences between lay definitions and professional ones, they missed an opportunity to debate and possibly resolve the differing values each held based on those definitions. Because these preservice teachers defined learning as an issue of motivation, they valued interestingness. Because they defined knowledge as a body of information that could be transmitted, they valued teaching formats

that would allow them to act as experts, as effective and efficient transmitters of that information. Since the differences in definitions were never explicitly or openly debated, neither were the differing values that had their roots in those definitions. The issue here is not whether Barnett or these preservice teachers were "right" but whether teacher educators and preservice teachers might learn more about teaching if they were able to recognize, debate, and perhaps resolve differences in definitions and values.

One additional value that these preservice teachers maintained, however, was not a result of a differing definition of terms. The English majors in this study placed a high value on seeing their students as capable. All six of them agreed that students could read literature texts on some level without teacher help. They believed that students could analyze text and could relate literature themes to their own lives without instruction. While Barnett did not argue this point directly, it is important to note that these English majors were reluctant if not unable to consider the possibility that their future students might be "deficit" in any way. They were clearly uncomfortable with even that thought. They believed in the inherent abilities of their students. Ironically, this value that they brought to their study of teaching made understanding Barnett's emphasis on mediating text demands very difficult.

Differences in available data. Some of the differences between Barnett's position and those of these preservice teachers stem from the access each had to data about students in classrooms. The preservice teachers used their own experiences as if these were prototypical and generalizable. They operated out of data that were limited to a case of one. Barnett's beliefs about the skill levels of the students they would likely encounter were based on a far larger data pool. One logical consequence of operating out of personal history-based beliefs is that all personal histories constitute a sample of only one. It is not reasonable to expect that every conclusion based on the personal experiences of one individual will be appropriate to generalize to all students.

By Barnett's standards, the beliefs that the English majors held about students' abilities as unaided readers radically overestimated the skills that their students would bring to the reading of literature texts. By his standards, the math majors underestimated the range of legitimate formats for teaching mathematics.

Differences in estimations of students' success as readers or of the range of subject-matter specific pedagogies seem to grow naturally and predictably out of the bias inherent in using self as a prototype. These nine preservice teachers had more limited information about students and subject matter out of which to develop their beliefs than Barnett had. When preservice teachers treat their own experiences as if these were prototypical and generalizable, they are bound to reach conclusions that differ from those available based on the larger, diverse data of years of research. An excellent case in point is the belief that learning is exclusively a matter of motivation as expressed by these preservice teachers. Their experiences as learners, while varied across subject matters, could not possibly reflect a full range of studenting experiences. For the preservice teachers who populate teacher education courses, learning has probably indeed been

almost exclusively an issue of motivation. As successful learners, they are unlikely to be more than tacitly aware of how or when they developed learning skills. They do not realize that they may be "special" cases. The use of self as a prototype led these preservice teachers to believe that all learners are essentially like themselves and quite competent. Their estimation of the need to develop reading, learning, or thinking skills with their students therefore differed from Barnett's.

Operating from a similar stance, the math majors held views of what math classrooms could be like that were very different from those assumed by Barnett. Their belief that math is a subject that must inherently be told to students was based on the limited experiences they had as students in math classrooms. Their personal histories led them to beliefs that differed from those Barnett had based on an enlarged data base.

Conclusion: Principles of a Pedagogy for Preservice Teachers

The personal histories of preservice teachers appear to function as prior knowledge of what "good". teaching should look, sound, and feel like. Preservice teachers have spent considerable time and energy in their lives as students attempting to make sense out of and account for their experiences as learners in specific subject-matter contexts. Their conclusions – their beliefs about what actions, states of mind, attitudes, and intentions combine to personify a "good" teacher – work behind the scenes as invisible, often tacitly known criteria for evaluating the potential efficacy of ideas, theories, and strategies of instruction they encounter as they formally study teaching.

Influencing the content of those beliefs is certainly one appropriate goal of teacher education. It may also be quite challenging and difficult. McDiarmid's course (1989) invited preservice teachers to explore their personal history-based beliefs about teaching mathematics. Ball's course (1988, 1989) challenged what preservice teachers know about mathematics, how it is learned, and how it is taught. Despite opportunities to experience learning mathematics by constructing ideas for themselves, investigating premises, and developing personal connections to the mathematics they were studying and teaching, the preservice teachers in these studies maintained previously developed rationales for explaining their experiences as learners and for predicting what their future teaching should/could therefore look like. Each study reports that, while new kinds of experiences as learners of mathematics had a powerful impact on preservice teachers' notions about the depth of subject-matter expertise required to teach mathematics and expanded the range of options for teaching mathematics that they perceived, their beliefs about the relationship between teacher-telling and student learning as traditionally associated with mathematics teaching remained intact. Each study concluded that preservice teachers' beliefs are well established, tenacious, and powerful.

The responses of preservice teachers to the principles of reading, writing, and talking to learn that they encountered in content area reading certainly reiterate

those that Ball and McDiarmid report from preservice teachers encountering new ways of teaching and thinking about mathematics. They add to our growing awareness of the importance and primacy of personal history-based beliefs and of the relative impotence of the experiences preservice teachers can collect in a single course given the longevity and cohesive character of those beliefs. They also extend our data to include documentation of the ways that preservice teachers use their beliefs as criteria for evaluating the potential of the ideas we try to teach them.

If, as teacher educators, we want to influence those we teach toward positive decisions about the value of our ideas, we would do well not only to explore the beliefs our students have developed about "good" teaching but also to investigate how they use those beliefs to defend the decisions they make. These data suggest that the rationales underlying preservice teachers' decisions must be understood and addressed by teacher educators. They suggest that helping preservice teachers develop more professional arguments and expanded, research-based attributions may be far more difficult and essential than training young teachers to emulate professional, research-based behaviors. Acknowledging the power of personal history-based beliefs and conceptualizations about teaching and accepting these as coherent, cohesive, and therefore legitimate premises from which preservice teachers begin their formal, professional studies means assuming that our role as teacher educators centers more around fostering the professionalization of those existing rationales rather than around generating professional rationales and behaviors from scratch. Helping our new colleagues discover, understand, challenge, enlarge, inform, and consider changing, reprioritizing, or reforming the premises upon which they base their arguments can become our primary and legitimate concern.

Conceiving of our job as teacher educators as one of entering into dialogue with preservice teachers and thus working together with them to evaluate and adjust the beliefs, premises, and arguments they will use to guide their practices implies the development of pedagogical practices that will (a) encourage preservice teachers to share the lay beliefs they currently use to guide their thinking, (b) identify differences between those beliefs and the principles we want them to explore, (c) challenge preservice teachers to question the attributional links they have established between their reactions as students and the behaviors of teachers, (d) expose both the strengths and the limitations of referencing personal experience as a data source, and (e) respect as well as utilize the beliefs of preservice teachers as standards against which we check our research-based principles. These principles, in turn, suggest characteristics of teacher education programs where such pedagogical activities would be possible.

To achieve these goals, we need vehicles – activities, experiences, and assignments – that will invite preservice teachers to share their rationales and beliefs. However, given the unequal distribution of power inherent in classrooms (Belenky, Clinchy, Goldberger, & Tarule, 1986), inviting "authentic" talk is, at the very least, a challenge. As long as we pass out grades that reward "correct" performance or thinking, we will continue to tempt our students to impression

management (Shipman, 1967) whether they are conscious of it or not. However, within the classroom structures currently available to us, we can alter the focus of the assignments we grade and the conversations we prompt. We can shift our purposes away from evaluating and attempt instead to probe preservice teachers' rationales rather than assess their abilities to apply our rationales. We can craft assignments and activities that invite our students to explore arguments rather than to generate practical applications.

Perhaps in part because of the unequal distribution of power in our classrooms, preservice teachers are reluctant to identify areas where they disagree with us. More significantly, they may well not even be aware of their own disagreement. We cannot depend on our students to challenge us with their dissenting or disagreeing voices. We must recognize that they need help identifying the premises with which they disagree. We must locate the differing definitions of terms, the differing values, the moments when their arguments are based on self as data. We must, in effect, understand the implications of preservice teachers' personal history-based knowledge and then invite them to consider those implications with us.

While we must certainly organize course work so that preservice teachers have an opportunity to question their prior beliefs about teaching, learning, classrooms, and students, we need to do so with some sense of caution. It is important to remember that these preservice teachers and others like them want to be teachers in part because they hold these very lay beliefs we want to encourage them to examine critically. They want to teach *because* they believe that students are capable, *because* they believe that students have not been given an adequate chance or excellent teaching, *because* they believe that, through the force of their own personalities and efforts to provide interesting, motivating experiences for students, they can make a difference to their students. Pieces of the beliefs cited here are intrinsic to preservice teachers' motivations to teach.

We also need to be careful to preserve what is most valuable about those beliefs. Since the beliefs that preservice teachers bring with them are direct reflections of studenting experiences, they can act as powerful checks on the validity of the research-based principles we teach, Their lived experiences as students retain the personal and social features of classrooms that far too often our research-based principles have eliminated from the general store of professional knowledge. What scientific research carefully wipes away as a "contaminating" factor, e.g., teacher personality effects, preservice teachers' lay beliefs return to the knowledge base. Their beliefs retain the personalities of teachers, the isolated events that with amazing frequency are validated by the personal histories of others in the class, the student-felt effects of teacher behaviors that underestimated students capabilities, ignored students' requests for help, or challenged students and interested them in classroom work. Drawing on their recent and still accessible histories as students, preservice teachers know something about the relationship of student engagement with material and student interest that our research has overlooked or obscured. Their knowledge is valuable.

When research-based principles claim to describe the effects of teaching behaviors on students, then the experiences that preservice teachers actually had as students ought to validate those principles. When preservice teachers dip into their personal history-based student data and reach very different conclusions, we might do well to reconsider our research base, its design, and its agenda. Honestly exploring with preservice teachers the experiences that act as premises in their arguments can serve to help us check the validity of the principles we teach.

Exploring personal histories with preservice teachers, locating the beliefs about teaching that are wrapped in those experiences, providing support for the personal courage required to question the completeness of longstanding explanations for personal experiences, and considering alternative explanations for those events – these activities will be central to a pedagogy that practices discovering what students already know and then linking research-based ways of thinking about classrooms and teaching to that knowledge. Such pedagogy will only be possible in teacher education programs where decisions about progress through the program are tied less to students'. abilities to produce desired behavior and more to students' abilities to propose, weigh, and justify a variety of possible teacher actions and then defend thoughtfully a choice from among them, where professors are able to know students personally, across time, and in a variety of contexts, and where explicit attention is given to helping preservice teachers discover personal theories that have colored both what they notice in classrooms and the sense they habitually make of it before asking them to return to field settings to somehow "see" something new. If we take seriously our own theory about the importance of prior knowledge, then teacher education programs must reflect the assumption that preservice teachers' personal history-based knowledge and beliefs are important for teacher educators to discover and for students of teaching to explore.

If rationales and their relationships to teachers' choices about instruction are to become the central focus of our work with teachers, then we must become explicit about the beliefs we assume teachers must hold in order to engage in the kinds of classroom actions we advocate. We will need to clarify for ourselves the rationales that support the strategies we expect new teachers to learn to use and the beliefs that support those rationales. In addition, our programs of teacher education will need to articulate clearly those rationales and beliefs across all course and field work. We will also need to develop a sense for how much time and what kind of support we might provide so that, when preservice teachers discover beliefs they want to challenge, our programs of teacher education invite them to continue that exploration. One isolated course does little to interrupt the continuity of preservice teachers' learning from the "apprenticeship of observation" to their adult lives as teachers (Ball, 1989; Lortie, 1975). We will need to consider how best to sustain and support the conversations and critiques we begin.

Preservice teachers' prior knowledge and beliefs about "good" teaching are indeed powerful and important elements with which we as teacher educators

must contend. They influence the decisions that preservice teachers make about the value of all we hope to teach them. Until we develop ways to invite our students to share their lay beliefs, ways to understand the implications of those beliefs, and ways to encourage and sustain critical conversations about those beliefs, we will fall short of actually practicing with our own students the very principles that we are teaching them to employ.

SECTION 2

Developing a Professional Knowledge Base for Teaching

Section Editor: Mary Lynn Hamilton

FOREWORD TO SECTION 2

This Handbook section addresses issues related to development of a professional knowledge base for teaching and investigates the ways in which the self-study of teaching practices has, if it has, affected this knowledge base. Topics in this section include a discussion about the nature of the knowledge, a review of the professional knowledge base including political, moral, and ethical issues, and an examination of how self-study of teaching practices influence this area.

To begin this exploration, chapter ten questions what counts as knowledge in the research on the self-study of teaching practices and offers possible philosophical answers. Regardless of the current back step toward traditional notions of research and knowledge production, the scholars involved in self-study of teaching practices consider uncertainty and multiple views of reality as elements of the work they do. Further, this chapter explores the professional knowledge base as it is currently defined and examines ways in which teacher education has been influenced by it. Using self-study to reveal one's authority of experience or to encourage teachers and teacher educators when they look carefully at their own practice, or to underscore the multiplicity of ways to consider the professional knowledge base in teaching dramatically changes teacher education.

Chapter eleven offers links between the work in the self-study of teaching practices and teacher education reform. In this chapter, Korthagen and Lunenberg analyze and offer illustrations of the recent progress of the research of self-study at the personal, institutional and collective levels. This chapter is replete with examples of the work done within the international community of teacher educators focused on self-study. In response to their analysis, these authors identify dimensions that fit the relation between traditional teacher education research and self-study research. They also offer guidelines for high quality self-studies. By chapter's end, they assert that research on the self-study of teaching practices can make major contributions to the improvement of teacher education.

Unfortunately, the teacher educators engaged in the self-study of teaching practices do not always have an easy time in their academic settings because of their challenges to the status quo. In chapter twelve, Cole and Knowles examine what counts as scholarship. The researchers involved in the self-study of teaching practices have relocated the heart of their work to experience, generating some resistance among the more staid and traditional researchers in teacher education.

The individual and collective works of scholars engaged in self-study has been examined, particularly as it relates to understanding their research, their practice and their academic settings. Once they explore the barriers, Cole and Knowles present a framework for rethinking academic norms and the settings that influence the work of teacher educators in the academy.

In chapter thirteen, Allender looks at humanistic research and its influences on self-study. As both self-study and humanistic research have a commitment to connections – among ideas and people – there is a relation between them. In this chapter, Allender explores this relationship through his long experience doing this work. Historically we can see the development of ideas that eventually contributes to the work of scholars engaged in the self-study of teaching practices. More than a focus on one theorist or philosophical view, there is a moral dimension to the work of humanistic research. That is, those involved ask questions about honesty, truth, and the best ways to provide evidence for those involved in the work. This is a commonality between self-study and humanistic research. For Allender, an essential question is: "In what ways are my teaching practices consistent with what I expect of the teachers I am educating?"

When considering knowledge, "what counts as knowledge" and "whose knowledge is it?", we can not escape questions related to race and class. In chapter fourteen, Brown explores the significance of these issues to professional knowledge and the work of self-study researchers. This chapter provides us with an historical glimpse as well as current examination of these issues as they relate to self-study. While there have been concerns raised about the lack of research done by self-study scholars focused on race and class, Brown offers a critique of what has (and has not) been done, provides a discussion that recognizes the quality of the work that has been done, and proposes recommendations for future work.

In chapter fifteen, Clandinin and Connelly explore ways to uncover knowledge in self-study using narrative. Before they begin that discussion, they address ways of defining teacher knowledge with particular attention to knowledge as something one has and knowledge as something one gains from experience. Once they build their argument for the power of narrative self-study, they illustrate their points with examples of self-studies that demonstrate the ways that teacher knowledge lives in practice. Further, they underscore the relation between the knowledge seen in the self-studies and professional knowledge. Importantly, they raise the point that the critical element of self-study is not what it reveals about the self, but what it reveals about the knowledge of the educational landscape.

Cochran-Smith and Lytle, in chapter sixteen, offer a look at the relationships among practitioner inquiry, knowledge, and university culture. They begin with a definition of practical inquiry that serves as an umbrella term under which self-study, among many forms of inquiry, may fit. From there they build their argument to substantiate this claim using ideological, political and historical perspectives for support. Once they present their view, they address features and assumptions that practitioner and traditional forms of research may or may not

share. In addition, they explore the common critiques of practitioner inquiry from epistemological, methodological, and political perspectives. In the final section of their chapter, Cochran-Smith and Lytle, draw on their more than fifteen years of work to illustrate the ways in which ethical, political, and practical dilemmas emerge over time and within the culture of a university.

Griffiths, Bass, Johnston, and Perselli examine issues of professional knowledge and social justice in chapter seventeen. As a conversation in four voices, they offer the reader a look at what they call little stories of practice and grand narratives of educational knowledge (after Lyotard) about the ways they think issues of social justice have been somewhat ignored in the work of the self-study of teaching practices and how that might be changed. To do that, they present their conversations and case studies. The case studies serve as ways to support and interrogate the arguments presented. At the beginning of the chapter they explore definitions of social justice. As they develop their definitions, Griffiths, Bass, Johnston, and Perselli consider the relationship of knowledge to self-study work through the lens of social justice. They assert that the telling of little stories helps counter, disrupt, and critique the grand narratives of educational knowledge. To that end, they invite the readers to consider bringing issues of social justice into conscious consideration as they prepare their own self-studies.

The development of professional knowledge in multicultural teacher education to prepare teachers for diverse settings serves as the focus for Schulte's chapter eighteen. Initially she presents a discussion of the challenge to prepare teachers for working with diversity and the addresses the ways that transformation might occur. From her view, critical reflection about values and beliefs can begin the transformative process. To support her view she analyzes self-studies to depict the ways this process can occur. She looks at the self-studies from both the individual view of the teacher educator and the view of teacher preparation programs. What Schulte finds is that there are good examples of the ways that professional knowledge develops in the preparation of teachers for diverse settings – but she notes that there are not enough. In the end, she calls for more extensive work that would further stretch these experiences and understandings of diversity issues to promote a more socially just world.

Bodone, Gudjonsdottir, and Dalmau explore collaboration in self-study in chapter nineteen. Because community represents a critical element of the work we do as self-study scholars, understanding the issues, the elements, and the perspectives of collaboration becomes essential. In their review of the literature they assert that collaboration is a strong component of the self-study of teaching practices from an ethical and a theoretical perspective. They find that the term *Collaborative agency* best describes the way self-study educators use collaboration to make a difference to the outcomes and understandings at all stages of self-study research. They provide an extensive review of the literature, offer a critique of the public discourse of self-study, and assess current questions about collaboration in the self-study of teacher education community.

In the final chapter in the section, Kelchtermans and Hamilton address three issues that emerge within section two. Those issues are the relationship between

the individual and the collective – both in the process of self-study and in the position of its outcomes, the content of the knowledge that is or ought to be produced, and the consequences for the form of that knowledge and the ways to achieve them. As a beginning, they define self-study and then launch into their discussion of the ways that individual and the collective notions in self-study support the work they do as self-study scholars. At this point, they turn to a discussion of the content on knowledge, offering dimensions as a tool for consideration, and the form that such knowledge might take. Finally, they discuss the role that emotion plays in the self-study of teaching practices. They assert that emotion plays a critical role in the development of professional knowledge and the self-study of teacher education practices can be a place where such work might be explicated.

This section of the Handbook locates a place for the self-study of teaching practices in the literature as well as redefining the ways that knowledge might be understood through the use of self-study. The authors grapple with a variety of issues related to knowledge, the ways in which it might be defined, the ways it might influence us, the ways it may be presented, and ways self-study might disrupt the traditional knowledge discourse. These chapters are provocative in the ways they encourage the reader to interrogate their own ideas about self-study. I hope you find that these chapters engage you in explorations of the self-study of teaching practices and uncover new ways for you to think about and articulate knowledge; it has been one important purpose for many of these authors.

Abstract

This chapter explores the relationship between professional knowledge and teacher education and the ways self-study research might strengthen that relationship. To do this, using a cartography metaphor, a series of questions are asked and answered with the overarching question of, ''What counts as knowledge in the research on the self-study of teaching practices?'' Topics in this chapter include: a discussion about the nature of knowledge; a review of the professional knowledge base as it relates to teacher education including political, moral, and ethical issues; and, an examination of how self-study can-should influence these considerations. In the last section of the chapter, the third space is explored as a place where alternative perspectives can challenge the traditional framework for approaching research.

Head in hands, at the dawn of the neo-post-retro-symbolic-magically-realistic age, a cartographer sits surveying the educational remains of a confused time. She asks herself, "How can I make sense of a(n educational) world where thinkers shortcut their understandings of the nature of knowledge and underestimate the strength of alternative views?" And she recognizes that looking back always offers an easy task because the lived experiences have been lived, pondered, and imbued with the genius of hindsight. What is hidden in details, she thinks, emerges in conceptualization. How will she proceed? Simply, she decides. To map the issues and concerns of this former time in educational research, she will ask herself a series of questions and begin the process of unraveling, if possible, the understandings of the time through her maps.

Claims have been made that the research recognized as the self-study of

---

teaching practices has been the most trend-setting work done in several generations of research in teacher education (Zeichner, 1999). What makes that so? In what ways has the self-study of teaching practices affected the professional knowledge base of teaching? This chapter explores the professional knowledge base as it is currently defined and examines the ways in which reform in teacher education has been influenced by it. To do this, the overarching question is what counts as knowledge in the research on the self-study of teaching practices? Topics in this chapter include a discussion about the nature of knowledge, a review of the professional knowledge base as it relates to teacher education including political, moral, and ethical issues, and an examination of how self-study can-should influence this area. Using self-study to reveal one's experience or to encourage teacher educators when they look carefully at their own practice, or to underscore the multiplicity of ways to consider the professional knowledge base in teaching has dramatically changed teacher education. This section of the Handbook locates a place for the self-study of teaching practices as is mapped out in the literature of research on teaching as well as redefines the ways that knowledge can be understood through self-study. This chapter initiates that process.

Metaphor

Using the metaphor of a cartographer (McLaren, 1986) in this chapter, I attempt to chart ideas. As a cartographer surveys land and locates mountains, rivers, and roads on a map, I attempt to map aspects of identified parts of the terrain to form a look at professional knowledge, teacher education, self-study and their relationships to each other and beyond.

When planning a map, a drawn or printed or graphical representation of something, a cartographer considers the map's purpose and its likely users. The design helps communicate information effectively. Maps are made through observation and measurement to locate boundaries, access distance, present angles, and chart elevations. Often thematic maps illustrate one particular feature. A topographic map, for example, shows the surface features of land. The language of maps expresses spatial, and other, relationships in a variety of symbolic ways. Sometimes a collection of maps is necessary to fully understand the places and the time.

In this chapter, I attempt to generate a mapped portrait of the world of educational research focused on professional knowledge. In this map series, I label the less apparent territories or ideas involved in our work as well as identify the obvious landforms. Other maps include a depiction of the weather that moves across the terrain, the water, the people, politics, the inner surface of the landscape, and more to plot ideas. The overlay of these maps will also provide a narrative representation designed to reveal the language used to describe this world. One important point is the distinction between maps and the "the real thing" – the land itself. While maps may tell a story, they may or may not depict the lived experiences of all involved.

First Map – Relationship Among Professional Knowledge, Teacher Education, and Self-Study?

To initiate the sense-making process, our cartographer begins by pondering, "What might a map of this time look like? Might I create a chart of landforms or peoples or history that would best represent this time?" She understands that if she starts the conversation in any old paradigms she will struggle and probably fail to fully comprehend the issues, that is, the worth of self-study and its contribution to understanding professional knowledge. She decides to prepare a map from space where she can scan the entire surface and ask, "what are the relationships among professional knowledge, teacher education, and self-study?"

Looking at this global view, there are relations among professional knowledge, teacher education, and self-study. Professional knowledge is addressed in teacher education programs and the rudiments of self-study are presented as a way to examine novice teachers' (and more experiences teachers') understandings of professional knowledge in the teaching setting. Just as from space one can see the broad outlines of where the landforms meet the oceans and the population centers blend into the empty spaces, the relations among professional knowledge, teacher education, and self-study meet with and blend into each other. Or do they?

The professional knowledge of teachers has most often been discussed in relation to teacher education and the teaching context. Clandinin and Connelly (1995; Connelly & Clandinin, 1999), for example, have identified this knowledge as influenced by people, places, and things and they suggest that it is a synthesis of theoretical and practical perspectives in teachers' lives (Clandinin & Connelly, 1996). For Munby (1987), professional knowledge "consists of more than what can be told or written on paper" (p. 3). Munby and Russell (1992) use Schön's (1983) notions of practice to situate experience as critical to the development of professional knowledge. In fact, Munby, Russell and Martin (2001) assert that there are a variety of definitions for professional knowledge and more generally regarding knowledge itself. Cochran-Smith and Lytle (1999, and chapter 16, this volume, for example) see professional knowledge within the context of teaching and delineate this knowledge as for-, in-, and of-practice. If we accept that professional knowledge for teaching has many influences and extends beyond practice to theory, it seems that teacher education has a relation with professional knowledge. Does self-study have a similar relation?

Within the past fifteen years, the self-study of teaching practices has emerged as one way to examine the experience of teaching teachers within the academic setting. In many ways, the professional knowledge of teacher educators is a given and very much set within the context of teacher education. The challenge comes from questioning in whether or not the work is viewed as valid and acceptable within the context of scholarship (Cole & Knowles, in this volume, for example). In turn, these questions address whether or not this work can be presented as professional knowledge in more than an anecdotal way. Allender (chapter 13, this volume) asserts that traditional academics balk at the relativity introduced

into their notions of research and raise concern about the alternative views of reality that have been imposed into their perceived canon. If this is true, then self-study seems to have a relation with professional knowledge and teacher education, but a tenuous one at best. Is this true?

The cartographer realizes that any one map may be incapable of capturing all that is necessary for understanding. While the map from space can offer outlines and fuzzy silhouettes, it does not seem to provide the detail necessary to understand the many elements involved. Perhaps, she thinks, I need to step back and consider the influence of weather on my map from space? Perhaps, she considers, I need to ask a more elemental question.

Second Map – What Counts as Knowledge

"Before clearly viewing the earth from space", our cartographer contemplates, "we need to understand the influence of the atmosphere, those clouds, those air currents, those pockets of pollution, and, more generally, the weather – on our perceptions." So, too, before considering the relations among professional knowledge, teacher education, and self-study, we need to seek some understandings of knowledge and the ways those definitions influence our view.

Weather maps offer charts and tables that trace the patterns and behavior of the atmospheric conditions. These maps can include sky conditions, wind, temperature, and barometric pressures that detail fronts, convey directions, enumerate pressures, and suggest climatic developments. And, of course, weather is an interaction between the atmosphere and the land. For example, when the atmosphere contains precipitation that reaches mountains, the windward side of the landform receives far more rain than the leeward side. As with weather, there can also be unpredictability in the exploration of knowledge.

Our cartographer begins by asking, what is the nature of knowledge? How can she present with some adequacy an understanding of the complexities of this question? She reminds herself that viewing this question from within old paradigms will only cause tension and potential failure of understanding as old notions interfere with understanding new ones. What was the "weather" like in this time?

Tensions Among Views

Howe (2001) claims that the qualitative-quantitative debate is "philosophically moribund" (p. 201). Citing Rabinow and Sullivan's (1987) interpretive turn, he sets the "philosophical debate ... between those who seek some new understanding of knowledge, rationality, truth, and objectivity (i.e. transformationists) and those who are ready to abandon these concepts as hopelessly wedded to the bankrupt modernist project (i.e. postmodernists)" (p. 207). In contrast, Richardson (2002) asserts that while "tensions between qualitative v. quantitative methodology died down for a while between the two Handbooks, they are again strongly present, but playing out in a quite different arena – Washington D.C."

(p. 15). In her search for a center of teacher education she finds that postmodernism "has questions that jar the very foundations of our understanding of research: These questions concern the nature of knowledge, who owns it, who produces it, and how is should be used" (p. 3). Further, from her perspective, the discord surpasses the "quantitative-qualitative methodology controversy" (p. 3) addressed in the third *Handbook for research on teaching* and focuses "on the very nature of research and knowledge and the uses of research in the improvement of practice" (p. 3).

Clearly Richardson sees the political implications (to be addressed later in this chapter) for the potential downpour on the metaphorical windward side and for the drought on the leeward side. The National Research Council (Shavelson & Towne, 2002) has published a report that questions the philosophical nature of knowing with Feuer, Towne, and Shavelson (2002) reiterating that perspective in a themed issue of *Educational Researcher*. From their view, they want a return to more traditional scientific approaches in research and the search for "the" truth. Curiously, they seem to support diversity while searching for the one truth. St. Pierre (2002) asks "Is the NRC report a volley in another skirmish of the paradigm wars?" (p. 27) and urges those researchers with differing views to continue the critique of current notions. Clearly, the weather of this time was turbulent. Views swirled. The cartographer asks again, what counts as knowledge?

For views that encompass a broader look at knowledge in educational research see the works of Anderson and Herr (1999), Clandinin and Connelly (2000, for example), Cochran-Smith and Lytle (1999, for example), Fenstermacher (1994), Korthagen & Lagerwerf (1996); Loughran (1999 for example), Munby, Russell, and Martin (2001), and Richardson (1994). For the purposes of this chapter, I am going to focus on aspects of knowledge related to educational research.

Our cartographer wonders if "how a person thinks about knowledge and meaning-making is critical to how that person understands the world." Is it a Cartesian binary knowing? A postmodern knowing? A poststructural feminist knowing? A new historicist knowing? A transformative knowing? And within that view, is knowledge static? Dynamic? How do social justice and position and power fit? Do they?

Possible Definitions

But first, how is knowledge defined? The Merriam–Webster dictionary defines knowledge as "being aware of something" or the "range of one's information or understanding" (2003). This definition extends to include "the fact or condition of having information" and "the sum of what is known: the body of truth, information, and principles acquired by mankind (sic)" (2003). Further, this definition includes the term scholarship and states that the use of this element of the definition "implies the possession of learning characteristic of the advanced scholar in a specialized field of study or investigation" (2003). These are, of

course, are the mundane definitions. None of them seem to provide a philosophical twist. The Cambridge Advanced Learner's dictionary continues along these same lines defining knowledge as awareness and "understanding of or information about a subject which has been obtained by experience or study, and which is either in a person's mind or possessed by people generally" (2003). A visit to the Stanford Encyclopedia of Philosophy (2003) finds no definition of knowledge without words like mutual or self-attached and, sometimes, equations. These definitions, however, seem to suggest there is some link with truth as asserted by a series of someones.

Perhaps a way to think about these definitions is in a psychological frame (including any notion in a person's head that s/he believes to be knowledge) contrasted with a philosophical frame (relying, at least in part, on warrant or justification). This suggests that any beliefs might be considered knowledge from a psychological view and that belief must have justification with an objective world from a philosophical view. Certainly this is a dualistic perspective, but is it too simplistic?

If we broaden our view by adding the philosophical categories of practical and formal knowledge, what happens? Practical knowledge, often defined as the knowledge that draws from experience and is used in a practical or everyday way (usually this knowledge utilizes theoretical or formal knowledge that is already known) and formal knowledge, often defined as the knowledge produced by researchers for generalizable use, are often presented in opposition. Are they oppositional? Do we need to contest limiting definitions to broaden claims for a different reality?

Weathering the Modernism/Postmodernism Storms

The question remains: "What counts as knowledge?" From a modernist perspective where we find positivism situated, what seems to count as knowledge are large-scale studies that have universal qualities and have evidentiary proof. Much of the process-product work in educational research fits this description. Work from this perspective includes levels of certainty, surety, and generalizability that occurred only in varying degrees after the interpretive turn. Often positivist work seems to suggest that knowledge is static and unchanging. If we call the modernist perspective the old paradigm, what do we learn about the new paradigm?

> For Kuhn (1970),

> the transition from a paradigm in crisis to a new one from which a new tradition of normal science can emerge is far from a cumulative process, one achieved by an articulation or extension of the old paradigm. Rather it is a reconstruction of the field from new fundamentals, a reconstruction that changes some of the field's most elementary theoretical generalization as well as many of its paradigm methods and applications. (p. 85)

Hamilton & Pinnegar (1998) suggest that Kuhn (1970) finds resistance to shifts

in ways of knowing [that] is not only expected but can also be extensive" (p. 235). Polanyi (1962) challenges the modernist perspective, stating that theories "of the scientific method which try to explain the establishment of scientific truth by any purely objective formal procedure are doomed to failure" (p. 135).

As ideas are deconstructed and restructured, a transformation of ideas occur from within one's understanding. Lyotard (1984) suggests that postmodernism does not, in fact, occur at the end of old ideas, but rather "in the nascent state" (p. 79). Rather than "coming after" perspectives have been developed, Lyotard asserts that postmodernism comes at the point of initial creation – decentering how we understand the term "post". From this perspective, the process of grappling with, critiquing, interrogating, and decentering seems a part of the intellectual growth process. For Jameson (1991), postmodernism confronts the modern as it is born from questioning old ideas – socially, socio-economically and beyond. From this perspective knowledge seems uncertain.

Considering her map, our cartographer sees turbulent weather with different forces of differing strengths asserting themselves into the atmosphere and against the land. As we reckon with these ideas, we see people resisting and clutching their points of view. Weather is not a static phenomenon – and time (and ideas) march onward, slowly.

Often Aristotle (1962), for example, is cited as the philosopher of choice to substantiate the more traditional views. We will not spend long discussing him because excellent discussions about his work and perceived value can be found elsewhere (for example, Fenstermacher, 1986, 1994; Hansen, 2001; Korthagen, 2001). Suffice it to say that he suggests the binary relation of practical and formal knowledge and views the practical side as necessarily flawed (Hansen, 2001) as a result of the lived experience of those involved. In contrast, Aristotle sets formal knowledge in a conceptual frame with rules to guide the reasoning argument toward a flawless, universal truth. With formal knowledge the warrant or justification for the argument must have evidence to substantiate it. Considering this from an atmospheric perspective, the weather is either hot or cold, sunny or not, humid or dry. From a reasoning perspective, there is an implied value on truth and conventionality of argument that practical knowledge does not have.

As the weather can shift back and forth and back and forth in temperature and outlook, since the 1950's (Jameson, 1991) the postmodern/poststructural views have been entering our atmosphere. Sometimes in great gusts, sometimes in subtle degree shifts. This interpretive turn (Rabinow & Sullivan, 1987) came, in part, in response to modernist rules and structures. As we see, these views still generate turbulent responses, including the rejection of this work by the National Research Council (Shavelson & Towne, 2002), as not particularly helpful in educational research.

Clandinin and Connelly (1996) assert, that what counts as knowledge depends on the situation, the people involved, the setting, and more. For those researchers with a postmodern/poststructural perspective, a binary view of the world brings little satisfaction. They recognize the world as uncertain (Hamilton & Pinnegar,

1998) and as a social construction influenced by personal history as well as social history. In their writings, these researchers claim that lives need to be viewed more fully (Bateson, 1989; Clandinin, 1995). Rather than reducing life to separate bits and pieces (Bateson, 1989), many from a postmodern/poststructural perspective attempt to view lived experience (Van Manen, 1990) within context. Moreover, many of these researchers ponder the shortcomings of knowabilty and the ways that these shortcomings contribute to deeper knowing (Felman, 1987).

Ellsworth (1997) asserts that accepted, "reality ... is always someone's reality, constructed in and through particular intentions and interests, and from particular locations on multiple networks of power relations" (p. 179). Citing Ronald Good (1993), Zembylas (2000) refers to the wispy or hard-to-hold-onto nature of postmodernism (p. 163). This intangible element prompts Sleeter (2001) to ask, "to what extent is our knowledge ... a product of our own minds? (p. 213) and continue asking, do "facts closely reflect reality but the sense we make of them reflect human subjectivity? Or are facts themselves also social construction?" (p. 132). The teller of the story affects the story and the ways knowledge is understood (Sleeter, 2001).

From the postmodern/poststructural perspectives neutral points of view are non-existent (Zembylas, 2000). Hoban (2002) writes that Lagemann (2000) views history as an imaginative reconstruction (p. 246). As such, Ellsworth (1997) sees it as representing infinite possibility. MacKinnon & Erickson (1992) claim that knowledge is mediated, never immediate" and that reference to context is necessary to the "role of meaning and cues" (p. 198). The unconscious as well as the conscious is critical from these perspectives and sometimes manifests itself in the voice of the Other (Felman, 1987). Put another way, Derrida (1976) suggests that presence always contains absence. That is, the Other is always present in idea if not in body as people explore their mental and physical worlds.

Importantly, the notion of a privileged center (to research) focused on culture or class or race or history subverts into a decentering and critical examination of the issues (Ellsworth, 1997) in postmodern/poststructural perspectives. An example would be the work of Griffiths, Bass, Johnston and Perselli (chapter 17 in this volume) who attempt to decenter social justice issues to encourage a deeper analysis of those issues as they relate to self-study.

Postmodernism "... does not encourage normlessness, but, much more important, requires that persons assume responsibility for truth" (Zembylas, 2000, p. 182) although it would seem that some critics might view it this way. Phillips (1987), for example, warns researchers to attend to warrant if they seek believability. Feldman (2003) asserts that "we must have good reasons to trust [findings] to be true" (p. 26). In keeping with this perspective, Hamilton and Pinnegar (2000) call for the need for integrity and trustworthiness in application to research but perhaps this is getting ahead of the mapmaker.

We return to the cartographer's question – what counts for knowledge? Like Clandinin and Connelly (1996), her answer must be it depends. If someone asks Aristotle (if he were alive, of course) the question, he might provide a formula

for finding the essentialized truth for all persons. On the other hand, if that same person asks a postmodern/poststructuralist this question, s/he might attempt to interrogate or trouble (Lather, 2001) the question and offer possible answers. What the cartographer is not going to do is offer the range of definitions from all perspectives. Instead, she presents possibilities.

Beyond the earlier definitions, Wells (1999) defines knowing as an "intentional activity of individuals who, as members of a community, make use of and produce representations in the collaborative attempt to better understand and transform their shared world" (p. 76). Knowledge has been defined as "that body of convictions and meanings, conscious or unconscious, which have arisen from experience, intimate, social and traditional, and which are expressed in a person's actions" (Korthagen, 2001, p. 233). In fact, teachers can map their knowledge in ways (Calderhead, 1988a) in ways that link knowledge and action (Calderhead, 1988b). These definitions offer a social and mediated view of knowledge.

In the literature, we find knowledge of people, knowledge of educational practice, knowledge of concepts, knowledge of process, and knowledge of control. There is management knowledge (Eraut, 1998), situated knowledge (Leinhardt, 1988) and nested knowledge (Lyons, 1990). Clearly, there are many ways to define knowledge (Munby, Russell, & Martin, 2001). Fenstermacher (1994) suggests that these simply represent ways to group ideas, but for now these are some of the ways to consider knowledge.

In a personal communication to Munby, Russell and Martin from Fenstermacher (cited in Munby, Russell, & Martin, 2001) he asserts that,

> The old criteria for "knowledge" are kaput, while there are yet no new criteria to take the place of the old. A difficult spot. … The question is whether this difficulty is temporary. Will we eventually gain a new, more generous and robust set of criteria for using the concept of knowledge, or are the post-modernists going to prevail with their claims that there are multiple sets of criteria, depending on one's culture and discourse? (p. 879)

What might be more generous and robust? Knowledge, it would seem, is more than a set or sets of beliefs. Richardson (1996), building on the writing of Feiman-Nemser and Floden (1986), reminds the reader that while there are similarities between knowledge and beliefs, there are differences as well. It seems that more than beliefs, knowledge entails some evidence of what accounts for truth according to a public audience. Would a public accounting strengthen robustness? Later in this chapter we will return to this issue. Suffice it to say now that the issue may well be more about who identifies the concept of knowledge as robust (by the definitions they use), rather than the actual robustness.

And might we define truth? From Aristotle's perspective there must be some level of universality, but the postmodern/poststructural views address difference and variety. Popkewitz (1997), addressing the interpretive turn, suggests that the struggles come from who defines "what counts as truth" and, "the rules on which that truth is based and the conditions in which that truth is told" (p. 27).

Conle, Louden & Mildon (1998) find that there are, "tensions between theoretical and practical reflection" (p. 237) when considering issues of truth. This might be a question of – whose truth is this? Clifford (1986) finds that truths can be intrinsically inadequate. To address the possible inadequacy, perhaps, like the earlier response to the equation of knowledge, the definition of truth also "depends." Richardson (2002) discusses a "better truth" (p. 17). This truth "is not final ... [and] should be larger, roomier, more complex, and more authentic" (p. 18).

This is not to say that empirical work is not valued in the work of postmodern/poststructural scholars, it is. Self-study researchers make assertions in their work and always query themselves about the evidence that supports them. Their warrant, however, seems to be of a different sort. Their warrant seems to be based on trustworthiness, integrity, and solid research methodology rather than the more formal approaches taken by the more conventional researchers. Now, not all self-study scholars do this all of the time. And, early into the work of self-study there was less visible attention given to these issues as we found our way in a new paradigm. The attention was there, but it was not made public. Hence, perhaps, the birth of concern demonstrated by more traditional readers of the work. But, again, we get ahead of the mapmaker.

Having visited many cites and readings trying to forge a more complete picture of the weather of this (educational) world, clear skies remains elusive. There are those with a more traditional, modernism perspective, but can one define perspectives that resist definition? It is this very resistance that is a part of the postmodern/poststructural perspectives. In his writing, Howe (2001) also connects the transformative perspective to the postmodern, and seems to advocate for that perspective because of their interests in transforming their situations. He and others (St. Pierre, 2002, for example) recognize the importance of challenging systems that seem to promote the singularity rather than diversity of ideas. Because this is a chapter focused on knowledge and teacher education and self-study, we will briefly, very briefly, and summarily, very summarily, look at a few relevant points to understanding these perspectives.

Postmodernism/Poststructuralism: A Brief Summary

While Vygotsky may not (if he were alive, of course) identify himself with either perspective, his notions of a sociocultural world (Vygotsky, 1978) that, "develop through the mediation of others" (Moll, 2001, p. 113). For him people work in relation to understand and participate in their world. Lacan, according to Felman (1987), finds the Other to be central in this. These are people with whom people consciously or unconsciously interact to understand their world and who help them consider who they are – and are not. In Buber's work (1983), we read about the connectors we have to others' lives. According to him, these connections are vital to our aliveness. Bourdieu (1990) promotes the multiple ways of knowing and understandings of the world that focus on experience and our relations with others in our world.

Lyotard's (1984) work decenters itself in its critique of the legitimation of knowledge. He asserts that there are grand narratives and smaller stories (petits recits). (See Griffiths, Bass, Johnston & Perselli, in this volume, for a broader discussion of this issue). If we accept that there is one large narrative that explains our lives or our experiences, without considering the influence of individual histories or background, we essentialize and, hence, stabilize the views of the dominant culture. He "promotes resistance to totalizing ideas and advocates for the deconstruction of the ways that … research has been traditionally undertaken" (Zembylas, 2000, p. 161). He also brings a support for diversity in understanding the world (Zembylas, 2000, p. 173). Zembylas finds that Lyotard:

> warns us that demanding consensus has become an outmoded and suspect value … Hence, using our imagination, intuition, and emotions we can invent, history, science, intuition, and emotion share common boundaries. Their domains oscillate into one another so that the idea of ever distinguishing between them becomes more and more chimerical. (Zembylas, 2000, p. 166)

Given this, the relation of knowledge and power suggests questions related to definitions of knowledge and who claims to know or own those definitions (Lyotard, 1984).

In the multiple postmodern/poststructural worlds, language is a key. How people express themselves and to whom is relevant to the ways people experience power and interact with their world. Foucault (1977, 1978) suggests that the self is fragmented and lacks unity. According to Zembylas (2002b), in a discussion of Foucault's ideas, "the self is shaped and reshaped as a continuous project of subjectivity" (p. 203). For Foucault, as mentioned earlier in a discussion of Lyotard, power and knowledge are linked together. Importantly, while these terms may have negative connotations for many of us, Foucault uses these terms in a neutral way viewing power as related to action" (Gore, 1993, p. 51). Gore writes: "As Foucault (1980) sees it, every relation between forces is a power relation, where force 'is never singular but essentially exists in relation with other forces, such that force is already a relation' (Deleuze, 1988, p. 70)" (Gore, 1993, p. 51). Cole and Knowles (chapter 12, this volume and elsewhere), for example, interrogate the power-knowledge relations in academia.

To this, we bring our "technologies of self" (Foucault, 1977) that express the manners with which people experience their lives. Personal history, experiences, the relation with the larger world, and more are part of these technologies. Fendler (2003) suggests that critically reflecting on one's experiences is no, "guarantee [of] an uncompromised or unsocialized point of view" (p. 21). From this perspective, we must attempt to decenter self from experience to help deconstruct and critique our lives. Viewing the self as text is a way to query oneself (Phillips, Donna, 2001, 2002). These technologies of self support people as they address the power-relations in their lives as well as the "regimes of truth" (Foucault, 1980, cited in Gore, 1993, p. 55). These regimes of truth, existing in any society, represent:

> Its 'general politics' of truth: that is, the types of discourse which it accepts and makes function as true; the mechanism and instances which enable one to distinguish true and false statements, the means by which each is sanctioned; the techniques and procedures accorded value in the acquisition of truth; the status of those who are changed with saying what counts as true. (Foucault, 1980, p. 131, cited in Gore, 1993, p. 55)

Zembylas asserts that, "experience itself does not constitute self-knowledge. … Only by interrogating the discursive place from which questions of identity are posed can we trace how identify is subjected to the social and historical contexts of practices and discourses" (Zembylas, 2003, p. 114).

Bakhtin is another theorist whose perspective should be mentioned here. For him, voice and language mediate the ways that people and their words shape and are shaped by their surroundings Daniels (2001) states that Bakhtin's perspective views language as:

> over populated with the intentions of others, reminds us that the processes of mediation are processes in which individuals operate with artefacts (words/texts) which are themselves shaped by, and have been shaped in, activities within which values are context and meaning negotiated. (p. 12)

Bakhtin uses voice to describe the consciousness brought to the conversation when a person speaks. This voice has a perspective, including values (Daniels, 2001). Further, Danielewicz (2001, p. 140), citing Bakhtin, asserts that he sees language, "for the individual consciousness, lies on the borderline between oneself and the other" (1994, p. 77).

While I have written this as if these ideas emerge in a linear and connected fashion, they have not. Rather, I have drawn these ideas together as I have attempted to understand my work and their work. The critical point here is that one view of how to understand knowledge, its definitions and the elements attached to it, essentializes it.

A Few Caveats

I recognize that postmodern and poststructural views differ. However, establishing my point about understanding of knowledge rather than an understanding of knowledge, I have linked them. In fact, there has been precedence set for this in earlier writings (Gore, 1993, for example).

Further, the views presented here clearly have a western perspective. Because there have been few detailed looks at these issues by self-study scholars prior to this time, I am hindered by history and recognize that some maps have yet to be opened. Recognizing this chapter as a beginning to this examination helps broaden the view and leads to greater inclusion.

Succinctly, our cartographer thinks, this map suggests that other ways of viewing knowledge exist and have equal value with earlier views. Privileging one view over another does not represent this world.

Third Map – What Counts as Knowledge in Teaching?

"At this point, to understand this, I need another map," our cartographer realizes. A topographical look at this world may help depict the rise and fall of the terrain in a representation of natural and selected features.

What does count as knowledge in teaching? Is it teacher research? Is it the study of one's own practice? Is it large-scale studies and grand narratives that attempt to essentialize teachers as if the good ones might be replicated? In the past, what counted as knowledge in teaching to some degree focused on information generated by researchers and learned by teachers.

The topography of knowledge in teaching has many dips and peaks. The terrain is marked with mountain ranges and deep lakes. Historically, educational researchers examining the knowledge of teachers have pondered what teachers know, how they know it, when they know it, where they know it, and, perhaps, most importantly, how they know they know it. More recently, teacher educators have attempted the same exploration. This section explores definitions of knowledge in teaching and possible distinctions among those definitions.

Korthagen (2001) suggests that teaching involves more than skill mastery. Rather, it entails a way of relating to self and others (Korthagen, 2001, p. 264). Teachers do need, "to be very knowledgeable about the subject or subjects they teach" (Porter, Youngs, & Odden, 2002, p. 265). This knowledge depends on content, age level, development as well as personal history. Many times teachers are "confronted with the inadequacy of their knowledge" (Zembylas, 2000, p. 175). Often there is a lack of respect for the knowledge of teacher educators (Hinchman & Lalik, 2000). Sometimes communities of teachers/teacher educators "share sets of important questions and varieties of methods for approaching problems" and support the exploration of knowing in teaching (Leinhardt, 2001, p. 336). According to Ellsworth (1997),

> teaching is not normalizable. It happens in disjoined and yet enfolded conceptual and social spaces ... Its in-betweeness and all-at-onceness corrodes the engine of system. Where, when, and how teaching happens is an undecidable. This is what saves it from being a skill or a technology. (p. 193)

Is this knowledge of teaching? Ball, Lubienski, and Mewborn (2001) suggest that there is, "a distance between studies of teacher knowledge and of teaching itself" (p. 449). While "teaching depends on knowledge ... knowing is not synonymous with teaching" (Ball, Lubienski, & Mewborn, 2001, p. 450). Further, they identify whether making the distinction that, "studies of knowledge are or are not studies of knowing in teaching" are important to make (p. 450).

In the past, teachers have been identified as users rather than producers of knowledge. Hence, the research on teacher education has been scattered with documents focused on the generation of knowledge bases that list what teachers should know and be able to do know in order to enter the profession (see Wittrock, 1986, *Handbook of Research on Teaching, third edition* and Richardson, 2001, *Handbook of Research on Teaching, fourth edition* for more information).

But what is this knowledge that teachers should possess? Critical among the considerations is whether or not to accept the conventional representation of knowledge or to decenter what has been seen as "the" view of knowledge to offer alternative representations. In reference to the previous section, another way to explore this is by asking the question – should knowledge be represented in a formal fashion with a traditional scientific structure or can less restrictive representations suffice? Fenstermacher (1994, 1997), Richardson (1994, 2000), and Loughran (1999, 2000) among others have recognized the need for careful research and thoughtful habits of mind when engaged in this work. In separate but similar calls, these scholars identified two issues – a clearer understanding about the definitions of knowledge and a better understanding of how that knowledge is expressed to the larger academic community – that need to be addressed. Before we discuss points about presenting this work to a larger community, (which we will do in future sections), we need to consider the definitions of knowledge in teaching.

Knowledge in Teaching

The texture of the land shifts and turns. Articulately the rise and fall of the terrain can be troublesome. How do you represent these ideas? Previously, scholars have drawn distinctions between those who produce knowledge through research (formal knowledge) and those who use knowledge (practical knowledge) (Fenstermacher, 1994; Huberman, 1991, 1996, for example). This argument elaborates on the link between thought and action, contrasting theoretical and practical arguments.

However, these views of teachers' knowledge have been reductionist (Carter, 1993) and adversarial setting up a negative power differential between the ones who produce knowledge and the ones who use knowledge (Stenhouse, 1975; Whitehead, 1993). Broadening this view, Clandinin and Connelly (1995, 2000), for example, define teacher knowledge as embedded in story and influenced by personal backgrounds and learning. Lytle and Cochran-Smith (1991 and in this volume) present teachers' knowledge as a triumvirate of knowledge in-, of-, and about- practice that also comes from backgrounds as well as learnings. Knowledge for practice might be characterized as formal knowledge.

These researchers and others (for example, Briscoe, 1992; Lather, 1986; Richardson, 1997; von Glasersfeld, 1989) see teachers' knowledge as a fluid, social construction that is more extensive than can be articulated (Polanyi, 1967; Korthagen & Kessels, 1999). Some (like, Carter, 1995; Carter & Doyle, 1987, for example) suggest that knowledge is event-structured and task-specific, and describe it as situated in practice (Leinhardt, 1988, for example). So knowledge may be seen as historically embedded, culturally imbued construct that is personal yet socially constructed and can be expressed in actions. Carter (1992) sees teachers' knowledge as elusive because teachers may not have the language to articulate it. Perhaps in response to the power relation, Duckworth (1991) points out that teachers seem to lack a seriousness about their knowledge and

often do not critically examine it. Teacher and teacher educator research provide ways to examine what teachers know and how they express their ideas (Elliot, 1989; Loughran, 1999).

Sanders and McCutheon (1986) find that practical theories offer reasons for actions and ways to guide those actions. This reasoning interprets, helps understand, and justifies teaching situations. Of course, this raises the uncertainty principle in teaching. Linearity and surety in teaching are elusive. Mapping teacher knowledge like mapping topography can be tricky.

Dewey, Experience, and Identity

Following Dewey (1916), Bullough 1997 suggests that experience bring significance to theory. Fitting with the ideas of Clandinin & Connelly (1996), studying education is studying experience is studying life. Importantly, to succeed in the study of experience, teachers/teacher educators must bring critical reflection to the task so they can act, "with intent; they are empowered to draw from the center of their own knowing and act as critics and creators of their world rather than solely respondents to it, or worse, victims of it" (Richert, 1992, p. 190). To support this process, teachers, in their reflective process, make "conscious and voluntary effort to establish belief upon a firm basis of evidence and rationality" (MacKinnon & Erickson, 1992, p. 196).

Teaching requires more than simply teaching subject matter. The image of that and what is needed for the classroom shifts as the teacher sees how the student develops. Dewey (1916, 1933) talks about creating environment for students in the classroom. Designing an environment suggest that the teacher moving the student from point A to point B is no longer adequate. The teacher may have a learning goal, but her focus on students may change over time.

Experience

Bullough (1997) claims that theories come into the experience of practice as they are applied. As experience expands, "knowledge in action gives the authority of experience" (Munby & Russell, 1994, p. 92). This:

> authority of experience gets transformed into the authority that says, I know because I have been there, and so you should listen. The authority of experience simply does not transfer because it resides in having the experience. This coincides with Schön's view that knowledge-in-action cannot be transformed into propositions. It is for this reason that Schön (1984) cautions those who wish to acquire professional competence that there is something they must know, something their teachers cannot tell them what it is. (Munby & Russell, 1994, p. 93)

As teachers reflect upon and publicly:

> "'name' their experience, they learn about what they know and what they believe. They also learn what they do not know. Such knowledge empowers

the individual by providing a course for action that is generated from within rather than imposed from without. (Richert, 1992, p. 190)

Maxwell (1999) situates the knowledge, practical knowledge, in teachers' personal and professional experiences as did Elbaz (1983) and Connelly and Clandinin (1985) before her. Munby and Russell (1994) find that emphasizing, "the contact between school knowledge and action knowledge (Barnes, 1976) marks how the experience of school can conceal the differences between the authority of reason and other forms of authority" (p. 92). Once "you come to know the surface of things … you … seek what is underneath" but often "the surface of things" seems infinitely deep (Mason, 2002, p. 29).With the acceptance of authority in experience, "then … research can be better understood as a form of … research that brings with it different research demands and dilemmas from traditional research" (Loughran, Mitchell, & Mitchell, 2002, p. 16). Recognizing the influence of experience on the development of knowledge empowers both the student and the teacher (educator).

Identity

A teacher's education often begins "by exploring the teaching self " (Bullough, 1997, p. 19). With "self you rehearse possible course of action" (Markus & Nurius, 1987, p. 161). Multiple, "often conflicting, identities …" can be "under construction" as the teacher identity develops (Danielewicz, 2001, pp. 3–4). As they continue developing, the "self … depends on a dialectic of identification: self-definition and definition by others, both of which are necessary (Danielewicz, 2001, p. 42). This constant construction, deconstruction, and repair of boundaries around the constitution of the self is fraught with emotions" as well as "new ideas". (Zembylas, 2003, p. 108). This continuing development "challenges the assumption that there is a singular "teacher-self ' or an essential 'teacher identity' hidden beneath the surface of teachers' experiences" (Zembylas, 2003, p. 108). This is where experiential and theoretical understandings and notions about reflection and the authority given to self and others come into the dialectic.

Identity is developed in relation; teaching is developed in relation. The teacher is the more capable Other. The more capable Other assists the learner in the learning process (Vygotsky, 1978; Tharp & Gallimore, 1988). Teacher educators in the role of the Other, often try to teach their students to be the Other. In turn (hopefully) they will move students forward in their knowing, being, acting, and doing. As Schön (1983) suggested, a move beyond technical rationality is required (see Kelchtermans and Hamilton, this volume for elaboration on this topic). A prescription for this process is less helpful than understanding its development. Understanding the importance of experiences and the development of teacher identify impacts understanding of knowledge, types of knowledge, and the use of that knowledge.

Types of Knowledge

Shulman (1986,1987), "has posited that the knowledge related to teaching exists in different forms" (Graber, 2001, p. 495) with a variety of labels. Of the types

of teacher knowledge identified by Shulman, the one that inspired the most attention was pedagogical content knowledge (Seixas, 2001, p. 546). While general pedagogical knowledge represents what teachers understand about the principles and strategies associated with classrooms (Graber, 2001, p. 496). Pedagogical content knowledge (Grossman's work, 1990, for example) focuses on the special pedagogy necessary to teach specific content. Shulman and colleagues recognize, "a special kind of teacher knowledge that link … content and pedagogy" (Ball, Lubienski, & Mewborn, 2001, p. 448). There is also personal practical knowledge (Clandinin, 1986) is based on the past and present experience in the life of teachers and can manifest personal, emotional, professional, and moral knowledge (Maxwell, 1999). Intuitive knowledge is another type of knowledge. Maxwell (1999) states that while "intuitive knowledge is only one piece of the puzzle being used … it is the very piece that is unusually shaped and touches the most number of pieces in the puzzle" (p. 91).

It would seem that Shulman, with the notion of pedagogical content knowledge, claims that some knowledge is 'better' than others are. Once this is claimed there is some expectation about achievement and performance.

Teaching Knowledge

Korthagen suggests that teaching involved more than skills mastery. Rather, it entails a way of relating to self and others (Korthagen, 2001, p. 264). Teachers do need to, "be very knowledge about the subject or subjects they teach" (Porter, Youngs, & Odden, 2001, p. 265). This knowledge depends on content, age level, development, and more. Sometimes communities of teachers/teacher educators share "sets of important questions and varieties of methods for approaching programs (Leinhardt, 2001, p. 336). Is this knowledge about teaching? Ball, Lubienski, & Mewborn (2001) suggest there is a distance between studies of teacher knowledge and of teaching itself. Although teaching may depend on knowledge, they state that "knowledge is not synonymous with teaching" (p. 450). Further, they find that distinguishing "studies of knowledge are or are not studies of knowing about teaching" (p. 450) is important.

Teacher Knowledge

Can students of teaching experience a depth of knowledge? Richardson (2002) finds that to, "be of use in action, a depth of understanding is required that becomes somewhat internalized such that in can be used in teacher planning, action, student assessment, and reflection" (p. 6). Huber and Whelan (1999) see teachers, as the owners and creators of knowledge. And this knowledge is both formed and expressed in context (Connelly & Clandinin, 1999, p. 2). Now, the "conceptual framework that characterizes teaching as a complex cognitive skill determined in part by the nature of a teacher's knowledge system to explain patterns in participants' planning, teaching and post-lesson reflections" (Borko, Bellamy, & Sanders, 1992, p. 49). Barnes (1992) finds that the identification of teachers' knowledge can be "potentially misleading, unless 'knowledge' is seen

as value-laden and dynamic" (Barnes, 1992, p. 16). In fact, a view of knowledge that is static does not expressly define it. Korthagen (2001) argues that we need to shift our view from that "scientific understanding (episteme) ... [to] ... practical wisdom (phronesis)" (p. 24). In part, this knowledge includes the "common dilemmas teachers face in classroom life" (Carter, 1995, p. 110). In the past, teachers' understandings and knowledge have been viewed in a less than a positive way as simply reactive to "externally imposed knowledge" (Clandinin, 1986, p. 4).

Clearly, these definitions are perplexing. On the one hand, we have calls for very specific strategies for and approaches to teacher knowledge. On the other hand, we have rather vague descriptors that seem to shy away from definition. Often the request for specifics comes from educational researchers, outside the realm of teachers. How do we come to terms with the tensions created here? How do you figure out how to best define teacher knowledge? If we trouble and push the issue, we come again to wonder, "whose knowledge is this? Who will actually be well prepared to teach? This terrain seems to have some of the swampy areas that are muddy and can mire you down. Trying to read the map almost requires that you know the landscape before it makes sense.

"What do we have here?" asks the cartographer. Now I can see that different views of knowledge mean different definitions of knowledge in teaching," she claims and realizes that the weather map is not enough. As the atmosphere interacts with the land, the land interacts with the waters. She realizes that she must now look at an oceanic map.

Fourth Map – What Counts for Professional Knowledge for Teaching?

"I need to understand how the waters mingle with the land," our cartographer speculates. There are many ways to map the waters of this (educational) world like looking at the geographic, the geologic, or the nautical spaces (Makower, 1990). However, for the purpose of this section, we offer a simple and general look at the nature of the waters and the continental margins. This," our cartographer thinks, "will provide a more vivid portrayal of this world." In this section, we look at some of the features of teachers/teacher educators' professional knowledge and the way that such knowledge might impact on teachers/teacher educators' practice. Clear-cut distinctions between knowledge are no longer possible because teachers/teacher educators' professional knowledge (whether it is preservice or inservice teachers) is more complex than originally thought.

Defining Professional Knowledge

Waters can be turbulent, swirling, in this case, with passion and emotion. Notions of knowledge and professional knowledge can sometimes blend and sometimes crash into each other. Mapping out these possibilities can require concentration. As mentioned in the last section, in the 1980's Shulman proposed categorical representation of teacher knowledge. He (1987) claimed that teachers needed

strong "pedagogical content knowledge" (p. 8) to be the best possible teachers. Around the same time other researchers speculated about teachers' knowledge bases and the professional knowledge of teachers (Grossman, 1990; Wilson, Shulman & Richert, 1987, for example). For him, teachers look uniquely at practice. Shulman and colleagues eventually expanded these ideas to include the work of teacher educators and other university instructors, calling it the scholarship of teaching. We will return to this issue later in this chapter.

At the same time, in the United States and globally, tools to define and measure teachers' knowledge along with strategies emerged to undertake standardization. This work did not explore uncertainties. Rather, much of this work took very conventional approaches. That is, researchers studied teachers' behaviors and beliefs seeking to reduce them to a standard. In fact, many researchers and policy makers essentialized teaching.

Early in the 1990's, an alternative to this conventional approach emerged. From this perspective, researchers pushed to find ways to examine what teachers knew. Early and prominent among these researchers were Clandinin and Connelly and Cochran-Smith and Lytle. Each set of researchers, while approaching teacher knowledge in different ways, attempted to unravel the ways in which teachers develop their professional knowledge. Researchers engaged in the self-study of teaching practices also brought their views to the static water.

Complicating the Definitions

As we saw in last section, the knowledge related to teaching has many definitions. Further, we read that there are varieties of different approaches to understanding this knowledge. The waters can be wide, deep, and unsettling. They can also be still and enigmatic. Certainly, charting the currents and the flow requires a calm and careful eye.

Politics

Earlier in the chapter I mentioned sociocultural perspectives that many researchers now bring to their understandings of their world and their research. What I only alluded to was the political elements of these understandings. Realistically, power and politics impinge on the questions we have previously mapped – whose knowledge is it? And so on. Postmodern/poststructural researchers take a politicized vantage – questioning knowledge ownership – so do the modernist researchers. Some of these researchers are more forthcoming than others about the political nature of their work. Sometimes issues are discounted or empowered because of the author, sometimes because of the institution, sometimes because of the nature of the relations between these issues. When looking at professional knowledge these relations must be addressed.

There are those who look more broadly at their educational settings and there are others who find that the more focused, personal view is the ways to understand the politics of the situation. For example, "Harding (1987), Orner (1992), and others suggest … looking to ourselves to explore the complexities of our

social existence. Collins (1991) argues that understanding our work is at the heart of understanding ourselves and our hidden knowledge" (Hinchman & Lalik, 2000, p. 183). Because it is not uncommon, according to Loughran, Mitchell, & Mitchell (2002), "for teacher knowledge to be dismissed ... [or] ... compared with more traditional forms of research knowledge" (p. 15), teachers/teacher educators' classrooms become sites for studying the interactions of the private and public worlds of the educational process. Who owns the knowledge, who shares the knowledge, and who presents the knowledge are questions with political elements and require consideration.

Ethics

Hansen (2001, p. 852) asserts that according, "to the literature ... teaching is inherently a moral endeavor." As such, teachers/teacher educators model behavior, ideas, and values (Loughran, 1996, for example) for their students. This means that whether or not they are conscious of their modeling, it happens. Whether they are conscious or not of the politics of a situations, they happen. Hansen continues that the practical wisdom perspective, "is an orientation more in keeping with the contingent nature of pedagogical work and with the always evolving more characteristics of both teachers and students" (2001, p. 849). This recognizes the power the teachers and their influences in the classroom. Further, understanding "teaching as a moral activity can give value and direction to teachers' technical knowledge" (Hansen, 2001, p. 849). Like Goodlad and colleagues (1993) suggest, the moral dimensions of teaching are important currents to the seas of educational research. The integrity and trustworthiness teachers bring to their classrooms and ways of being affect their students.

Caring

Hamilton and Pinnegar (2000) suggest that care, trustworthiness and integrity are necessary aspects of professional knowledge. Noddings (1984, 2001, for example) asserts that caring is a way of being in relation to self and others, not a specific set of behaviors (Danielewicz, 2001, p. 17). This care involves elements of kindness, but more importantly includes commitment to learning and success. Along with caring, Hamilton and Pinnegar assert that trustworthiness and integrity in the work of teachers and teacher educators are critical to helping their students and their students' students realize their potentials. How to do that? Like other issues already discussed, caring, trustworthiness, and integrity elude categorization and limitations. Conscious exploration of critical questions may be the appropriate current here. Understanding that teachers' professional knowledge has a complexity and sophistication may guide them through the choppy depths.

Judgments

Goodlad and colleagues (1993) have also explored the professional knowledge base of teachers. He suggests that the public pays teachers for their judgments

rather than for the technical elements of their work. While technical skills and practice inform judgment, that judgment is also drawn from the sociocultural, moral and political elements of the person. The quality of the reasoning and the quality of the action influence the teacher/teacher educator's judgment in the setting and also influence peoples' judgments about teacher success. In addition, the quality of teachers/teacher educators' judgment is always in relation to students to colleagues, to others. Success as a teacher requires both the student and teacher to buy into the learning process when the teacher/teacher educator prepares lessons or class, they make judgments about content and more. Teaching, "involves informed interpretations of and responses to students' orientations to knowledge" (Daniels, 2001, p. 103). They draw from their experience, have knowledge of content, sense of students, and from the relation with context, students etc., make judgments about how to proceed. To do that they must have knowledge about and understanding of their students.

We develop our own judgments and the judgment of our students, but what should count in that judgment? What is the range that teachers/teacher educators must consider about themselves, teaching, and their students? Relevant here is the Fenstermacher (1986) notion of studenting. He suggests that beyond the teacher's part in the learning process, the student must also take responsibility for it. This relation is critical to the development of teacher and student. Teachers (from Dewey's (1933) perspective) bring openmindedness, whole-heartedness and responsibility to teaching and to the relation between teacher and student and students bring those same notions to their role as student (see Loughran, 1996 for more detail on modeling and issues regarding Dewey.)

This, of course, suggests an uncertainty about teaching. Professional knowledge does not seem to be simply a still lagoon of lists or attitudes or strategies. Rather, it seems to be an ocean of tensions, turns, and contradictions. Consequently, making teachers or teacher educators fit a standard in particular ways may be difficult. The wisdom of practice is an ineffable thing that resists countability and reification.

Troubles

It seems important to state that there is no list in this chapter of the specifics of professional knowledge and acknowledge that this seems to be a future task because of the various available viewpoints. However, it is also important to acknowledge that there are skills and attitudes that teachers must bring to teaching, like openmindedness, wholeheartedness, responsibility, and reflection. More than that can be found in other texts.

Additionally, addressing issues like trustworthiness and integrity can generate undercurrents in the seas of educational research. As Hamilton and Pinnegar (2000) speculate, there is a tension in the relations between the teacher/teacher educator and the students' perceptions of her/him. The students (or our colleagues) decide trustworthiness. Teachers/teacher educators can act with integrity, but do they see that integrity? That, according to Hamilton and Pinnegar, is what students (or colleagues) must decide for themselves. Moreover, the issues

of trustworthiness and integrity come back to the public nature of the work. Are colleagues willing to accept that teachers/teacher educators have the knowledge they claim to have?

Pondering this, our cartographer declares "this is not enough!" Now I need to consider how, metaphorically speaking, the people fit into this picture. She says, "I have seen that if I accept the possibility of postmodern/poststructural views of the world, I define knowledge as multi-leveled and textured. And if I accept that, I define teacher knowledge as somewhat elusive and particular. And if I accept that, I define professional knowledge as involving more than skills. Accepting all of that, issues of politics, ethics, care and judgment contribute to the professional knowledge in teaching. However, where does professional knowledge base fit? "How might I consider that?" she asks.

Fifth Map – What Counts as a Professional Knowledge Base for Teaching?

At this point, our cartographer realizes that she needs to see a people map. Census maps generally shows the distribution of population across areas. These maps can illustrate the interests of an area, or the density of population, or even the voting registration of citizens. To answer the question of what counts as a professional knowledge base for teaching, she simply will explore interest.

The purpose of this section is to examine some of the features of teachers' professional knowledge base and the ways that such knowledge impacts on teachers/teacher educators' practice. Internationally, there has been an ongoing focus on teacher education reform with an emphasis on teachers' knowledge and teachers' pedagogy and the ways in which these come together to form a knowledge base. An exploration of the (various) knowledge bases is important, particularly in light of the ways in which these knowledge bases impact on teachers/teacher educators' approaches to, and practices of, teaching (see Hamilton & Pinnegar, 2000, for more information.)

Currently, professional knowledge is standardized in a way where knowledge is seen as a static thing to be attained in a finite way. While we promote life-long learning, teachers are expected to learn the skills for teaching quickly and with some level of competency. Although some degree of standardization may be appropriate, expecting sameness among teachers, students or strategies seems both unrealistic and unreasonable. Maybe this is possible in the modernist paradigm, but from other standpoints standardization is oppressive and power draining.

Professional Knowledge Base

Professional knowledge is, "composed of a wide variety of components and influenced by a wide variety of people, places, and things (Clandinin & Connelly, 1995, p. 4). Expanding our view, we see that the professional knowledge bases of teaching are as broad and diverse (Christensen, 1996, p. 38) as the peoples

our cartographer examines. For Christensen (1996), "many programs have many different knowledge research bases upon which they depend. There is no one best base, but some are more supportable than others are" (p. 38). Wisdom, "language, critiques and theoretical frameworks of school-based teachers are as essential to a knowledge base for teaching as are those of university based teacher educators and researchers" (Cochran-Smith, 1994, p. 151). Building on Schön's work (1983) Munby (1987) looks at teachers' professional knowledge suggesting that this refers to "the non-propositional forms of knowledge that are assumed to be of importance to professional action" (p. 1). If we broaden that to imagine a base, it alters the understanding that a base might simply include a set, or sets, of skills.

Clandinin & Connelly (1996) propose that, "professional knowledge context shapes effective teaching, what teachers know, what knowledge is seen as essential for teaching and who is warranted to produce knowledge about teaching" (p. 24). Further, they position professional knowledge at the "interface of theory and practice in teachers' lives" (p. 24) and a base of such knowledge might look different from traditional knowledge bases. This again seems to underscore the uncertainty of teaching.

If as Richert (1992) asserts when "thoughtful teachers do their work – all the while thinking about what they are doing and what they have done – they create knowledge about their practice which they then draw upon (and revise) as they continue to teach" (p. 189), how do we define a knowledge base? I would suggest (with the help of Pinnegar, 2003) that rather than defining knowledge base as the lowest common denominator of ideas, we consider viewing this base as an anchor, a point where the social, moral, political, personal, and emotional fit together. Establishing boundaries for knowledge seems confining from postmodern/poststructural views. Moreover, it does not seem to fit with the uncertainties of teaching to which we have previously referred in earlier sections of this chapter. Thinking of stories and information that serve as a touchstone may support novice teachers in the critically reflective perspective they need to bring forth to contribute to their teaching.

There are important issues to consider here beyond the skills often addressed – social justice, privilege, and emotion. Are these really elements of a knowledge base? Who decides? How do we decide that someone has contributed to the knowledge base?

Social Justice

Recognizing social justice as a foundation for a knowledge base seems critical. Access to knowledge varies by race, class, gender, age, and more (Dilworth & Brown, 2001). This suggests that some people may receive more, less, or, perhaps, no information to develop their knowledge. As Cochran-Smith (1995 for example, among many others) has indicated this imbalance in how students learn, teachers teach, and, ultimately, how people within our global society interact privileges some people more than others. Evidently, some people, because of their socioeconomic class or the color of their skin (or other reasons), have more privilege in

society than others (Pewewardy, 2003). Since, at least in the United States, we are affected by institutional racism, we need to understand that the ways we (whoever we are) make meaning of the world influences the ways that we see beyond ourselves. As mentioned earlier in the text, Foucault's (among others) power-knowledge relation must be applied here. Sometimes this privilege can be ignored or hidden from view but it is always present in its [often explicit] absence. While there are some programs with good intentions, there are few programs that claim success addressing issues of social justice and diversity in a teacher education setting (Ladson-Billings, 2001). Ellsworth (1997) claims that "most educational literature and practices aimed at ending racism seem preoccupied with identifying, inciting, and proliferating discrete turning points in students' attitudes, understandings, and behaviors towards race and racism" (p. 155), but this does not necessarily prepare socially just teachers. Supporting this, Danielewicz (2001) asserts:

> Friere's liberatory pedagogy demonstrates how the whole educational enterprise can be opened out to include the voices and perspectives of all participants, regardless of their status. Inclusion of all voices and perspectives would expose the submerged assumptions about language, knowledge, and power that drive the traditional curriculum. (p. 147)

In postmodern/poststructural perspectives there is an implicit understanding, "that 'all' collapses the differences and diversities of students to a totalising entity that covers everyone" (Zembylas, 2000, p. 178). As is fitting with a quest for identity, knowledge and moral stance, for a socially just world, a professional knowledge base needs to be expansive rather than rigid. That is, expectations need fluidity instead of rigidity. Brown (this volume) and Schulte (this volume) offer excellent insights into these issues along with Griffiths, Bass, Johnston, and Perselli, (this volume). Surveying her maps, our cartographer sees a variety of interests but wonders how people decide on those interests.

Emotions

Another influence on the knowledge base and peoples' understanding of knowledge is emotion. Often avoided as a topic because it skirts the margins of rationality, emotion affects they ways we are in the classroom and in our lives. In an organic society (Reason, 1994), we see how emotion imposes on the understandings that people bring to their experiences. Zembylas (2002b) finds that in:

> education, the emotions associated with learning and teaching are by no means new terrain for researchers and educators, but there seems to be a renewed interest especially in the emotions of teaching, the emotional politics of teacher development and educational reform, and their implications for teacher education. (p. 187)

Controversies about culture and teaching are "not simply 'academic' questions,

but rather highlight and touch on issues that are highly personal, emotionally charged, and at times appear to be rather divided (Liston & Zeichner, 1996, p. xvii). Flynn (1995) suggests that the, "roles of emotions … lies in their capacity as a motivating force to support peoples' relationships with the world around them" (p. 367). He suggests a relationship among body, feeling, emotions, and concerns. Bondi adds that studying emotion addresses questions of positionality (Bondi, 2002) and influences meaning making and understanding that creates knowledge (Bondi, 2002).

The "emotional geographies of teaching" (Hargreaves, 2000) illustrate ways to the delineate the lived experience of self and offer "powerful testimony of the importance of attending to the much neglected" issue of emotion (Day & Leitch, 2001, p. 403) in understanding the knowledge base of teaching (for elaboration on this topic, see Kelchtermans & Hamilton, this volume).

Early self-study work looks at issues of emotion. Lighthall & Lighthall (1996, 1998), consider the complexity of emotions set in narrative from a cross-cultural perspective and ask teachers to tell "self-involving" stories that explore their emotional understandings. Others mention emotions and "inner" feelings (Smith, 1996; Manke & Allender, 1998). As described, emotions involve not just feelings, but the body, the soul, and more (Lighthall & Lighthall, 1996).

How might emotions fit into the question of what counts as knowledge base? For some researchers, "emotions can be sites of social/political resistance and transformation of oppressions," and examine "contradictions within discourses of emotions – what can be called 'counterbalancing discourses' or 'disrupting discourses.' These discourses can become sites of power and resistance" (Zembylas, 2001, p. 2). Teacher/teacher educators' identities are mutable, lived, experienced, and expressed in the acts of teaching, sometimes through emotion. Further, because emotions are potentially public and visible in their actions, their words, and their bodies (Zembylas, 2003), understanding the impact of them on teaching and the professional knowledge base is important.

The sense of vulnerability that teachers experience in their work fits here. Kelchtermans (1996) defines vulnerability as "one way in which teachers experience their interactions with other actors in the school and the community. It … encompasses not only emotions (feelings), but also cognitive processes (perception, interpretation)" (p. 307). When teaching, the living contradictions that emerge in the classroom to unmask vulnerabilities. For example, Parker reveals her own vulnerability when looking at her teaching experience (Lomax, Evans, & Parker, 1998). The contradictions seen or the tensions felt in the classroom affect how teaching happens there. They also affect the sense of knowing developed there. Emotions seem central to the learning-to-teach process (Zembylas & Barker, 2002). These uncertainties seem to contest the notion of providing a standardized knowledge base that fits most experiences.

Wonderings

The distribution revealed by the map survey suggests that the areas of social justice and emotions have a low density. That is, the influences of social justice

and emotions on the lives and the knowledge of teachers/teacher educators seem less significant. However, the importance of these issues cannot be overestimated. Casting them into the margins undermines the preparation of novice teachers for the teaching world.

Addressing issues of social justice and emotion can be less concrete then a formula for planning or a teaching strategy. This would be a problem for those people and institutions that seek comfort in prescriptions for teaching. The distinctions among the traditional and less traditional views of viewing teaching and its professional knowledge bases seem clear-cut and sharp. How to accommodate these variations seem less so.

Our cartographer looks at her map. I can see," she remarks, "that there are many interests and broad range of possibilities." "Now I notice," she declares, "that there issues beyond skills." From postmodern/poststructuralist views, interrogating justice, privilege, and emotion as well as contesting related questions and concerns must be a part of the process of making sense of the knowledge bases that count for teaching.

Sixth Map – What is the Relationship Between Professional Knowledge Base for Teaching and Teacher Education?

At this point, our cartographer also sees that she needs more information. While these other maps have been important, she still wants to develop more insight. Perhaps understanding the boundaries and margins will contribute to a deeper understanding" she wonders. A political map outlines the boundaries of the world, separating nations and states and she decides to undertake that task. In this section we will very briefly explore along the boundaries of professional knowledge and teacher education.

With relative ease for the most part, our cartographer can see the initial boundaries among territories of professional knowledge bases and teaching and teacher education. We have identified them already as modernism, postmodernism, and poststructuralism. What is key is how we address the margins and unnamed borders. These margins and borders both separate and blend issues. Generally teachers and teacher educators use the professional knowledge base in thinking about teaching and/or ways to teach teachers. This may be an explicit or implicit activity. Significantly, the issue is how teachers/teacher educators engage with the professional knowledge base. From the perspectives of postmodernism/poststructuralism this professional knowledge base serves as a guidepost or opportunity rather than a list of fixed points of information. Teacher educators from postmodern/poststructural perspectives, for example, might encourage their students to be more open to the multiple realities around them.

Teacher educators have a similar, yet different experience from teachers in the public schools. Teachers attempt to empower their students, teacher educators attempt to empower their students to empower their students (Pinnegar, 2003). From this perspective, teacher educators are the more capable Others preparing their students to be more capable Others for their students in the public school

settings (see Kelchtermans & Hamilton, this volume, for elaboration on this topic). Teaching and learning in relation is a powerful perspective to consider when exploring knowledge and the knowledge bases for teaching. Korthagen and Lunenberg (this volume) address these issues in relation to teacher education reform.

How might teacher educators from postmodern/poststructural perspectives present these issues to their students? Heaton and Lampert (1993) suggest narrowing, "the distance between teaching and teacher education" to "examine the problems of an unfamiliar kind of teaching practice in the context of daily lessons with a class of diverse learners" (p. 44). One way might be through critical reflection and the preliminaries of the self-study of teaching practices.

Caveats

Who establishes the professional knowledge base for teaching? In teacher education those people that might contribute to the development of the professional knowledge base include teacher educators, teachers, but more likely people less affiliated with classrooms and more affiliated with research. Unfortunately, the lack of respect for the knowledge and judgment of teacher educators can undermine their experiences as researchers (Hinchman & Lalik, 2000). Teachers/teacher educators' practice and the knowledge tend tacitly to influence that practice. Hence, attempts to articulate those links have often been difficult. Further, teachers have a difficult time because in school teaching there is little expectation for such articulation as the demands of time, curriculum and student achievement tend to create a focus more on doing teaching rather than explicating the associated pedagogical reasoning.

Self-study scholarship in teaching may well be highlighted and made accessible to others by better understanding the underlying knowledge/ideas/theories that influence teachers' pedagogical reasoning so that what is often viewed as exemplary practice is able to be discussed and examined in ways that go beyond the practice itself. Self-study scholarship in teacher education highlights similar information in different settings. Florio-Ruane (2002) promotes expansion beyond traditional approaches to study the complexities of practice. This is an important step in coming to better understand what really comprises teachers/teacher educators' professional knowledge and in beginning to make that knowledge available to others.

Seventh Map – What Does Self-Study Contribute to Teacher Education in the Creation of a Professional Knowledge Base?

Our cartographer has now collected maps that focus on space, weather, water, land, people, and politics, but that still is not enough. To understand this educational research world, she finds that she must consider its inner structure. Just as the examination of the earth's interior, looking at its geologic history and core structure in cut-away form, can be a part of a cartographic collection,

she sees she must question the ways that self-study might contribute to the professional knowledge base and its usage in teaching and teacher education. She investigates a few critical aspects of self-study, related issues for distinguishing self-study in an academic setting, and contributions of self-study to the professional knowledge base.

Self-Study

Hamilton and Pinnegar (1998) define self-study as, "the study of one's self, one's actions, one's ideas, as well as the 'not self'. It is autobiographical, historical, cultural, and political … it draws on one's life, but it is more than that. Self-study also involves a thoughtful look at texts read, experiences had, people known and ideas considered" (p. 236). Cited by Mason (2002) as an element of discipline of noticing, "laying strands of your own experience alongside each other, comparing them, testing whether they do indeed sharpen sensitivities, conform with each other, and inform practice" (p. 90) are also elements of self-study. Autobiography and the development of voice are additional aspects of self-study (Goodson & Walker, 1991). Dinkelman (2003) states that by, "self-study, I mean intentional and systematic inquiry into one's own practice" (p. 8) that "yields knowledge about practice" (p. 9). In self-study work, while the "self" is important, the contextual aspects of the work and the theoretical components remain in the foreground as the researchers come to focus on knowledge generation. Contributions to the professional knowledge base of teaching as well as generating understanding of the world are the focus for self-study scholars.

One critique of self-study comes from the public's misunderstanding of this focus. For example, Louie, Drevdahl, Purdy, and Stackman (2003) suggest that many, "self-studies … fail to capitalize on the potential of their inquiries for creating transferable knowledge that is of benefit to colleagues and other educators" (p. 154). This occurs partly because of the risky nature of self-study research (Pinnegar & Russell, 1995; Bullough, 1997). Why? Rather than maintain distance this work, "reveals participants as both educators and human beings through documentation of successes as well as shortcomings" (p. 155). However, when scholars do, "engage in self-study to advance theoretical knowledge, they connect their work with existing knowledge and theory in the field, engaging in 'praxis'. … that is at the core of knowledge creation" (Louie *et al.*, 2003, p. 160).

Along with risky, self-study has sometimes been seen as self-praising rather than critical. Feldman (2003) warns that, "odes to ourselves are of little value to those who we want to help … we need to do more than represent our findings; we must demonstrate how we constructed the representation" (p. 27). Another warning is that critical reflection, "will reveal no more than what is already known. … Because reflection entails circular ways of thinking, research about reflection is problematic and can be dangerous if it assumes a privileged status in teacher education" (Fendler, 2003, p. 21). As many others have warned self-study scholars, Mason (2002) exhorts that studying, "oneself can become solipsistic and even narcissistic, if gaze is always inward. If gaze is only sometimes

inward, studying oneself can provide the basis for communicating with and developing sensitivity to others. If gaze is always outward, then the most valuable resource one has as a researcher, namely oneself as instrument, is denied" (p. 174). Richardson (2002) asks, "does teacher research and self-study warrant different methods and procedures than research that leads to formal knowledge?" (p. 15). She answers that self-study work "says important and useful things" about particular contexts and participants, but, "more work is required if it is to add to the field's understandings of teaching practice" (p. 20).

From a methodological standpoint (addressed more fully in Section Three of this volume) static knowledge, that is, knowledge presented as "the" truth, is easier to undertake. The distance that comes with work seeking traditional scientific warrant leaves the researcher less vulnerable and less available to personal process. Self-study research, on the other hand, represents a trend away from modernism and its assumptions about legitimate knowledge and knowledge production toward broadening what counts as research (Bullough & Pinnegar, 2001, p. 13) brings personal biography and history together with context and social history (Bullough & Pinnegar, 2001). This is not to say that self-study is all about "self." Rather, it is recognition of the contribution that "self" makes and the role "self" takes in the multi-layered world. The self is a part of the study, but the focus is on the nexus of self, practice, and context (Bullough & Pinnegar, 2001). In fact, self-study attempts to diminish the gap between theory and practice (Bullough, 1997). In some ways we could assert that a relation between self-study and teacher education could balance teachers/teacher educators' understanding of professional knowledge bases. This knowledge has to be useful to the teachers/teacher educators and fit with or contest their world.

Hamilton and Pinnegar (1998) conclude that self-study goes beyond the boundaries of qualitative research: "More than a qualitative approach to a situation, self-study scholars attempt to embrace … uncertainty and reject calls for validity and reliability as they are traditionally known. The multilayered, critically-imbued, reality-laden world is the text of the self-study scholars …" (p. 235). And, "one of the research by-products of self-study is the way in which it pushes the boundaries of what counts as research" (p. 240). As teachers and teacher educators come to know something, they play with words and concepts, appropriate them, and make them their own. In turn, they hopefully take responsibility for that process and the ways that they transform ideas. Self-study helps with balance among the various research approaches.

While the self-study of teachers/teacher educators can adequately support the questions studied with more breadth and depth to the work, the self-studies of student teachers can often be shallow because the students have few contexts with few experiences to develop their personal theories that are, in turn, relate to theoretical frames (see LaBoskey, this volume, for elaboration on this topic). Critical is the acquisition of a "sense of self-understanding" by the student teacher "as a basis for developing their own unique potential" (Korthagen, 2001, p. 263). This sense of self-understanding helps the student teacher prepare for a successful teaching career and helps them frame the professional knowledge they

learned. Although undertaking a broad self-study may not be possible at this early point in their learning-to-teach process, learning the preliminaries to this work in their university classes can be helpful when they begin teaching.

There are numerous self-studies in Castle Conference Proceedings (Richards, & Russell, 1996; Cole, & Finley, 1998; Loughran & Russell, 2000; Kosnik, Freese, & Samaras, 2002), in texts (Allender, 2001; Hamilton, 1998; Loughran & Russell, 2000; for example), in journals (Arizona Group, 1994, 1996; Cole, Elijah, & Knowles, 1998; Finley & Knowles, 1995; Knowles & Cole, 1994; Louie, Drevdahl, Purdy, & Stackman, 2003; Phillips, 2002; Pinnegar & Russell, 1995, Trumbull, 1990, for example), and in conference papers (Guilfoyle, 1991; Knowles & Cole, 1991; Northfield & Loughran, 1996; Phillips, 2001; Pinnegar, 1991, 1993; Placier, 1991, for example).

There are also studies, not identified as self-studies that fit those criteria. Heaton and Lampert (1993) for example, explore practice and their collaboration while teaching in elementary school. In her work, Dillard (2002) looks at community and authenticity in teacher education. She asserts that, "Freire (1970) and hooks (1989) suggest that critical consciousness and broader perspectives are developed by coming face to face with contradictions in life that require a reexamination of values, cultural understandings and decision making" (p. 384) and advocates a personal, critical approach for research. Hinchman and Lalik (2000) examine their discourse in order to explore their practice. Whether labeled self-study or something else, the work of examining practice within the context of the classroom and the teachers/teacher educators' experiences, is critical to understanding teaching practice.

Perhaps the most distinctive element of self-study is the way it contests the traditional approach to research. The levels of intimacy and vulnerability described earlier in this chapter make self-study contrary to those who might like to suggest greater ownership over knowledge. Curiously most often other scholars attempt to subsume self-study under other headings, like action research or practitioner research (Zeichner & Noffke, 2001, for example) or scholarship of teaching (Hutchings & Shulman, 1999; Shulman, 1999). However, that seems to misdirect attention away from the critical element of self-study – the work of self-study scholars interrogates traditional ways of thinking about and practicing research. This work challenges the ways we see and value knowledge and the ways that we seek answers to questions. This is not to say that only those engaged in self-study take up the challenge. Other researchers do also do excellent work that causes reconsideration of old ideas. Instead, it seems that situating self intimately within work provokes deeper worries about researcher-identity and understanding about knowledge ownership and knowledge production. Elements within the core of this educational world can fluctuate depending on perspectives. While there may be cold spots where certain sets of ideas seem caught, there is also the heat of passion and enthusiasm for generating change.

Collaboration

Amidst the ebb and flow of inner core, our cartographer sees a pooling of certain currents. Collaboration and collegiality among self-study scholars is legendary

beyond its community. From some research perspectives this is not vital. From others collaboration, "is not merely an actual or potential attribute of human nature, but constitutes human nature" (Reason, 1994, p. 38). These scholars support each other in developing as well as critiquing ideas. Self-study scholarship fosters collaboration in a variety of ways. Collaborative conversations may, "provide spaces for teachers to become aware of and name what is learned and how it is learned" (Zembylas & Barker, 2002, p. 332). Colleagues may observe and discuss work (Heaton & Lampert, 1993). In these situations the colleagues actively participate and engage in the work. Loughran and Northfield (1998) called it the "shared adventure of ... self-study" (p. 16) where they worked together to depict their knowledge and explore their practice. Self-study also brings, "together ways of seeing ... teaching that are rooted in a shared context [and] characterized by common experiences stemming from participation in a mutually constructed set of teacher education activities" (Dinkelman, 2003, p. 14). He identifies this as collaborative self-study and describes it as facilitating a "sum-is-greater-than-its-parts" experience for those involved (Dinkelman, 2003, p. 14).

Another way researchers engage in self-study work is individually. Although some, like Loughran and Northfield (1998) assert that self-study involves a critical Other actively engaged in the process, others approach this critical Other from an alternative frame. For these scholars (Hamilton, 2002, for example) the critical Other is a strong, yet more subtle element and involves the voices of critical friends with whom the scholars have interacted in the past (see Kelchtermans & Hamilton, this volume for a more developed argument on this point). In Hamilton's work, she employed the writings and the paintings of a 19th century American artist to push forward her ideas about teaching and learning. Others, like Finley and Knowles (1995) and the Arizona Group (2000) have used artist alternative representations to push forward their ideas. These approaches help the researchers better understand the alternative representations and ways they promote an understanding of multiple realities (see Bodone, Gudjonsdottir & Dalmau, this volume, for elaboration on this topic).

Making the Work Public

From early in the creation of the body of self-study research, public representation has been a critical element. With a desire to explore ideas and expose colleagues and students to new ways of thinking about practice, conference presentations and public conversations accompanied the work itself. Like many others, this group of scholars believes that opening their research for public discussion contributes to the development of the professional knowledge base and encourages colleagues to consider alternatives. These scholars also prepared manuscripts for publication with varying results. Because the nature of work and newness of ideas, initially publications resisted and rejected the text. The publication of this Handbook illustrates that times have changed.

Returning to the question, what does self-study contribute to teacher education in the creation of a professional knowledge base? Perhaps most importantly,

self-study and the research associated with it provide an alternative to exploring teacher education – from a particular and critical perspective. In turn, the researchers model for their students and their colleagues ways to consider more deeply their own practices. Some might say that this is not knowledge generation because it lacks breadth, however, self-study scholars challenge and contest that view of research.

As collaboration is an important element of self-study and "essential to the success of self-study" (Barnes, 1998, p. xii), the public part of collaboration is not overlooked. A central purpose for going public throughout the process as well as at the conclusion of the work is to obtain critical review and evaluation from colleagues, including most particularly other teacher educators and researchers, classroom teachers and their students, and the students of the teacher educator engaged in self-study. How do these ideas hold up? How do we make sense of all of this? In the discipline of noticing, the fourth element includes, "the construction, refinement, and modification of means to communicate" so that those engaged in this reflexive action can publicly explore the work (Mason, 2002, p. 94).

There is an expectation that researchers engaged in self-study will carefully check data gathered and interpretations made with others. Loughran and Northfield (1998) state that the, "value of the involvement of others becomes evident in practice and is well demonstrated when interpretations, conclusions or situations resonate with others who have had the opportunity to analyse the data independently" (p. 12). The public nature of the work affords researchers and colleagues to bring alternative perspectives to bear during the analysis and interpretation of the data collected. In turn, this confronts the perceptions that the researcher has about the teaching process under investigation and to help reframe knowledge and understanding (Barnes, 1998). From this point, the self-study researcher also interacts with published and/or collected text to deeper understandings and explores knowledge. As Hamilton and LaBoskey (2002) state, although, "the work has been engaged in order to directly inform and transform the understanding and practice of those involved in the self-study, the intention to be useful by other members of the scholarly community is also inherent in the work" (p. 6). Work in the self-study of teaching practices can influence the teaching practices of teachers and teacher educators as well as contribute to the knowledge held about practices and institutions by members of the educational world (Zeichner, 1999). For Hamilton and Pinnegar (1998), as "one's educational practice improves, accounts of it and therefore knowledge about it is added to the knowledge base of the teaching and research community" (p. 243).

A Caution

Watching the intense activity of this world's core suggests tension and pressures. Should objectivity be something pursued? Is this something that exists in ways currently defined? Our cartographer wonders about this, and realizes she has

again returned to tensions mentioned earlier in her mapwork. The turbulence seems inescapable.

While questions about the continuum of objectivity may continue, certain issues about self-study can be addressed and acknowledged. For example, what self-study scholars might learn from these queries into the work is the value of offering solid evidence about where the knowledge is in the practical knowledge we assert that teachers have. These questions seem haunting like the work and worry of Whitehead (1993, for example) that suggests that we need to explore our living contradictions and provide concrete evidence for our assertions. For example, if we say we have practical knowledge – where's the evidence? Clearly Fenstermacher and others focused on their notion of an objectively reasonable search for knowledge. Self-study scholars seem more committed to a conscious, clear, trustworthy research path where they demonstrate their integrity through research action. Further, Baird (2000) suggested that self-study researchers manifest their intention in their work – that is, the intention to make their work conscious, clear, and public.

A critical point here is that the power of self-study work can be undermined by a lack of apparent methodology and approach to the research. Richardson (1994) suggests that there is no formal methodology to this work, although she later suggested the possibility of different warrants being involved (Richardson, 2000a). She and others wonder about the need for general laws and she (2002) cautions researchers to remain semi-skeptical … [and] honor … strong intellectual critique of [their] work (p. 20). Yet, the postmodern/poststructural perspectives would suggest that general laws may not fit this reality. While it may be the intention of self-study researchers to be explicit about their work, sometimes, at least earlier in the history of this work, they did not always succeed. Erickson (2000) addressed the importance of the work and encouraged the self-study community to bring it into the mainstream academic world.

Eighth Map – What is the Relationship Between a Professional Knowledge, Teacher Education and Self-Study?

Our cartographer gathers her maps together. She ponders, if we accept that a base of knowledge is a foundation rather than "the" structure itself, and there are multiple possibilities for knowing, and if we accept that studies of particular experiences can contribute to that base, and if we continue with our metaphor, our cartographer is now ready to return to space with better clarity about what she sees. This time, because she has gathered her cartographic treasures together, she decides to use cameras that scan to record information in high resolution. She will again view this (educational) world. Along with seeing the clouds, the land, the peoples, and more, she sees something else. From her vantage she sees a "third space" (Bhadha, 1994). This third space is the space between – that slips into and out of the margins to questions about the regimes of truth. Ellsworth (1997) offers this example: "good/ /bad" with the space in the middle as a third space (p. 145).

Third Space

The shifting areas between self-awareness and inquiry (Jackson, 2000) exist in the third space. Walter (2002a, 2002b) calls it a borderland and, citing Rosaldo (1993), asserts that the "spaces 'between order and chaos' are borderlands endowed with 'a curious kind of hybrid invisibility' (p. 208)" (p. 3). This space is, "a space between public and private spheres, secular and religious duties, male and female roles, and between socioeconomic locations among the classes" (Walter, 2002b, p. 15). This third space challenges the categorization of referent points. Out beyond technical rationality in the indeterminate zones of practice (Schön, 1983) among borders and margins, knowledge and identity brush together. This third space contests the Cartesian dualities that hinder and obfuscate the space beyond traditional boundaries.

In this third space, as we challenge and interrogate possibility, when Fenstermacher (1994) says,

> In my opinion, objectively reasonable belief is an acceptable form of knowledge with in the context of educational practice (although it may not satisfy the canons for educational research, at least not in the more conventional science conceptions of educational research). (p. 24–25)

How does that statement differ from the "I's" of self-study? When Richardson says,

> ... I feel that those who are intent upon turning practical inquiry into formal research need to move across similar studies in the literature, and begin to place their work within theoretical frameworks that allows their work to contribute to theory in significant ways (2002, p. 20),

how does that differ? When others write about their work that examines their practice, how is that different? And if their "I's" are more powerful is that in relation to the texts they cite?

Even the distinction of formal knowledge/practical knowledge throws us back to a dualistic, false opposition. As others have suggested before (the works of Connelly & Clandinin including chapter 16 in this volume, the works of Cochran-Smith & Lytle, including chapter 17 in this volume to name a few) perhaps these issues reflect a power-knowledge relation. When someone in higher education offers a point of view, or a teacher offers a point of view, or a student offers their point of view, we might consider those possibilities and more.

Bhabha advocates a dramatization of the, "space between theory and practice ... [with] ... mutual exchange and relative meanings" (Graves, 2003, p. 1) and suggests that in "splitting open those 'welds' of modernity" a different view emerges (Bhabha, 1994, p. 238). In the third space there is, "no longer a single set of discourse about progress and change" (Kanu, 2003, p. 77). Instead, it "destroys this mirror representation in which cultural knowledge is customarily revealed as an integrated, open, expanding code" (Bhabha, 1994, p. 37).

This space challenges modernist understandings. Here you trouble the categories (Lather, 2001), negotiate identity (English, 2002), and interrogate meaning. English (2002) cites Todd's (1997, p. 251) description of the third space as a, "mucous space, a shared space where each is involved in an exchange with the other" (p. 110). This slippery, sticky space is hard to hold onto and see with clarity.

From this space, even the "authority of experience", addressed by Russell and Munby (1994, for example), and Loughran, Mitchell, and Mitchell (2002), can be challenged. In her writings, hooks (1994) explores essentialism and experience, that is, when one is asked (or implicitly expected to) represent the many. As she critiques this notion she states that if, "experience is already involved in the classroom as a way of knowing that coexists in a nonhierarchical way with other ways of knowing, then it lessens the possibility that it can be used to silence" (p. 84). She continues that,

> I am troubled by the term 'authority of experience,' acutely aware of the way it is used to silence and exclude. Yet I want to have a phrase that affirms the specialness of those ways of knowing rooted in experience. I know that experience can be a way to know and can inform how we know what we know. (p. 90)

As she troubles this issue, addressing the value of having a black professor teach a college-level black history class, hooks resolves that, "to me this privileged standpoint does not emerge from the "authority of experience" but rather from the passion of experience, the passion of remembrance" (p. 90).

As teacher educators, as self-study scholars, we cannot easily discount our use of the terms authority of experience, nor is that the purpose of raising the issue here. Further, it is not the purpose here to take issue with hooks' perspective. Instead, looking at hooks' work in relation to our own can provide a third space to consider alternative views.

Our cartographer sits back and surveys her maps. When I began," she contemplates, "I asked 'How can I make sense of a(n educational) world where thinkers shortcut their understandings of the nature of knowledge and underestimate the strength of alternative views?' and I need to ponder my answer." She arranges her maps; she looks at her tools and asks "What do I know?" In the questioning process we see that several paradigms exist. While there are certainly more than two, in this chapter we delineated two possibilities to explore alternative views. The modernist view seems to take a more standard view that attempts to capture in a static way the view of knowledge having right and wrong answers. The alternative view presented here is a postmodern/poststructural view that seems to take a view of multiple perspectives that opens rather than closes the consideration of truth. The educational world explored seems to have these perspectives and more within it.

We must consider whether we will accept the view of a professional knowledge base as an anchor to the real world of teaching with real events and where

evidence for beliefs and ideas are supported with evidence. In turn, this knowledge base serves as a foundation for teacher education programs. The knowledge shared in classrooms as well as the strategies and models used to present the knowledge are elements of that base. For the professional knowledge base and the teacher education programs, self-study appears to be valuable way to explore these issues.

Good self-study where a range of acceptability may be wider, that is, researchers are not worried about a level of objectivity beyond self, and the interpretations includes questions like: "What is data?" "What counts as knowledge?" "What counts as data?" From there, the researchers are willing to account and accept multiple interpretations.

The subjectivity in self-study research is on the part of the researcher who takes responsibility for that subjectivity and on the part of the reader. It is the reader who decides about the evidence and the value of the work. The self-study scholar can do good work, present good information in a reasonable way, can offer a valid interpretation, but the reader decides whether or not to accept it. That is the nature of the work. Self-study research is more than practice and more than thinking about practice. As we consider the relationship of professional knowledge, teacher education, and self-study, in this third space we see a strong relationship between the anchor of professional knowledge and the structure of teacher education, along with a way to study this relationship using self-study. Moreover, there is encouragement to keep looking beyond the traditional boundaries. Our cartographer appears ready to embark upon her next task.

LINKS BETWEEN SELF-STUDY AND TEACHER EDUCATION REFORM*

Fred Korthagen[a] and Mieke Lunenberg[b]
[a] *Vrije Universiteit;* [b] *Utrecht University*

Abstract

This chapter begins with an analysis of the gains of self-study research at the personal, institutional and collective levels and illustrates these with a variety of examples. They show that self-study has – at the personal level – the potential to improve individual teacher educators' practices, but that – at an institutional level – it can also lead to program reform and – at the collective level – to the identification of issues important to the international community of teacher educators. Next, in response to the question of where the sudden outburst of self-studies comes from, relations are explored between self-study, developments in teacher education, and the context in which teacher education takes place. On the basis of this exploration, four dimensions are formulated on which developments in teacher education run parallel with the nature of self-studies. These four dimensions also help clarify risks and possible flaws embedded in self-study research. This leads to a number of guidelines for quality in this research. Finally, the chapter ends with a discussion of the possible position of self-study within future reform of teacher education.

As Zeichner (1999) indicates, a new kind of scholarship is emerging through self-studies. In this chapter, we will discuss the connection between self-studies by teacher educators and teacher education reform and explore ways of strengthening this connection by improving the quality of self-study research. First, we will discuss the nature of the gains of this new kind of scholarship. By looking at concrete examples of self-studies, we will see that there can be gains at an individual, institutional and collective level. Next we will pose a question about

---

the origins of the sudden outburst of self-studies. We will answer this question by showing links between self-study research work, developments in teacher education, and the setting in which teacher education takes place. In this way it will become clear that the nature of self-study research is rather congruent with the characteristics of recent reforms in teacher education and that it may thus be no coincidence that the self-study movement emerged during the last decade.

Next, we will focus on four dimensions enabling us to characterize this congruency between self-study research and teacher education reform. In this way, the specific strengths of self-study research will become clear. However, each strength has its weakness: each of the four dimensions also makes us aware of the possible risks and flaws of self-study work. By analyzing them, and combining our analysis with guidelines formulated by Bullough and Pinnegar (2001), we will arrive at a number of guidelines for quality in self-study research. We will end by discussing the promise self-study research holds for the continuous improvement or even the re-conceptualization of teacher education. However, in the chapter we will also see that power relations influence the possible impact of self-study on teacher education.

Personal, Institutional and Collective Gains

Before analyzing self-study research and its connections to developments in teacher education, it may be helpful to first discuss the legitimization of this kind of research in terms of its outcomes. What does it result in? What are the gains from self-study research? We will look at three different levels at which gains can be seen.

Personal Gains

Our review of the self-study literature first leads us to the conclusion that self-studies strongly support the professional development of individual teacher educators. Almost all self-studies show a variety of learning effects, often concerning a higher level of consciousness or a more detailed form of reflection. We will give a few examples. In the book *Teachers who teach teachers* (Russell & Korthagen, 1995), several teacher educators described how studying their own teacher education practice helped them to become aware of its weaknesses as well as of possible improvements.

Zeichner (1995), for example, became aware of a discrepancy between his beliefs and his practice as a teacher educator. In studying his practice and the comments from student teachers, he began to realize that his commitment to educational equity and to the building of a more decent and humane society was not in line with his ability to enact those beliefs in his own classroom. Zeichner writes:

Throughout my career, I have been focused on the issue of preparing

teachers to teach everybody's children, not just children like themselves. …
I have been concerned with helping teachers examine the moral and ethical
aspects of their practice and make teaching decisions with an awareness of
their social and political consequences. (p. 11)

In this respect, Zeichner experienced a conflict between his ideals and his own
practices as a teacher educator. On the one hand he considered it important to
create a classroom environment in which his students felt empowered to speak
about their concerns, but on the other hand he recognized that, in a mainly
white university environment, it was very easy to forget about taking the perspec-
tives of people of color into account. Hence he decided to insert 'critical content'
into his seminars i.e., he deliberately introduced literature and discussion on
issues of race, gender and culture. However, from his self-study on this emerging
seminar practice, it became clear, "that our approach … was not having the
impact I wanted" (p. 17). Although some students became more aware of racism
and sexism, most did not connect their greater awareness to their own teaching.
This finding was the start of a process of re-organizing his work with student
teachers: "Over the last decade, we have moved … closer to the place where
students' own issues and practices become the starting place …" (p. 17). This
new approach means that Zeichner and his colleagues now draw attention to
issues of social justice as they arise in student teachers' own discussions or
inquiries.

Oda (1998) studied the influence of her Japanese heritage on her work as a
teacher educator. Through this, she became conscious of her focus on harmony,
her appreciation of others and her respect for great teachers who had preceded
her. For example, through studying her own practice, she became aware that
she often answered her students starting with words like: "You are absolutely
right" or "I don't disagree with you" (p. 117). She became more aware of the
fact that avoiding conflict can also create difficulties and that kindness may be
mistaken for weakness.

Oda describes a discussion with student teachers about the celebration of
Martin Luther King Day in schools. She explains to them that honoring a
person who had been a great teacher is unquestioned in Japanese culture and
that: "Also, consideration and appreciation of diverse populations can be pro-
moted without having a large representation of particular ethnic minority
groups" (p. 117). In this respect, she made her awareness of cultural differences
productive to her teaching. She found that her Asian-American background was
a good example for her students, "of how a teacher's culture can be included
naturally in a classroom without being imposing" (p. 123). Her growing aware-
ness of these issues supported Oda in her work as a teacher educator.

Bal, Lunenberg, Swennen, Tanja and Wetsteijn (2002) supported each other
in gaining more insight into their own teacher education practices. They did so
by interviewing each other and observing each other's teaching. They summa-
rized some of the personal gains from their self-studies for their work as teacher
educators as follows:

- By participating in this study I became more conscious about my pedagogical approach and I can explain it better to my students.
- I became more conscious and explicit about the differences between the frame of reference of my students and myself.
- My ideas about teacher education did not change, but my practice did.
- Since participating in the study, I give more attention to explicit modeling. (p. 32)

In her self-study, Wilkes (1998) focused on paradoxes she discovered in teaching and teacher education. For example, the paradox that moving too quickly in teaching disadvantages low-achievers, but that sometimes speeding up the curriculum can help at-risk students because it gives them a broader picture. Her self-study helped her to reflect critically on her teaching approaches, which were until then based on day-to-day intuition. In the case of this example, her intuition told her to slow down to help the at-risk students, but she started to question this routine.

In sum, studying paradoxes helped Wilkes to rethink her personal role in teacher education. She ended her self-study with the conclusion:

> I have learned that the key to reflection is not what we know about ourselves, but the continual quest for what we do not know about ourselves. … And I have learned that I cannot really know and understand my teaching without attempting to know and understand the other parts of my life as well. (p. 206)

Hutchinson (1998) also focused on the personal gains for her daily practice resulting from her self-study into her use of cases in her teaching. This led her to discover many different aspects, as she wrote to a colleague:

> I find all of this stuff about our teaching fascinating. There are so many dimensions to what we each do. Sometimes I think two parts of what I do are contradicting each other, but I choose to do each because I see it encouraging the students to take ownership of their own learning. … I am puzzled by my own teaching, let alone someone else's. (p. 133)

Finally, Hutchinson concluded that it was precisely the simultaneous reflection on, and learning from, many different aspects of her teaching that made sense, because it mirrored the multiplicity of foci in the teaching context: "Back and forth I go, it seems, between the experienced and the theoretical and the experienced in a disjointed, recurrent and gradually enlightening way. Perhaps this is what it means to learn to teach" (p. 138).

Although the self-studies of Zeichner, Oda, Bal *et al.*, Wilkes, and Hutchinson focus on different aspects of teacher education, they all emphasize the benefits to their work as teacher educators. We found only one self-study also reporting a shadowy side. Nicol (1997), a beginning teacher educator, reported:

> Researching my practice as a teacher educator also weakened my credibility.

> [It] was an indication to some prospective teachers that I did not have the necessary expertise and knowledge needed to teach a methods course. … The fact that this was the first time I had taught the course in this way and that I wanted to investigate the teaching and learning that occurred was evidence for some prospective teachers to doubt my ability to teach in this context. (p. 113)

From Nicol's self-study, we can learn that it is important to think about the ways teacher educators share their experiences with their students within the self-study setting. Nicol's experience can be a warning to beginning teaching educators not to make themselves too vulnerable. It also points to the fact that student teachers do not automatically appreciate teacher educators' modeling of how to question one's own practices. They have to discover the benefits of this, so teacher educators have to make these benefits explicit to them. An example of such an attempt to make one's own modeling explicit to student teachers can be found in the Berry and Loughran (2002) self-study, which we will describe later on in this chapter.

Institutional Gains

Self-studies may not only hold significance for individual teacher educators, but cases of a joint self-study by two or more teacher educators show a 'surplus' emanating from the exchange of ideas. This may have a strong impact at the institutional level.

Clandinin (1995), for example, describes the history of developing a new and alternative program within her school of education. Through self-study, she became aware of the fact that over and over again she lived a "sacred story" in which the university "hands down" the theory that student teachers should apply to their practice, and she became conscious of the limitations of this story. Together with her colleague Connelly, she began a search for another story line. To start with, the university teachers and the co-operating teachers worked together to plan the alternative program:

> Everyone told the story of the fall term as very exciting, full of what we would call 'awakenings' – retelling our stories – and 'transformations' – reliving our stories – as students, teachers and university teachers. We read, talked, wrote and tried to hear each other's voices, and we tried to find ways to hear children's voices. (p. 27)

With some ups and downs this process finally led to a reshaping of the teacher education curriculum. Clandinin's story is a powerful example of an institutional gain resulting from a self-study.

Conle (1999) gave another example of such an institutional gain. She discovered that her student teachers systematically evaluated her skills as an instructor as being less than her other competencies. Reflecting on these findings, Conle became aware of the fact that she did not want to focus on developing her skills

as an instructor, because that did not 'fit' with her ideas about teaching and learning. She discussed the issue with colleagues and they concluded that the (institutional) assessment forms were based on values they no longer subscribed to. The forms seemed to measure the quality of teacher-centered education, while Conle practised a student-centered approach: "We felt that as a faculty we needed to clarify the value system we were indirectly promoting by our teaching assessment form" (p. 812). The finding in Conle's self-study that the assessment of teacher educators did not match the educational values of her institution, resulted in a faculty discussion about the assessment procedure to be used.

The previous example concurs with the finding of Clift, Allard, Quinlan and Chubbock (2000) that self-studies can also help to analyze what is going wrong at an institutional level. They were involved in creating a partnership between regional education offices and a university aiming at creating a professional development program for novice teachers. Their self-study showed, among other things, the importance of shared histories, shared experiences and the development of positive personal relationships within the steering committee of the new partnership. This self-study also showed how problems surfaced when the ideas of the steering committee had to be institutionalized. Two of these problems were the discovery that each of the participating institutions continued to put their own needs first and that, with the expansion of the group, there was not enough time to share histories and experiences with the new members. Hence the authors had to admit that, as a result of these problems, "it still may not result in any form of an enduring partnership" (p. 36), an important conclusion at the institutional level.

However, not all institutions seem to recognize gains from self-studies. Anderson-Patton and Bass (2000), for example, write: "Institutional politics allowed our experiment [because] both [our courses] are marginalized courses" (p. 10). Guilfoyle, Hamilton, Pinnegar and Placier (2000), too, point to the fact that there are problems involved in uplifting individual gains from self-studies to an institutional level: "In public, we talk about structures and rules. In private, we talk about burning out, about student resistance to multiculturalism, technology, and other program purposes; of inconsistencies that we know exist but have not had time to address" (p. 21).

Guilfoyle *et al.* also complain that institutional reform often seems to take place on the basis of political power or a model "the Dean has forced us to adopt" (p. 22). In these situations, self-studies seem more of a way for individual teacher educators, "to keep things in perspective … to stand back and look at the back picture" (p. 23), than a raising of individual gains to an institutional level.

Fitzgerald, East, Heston and Miller (2002) described a more positive experience, in which a process of political empowerment seemed to have taken place. They analyzed the contradiction between the professional intimacy of their own group and the, "frequently inauthentic conversations that occur in many of the meetings we have with other colleagues" (p. 79). However, they found that they had gradually developed a new confidence that made them speak "truth to

power" (p. 79). Looking back on a period of several years they found that they themselves had become more powerful and could influence decisions on the reshaping of the curriculum.

This finding of Fitzgerald *et al.*'s may represent a more general conclusion. From the self-studies discussed above, we derive the hypothesis that self-studies by teacher educators may have a strong impact at an institutional level, if the teacher educators concerned wield some power within their faculty or if persons in leading positions are open to the outcomes of self-studies. If this is not the case, lack of political power may diminish the possibility that self-studies have a structural impact on teacher education practices within institutions, although they may also be beneficial to a process of empowerment.

In addition, we should not forget that (perhaps) many self-studies never even reach the publication stage, as before that stage the researchers may already have lost their jobs or have deliberately moved into another area because of disappointment with the status of teacher educators within academic institutions or the status of self-studies within the research community. The review of self-study research in this Handbook is mainly based on the work of those scholars who have 'survived' the system.

Collective Gains

During the last decade, the gains from self-studies of teacher educators at a collective level have become increasingly clear. The collective level can refer to a group of teacher educators collaborating as well as to the professional community of teacher educators participating in international conferences or reading professional publications and exchanging insights.

We will present some examples, but it is important to first mention an observation put forward by Kubler LaBoskey, Davies-Samway, and Garcia (1998), who clearly state that collaboration in self-study often differs from other forms of collaborative research. Conventional research carried out by more than one researcher generally aims at consensus and is usually written with one voice. Collaboration in self-study can be characterized as a multi-party self-study and is interactive.

An example of this is to be found in the studies of the Arizona Group (Guilfoyle, Hamilton, Pinnegar & Placier, 1995; Guilfoyle, Hamilton & Pinnegar, 1997). They exchanged narratives of the processes they went through as beginning teacher educators. Through the confrontation of their different experiences and views they arrived at collective gains from self-study for both their own group and the larger professional community. An example of the latter is the growing awareness of the lack of support for beginning teacher educators. Conle (1999) also points towards the richness of perception that ensued when several people exchanged interpretations. This is confirmed by, among others, Russell (1997). In his self-study he described his and Loughran's gains during a term in which Loughran was present in his classes: "Our discussions … were among the

most exciting of my career because they were about my personal practices as well as the general issue of how we help teachers learn to teach" (p. 44).

Fitzgerald, East, Heston and Miller (2002) mentioned that their collaboration on self-study not only made them better teacher educators, but also provided spiritual growth and helped them to rediscover their "teacher hearts" (p. 78) and their compassion. Kubler LaBoskey, Davies-Samway and Garcia (1998) found that motivation, clarifying and providing ideas, were the main gains from working together. Smith's study (1998) on the results of a self-study group he participated in confirmed these findings. All nine members pointed to the support the group gave to conduct a self-study, to increase the level of reflective notes, to start a portfolio or to feel less isolated. Smith added that the collective gains were not restricted to the study-group: while at the start of the group only three members were planning a presentation or publication about their self-study, in the end all nine did.

An important contribution to the collective gains from self-studies for the larger professional community were the *International Conferences on Self-Study of Teacher Education Practices* in 1996, 1998, 2000 and 2002. The proceedings of these conferences give a good overview of the increasing gains from self-studies of teacher educators. Started in 1996 as a North-American initiative, the first conference mainly focused on the primary processes in teacher education. In 2002, self-studies from North America, Australia, New Zealand and Europe were presented at the conference, and the focus of self-study was broadened. Not only the primary processes in teacher education, but also issues such as the structure of teacher education programs and partnerships in teacher education had become objects of self-studies.

Moreover, self-studies are at present more frequently published in well-reputed academic journals. Zeichner (1999) concludes:

> Contrary to the frequent image of the writings of teacher educators in the wider educational research community as shallow, under-theorized, self-promotional, and inconsequential, much of this work has provided a deep and critical look at practices and structures in teacher education. This work can both inform the practices of the teacher educators who conduct it and contribute to knowledge and understanding of teacher education for the larger community of scholars and educators. (p. 11)

Zeichner emphasizes that self-study seems to be a productive way for teacher educators to connect the academic task of conducting research with their own professional development. In this respect, a new kind of scholarship has emerged, which allows teacher educators to kill two birds using one stone.

Relations between Self-study, Developments in Teacher Education, and its Context

When considering these gains at different levels, one may well ask why self-study research has not surfaced much sooner amongst teacher educators. In this

section, we will answer this question by exploring relations between self-study, teacher education reform and the context in which this reform took place.

Developments in teacher education are especially striking when one compares recent practices in teacher education with teacher education curricula of a few decades ago. We will briefly look at this development in order to show interesting links with self-study work.

Traditional curricula generally followed a "theory-to-practice" approach (Carlson, 1999) or, as Wideen, Mayer-Smith and Moon (1998) put it, the implicit theory underlying traditional teacher education was based on a training model:

> in which the university provides the theory, skills, and knowledge about teaching through coursework; the school provides the field setting where such knowledge is applied and practiced; and the beginning teacher provides the individual effort that integrates it all. (p. 133)

In line with this observation, Barone, Berliner, Blanchard, Casanova, and McGowan (1996) note that traditional program structures generally showed a collection of isolated courses in which theory was presented without much connection to practice, leading to what Ben-Peretz (1995) calls, "a fragmented view of knowledge, both in coursework and in field experiences" (p. 546). She states that in such teacher education programs, knowledge was generally presented as "given" and unproblematic. Schön (1983) named this model of teacher education *the technical-rationality model*, which he said was based on the notion that, "professional activity consists in instrumental problem solving made rigorous by the application of scientific theory and technique" (p. 21). In her self-study, referred to above, Clandinin (1995) calls this the "sacred theory-practice story".

Starting at around 1975, research on first and second year teachers and studies on the effects of teacher education on teachers clarified the lack of impact of traditional teacher education practices. Lortie (1975), for example, started to awaken the teacher education community by showing the dominant role of practice in shaping teacher development. Many later studies confirmed his observations. Since it is less well known in the English-speaking research community, we mention here an influential study carried out in Germany (Müller-Fohrbrodt, Cloetta, & Dann, 1978). It showed that teachers pass through a distinct attitude shift during their first year of teaching. Although they often develop sound ideas about teaching and learning during their preparation period, teachers quickly abandon these ideas as soon as they become teachers. This leads to an adjustment to current practices in the schools, not to theoretical insights presented during their preparation.

Building on this research, Brouwer (1989) did an extensive quantitative and qualitative study in the Netherlands among 357 student teachers, 128 cooperating teachers and 31 teacher educators, also showing the dominant influence of the school on teacher development. Brouwer found that an important factor promoting transfer from teacher education to practice was the extent to which teacher

education curricula showed continuous alternation and integration of theory and practice within the program. Other studies in a variety of countries also showed problems of transfer in teacher preparation (e.g., Cole & Knowles, 1993; Veenman, 1984; Zeichner & Tabachnick, 1981). In their overview of the literature on teacher education, this led Wideen, Mayer-Smith, and Moon (1998) to the conclusion that the impact of traditional teacher education programs on their graduates was relatively little and that teacher education can only have an impact on students if the total ecology of teachers and teacher preparation receives more attention. This development, which we could only summarize here in a nutshell, shows that the traditional culture of teacher education started to be questioned. Program structures and practices that had for a long time been taken for granted began to be discussed and came under closer scrutiny than before.

This cultural change has also been strongly promoted by the fact that many countries experience teacher shortages (Buchberger, Campos, Kallos, & Stephenson, 2000), leading to political pressure to find solutions to the possibly dramatic consequences for the education of children. These solutions were often sought in alternative programs offering quick routes into the profession. In many of these programs, prospective teachers were put in the position of a teacher right from the start or after a few weeks of practical training. In other words, as a result of the pressure to increase the number of teachers in the schools, many teacher education curricula changed into fast-track routes, which were often not much more than lessons in classroom survival, and sometimes contained hardly any theory at all. In other places, professional development schools are shaped as links between practice and theory (Bullough & Kauchak, 1997; Darling-Hammond, 1994; Levine & Trachtman, 1997; Ross, 1995), or institutions for teacher education try to establish fruitful connections between teachers in schools supervising novices and teacher educators focusing more on the theoretical aspects (for example in the Oxford Internship Scheme; see McIntyre, 1995 or McIntyre & Hagger, 1992).

Although, as Hagger and McIntyre (2000) rightly note, teacher educators were relatively slow to accept the need for change and the need for a much stronger role for schools and their experienced teachers in particular (see also Lunenberg, Snoek, & Swennen, 2000), the influences mentioned have gradually led to what we can view as a paradigmatic change in perspective. Whereas during the larger part of the 20th century, teacher education was mainly *deductive* in nature (practice to be deduced from theory, the theory-to-practice model), new approaches are placing practice more to the forefront, literally both in terms of program design and in terms of the ways teacher learning is being framed. We can now speak of *inductive approaches:* theory is induced from practice. In their major review, Munby, Russell and Martin (2001) offered an extended overview of this radical change in teacher education. It went hand in hand with a process of reshaping the pedagogy used in teacher education.[1]

A logical consequence of this teacher education reform process was that teacher educators developed the wish to study the processes involved in their

attempts to improve teacher education practices and their results, in other words, to carry out self-study research. Teacher education practices, which for a long time – if not always – had been considered as self-evident, started to become an object of inquiry.

Another explanation for the sudden birth of self-study research can be found in the fact that new developments in the views on learning and teaching, for example under the influence of constructivism, encouraged new views on teacher learning and teacher education. "Telling it like it is" (Hamilton & McWilliam, 2001, p. 23) had proved not to be very productive.

Nowadays, the assumption that people construct their own knowledge on the basis of their experiences is quite generally accepted and constructivist approaches to learning are promoted in most teacher education programs. It would, at the least, cause questions if a teacher educator were to lecture for an hour on the theory of why students should be involved in practical experiences as a basis for developing understanding. As a result, issues such as the development of meta-cognitive learning strategies have entered teacher education curricula, and not only as far as children's learning is concerned: reflection on practice by student teachers has become one of the central principles in most teacher education programs all over the world (Korthagen, Kessels, Koster, Lagerwerf, & Wubbels, 2001, pp. 51–52). A logical consequence was that teacher educators started to apply the same principle to their own situations and started to critically reflect on their own practices.

Last but not least, from the mid-eighties onwards, views on educational research started to change. Positivistic forms of research were no longer considered as the only way to arrive at helpful knowledge, and new research methodologies started to surface. This has certainly made it easier to experiment with different research approaches in self-studies. Moreover, "critical educational research began to interrogate Eurocentric and androcentric knowledges and cultural practices in terms of their capacity to delegitimate the claims of those disadvantaged by their identity position in terms of race, class, culture, gender, and ecology" (Hamilton & McWilliam, 2001, p. 31). This promoted teacher educators' awareness of their often lower status in academia, their wish to gain more influence, and it stimulated them to use research approaches that were more suited to their situations and identities.

Teach as You Preach, Learn as You Teach: The Teacher Educator

In the previous section, we have presented an historical analysis clarifying why self-study in teacher education has begun to surface in the final decade of the 20th century. Another important reason may be that for a long time, in line with the traditional view of teacher education, people involved in teacher education did not define themselves as teacher educators, but as academics in a certain field, for example psychology, or science education (see for example the analysis by Feldman (2002) of his own professional identity). Even today, such fields enjoy more status than teacher education as a field of inquiry. This clearly

creates problems for those teacher educators who are becoming increasingly aware of the discrepancies between new insights about teaching, learning and the role of research on the one hand and the traditional academic context in which they work on the other. One example is vividly described by Knowles and Cole (1995). They explain how they almost turned into split personalities. In their practice, they worked with views of knowledge as context-bound, personal and dynamic. In their research work, however, they had to show their faith in traditional ways of knowledge growth. As they developed more self-confidence as teacher educators and researchers, they started trying to use their own professional experiences as research data. This proved tough, as the following text sent to Cole by Knowles illustrates:

> I'm back to talking about the journal review process – again! Journal reviewers have recently called some of my work 'narcissistic', 'self-centered' and 'egotistical', among other things … and I think that I understand where they are coming from – yes, a place very different. (p. 86)

Cole reacts by saying:

> You're right. A piece I wrote was harshly criticized for being 'self-indulgent', and for giving authority to the subjective voice. … Placing value on my subjective experience by using it as an important and valid source of knowledge was interpreted as 'a pattern of persuasive ignorance' reflecting a 'novice researcher's' miscalculated attempt to write authoritatively about the topic'. (p. 87)

Knowles and Cole recognize that, beyond reviewers 'not getting it', there are differences between their epistemological position and the positions of the editors and reviewers of recognized academic journals. Indeed, manuscripts accepted by the main stream journals almost always showed a certain degree of distance between the author and the topic described, a distance that could be very well accounted for with the aid of the then dominant research methodology. As Zeichner and Noffke (2001) note,

> It has always been assumed … that researchers do research about someone else's practice. … Rather than regard practice itself as a form of systematic knowing, the practitioner's role in this view is merely to consume the research produced by others. (p. 298)

A failure to live with the resulting split-personality syndrome was, and still is, penalized by the rejection of manuscripts by academic journals and by expulsion from tenure positions. And, as Korthagen and Russell (1995) note, "the academic world has other means to safeguard its dominant paradigms: publications that are regarded as out of the main stream are often just not cited by the veterans in teacher education" (p. 189).

The result of this situation was that, as Zeichner (1999) notes, until recently

very little knowledge existed of what actually happened inside teacher education programs. Indeed, just as the content in teacher education was seen as "given" and unproblematic, the work of teacher educators has for a long time been seen as such. One became a teacher educator either because one had been a good teacher, or because one was an expert in a certain knowledge domain. The fact that the profession of teacher educators involves specific competences, and often a completely different view on learning than is characteristic for traditional mainstream academia, has only recently begun to emerge. The book *Teachers who teach teachers* (Russell & Korthagen, 1995), shows many examples of the struggle this created in many teacher educators. For example, Hamilton (in Guilfoyle, Hamilton, Pinnegar, & Placier, 1995) says, reflecting on her first years in the teacher educator profession:

> I worked hard to train teachers to integrate their curricula with multicultural perspectives or gender concerns. I spent long hours designing materials to be presented to teachers for use in their classrooms. But who taught me how to do that? Really, no one taught me. I learned by watching these people around me, by reminding myself about what happened in my own classrooms with high school students, by trying to remember the stages of development and how these might fit with what I needed to do. I also learned by making errors, major errors in front of the classroom. No class at the university discussed the process of becoming a teacher educator. (p. 40)

In a completely different, Israeli context, a teacher educator states:

> I was very excited and flattered when I was offered the job, but at the same time full of anxiety as I had no specific preparation in the field of teacher education. My previous experience as a cooperating teacher was not sufficient. As a teacher educator I was expected to help students place their experiences in theoretical frameworks, make linkages between theory and practice, fill in gaps in pedagogical knowledge, create sequences, and suggest meanings based on sound rationales. How to do this was beyond my knowledge. (Kremer-Hayon & Zuzovsky, 1995, p. 160)

A study into the situation of teacher educators in Europe, conducted around 1990, showed that the situation in that part of the world was rather similar. From this, Wilson (1990) concluded that in almost all EU countries, one became a teacher educator without any formal preparation, and often with little or no support from more experienced colleagues.

Ten years later, Buchberger, Campos, Kallos and Stephenson (2000) analyzed the situation again and concluded:

> Most teacher educators … have never received education and training in methodologies of teaching, co-operation and learning appropriate for *adult learners* (student teachers and professional teachers). A number of problems

of teacher education could arise from the fact that the whole issue of education of teacher educators has been rather neglected. (p. 56)

We can draw the remarkable conclusion that in teacher education, which has as its focus the professional development of teachers, there has been a striking lack of attention for the professional development of teacher educators. The fact that teacher educators generally receive little preparation for, or support during, their work seems to have had one advantage: those who took their own profession seriously, started to feel the need to at least critically reflect on their own work as an incentive for improvement and professional growth. Besides the factors described in the previous section, this has certainly been another aspect promoting the surfacing of self-study research. At the 1992 and 1993 Annual Meetings of the American Educational Research Association, a trend became suddenly visible: more than a few teacher educators presented reflective accounts on their own work in teacher education or their own professional development. Among them were some reputable researchers. This triggered the founding of a new AERA Special Interest Group, named Self-Study of Teacher Education Practices. Within two years, it showed a rapid growth towards more than 200 members from all over the world and became one of the largest Special Interest Groups within AERA. A new kind of scholarship, as Zeichner (1999) named it, was born.

What is most characteristic is that self-study researchers bring a certain degree of congruence into their work: they themselves do what they preach, i.e. they reflect on their own practice, and they try to structure their own professional learning in ways that match the pedagogical principles they teach in their courses. To give an example of the latter: journaling and exchanging narratives about practice are generally considered important incentives for student teachers' professional learning and many researchers in the self-study tradition use the same strategies to promote their own learning (see for example Guilfoyle, Hamilton, Pinnegar, & Placier, 1995; Hutchinson, 1998; Lomax, Evans, & Parker, 1998).

The Congruency between Teacher Education Reform and Self-study: Four Dimensions

The difference between traditional research and self-study research has most of all to do with the usefulness of research for practice. Traditional research seemed to focus more on the question of how isolated variables in teaching and learning relate to each other, but generally tells little about the question of what this should mean for the often different and complex situations teacher educators have to deal with. As Hagger and McIntyre (2000) remind us, at the core of expert practice is the need to make subtle judgements in unique situations.

Until the third millennium, teacher education was seldom an object of research: traditional research focused primarily on teaching in schools. Self-studies are different in the sense that they try to improve teacher education from within, starting from the reality and complexity of real practice, the concerns of teacher

educators and their student teachers. As such, this kind of research starts from an *insider perspective* (see for example Anderson & Herr, 1999), rather than an outsider perspective, thus greatly enhancing chances that its results will be fruitful and applicable (Kennedy, 1997). As explained above, in this respect self-study research is a logical consequence of changing views on teacher education and on professional development.

We will now analyze in more depth the congruence between these changing views and self-study, by extracting from our previous discussion four dimensions on which we see significant shifts. We will also give additional examples of self-studies to illustrate the four dimensions.

Dimension 1: From a Focus on Expert Knowledge to an Emphasis on the Authority of Practice

Traditionally, for more than one reason, a focus on expert knowledge was important for teacher educators. In the first place, as described earlier, there was the implicit idea that the teacher educator provided the theory, methods and skills to put into practice in the schools (Wideen, Mayer-Smith & Moon, 1998). Secondly, a focus on expert knowledge was (and perhaps still is) important to safeguard – the often not too high – academic position of teacher educators (Ducharme, 1993). The change in research towards reliance on "the authority of practice" (Munby & Russell, 1994) was not an easy one for many teacher educators. For example, in his chapter in the book *Teachers who teach teachers*, Zeichner (1995) described his personal weighting as follows: "I considered describing the various research projects with which I have been involved. ... There is another aspect to my research ...: the more informal research that I have conducted, over the years, on my own teaching ..." (p. 14).

Although in this book chapter, Zeichner chose the second option, he emphasized that, because his contribution was about himself and not about others, he found it more difficult to write.

Indeed, teacher educators/researchers are not used to this form of making their work public and to rely on their own experience as the basis for research. It requires courage, the willingness to make oneself vulnerable. And it asks for some autonomy, the ability to recognize the value of one's personal experiences. This is exactly what characterizes self-studies, as Pinnegar (1998) concludes: "Self-study research always presents evidence of meaning and relationship among phenomena from the authority of their own experience (Munby & Russell, 1994)" (p. 32).

Not only at the level of the individual researcher, but also at institutional levels the change from a focus on expert knowledge to an emphasis on the authority of practice took time and effort. In the self-study by Clandinin (1995), that we referred to at the beginning of this chapter, she gave an overview of the development within her faculty of education of a new and alternative teacher education program. The idea was that teacher educators and teachers together should elaborate the program, but soon "the co-operating teachers agreed to

leave the matter of assignments … to the university teachers" (p. 27). Moreover, although everybody involved found the new program very exciting, only a few of the required assignments were turned in by the student teachers. The usual excuses were heard. Then, after a new set of assignments had been developed, this time through negotiation by the students teachers, the teachers in the schools and the teacher educators, they finally led to fruitful pieces of work, illustrating a thoughtful consideration by the student teachers of learning and teaching inside the schools.

In her chapter, Clandinin describes and discusses this entire process of what she calls "re-storying the professional knowledge landscape" and in doing so, she contributes to a re-storying of the research landscape. Clandinin states that student teachers and teacher educators have to recognize the authority of their own practice to give productive learning a chance. The research community also has to recognize the authority of practice to conduct research that supports the development of this productive learning. By writing her self-study on the basis of her personal authority, an authority developed through her involvement with the practices in her teacher education program, Clandinin gained more insight into her teacher education practices and at the same time she has illustrated how self-study can reform the research landscape. The congruency between new views of student learning in teacher education and new views of what is relevant research in/on teacher education is beautifully summarized in the title of her chapter: *Still learning to teach.*

The shift from expert knowledge to the authority of practice in teacher education also had more problematic sides, as MacKinnon and Scarff-Seater (1997) discovered. In their self-study, they showed the pedagogical limitations of an approach in teacher education emanating, "from misguided attempts to honor students' understandings at the expense of 'right answers'" (p. 39). MacKinnon and Scarff-Seater agreed that teacher education students needed opportunities for testing, discussing, and comparing various perspectives on teaching. However, they discovered that this point of departure could lead to misunderstandings in student teachers about 'theory', as the following example, written by one of their student teachers, showed: "Constructivism has taught me (that) I do not need to know any science in order to teach it. I will simply allow my students to figure things out for themselves, for I know there is no right answer" (p. 53).

MacKinnon and Scarff-Seater concluded that attention is needed for the manner in which students learn about constructivism and the way a constructivist perspective is used in teacher education programs. Again, we see that their analysis, which may be highly relevant to other teacher educators, is based on their personal experiences and the authority of practice gained from these experiences, and thus congruent with changing views of learning in teacher education. There may, however, be another dangerous congruency involved here. How do we know that self-studies, as for example the one by MacKinnon and Scarff-Seater, which strongly rely on personal experience and the interpretation of this

experience by the actor, do not lead to misunderstandings and invalid theories in the people doing these self-studies?

In other words, the strength of self-study research work may be the congruency with what we have started to see as relevant learning by teachers, namely learning by reflecting on practice, but at the same time this may be its weakness, as it threatens traditional scientific norms of reliability and validity. We will return to this complex issue.

Dimension 2: From a Focus on Academic Theory to an Emphasis on Personal Practical Theory

Self-study research implies a shift from a focus on academic theory to an emphasis on personal practical theory. Again we give some examples. Hoban (1997) studied the learning methods of his student teachers by asking them to document how they learned during the program. The findings were classified into three categories: personal influences (49 times), social influences (84 times) and influences related to the type of activities (87 times). The category 'type of activities' included 'theory in lectures' which was mentioned only seven times. So, the contribution to the learning of students made by narrating academic theory appeared to be limited. Therefore, Hoban concluded that it was important for him to, "engage pre-service teachers as reflective thinkers in the knowledge-generating process" (p. 145). In this self-study we can see an interesting congruency: not only does Hoban emphasize that his student teachers should learn to develop their own practical theory on the basis of their experiences with the teaching of students at school, but Hoban did so himself in the course of carrying out this study on his own students.

Another example of such a congruency is the work by Regenspan (2002), who put much effort into shaping her study guides in such a manner that they show that, "we get knowledge from a wide variety of sources by drawing from a range of concepts formally explored in courses to very personal contributions of students in class that I request their permission to include. They often refer to other texts, to realities of lives outside of school, to the students' current classroom internship and to personal history and memories" (p. 548). Regenspan pointed out that she learned that her previous emphasis on texts she wished her students to know was counterproductive to what she wanted to model, namely the importance of developing ownership of knowledge. The congruency is that in this way she developed her own personal theory of practice in teacher education.

Schulte (2002) became aware of the discrepancies between her own struggles in teaching as a teacher educator and the advice she gave to her student teachers for their teaching. This led her to conclude that both teaching at schools and at the university requires simultaneous thinking at many levels. An outsider could utter the criticism that this outcome of Schulte's self-study only confirms what has already been described in academic descriptions of teaching practice. It is the very point, though, that by arriving at this conclusion Schulte has developed

a personal practical theory with a very specific and practical meaning for her as a teacher educator, as it is grounded in concrete and personal confrontations.

As with the first dimension, it is not too difficult to also see a disadvantage related to the second dimension, described here as a shift from a focus on academic theory to an emphasis on personal practical theory. If researchers in the self-study tradition rely too much on their own practical theories, they may overlook valuable academic theory, which itself may cast an important light on the processes going on in their work as teacher educators. For example, classical theories on interpersonal communication such as the Systems Theory developed by Watzlawick, Beavin, and Jackson (1967) or theories about helping interventions during supervision are undoubtedly useful to the understanding and improvement of one's practice as a teacher educator. It would be risky if such a theory is not linked with the personal reflections of the teacher educator/researcher and if teacher educators start to reinvent the wheel on the basis of a limited theoretical framework. This is also emphasized by Bullough (1997). He explains how on the one hand the principles for teacher education he identified emerged from thinking about his own practice, from his own experience of being a teacher educator, but on the other hand how important the help of 'public theory' was in nurturing and refining or in undermining the findings of his experiences. He states: " Public theory has on occasion helped me to know what to look for and helped me better to see, to anticipate consequences" (p. 20).

The same focus on the need of a balance between the development of personal theory and the use of more traditional academic frameworks is seen in Russell's (1995) work. He went back to the classroom as a teacher and documented his learning processes. He states that, "always in the background [was] the literature of science education [challenging] me to attempt different teaching strategies [and] my teacher partner [who] had natural and appropriate inclinations to assume that I would conform to some of his practices" (p. 107).

When, in the process of developing a personal practical theory about teacher education practices, more traditional academic theory is not completely dismissed but incorporated, the community of teacher educators may finally arrive at the formulation of a sound "pedagogy of teacher education". This is something that is largely non-existent at present (Korthagen *et al.*, 2001, pp. 15–18), thus almost leaving this community in a pre-professional stage.

Dimension 3: From a Focus on Generalization to a Focus on Unique Situations in their Contexts

Both in teacher education and in research on teacher education, we have witnessed a shift in focus from the general to the particular. For example, Barksdale-Ladd, Draper, King, Oropallo, and Radencich (2001) wrote case stories about their students writing case stories. They found that writing case stories helped their students to develop context-specific understandings. And the same appeared to be true for the authors themselves: they developed their understanding of the

principles involved in using case stories in teacher education through their focus on the unique case-studies of their student teachers. For example, one of the things that came to the fore through their self-study was that although providing a forum to their student teachers to express and explore the dilemmas they faced in their unique situations in the schools, Barksdale-Ladd and her colleagues could not always provide solutions for the sometimes touching and painful teaching dilemmas of their student teachers. Of course, this is not unique for their teacher education program, but because they studied so intensely the specific situations of their student teachers, this problem became more clearly (and painfully) visible than in the work of teacher educators who paid less attention to the unique situations in which their student teachers worked.

Tidwell (Tidwell & Heston, 1998) used her students' work to study her own practice. Her students tutored a child in a one-to-one setting for an aggregate of 30 hours. These sessions were videotaped and the students previewed the videos, using a practical argument approach, from two perspectives: the perspective of the tutor and the perspective of the other. Next, the students shared their findings with a supervisor, for example Tidwell or another faculty member. Tidwell found the use of plans, videotapes and practical arguments very helpful: they informed her about the effects of her own teaching and the teacher education program. For example, she discovered that the students did not use techniques for assessing the progress of the children they tutored, although these techniques had been presented to them in the teacher education program and the supervisors had tried to stimulate assessment by asking questions such as: "How do you know your client is improving?" Tidwell re-addressed this issue in her class by using the same type of self-study approach that she promoted in her student teachers. In this way, she developed an approach to improving the unique situations of her students in their role as tutors as well as the specific practices in her own teacher education class.

Bass, Anderson-Patton and Allender (2002), functioning as critical friends to each other, also studied their individual unique situations. Bass and Anderson-Patton developed teaching portfolios while mentoring student teachers developing their portfolios. Bass taught remedial students and described her purpose as, "transforming working-class students into middle-class workers" (pp. 62–63). Anderson-Patton discovered that she could not ask students to foster creativity in their teaching while ignoring her own internal creative voice and resumed studying the piano after a ten-year gap. Allender combined stories written by his students about their tensions and frustrations with stories he himself wrote about his own tensions and frustrations as a teacher educator. Working with his female colleagues Bass and Anderson-Patton he discovered that his male, white and educated entitlement made him work from the assumption that he should take the lead in showing people where he thought they needed to go and that it would be difficult for them to get there without his help. What he learned through his self-study was to put more trust in other people's own potential and to recede into the background more often. The focus of these three self-studies was on the process of personal meaningful learning in unique, often very personal

situations, and the positive ripples of this learning "in terms of one's ability to remain flexible with and for others" (p. 67).

We can conclude that these examples show significant outcomes for the teacher educators doing this kind of research. However, the risk of the third characteristic of self-study work may be that researchers may become too focused on their own unique practice and forget to reflect on the significance, or lack of significance, of their work for others, not only in terms of a better mutual understanding, but also in terms of the production of knowledge. Hence, the most fundamental criticism of certain self-studies may be summarized by the phrase "So what?" In the light of further acceptance of self-studies by the broader research community it is important that researchers in the self-study tradition explicitly deal with questions of generalizibility. This does not imply that the development of insight into specific, unique situations would not be of importance in its own right, but at least that the authors who describe and discuss their insights into their own situations, are aware of the limitations of their work.

Dimension 4: From an Exclusive Focus on Individual Learning Towards an Emphasis on both Individual and Collaborative Learning and their Interrelatedness

Loughran (1996) was one of the first educators who started to study his own teacher education practice. He was also one of the first to recognize the added dimension of combining individual learning and collaborative learning. What started as an attempt to demonstrate to students the bonus of teaching together, also became a joint learning process for Loughran and his colleague Berry, as illustrated by the following text of Berry's:

> As part of the lecture, I drew a concept map on the white board with linking lines between the words. When I had finished the map, John [Loughran] asked 'What are the lines for?' I had thought this was self-evident, so I hadn't described their purpose. I knew he knew what the lines were for too, so I figured his question was to point out to me my assumption that the students would know what the linking lines were for, when perhaps they didn't. … I quickly answered his question and moved on. I didn't pick up on the idea that we might capitalise on the moment as a teaching situation because, at the time, I was not comfortable to look. … I have to trust that I will see and know how to capitalise on these opportunities for learning. That is unsettling. But it's also okay because we do trust each other. (Berry & Loughran, 2002, p. 18)

Another example of a collaborative learning process is described by Wood and Geddis (1999). Wood explored the 'thinking aloud' manner of explaining pedagogical choices to his student teachers, which he called 'giving metacommentary'. While he was teaching and reflecting, Geddis observed Wood's course and questioned him thoroughly afterwards. In this way, both were learning.

Heston describes how she discovered that her students did not pick up on her

theoretical instruction (Tidwell & Heston, 1998). As a result, she switched rather drastically to trying to engage students in collaborative thinking and she found she had "a noisy, active classroom" in which she thought everybody appeared to be learning. However, the results of the assignments she gave to her student teachers did not confirm that a better type of learning had taken place. Heston organized a discussion group of colleagues to study their own beliefs. One of her important discoveries was that she would like her students to be, and learn, the way she herself did. So, while engaging her students in thinking, in fact she was still 'telling' her students how to learn instead of supporting them to find their own paths. Without including her colleagues in her self-study, her focus might have stayed biased and she might not have made this important and confronting discovery.

Guilfoyle, Hamilton, Pinnegar and Placier (1995) started documenting their own individual learning processes as teacher educators. They analyzed these processes both individually and together: "We examine both our successes and our failures, and we ask our students to join us in this examination" (pp. 52–53). These authors emphasize the more overall results of self-studies of teacher educators. They are convinced that through walking one's own path and documenting this, combined with reading, reflecting and analyzing, individually as well as collaboratively, that teacher educators will "re-create and redefine teacher education".

Improving the Quality of Self-study

In spite of all the positive gains from self-study work at the personal, institutional and collective levels discussed above, and the interesting congruency between the nature of self-study and developments in teacher education, which we have summarized with the aid of the four dimensions, we have also pointed at flaws and risks involved in self-study work. Partly, these may be the inevitable consequence of this form of research, the negative side of all the positive gains from self-study work. However, now that we approach the end of this chapter, we think we have to go as far as possible in extending the conclusions formulated in the previous section and further elaborate possible points for improvement of the quality of self-studies. The reason lies in our belief that high quality self-studies are a necessary requirement for the continuous improvement of teacher education: top-down approaches to the restructuring of teacher education are simply ineffective, as they only indirectly affect the everyday practice of the teacher educators involved. Real improvement, we believe, has to come from within teacher education, in an inductive way. Sound self-study work cannot only support such developments, but as we have seen in many examples in this chapter, it can also elicit them.

It seems to be possible, by careful reflection on the principles contributing to high quality self-studies, to at least avoid some of the problems associated with research in the self-study tradition. With their study, Bullough and Pinnegar (2001) contributed to such a careful reflection. They stated that self-studies stand at the intersection of biography and history. In their view, self-studies should

not focus on the self only, but on the space between the self and the practice, embedded in context and time. Bullough and Pinnegar warn us that even when a self-study is valuable for the personal development of the writer, this does not mean it has to be published. This remark resonates with our own experiences when preparing this chapter for the Handbook. We found several examples of self-studies describing the experiences of a teacher educator using a specific approach and perhaps also the evaluations of his or her students on this approach, but which did not add something superseding the uniqueness of the situation or that raised doubts about the methodology involved.

When we combine the outcomes of the discussion of the four dimensions (as presented in the previous section) with the variety of ideas formulated in the Bullough and Pinnegar paper, each of the four dimensions can be translated into guidelines for quality in self-studies:

Guideline 1: It is important to base self-study in teacher education on practical experiences, while at the same time addressing issues of validity and reliability

Above, we pointed to the risk of a strong reliance on personal experience and the interpretation of this experience by the actor, which can lead to misunderstandings, unreliable conclusions and invalid personal theories. Bullough and Pinnegar point to another aspect of the validity problem: the importance of discussing and perhaps reformulating the definition of validity. In this respect, they try to broaden mainstream views of what counts as sound methodology. For example, re-definitions of validity as trustworthiness or accuracy seem to be more proper for self-study research than the traditional definition. In this context, Bullough and Pinnegar point to intellectual traditions such as psychoanalysis and phenomenology. These can throw a new light on the conditions for validity in self-studies. They conclude that while on the one hand self-studies should meet the quality criteria of research in social science, self-studies can also help to broaden what counts as research on the other.

Guideline 2: It is important for a self-study to develop personal practical theory about teacher education, which can lead to a fruitful 'pedagogy of teacher education', while at the same time connecting this theory with more traditional academic theory

Citing Mills (1959), Bullough and Pinnegar state that there is an important relationship between personal growth and understanding and public discourse about that understanding. Through a personal theory, the public theory can be translated, come alive and influence educational practice. This parallels our second principle that it is important to develop one's practical theory about teacher education, while at the same time connecting this theory with more traditional (public) theory. In this context, it is also interesting that Loughran (2002) points at the importance of reframing in self-studies: "It is not sufficient

to simply view a situation from one perspective. Reframing is seeing a situation through other's eyes" (p. 243).

However, Loughran and Northfield (1998) state that it is, "very difficult for individuals to change their interpretations (frames of reference) when their own experience is being examined" (p. 16). Our own experience is that the confrontation of one's personal practical theories with academic theory can often offer such a change of perspective.

Guideline 3: It is important for a self-study to use the power of studying unique situations in their contexts, without forgetting to consider the degree to which the results of these studies can be generalized towards other situations

Above we emphasized that there is a certain risk that researchers in the self-study tradition forget to consider the significance of their work for others. This warning can also be connected with the findings of Bullough and Pinnegar: "As we read teacher educator autobiographies, our own included, we find ourselves asking: 'If we did not know this person, would we care, would we read on'?" (p. 17). It seems to us that teacher educators who carry out a self-study should explicitly and critically reflect on the degree to which the findings can be connected with and embedded in the discussion within the professional forum.

Guideline 4: It is important to realize both the value of individually oriented self-studies and more collaborative studies and their interrelationships

In one of the previous sections, we described personal and collective gains, but also discovered that in an institutional context self-studies were not always appreciated. Myers (2002) gave a possible explanation for the finding that collective learning through self-study in general seemed to be more successful than institutional learning. He saw three reasons:

1. Within an institution, people cannot choose their colleagues and therefore persons not having a positive orientation towards self-study also tend to become involved.
2. Within an institution, people see each other's day-to-day work whereas in working collaboratively with persons from other institutions one can hide what one chooses to hide.
3. Self-studies among colleagues within an institution will tend to focus on programmatic aspects rather than on personal activities. (p. 138)

As Bullough and Pinnegar emphasize, collaborative self-studies may have the advantage that they facilitate estimations of the usefulness of a self-study to others and that they stimulate the generalization of the results to other situations (see guideline 3 above), because in collaborative self-studies, the participants function as producers as well as consumers of knowledge.

As mentioned earlier, Kubler LaBoskey, Davies-Samway, and Garcia (1998)

stated that collaboration in self-study does not aim at consensus, but at inter-action. Elaborating on this, Bullough and Pinnegar also warn against the pitfalls of collaborative self-studies. The methods used for collaborative self-studies, such as correspondence, email exchanges and recorded conversations, ask for editing and logical organization, and can therefore lead to self-censorship, and lack of openness. Evidence of what the conversations reveal, but also of contradictions, disagreements, limits of views and critical interrogations about the relationships, must be provided.

Although these are, in our view, four important guidelines for quality in self-study, of course more can be formulated. Some examples of other guidelines that Bullough and Pinnegar formulate, and that we very much agree with, are:

Guideline 5: It is important that self-study is honest and allows the reader to connect with the writer

The self-study has to provide an insight into teaching and learning to teach and should confront problems and issues an educator has to deal with. Most self-studies cited in this chapter meet these guidelines. They describe for example the challenges of multiculturalism (Oda, 1998), of the multiplicity of foci in teaching (Hutchinson, 1998), the problems of institutional resistance (Guilfoyle, Hamilton, Pinnegar & Placier, 2000). They also describe the joy (Russell, 1997), the compassion and the professional intimacy (Fitzgerald, East, Heston & Miller, 2002) that teaching teachers can offer.

Guideline 6: It is important that a self-study worth publishing shows a character development, offers a fresh perspective on established truth and has an emotional impact

The self-study by Conle (1999), who put her own professional future at stake, is a powerful example of a self-study that meets these requirements.

Conclusions and Discussion

The many examples from self-studies presented in this chapter show the impact of these studies at the personal, institutional and collective level. In this way, we have demonstrated the great importance of self-study research for the improvement of teacher education. Hamilton (1998, p. 111) even states that self-studies may help teacher educators to reconceptualize their whole notion of teacher education.

We also pointed to the potential limits to the influence of self-studies. We found that the degree to which self-studies impact on the institutional level, but also on the collective level, seemed to be influenced by those who wield power. Leaders in academia as well as editors and reviewers of academic journals can stimulate or block the impact of self-study results.

We have devoted much attention to the direct and important relationships

between developments in teacher education and self-study research. For example, we have concluded that the nature of the developments in teacher education is congruent with characteristics of the shift from traditional research to self-study research as has been shown with the aid of four dimensions:

1. Both in teacher education and in teacher educator research, we see a shift from a focus on expert knowledge to an emphasis on the authority of practice.
2. In both fields, we see a shift from a focus on academic theory to an emphasis on personal practical theory.
3. In both fields, we see a shift from a focus on generalization to a focus on unique situations in their contexts.
4. In both fields, we see a shift from an exclusive focus on individual learning towards an emphasis on both individual *and* collaborative learning and their inter-relatedness.

At the end of the chapter, we returned to these four dimensions and used them for a careful examination of the quality of self-studies. For this reason, we have formulated guidelines to be taken into account in self-studies and elaborated on them by using the work of Bullough and Pinnegar.

Through the application of these guidelines, self-study research work may become both increasingly more accepted as sound academic research, and can at the same time contrast with more traditional research, which Zeichner (1995) referred to as *an activity conducted outside the classroom for the benefit of those outside the classroom*. In this way, self-study research can produce "living educational theory" (Hamilton & Pinnegar, 1998, p. 243) and influence views of, and practices in, teacher education. In the first place, those of the educators carrying out the self-studies, but self-study may – as we have seen at the beginning of this chapter – also have a strong impact at institutional and collective levels.

We very much agree with Loughran and Northfield (1998), who state:

> In addition to encouraging self-study, we believe its proponents have a responsibility to critically analyse the nature of the process and the features of the new knowledge it yields. In the end, the value of self-study depends on providing convincing evidence that it can be undertaken with rigour. This requires addressing the issues of quality, reliability, and validity if self-study is to continue to make a contribution to knowledge and understanding. (p. 16)

We expect that if such critical reflections as well as the guidelines for high quality self-study research are taken seriously by the community of teacher educators, self-studies may, in the long run, also convince policymakers and may appear to have an influence on teacher education much greater and much more positive than conventional research approaches have ever had. This expectation is grounded in the observation that self-study research does not require the difficult and sometimes impossible translation step that traditional research requires

from the practitioner. Self-study is already rooted in the practice that the practitioner finds relevant to study. This not only enormously enhances chances that the outcomes are immediately useful, but the most important characteristic of self-study research may be that it is carried out from an insider perspective, and that the language with which the design and results of a study are captured is the language of the teacher educators themselves. This implies an impressive step forward in the possibilities of teacher educators to make the outcomes of their professional efforts understood by their colleagues. As such, self-study research contributes to a process of growing professionalism and empowerment of the teacher educator community as a whole.

Notes

1. However, a more fundamental problem has also surfaced: effective teacher education does not seem to be based on either practice or theory, but on the integration of both (Brouwer, 1989; Korthagen *et al.*, 2001). The question of how to integrate and tailor practice and theory within teacher education curricula is currently far from being answered in any definitive way (Korthagen & Kessels, 1999).

RESEARCH, PRACTICE, AND ACADEMIA IN NORTH AMERICA*

Ardra L. Cole and J. Gary Knowles
Ontario Institute for Studies in Education of the University of Toronto

Abstract

The self-study of teacher education practices has found its place on the teacher education landscape as a principled, scholarly practice that has begun to shift understandings about the nature and significance of teacher educators' work and what counts as acceptable academic scholarship. Self-study scholars have brought their individual career histories and commitments to teacher education to bear on their academic roles within the context of the university and, in so doing, have taken up a challenge to shift status quo perspectives on the role and status of teacher education in the academy. Through individual and collective action self-study scholars have responded to criticisms levied against the place of teacher education in the academy, dilemmas presented by the nature of their work and roles, and challenges facing them in their professional and academic work. In this chapter we focus on the tenure system in North American universities and the role it plays in monitoring, mediating, and moderating the individual and collective practice of teacher educators. We offer a framework for reconsidering the norms of academic convention and the socializing forces that govern teacher educators' work in the academy and a vision of what such a reorientation might mean in practice. We then draw on this framework to explore how the self-study of teacher education scholarship and practice, as a genre, has positioned itself to challenge the status quo of academic convention for schools, departments, and faculties of education.

Faculty members in schools, colleges, faculties, and departments of education have been variously described as: *the most maligned of academics* (Lasley, 1986);

---

the least welcome guests at the educational lawn party of the establishment of higher education (Ducharme, 1986); and, *marginal people at the periphery of the university* (Ryan, 1975). While blanket generalizations about education faculties as a whole have limited validity, at least from a post-positivist standpoint, there are certain truisms about which there is little question and for which there is abundant empirical support. Regardless of institutional status (according to the Carnegie classification of universities), whether elite research universities or lower ranked colleges of education modeled after normal schools or 'teacher training' institutions of the early twentieth century, education schools, colleges, faculties or departments within those institutions are at the bottom of the heap (see for example Lanier & Little, 1986; Lucas, 1997). They have low prestige, minimal resources, and negligible institutional power and authority.

One of the most powerful systemic forces governing faculty practice or expression of knowledge in North American universities is the tenure system. In this chapter we focus on the tenure system and the role it plays in monitoring, mediating, and moderating the individual and collective practice of teacher educators. We offer a framework for reconsidering the norms of academic convention and the socializing forces that govern teacher educators' work in the academy and a vision of what such a reorientation might mean in practice. We then draw on this framework to explore how the self-study of teacher education scholarship and practice, as a genre, has positioned itself to challenge the status quo of academic convention for schools, departments, and faculties of education.

As a starting point, we draw parallels between knowledge that is individually developed, held and expressed, and knowledge that defines a collection or community of individuals. We begin with the assumption that what individual teacher educators know and how they know is a reflection of who they are and where they have been. How they express their knowledge within academic institutions is marked by the intersection of lives and context. In other words, the knowledge that individual teacher educators bring to bear on their practice is multifarious and idiosyncratic, informed by experiences, conditions, and events over a life and career span. How that knowledge is articulated is a function of the relationship between who they are as individuals – what they stand for, believe in, strive toward – and the institutions and systemic structures within which they work. Similarly, as a community or professional body, teacher educators are defined by, and operate from, a collective (albeit diversely nuanced) knowledge base that differs and sets them apart from other professions and disciplines. The collective knowledge of teacher educators is mediated within and by the institutional contexts within which it is situated. This idiosyncratic collective knowledge is a reflection of what teacher education is, how and why it has developed, where it has been situated historically and its current location within the university.

What we intend to show in this chapter is how, as a collective, self-study scholars have brought their individual career histories and commitments to teacher education to bear on their academic roles within the context of the university and, in so doing, have taken up a challenge to shift status quo

perspectives on the role and status of teacher education in the academy. Self-study scholars, through individual and collective action, have responded to criticisms levied against the place of teacher education in the academy, dilemmas presented by the nature of their work and roles, and challenges facing them in their professional and academic work. We begin with an historical overview that sets the context for our analysis and commentary.

The Teacher Education Professoriate

Over the last two decades of the twentieth century the profile of teacher educators put forward in much of the literature on the teacher education professoriate is highly pejorative. Examples abound. Lanier and Little (1986) in the *Handbook for Research on Teaching*, ascribe teacher educators the following characteristics: low level knowledge and skills primarily associated with a practical focus rather than high level or abstracted knowledge; practical rather than theoretical or abstract orientations; less scholarly productivity than their academic "peers"; lack of cognitive flexibility necessary for the kind of knowledge development and creativity expected in higher education; conservative and conformist orientations; and, lack of indoctrination in cultural norms and values of the academy. Lanier and Little acknowledge the identity struggle that characterizes teacher educators' careers in the academy and, to justify the situation, blame teacher educators themselves – their "humble social origins" and "cultural characteristics" – for their lack of fit in the academic culture. Adopting a blatantly classist stance they describe teacher educators as a group having lower social class origins which fundamentally affect their ability to belong to and adequately function within institutions of higher education.

Ducharme and Agne (1989) similarly malign the teacher education professoriate with its faculty members of humble social and intellectual origins. These authors basically attribute the low status of education within universities to the anti-intellectual orientation, inferior social standing, and questionable academic pedigree of its faculty. Even though, in a more recent study, Ducharme (1993) acknowledges that a shift in profile has occurred, that teacher educators are more closely approximating academic standards, still, the classist, elitist, patriarchal stance reflected in these analyses is disarming.

Raths, Katz, and McAninch (1989) offer another of the more disparaging profiles of teacher educators. They use a framework developed by Freidson (1972) to analyze the medical profession in order to compare the orientations to knowledge, research, and practice of health care scientists with the orientations to knowledge, research, and practice of clinicians such as teacher educators. According to this analysis (which the authors claim to be "descriptive and neutral" with no "derogatory connotations" intended), scientists are reflective and inclined to seek further information, concerned with adequacy of methods and robustness of data, want to develop concepts and explanations that make sense, are scholarly and read research reports of others, and strive to uncover laws that account for phenomena. By implication, teacher educators reflect none

of these qualities, interests, or practices. Instead, as mere (adjective implied not stated) clinicians, they act unquestioningly, show concern primarily for whether something will work (presumably regardless of its moral worth or philosophical, pedagogical or other merits), rely on personal experience as a test of virtue or validity, and believe that real world phenomena are too complex to be lawful.

Raths and his co-authors question the suitability of the university as a home for teacher educators given their lack of regard for research and, by extension, lack of facility for researching. They maintain that, as "norm breakers," teacher educators will continue to be sanctioned for their non-conformist attitudes and behaviour until either the teacher educators comply with university standards or leave:

> Teacher educators often show their disdain for research and research process. They generally do not engage in research; they find it uninformative. Furthermore, they share negative views about research with their colleagues. … Their generalized lack of respect for research and their abstention from research rebounds against them. (Raths, Katz, & McAninch, 1989, p. 114)

The authors go on to suggest that teacher educators should perhaps be removed from university settings and assigned to "special purpose institutions" (not unlike the normal schools or teachers colleges of earlier times) or perhaps be isolated within the university so that they can carry on with their anti-intellectual work. While there is merit in a debate about the place of education in universities it is the disparaging tone of these authors that stands out. It is teacher educators' clinical, anti-scientific mentality that is 'the problem'. Similarly, Burch (1989) demands that education professors "examine their individual behaviors and attitudes to determine if they reflect the commitment to [narrowly defined] scholarship fundamental to professing" (p. 103).

Who are these teacher educators of whom these various authors speak? Such depictions bear little resemblance to the teacher educator scholars we know and have studied. The characteristics and practices described certainly in no way resemble what those involved in the self-study of teacher education practices stand for and express. Is it the teacher educators who are the problem; or could it be that teacher educators' status within universities is perpetuated, in part, by these characterizations and by a blatantly functionalist view of the university as a static, unshakable, unquestionable culture? While it is not our purpose here to explore how teacher educators have earned such a reputation, this acknowledgment does underscore the magnitude of the challenge teacher educators face as they struggle for acceptance in the academy.

If the above depictions do, in fact, describe any teacher educators they are likely a small minority, certainly not a broad swath of the contemporary professoriate and certainly not enough to define an entire professoriate. We suggest that there are more resonant portrayals. For example, in a study of teacher educators conducted in Canadian universities (and we assume that there is sufficient similarity between Canadian and American teacher educators to extrapolate),

Cole (1999) put forward the following characterization that stands in dramatic contrast to the analytic profile of the teacher education professoriate described in much of the literature:

> The teacher educators who participated in the study ... all took up their tenure-track positions after working numerous years as classroom teachers, school administrators, curriculum consultants, special education/resource specialists, or staff, program, and/or community developers. Many had several years' experience teaching part- or full-time at a community college or at a faculty of education in a non-tenure track position. Among the group were two winners of awards for outstanding [doctoral] theses, the winner of an award for outstanding writing, book authors, winners of major research grants, and journal editors – in short, they had made significant scholarly contributions to the field of education.

> Almost without exception, their choice to become teacher educators involved career changes with high associated costs. For various reasons, they left or chose not to return to secure jobs with associated professional status and established reputations, instead taking up positions at a lower salary and with no job security, no status in the institution, no established reputation, and, therefore, minimal credibility with students and/or colleagues. In addition, there was often little technical or clerical support for their work. ... A tireless commitment to education and to work in general is a driving force in these teacher educators. Education is my life," said one, although most admitted they were being driven to exhaustion by work demands. Their commitment to teacher education and to "making a difference" seems to outweigh any concerns associated with their vulnerable status in the institution. (pp. 283–284)

Other similar portrayals can be found in Cole, Elijah, and Knowles (1998), Hamilton (1998), Knowles and Cole (1996) Pinnegar and Russell (1995), Russell and Korthagen (1995). Authors in these edited volumes, through intensive and often personal examinations, with self-study being a primary goal and process, permit more than a glimpse into the education professoriate. They reveal the passions, anxieties, frustrations, commitments, and complexities that characterize teacher educators' work. The result is a starkly different depiction than that offered by the aforementioned critics of teacher educators. Perhaps it is in part, as Ducharme (1993) posited, that the changing times have shifted the profile of the new generation of teacher educators. Or perhaps, it is not that teacher educators have changed but rather that, in large part through the collective will and practice of those such as self-study scholars, a shift has occurred in the way that teacher educators are viewed and understood within the broader academic community (a point we will address in the next section).

While we do not wish to romanticize or overestimate the current status of teacher education within the university and the role that the self-study community has played in facilitating any positive gains in status or acceptance, or

to claim any empirical evidence of such a shift, we do wish to point out that the scholarship of self-study of teacher education practices professors bears a strong resemblance to Wisniewski's (1989) vision of "the ideal education professor":

> Professors who are active in their field ... persons committed to strengthening their teaching, to probing and expanding their scholarship, to working closely with public schools; ... who share the excitement of experimentation in education; ... from whom one can learn as a peer or as a student. ... One who values and takes pride in the interrelationship among scholarship, teaching, and professional service. ... recogniz[ing] that these activities nurture one another and cannot be separated. (p. 144)

We also argue that this group of scholars, along with members of the American Educational Research Association Division K, Teacher Education, has been largely responsible for establishing teacher education as a *bona fide* field of study within the academy.

Teacher Education as a Field of Study and *Bona Fide* Discipline

In a recent, compelling analysis Tony Clarke (2001) traces the evolution of teacher education as a recognized field of study. Using a cartography metaphor to chart points on the teacher education landscape, he demonstrates how a rise of institutional regard for teacher education and teacher educators has occurred over the past fifty years along with a concomitant increase in teacher educators' emphasis on scholarship and scholarly work.

The chronic discrepancy between institutional regard for the role of educator 'teacher' and 'scholar' ", he asserts, have been "a constant impediment to the development of teacher education as a field of study." He goes on to posit that such a discrepancy "has diminished in recent years to such an extent that the two are coming together in unprecedented and productive ways (Clarke, 2001, p. 599).

The critical points to which he attributes this shift in status are: the emergence of refereed journals specializing in teacher education, publication of several academic reference texts on teacher education, and the establishment of a number of significant academic associations focused on teacher education.

All of these events, Clarke argues, evidence the development of a concerted interest in and effort to define and bring coherence to the field of teacher education and to develop a body of specialized knowledge within the field. Between 1970 and 1990 seven new refereed journals specializing in teacher education emerged. Over a period of nine years alone five comprehensive reference texts in teacher education were published: *International Encyclopedia of Teaching and Teacher Education* (1st edition) (Dunkin, 1987); *Handbook of Research on Teacher Education* (1st edition) (Houston, 1990); *International Encyclopedia of Teaching and Teacher Education* (2nd edition) (Anderson, 1995); *Handbook of Research on Teacher Education* (2nd edition) (Sikula, 1996); and

Teacher Educator's Handbook (Murray, 1996). Between the early 1970s and early 1990s several international associations were formed to provide forums for meetings and discussions about teacher education. Among these groups are: the Canadian Association for Teacher Education, a subdivision of the Canadian Society of the Study of Education; Division K, Teaching and Teacher Education, of the American Educational Research Association; and, the Self-study of Teacher Education Practices, a Special Interest Group of the American Educational Research Association.

Ken Zeichner (1999) traces the development of teacher education research in the United States over the last 21 years and summarizes its evolutionary significance in this way:

> Given all the developments that have taken place in teacher education research over the last two decades, it is time that research in teacher education be given the respect that it is entitled to in the educational research community. … That this research has not received the attention it deserves in the educational research community and in policy circles is more a reflection of the historical prejudices against teacher educators and teachers than it is of the quality of the research itself. (pp. 12–13)

From an historical perspective, what is the significance of the appearance of teacher education as a legitimate field of study? Using Burton Clark's (1988) analysis of academic cultures and observation that a clearly defined disciplinary identity is key to establishing a legitimacy and presence in institutional settings, we argue, along with Clarke, that, until relatively recently, teacher education has neither identified itself nor been identified as having a body of specialized knowledge. This lack of recognition as a 'subject' per se has, in part, contributed to education's low status within the university – a status which Clarke conjectures has significantly shifted over the past few decades and will likely continue to do so. It is helpful, then, to briefly explore the history of teacher education within the university as a backdrop to understanding the role that self-study scholarship has played in shifting understandings of the place and status of teacher education in the academy.

Education in the Academy

In North America, teacher training institutions moved into universities throughout the twentieth century. Prior to being affiliated with or located in universities, most formalized initial teacher preparation took place in community or land grant colleges (in the United States of America), normal schools, provincially mandated teachers' colleges (in Canada), or other tertiary institutions with solely a professional mandate. (For a comprehensive account of the history of teacher education in America, see Lucas, 1997 and for a similar account of Canadian teacher education, see Johnson, 1968). Such a move was a strategy intended to professionalize teaching and raise the status of the education profession that,

historically, suffered low social status and lack of economic resources (Clifford & Guthrie, 1988). Recent moves to offer a variety of alternative teacher certification programs with little or no involvement of higher education institutions, particularly in the United States, and programmatic decisions (in both Canadian and American universities) that are largely market driven, serve to powerfully perpetuate the status quo reputation of education faculties, schools, and departments. Such moves keep schools of education struggling for acceptance by and legitimacy within the university system.

In a long struggle for acceptance and identity within the university, educators and educational researchers historically have been as round pegs misshapen to fit the square holes of the university's value system as it pertains to academic credibility or merit. Regardless of its adequacy or appropriateness as an approach for researching educational issues or problems, universities set the scientific method, originating in the natural sciences, as the standard by which academic worth is judged and they have challenged educational researchers to prove their academic worth. One result has been a frenzied proliferation of educational research that measures up to scientific standards but has little or no direct relevance to educational practice. A concomitant result has been the alienation of educational researchers from their own discipline. As Shib Mitra (1974) puts it, "In the field of education, one would like to see a systematic study of significant problems rather than a scientific study of insignificant problems" (p. 234).

Pulled between commitment and allegiance to the professional community and identification with and acceptance by the academic community, schools of education have been caught in an institutional tug-of-war. The professional community has lost considerable ground as the stronger forces of prestige and status pulled schools of education closer to the norms of the university. But, as Schwebel (1989) asserts:

> There is nothing appealing about having to "look up" to one's supposed peers in the academic community. Or, at the same time, in "looking down" at those in the schools to receive sneerful expressions about the impotence of their research. (p. 58)

With the pleasures associated with pseudo-academic recognition have come confusion and uncertainty about identity, roles, rules, and conditions of the relationship between Education and the disciplines of the rest of the university. One painful discovery for education professors is that, "There is an inverse relationship between professional prestige and the intensity of involvement with the formal education of teachers" (Lanier & Little, 1986, p. 530). The pain in this discovery lies in the conflict of values this represents – a conflict apparent both within schools of education, between those faculty members who align themselves with the profession, and those who see themselves as theoreticians and academicians (Hazlett, 1989; Roemer & Martinello, 1992), and between schools of education as professional schools and the academy as an elite bastion of narrowly defined intellectual discipline.

Donald Schön (1983) describes the hierarchical relationship between universities and professional schools. Citing Veblen (1918/1962, p. 36) he states:

> Quite simply, the professions are to give their practical problems to the university, and the university, the unique source of research, is to give back to the profession the new scientific knowledge which it will be their business to apply and test. Under no conditions are the technical men [sic] of the lower schools to be allowed into the university.

This analysis also applies even *within* schools of education. It is poignantly apparent in the following statement by Ducharme and Agne (1989):

> On many campuses, [education] faculty fills three metaphorical roles: beasts of burden, facilitators, and academicians. In the first are those who flit from place to place, carrying equipment, reprints, games, and transparencies as they do differing versions of academic dog-and-pony shows; the second, those largely "contentless" persons who apparently see their function in life as bridging the work of others; and the third, those who teach, advise, study, and write with inquiry, rigor, and scholarship uppermost. (p. 83)

When teacher training institutions joined the university they brought with them faculty who were practitioners and who had little or no expertise in researching. These teacher educators had many skills but those associated with research were not among them. Being researchers had not been required of them and was, therefore, not part of their orientation or knowledge base. At the time, the definition of research was narrow and that definition had very little to do with practice or professional education. Research was for scientists and scientists had highly specialized skills and areas of research. Teacher educators did not belong to this elite group. This created a class system of the separation of those who teach and those who research within higher education institutions that specialize in teaching and universities that specialize in researching.

A demand for a more scientific approach to education was well received by some educators and rejected by others. Those who wanted to develop the science of education and who wanted to be education scientists themselves worked hard to establish programs of educational research, based on the scientific method of course and that had little or no direct relevance to the day to day practice of teaching. Within programs of education these educational scientists (often educational psychologists, for their work was grounded in an accepted discipline) earned some favor within the university and broader academic community and carried on with their agenda of developing a science of education. Burdened by large numbers of students and the pressures of teacher certification, other faculty members in schools of education continued to place their energies into the professional preparation of teachers where scientific enterprise had little value. Thus began the unfair division of labor that prevails in many schools of education along with instrumental, overly-structured teacher education curricula that make professional preparation programs more like high school than university work;

the kind of division to which Ducharme and Agne (1989) refer. To be other than a scientist of education engaged in the "scientific study of insignificant problems," as Mitra (1974, p. 234) put it – that is, to be a professor committed to the improvement of preparation programs and the quality of teaching and learning in schools, for example – required more grounded interests and actions contrary to the models of research valued by institutions. So it is, as Milton Schwebel (1989) states, that a key dilemma continues to trouble education faculty:

> [Do they] perhaps become mired in finding ways to make the schools work for larger proportions of children, or follow a safer, more traditional academic path[?] If education faculty are to 'make it' under the new priorities in the university, and if their research is to be useful in the schools, they must choose the riskier course. (p. 64)

Those who engage in self-study research have chosen this riskier course although, for self-study scholars, it is not an 'either/or' but a 'both/and' solution. The broad agenda defining the work of self-study scholars consists of finding ways of making schools work *through* programs of relevant, academic scholarship. For self-study scholars, among others, this also means challenging the conventional definition of research and replacing mainly positivist approaches with those that better reflect both the complex and nuanced nature of education and the interrelationship of practice and theory. Although there are multiple approaches to self-study, in general self-study research is personal, explicitly subjective, practically-oriented, aimed at improving professional practice as well as developing knowledge beyond the self, qualitative in nature, and usually creatively communicated in narrative form. As such, in epistemology, purpose, method, and form self-study research stands in opposition to the norms and conventions of academic scholarship.

Roles and Expectations of Teacher Educators

In this section we elaborate on the dual allegiance of teacher educators to the university and field. We delineate the expectations demanded by each community and discuss how self-study practice and scholarship sits at the nexus of the two communities.

Faculties in schools of education are caught in a bind. On the one hand, they are committed to meeting university standards of scholarship, research funding, prestige, and general operations associated with academic institutions (Newport, 1985). On the other hand, they are obliged to respond to standards associated with teaching excellence, professional service, and relationships with schools and community set by the professional community and the public (Nolan, 1985). As Watson and Allison (1992) point out in a report based on an analysis of policy documents and interviews with ten deans of education in Ontario, Canada these faculty members to do it all. These authors note, however, that despite valiant attempts to, "walk the thin line between the university and the field," the

"question of possible conflicts between research and teaching, and research and involvement in the field continues to bedevil faculties of education" (p. 21).

The academy, it seems, is a sacred place held in high esteem because of the power it holds and grants to its worthy members. For those with aspirations and commitments to make a difference in the lives of students and teachers and, by extension, to better institutions and society, the academy is a place where that kind of influence is deemed possible. Such individuals with secure, well paying jobs in schools or other educational settings often leave those situations to take up positions as university-based teacher educators, usually for much less salary, status, and little or no job security. Frequently, their quest for an academic life uproots them; they leave region, community, home and family. Sometimes they literally leave behind spouses and children; other separations might be more metaphorical. Once affiliated with the academy, the desire to stay is so strong that these faculty members become increasingly self-sacrificing. They become encompassed and consumed by work. Pressures to perform as teachers, researchers, scholars, and community members and personal ambitions to "make a difference" leave little time or room for life outside work, especially when those two sets of goals require different but equally demanding ways of working.

Teacher educators' work is a balancing act of activities, demands, obligations, commitments, and aspirations. The multiplistic and diverse nature of their work and the time and energy commitments involved in the elusive pursuit of a balanced professional life also makes a search for balance between the personal and professional realms of life a fruitless effort. The dual mandate of teacher educators' work that requires them to serve both the academy and the profession keeps their gaze focused on the fulcrum of their lives always striving for balance. Work and personal commitments (self, family, and community) work against one another as do professional and academic commitments. Time spent on teaching and staff development activities must be kept in check so that sufficient time is available for research and writing. Decisions about the kind of research to engage in, where to publish, and for what purposes must take into account the different sets of values that define the profession and the academy. Aspirations and commitments to work collaboratively must be carefully monitored (even in spite of rhetoric that suggests otherwise) so as to live up to the university's standards of individualism, especially for purposes of tenure and promotion. A divergence in research interests must be curtailed in order to establish a specialized and unique program of research. Given their tenuous positions within the university and along career paths, attitudes, values, and practices cannot be overly challenging of the status quo upon which structures, policies, and norms are based.

The problem for most teacher educators, especially those committed to change in teacher education, is that no matter how hard they try, the scales are impossible to balance because the weights are uneven. According to the values and standards of the university, teaching, service, professional and community development, and other activities, that have mainly local or professional implications and which demand inordinate time and energy commitments, do not carry much

weight. The university more heavily weights those activities that result in intellectual and financial prestige and international acclaim. For most teacher educators, it seems, any balance that *is* possible to achieve is always imperfect.

In a large scale survey of teacher educators' perceptions regarding self-esteem and the perceived value of their work by other academic disciplines, Reynolds (1995) ranks the unanimous affirmation by teacher educators of the conflict associated with, "serving two masters: the teaching profession and the academic community" (p. 222) among the most notable findings. Mager and Myers (1983) studied the work patterns of new education professors and concluded that 73 to 81 percent of new professors' 50 to 69 hour work week is spent on teaching, advising students, and administrative work; research and program development work could only be done by extending the work week beyond 70 hours. This is precisely what happens. Scholarly work of various kinds is squeezed into the odd cracks of workday, evening, and weekend time. We make this point knowing that this has particular relevance for new and untenured faculty who usually have different and greater pressures to perform than their more experienced and tenured colleagues.

Weber (1990), in one of the earliest in-depth interpretive studies of teacher educators, captures the essence of six participants' experiences as teacher educators and highlights, among other things, tensions related to the duality of commitment. In a similar study by Whitt (1991), the essence of the professional realities of six beginning professors of education is depicted in the title, "Hit the Ground Running." Knowles and Cole (1994), in an early piece of self-study research, compare their own experiences as beginning professors to their earlier experiences as beginning teachers and to the experiences of beginning teachers they studied. They analyzed those experiences amidst the backdrop of literature on the education professoriate and raised questions about the role the university plays in the career development of beginning professors. Writing within and about the Canadian context, Acker (1997) and Acker and Feuerverger (1996) report on an in-depth study of mainly women teacher educators and their struggles within university contexts as women, as teacher educators, and as untenured professors. Cole (1999) also writes about the challenges faced by untenured, progressive teacher educators working within conservative institutional contexts. She, along with co-creators, also poignantly depicts some of these challenges in a three-part, three-dimensional, multi-media, representation (Cole, Knowles, brown, & Buttignol, 1999a, 1999b, 1999c).

Time is the one commodity for which most teacher educators crave more. Time, assuming the presence of intellectual and physical energies needed for innovative, embryonic work to develop, is a key component which makes possible the development of conceptually sound and professionally meaningful scholarly inquiries. Time for research often comes at great costs. Teaching and supervising agendas, not to mention bureaucratic directives in the form of meetings and paperwork, simply drain many teacher educators of their energies for activities associated with research and scholarship. Such community activities are essential for the development of sound programs of instruction and the articulation of

appropriate pedagogies. Their absence in teacher education can only reflect poorly on the state of programmatic development. However, it is these very same activities (which become demands) and their institutionalization within bureaucratic structures which can deplete the energies for creative inquiry and its resulting scholarship. The line is fine indeed.

Teacher education scholars are in a unique position because so much of their work is situated in professional practice located outside of the protected sanctuaries and ivory towers of the "pure disciplines" of the arts and sciences, the standard bearers of scholarly expectations within contemporary western universities. The pressures are even greater when considered alongside the ways education departments often arrange and allocate teaching, field supervision, and field and institutional development roles and responsibilities. Colleagues in other academic disciplines would simply not tolerate the workloads endured by most teacher educators.

In the professional lives of teachers educators, generally speaking, expectations and activities associated with research and scholarship and those related to other professional demands – teaching, service, professional and community development, school-based work, reform efforts – pull against one another creating dilemmas for teacher educators that are seemingly unresolvable. Teacher educators' work is becoming increasingly difficult within the current climate of economic rationalism where: teacher educators (and others) are required to do more with less (fiscally, programmatically, professionally); emphasis on quantity (especially for purposes of evaluation) makes quality difficult (more coursework, more students, more publications, more grants); increasing outside interference by government and other legislative and policy-making bodies restricts academic and programmatic freedoms; expectations are reaching unachievable limits and stress, burnout, and disillusionment are pervasive.

Schools of education, by virtue of their position and location in the university community, traditionally have given priority to meeting university standards of performance. For faculty members, this means working within reward structures based primarily on academic merit (that is, rigorous standards of research and scholarship). It also means, as Roemer and Martinello (1982) observe, that schools of education are pressured by the university to retain a competitive edge in attracting both large numbers of high quality students to their programs and high profile academicians and researchers to serve the priorities of the university agenda. According to Clifford and Guthrie (1988):

> Schools of education … have become ensnared improvidently in the academic and political cultures of their institutions and have neglected their professional allegiances. … They have seldom succeeded in satisfying the scholarly norms of their campus letters and science colleagues, and they are simultaneously estranged from their practicing professional peers. (p. 3)

A commitment to teaching (and, by extension, to the teaching profession) historically has suggested that schools of education sacrifice their position or struggle

for status within the university structure as it is currently defined – a sacrifice few if any, it seems, are prepared to make, or prepared to even negotiate. For, as several authors remind us, the struggle for acceptance by and legitimacy within the university system has a long history and schools of education are not likely to relinquish any gains, however incremental, that may have been made over the past century (see, e.g., Clark, 1978; Clifford & Guthrie, 1988; Ducharme, 1993; Hazlett, 1989; Jones, 1986; Lucas, 1987; Reynolds, 1995).

Those who engage in the self-study of teacher education are able to maintain their dual commitment to teacher education and the academy so that they can live out their heart-felt, moral, and intellectual commitments. Through their efforts, changes in teacher education are taking place. If our comments seem to assign self-study teacher educators with qualities bordering on heroism, that is intentional. To challenge the status quo of (teacher education) institutions requires initiative, innovation, and considerable risk-taking-qualities not genuinely fostered in institutional contexts expressing long entrenched conserving values. Those who do persist, often in the face of great personal and professional risk, are heroes of a kind.

Academic Freedom, Tenure, and Rewards Structure within the University

In this section we describe the rationale for the tenure system in North American universities, how it works, and how tenure is gained. Related to this is a discussion of academic freedom within the university, its integral connection to tenure, and what it means in schools of education.

Academic Freedom

While the concept and implications of academic freedom have been widely debated and its future questioned (e.g., Tierney & Bensimon, 1996), by and large it is a right (and privilege) jealously guarded by academics. The 1940 Statement of Principles on Academic Freedom and Tenure, published by the American Association of University Professors, states:

> [University and college] teachers are entitled to full freedom in research and in the publication of the results, subject to the adequate performance of their other academic duties ... are entitled to freedom in the classroom in discussing their subject ... [and as] citizens ... and members of a learned profession ... should be free from institutional censorship or discipline. (reprinted in DeGeorge, 1997, p. 118)

Bowen and Schuster (1986), in their analysis of the Professoriate, more broadly interpret the concept of academic freedom. Citing academic freedom as one of the hallmarks of the academy, they state:

> Academic freedom includes the right of faculty members to substantial autonomy in the conduct of their work, and to freedom of thought and

expression as they discover and disseminate learning. This freedom is essential to the advancement of learning. (p. 53)

Shils (1991) asserts that the concept of academic freedom pertains to the rights and freedoms of academics to teach, conduct research, and communicate knowledge derived from their studies – a definition of academic freedom that should remain pure and, therefore, quite narrow. Those, such as Bowen and Schuster (1986) and Russell (1993), who argue for a broader and perhaps more contemporary definition of academic freedom, have been criticized by those who suggest that such elasticity weakens the concept. Skolnik (1994), for example, in a review of Russell's book, *Academic Freedom*, suggests that, "to stretch the term, academic freedom, too far, is to risk losing credibility and understanding with those groups outside the university whose respect for this principle is essential" (p. 109). DeGeorge (1997) concurs that academic freedom is necessary for the good of society and is a necessary protection that allows academics to conduct their research without fear of reprisal from political powers and pressures outside the university and, we would add, within the university. As Clark (1989) notes, with the university's increasing expansion and diversity, a universal definition of academic freedom is no longer appropriate. The concept necessarily has been interpreted to reflect the various roles and mandates of contemporary universities – a point to which we will return in a discussion of academic freedom within schools of education.

Academic Tenure and the Rewards Structure

In North America, in particular, academic freedom has come to be intricately linked with academic tenure and job security. The tenure system was created as a way of protecting academic freedom. At Stanford University in 1900, a landmark firing of a popular economics professor for his overt socialist, political views, gave rise to a series of meetings and talks which resulted in the formation of the American Association of University Professors (AAUP). This association subsequently published a report in which the concept of academic freedom was defined as a fundamental principle of all universities and colleges. The document, according to Tierney and Bensimon (1996), "set academe on the road to constructing the system of tenure that is in place today" (p. 25). The 1940 Statement of Principles on Academic Freedom and Tenure (AAUP, 1940) states:

Institutions of higher education are conducted for the common good. … The common good depends upon the free search for truth and its free exposition. … Academic freedom is essential to these purposes and applies to both teaching and research. … Freedom and economic security, hence, tenure, are indispensable to the success of an institution in fulfilling its obligations to its students and to society. (reprinted in DeGeorge, 1997, pp. 117–118)

Bowen and Schuster (1986) argue the significance of the relationship between

academic freedom and job security and cite academic tenure as part of the wider contractual commitment to academic freedom. They assert that job security is necessary so that faculty members have:

> long periods of unbroken time and freedom from distractions to perform their duties well. … Thinking and communicating are exacting tasks that require concentration and peace of mind. … One of the most costly aspects of the current anxiety among faculty about job security is the adverse affect on their productivity. (p. 236)

Most critics of the tenure system attack the close relationship that exists between the promise of academic freedom and the reward system of the university. According to DeGeorge (1997):

> The main purpose of academic tenure is to prevent the possibility of a faculty member's being dismissed because what he or she teaches or writes about is considered by either administrators or some people outside the institution to be wrong or offensive. … Without tenure, faculty members have no guarantee that they will not be penalized for presenting new ideas, for challenging accepted truths or ways of doing things, or for criticizing institutions, governments, mores, and morals. (pp. 10, 11)

In contrast, Shils (1991) maintains that tenure (or its denial) is but one of any number of potential sanctions against academic freedom. Similarly, Tierney and Bensimon (1996) criticize the integral relationship that exists between academic freedom and tenure, arguing that academic freedom is a false promise:

> If one of the reasons for the creation of tenure was to protect faculty so that they could engage in intellectual battle without fear of reprisal, then that purpose has been lost. … If a faculty member does not walk the ideological line, he or she will be at risk of not attaining tenure and promotion. (p. 8)

Tierney and Bensimon go on to assert that, because of the tenure system, the pursuit of knowledge under the protection of academic freedom has become more of a rhetorical than a real goal. They suggest that obtaining tenure rather than advancing knowledge, has become the real goal of most junior faculty members. In a subsequent analysis Tierney (1998) calls for an overhaul of the tenure system. While "protecting academic freedom as the bedrock of the academy is imperative" (p. 59), he argues, the tenure system as we know it needs to change to more appropriately function in contemporary society. According to Tierney, the focus of such change needs to be placed on the academic and institutional culture within which the tenure system is embedded.

The punishment of expulsion from academic positions is a practice with a long history. When the topic of tenure denials is raised in informal conversations among academics, it is only a matter of minutes before collective remembering

produces a lengthy list of names of prominent and not so prominent scholars, those who Tierney and Bensimon (1996) might call "radical riff-raffs purged by their universities". Given the profile and reputation of many of these scholars and the perspectives they reflect, there is little doubt about the real, though not necessarily stated, grounds for their dismissals. In some way – ideological, personal, or political – these individuals represented a threat and challenge to the status quo of the institution and were removed.

The tenure system is, as Tierney and Bensimon argue, a powerful socializing force and one of the most potent instruments of conservatism in the university. However, DeGeorge (1997) argues, it is not clear that eliminating tenure would guard against internal threats to academic freedom. In developing democratic societies such as in North America, the academic tenure system makes sense, says DeGeorge, because, "there is a widespread belief that knowledge is useful, ... not everything is known. ... and creativity and originality have an important function" (p. 15).

Many academics have openly engaged in research and practices counter to the dominant discourse of an institution and have successfully achieved tenure and the protection of academic freedom. Among this group are numerous self-study scholars. A number of self-study scholars, however, have openly defied the academic conventions of their institutions and have paid the price. Being fired for non-conformist practices, as DeGeorge says:

> has a chilling effect ... on many, many others. ... The result will be a less dynamic and bold faculty, with less in the way of new truths or techniques being developed. ... Without the example and encouragement of teachers who are bold and seek the truth wherever it may lead them, students will in turn be taught by example to be conservative and safe. The detriment to society is a less critical citizenry. (p. 13)

This 'chilling effect' achieves hypothermic proportions in schools of education where those who teach teachers, who, in turn, are responsible for the education of future leaders of society, are penalized for challenging the status quo.

Academic Freedom and Academic Tenure in Schools of Education

Is academic freedom even an issue in schools of education? In an exploration of this question Hutcheson (2001) suggests that, in the past, academic freedom might not have been of great concern for teacher education professors who, for the most part, engaged in rather non-threatening and conservative practices. More recently, however, academic freedom has become an issue as education professors' work reflects greater dissatisfaction with the social order and becomes more controversial. While the significance of the concept of academic freedom, on its own, is not so clear in the lives of teacher educators, the issue of academic freedom as it is tied to the tenure system is more straightforward.

What counts as knowledge? What counts as research? What counts as scholar-ship? These are questions to which the academy has definitive answers; questions

that are met with uncertainty in schools of education. One of the explanations given for the lack of acceptance of schools of education by the academy is the practical orientation of many of its faculty members (see e.g., Lanier & Little, 1986; Raths, Katz, & McAninch, 1989). As Burch (1989) notes, "Academic reputations are rarely made as a result of good teaching or professional service" (p. 88). For teacher educators, the weight of the pressure to publish and carry out the kind of work rewarded by the university, at the expense of other aspirations, is often burdensome.

The notion of academic freedom in schools of education provokes interesting debates. One argument is that, if academic tenure is a reward for proving oneself worthy of job security and promotional rewards and if such rewards are primarily based on conventional views of scholarly production (i.e., articles in prestigious, refereed journals or other scholarly venues deemed meritorious by university standards), then teacher educators and teacher education institutions must make a commitment to the production and communication of knowledge in ways that uphold the values, priorities, and orientations of the university. One result of following this conservative line of argument is that:

> Education faculty quickly comes to understand which research and publication efforts "count" and which do not. ... The result is that education faculty veer away from professionally demanding activities and toward those understood and hence rewarded in academic departments. (Clifford & Guthrie, 1988, p. 337)

In other words, to earn academic tenure, education faculty essentially are forced to overlook or turn their backs on their commitment to the professional community and field, that is if they want to become and remain *bona fide* members of the academy. This calls into question the meaning of academic freedom in schools of education.

There are those who argue that the definition of academic freedom, which ties it to the reward structure, is inappropriate for schools, departments, or faculties that have a professional as well as scholarly commitment (e.g., education, social work, nursing) and that a redefinition is in order. For example, Nixon (in Nixon, Beattie, Challis, & Walker, 1998, pp. 282–283) calls for "an ethical turn" from an exclusive to a more inclusive notion of academic freedom. His suggestion for redefinition includes redefining what counts as research; putting the teaching relationship first; developing professional selves; and, turning collegiality inside out. This suggestion merits serious consideration because the ideas reflect and take into account the goals, values, and commitments of teacher education as a field or discipline. Few contemporary teacher educators, especially those who define themselves as such, would argue with any of Nixon's suggestions; they likely would find his ideas refreshing. Not only do universities need to rethink or extend the definition of academic freedom to better suit, but not diminish, professional schools, teacher education institutions also need to engage in a broader examination of the concept of that freedom as provided to and experienced by faculty. Indeed, Hutcheson (2001) intimates that the role of education

professors in performing a service to a nation (or society or professional community, we would add) raises substantial questions about the appropriateness or relevance of academic freedom for this group.

Many education professors soon discover that, "the more one's work ties that faculty member to the public schools, the more marginal the rewards and status in the education school" (Holmes Group, 1995, p. 64). For, as the Holmes Group authors go on to say, "the university's reward system continues to favor a steady stream of publications over all other criteria for promotion, tenure, and merit pay" (p. 65). Even those who work in institutions where the dean of education gives prominence to teaching may run the risk of discovering, too late, that the university (usually meaning the provost, chief academic officer, or a university-wide promotions and tenure committee) actually rewards research and scholarship over everything else (Tierney & Rhoads, 1993). It is easy for deans to overtly support alternative agenda within their own faculties but the reality of their willingness to 'go to bat' within the broader institution to support such agenda is more difficult and often lacking.

In a critical commentary on the reward structure of the academy, Skolnik (1998) attributes the academy's antiquated management practices and failure to practice espoused values to a reward system that, "elevates individualism over community, competition over collegiality, quantity over quality and secrecy over openness" (p. 16). For teacher educators the implications of this analysis are amplified.

The values and priorities of the academy, which emphasize scholarship (narrowly defined), research funding, and academic prestige, are reflected in the kind of work faculty members do and get rewarded for; the values and priorities of the professional community, which emphasize teaching excellence, service to the professional community, and ties with the public and professional sector, also are reflected in faculty work. For teacher educators, the mandate to "serve two masters" (Reynolds, 1995, p. 222) demands that they be super-faculty members if they are to survive and thrive within the academy.

Each set of values and priorities demands a different kind of commitment and way of working which, in turn, requires different facilitating conditions. Schools of education, with their cultural history and ethos rooted in practice and the demands of practical problems, are not set up to support the work of teacher educators endeavoring to meet the demands of the academy. Similarly, the academy is not set up to support the work of teacher educators intent on serving the professional community. The academy is committed to protecting the academic freedom of those members deemed worthy by virtue of their ability to uphold its academic "ideals" (which are conservative translations of scholarship or what it means to advance knowledge). This is so that, as Bowen and Schuster (1986) assert, scholars can proceed with the tasks of thinking and communicating free from distractions and with peace of mind. The realities of teacher educators' work are fraught with, perhaps defined by, distractions, demands, and obligations that make "peace of mind" and, therefore, academic freedom almost an impossibility.

If one of the reasons for placing teacher education in the academy was (and is) to raise its status as a *bona fide* field or discipline, then, in order for that to happen simultaneously with the successful honoring of the academic-professional dual mandate, a rethinking of the concept of academic freedom is required. This rethinking requires teacher education institutions to closely examine the working conditions of its professoriate. At the same time, the broader university policy on academic freedom, particularly as it is tied to job security, career mobility, and financial remuneration, needs to be examined and expanded to take into account the nature of teacher educators' work and commitments. As indicated earlier and despite Ducharme's and others' suggestions to the contrary, teacher educators, particularly self-study teacher educators, are often former elementary and secondary teachers, well socialized to public schools, who have explicit notions about the ways schools could be. By virtue of their career histories and their commitment to teaching and the improvement of schools, professors of teacher education generally have a reform agenda more in line with professional community standards or priorities (as outlined earlier) than with university standards. This allegiance reflects both who they are as professionals and the institutional norms with which they are most familiar.

It is an historical reality that, "traditionally feminized occupations [such as education, nursing, and social work] are not accorded equal status and resources with male undertakings" (Clifford & Guthrie, 1988, p. 328). Acker and Feuerverger (1996) use the phrase "doing good and feeling bad" to sum up the sentiment of women education academics. They cite women's "outsider" status in the academy as one reason for their tendency to keep trying to work harder in order to prove themselves successful and comparable to their male counterparts. This same line of argument can be applied broadly to schools of education as feminized institutions. As members of a feminized occupation, teacher educators (both male and female) are used to, in Ann Oakley's words, "taking it like a woman" (Oakley, 1984). That is to say, they are so entrenched in their feminized roles that they keep working harder to meet personal, professional, and institutional demands without overtly questioning the fairness and appropriateness of such demands and the resources available to meet them. The kinds of infringements on the personal time and space that many teacher educators experience, the lack of resources available to support their work, and the sheer volume of work expected make it almost impossible for teacher educators to feel good about what they are able to accomplish and to feel like they have academic freedom or other kinds of freedom.

Feeling overwhelmed by and unable to meet high expectations and demands of the work of being a teacher educator are widely experienced. Accounts of such challenges are reported in the literature on the teacher education professoriate (e.g., Acker, 1997; Acker & Feuerverger, 1996; Cole, 1999; Cole, Elijah, & Knowles, 1998; Knowles, Cole, & Sumsion, 2000; Weber, 1990; Whitt, 1991). For example, Jennifer Sumsion (2000) writes:

My plans to stay home tomorrow to write have long since evaporated. If I

put in at least another 12 hours in my office instead, I *might* be able to salvage a writing day later in the week. I had such high hopes of the writing that I would do during the semester break but these were eroded by an onslaught of assignment marking and faculty meetings; on-campus sessions for distance education and … graduate students; obligations arising from a recently awarded teaching development grant; and the vast number of telephone calls associated with coordinating a practicum, and supporting students, cooperating teachers and university advisers through the personal and professional crises that a practicum so often precipitates. The debris of those various responsibilities surround me now. (2000, p. 78)

These comments concisely summarize the demands on teacher educators. No wonder so many become disillusioned, frustrated, and overwhelmed.

A group of teacher educators, in writing about their work and its demanding nature, connect their disillusionment with their work environment with the concept of, what they call, "professorial autonomy":

We came to the professoriate with false impressions about the work environment. We thought university teaching would offer more personal and professional autonomy than it does. … While many of us teaching in the program are convinced that we are preparing a better beginning teacher, the effect on personal and professional autonomy is significant. … [Striving for] programmatic integrity in teacher education may mean abandoning notions of professorial autonomy. (Kleinsasser, Bruce, Berube, Hutchison, & Ellsworth, 1998, pp. 308–309)

Whether it is due to outdated management practices and associated workplace conditions or simply a matter of too much work for too many diverse purposes, few teacher educators would argue that there is just not enough time to do all that is required of them, especially when what is required is rooted in two very different perspectives on academic life and work.

Most teacher educators do not experience the kind of freedom Bowen and Schuster (1986) deem necessary for academic productivity or, for what Mager and Myers (1983) would call, developing a life of the mind. Hence, creativity and commitment are difficult to express in a meaningful way. A teacher educator interviewed as part of a study of pretenured teacher educators (Cole, 2000) commented:

I get renewed by the kind of work that I love to do. Work is such a central part of my life and who I am. I wouldn't want to be not working but I've spent a lot of time doing work that doesn't renew me. [For the seven years prior to receiving tenure] I was badly exhausted, under stress, and suffered serious health problems. Creative work does not do well under those conditions. [Creativity] is about being playful with words and ideas and I don't play under stress. If you're going to be creative you have to have loads and loads of failed experiments. [Before receiving tenure] I could never afford

the time to have one let alone five failed experiments. I had to have a product at the end of a certain number of hours of work. That burns you out because when you grind out a product that you're not absolutely delighted with you don't have time to go back and work on it until you are. You think, "Oh God, now I have to do another one." (p. 42)

This comment is reminiscent of Park's (1996) and Skolnik's (2000) observations that the academy values quantity over quality, a comment that an outgoing editor of a reputable scholarly educational research journal recently underscored. In her final editorial comment as journal editor, Beth Young is highly critical of the quality of many of the manuscripts submitted for peer review. She states:

In the press to publish or perish ... some academics and aspiring academics are much more interested in pumping out articles than in making a scholarly contribution; much more willing to "talk" about their work than to read anyone else's, however it might inform their own; much keener to be published in a widely indexed and circulated journal ... than to support the journal by subscribing to it themselves. (1998, p. 250)

Her comment reflects a sad-but-true reality for education academics. They simply do not have the time (and, in some cases, the commitment) to fully engage in the consuming and creative task of producing high quality scholarly writing.

The above comments are also a commentary on the inappropriateness of the conventional definition of academic freedom for schools of teacher education, especially, as it is tied to the university's reward system. The following excerpts from the experience-based writing of teacher educators further elucidate this notion. First, a published journal entry of one teacher educator from the Arizona Group:

Being a teacher educator in a U.S. research university does not mean spending one's time educating teachers. Though that work may be the most socially important work I do, and the work to which I feel the highest moral obligation, it becomes only one isolated piece of my position. It is also not the one that "counts" the most in terms of establishing job security. (Arizona Group: Guilfoyle, Hamilton, Pinnegar, & Placier, 1998, p. 177)

And another:

I cannot allow myself to be cultivated into the academic teacher education community at the expense of losing the value I attach to classroom practice. ... I cannot forget my place as a classroom teacher ... since this is the place from which I am educating my students. (Olson, 1998, p. 167)

Most contemporary teacher educators share a passion for teaching and field-based activities related to the betterment of teacher education. Indeed, "for teacher educators who want to fundamentally change the ways in which teachers are prepared and how they play out their professorial roles in the academy,

teaching is 'the heart of the matter'" (Cole, Elijah, & Knowles, 1998, p. 9). It is the case, however, that, as Park (1996) notes, "The decisive factor in tenure and promotion (and salary) decisions is research" (p. 48). Many teacher educators find themselves torn between their survival as academics and their ability to flourish as creative and productive teachers, teacher educators, and researchers. The enormous time and energy demands required to meet the university's standards of academic worth is time and energy taken away from the work they most want to do and the work that they feel that they do best. They do what they have to do to stay employed or to gain status within the university and to gain the "freedom" associated with those rewards; however, this investment is often at the expense of their own passions and interests (in teaching, program development, and / or community work).

Some teacher educators have a passion for research or for writing, perhaps in non-conventional ways to reach other than academic audiences; others find challenge and joy in creative moments associated with program development; still others crave more time to spend on understanding and improving their teaching as part of a broader teacher education agenda. However the commitments are articulated, each is in the interest of the mandate of serving the professional community and field of education. These are not, however, necessarily viewed by the academy as meritorious activities – a situation that seems like an inherent contradiction to the definition of academic freedom stated earlier, that is, "the right of faculty members to substantial autonomy in the conduct of their work, and to freedom of thought and expression as they discover and disseminate learning" (Bowen & Schuster, 1986, p. 53).

In most of the analyses in the literature about the role and place of education and teacher education in universities the inevitable conclusions or recommendations are in the form of challenges to educators to change their ways, to engage in more seemly work that is fitting of academic faculty, to measure up, to publish or perish. An example:

> SCDE [schools, colleges, departments of education] professors should examine their individual behaviors and attitudes to determine if they reflect the commitment to scholarship fundamental to professing. Efforts to enhance scholarship and research do not mean that one can afford to be less concerned with teaching competence or professional service responsibilities. … It is critical that professors find ways of responding to these expectations while engaging in scholarly activity at a level commensurate with university standards. (Burch, 1989, p. 103)

Suggestions that the university make changes to respect the work of educators are made but seldom with much hope that anything will be done. Yet, that is precisely what needs to happen. We return, for a moment, to Clark's (1989) comment about the need for contemporary universities to more loosely interpret the concept of academic freedom and to Tierney's (1998) call for a reconsideration of the culture within which tenure is embedded. We suggest that such

reinterpretation needs to happen where schools of education are concerned. We are not suggesting a 'dumbing down' of academic expectations but, rather, a thoughtful reconsideration of what counts as meritorious activity, knowledge, and scholarship in schools, departments, and faculties of education.

We also call for a reconsideration of the role that education plays, or has the potential to play, in a world of true academic freedom, in advancing citizenry and society. To initiate such a reexamination we offer the following framework: a set of presuppositions that have come to define academic life. In a sense they are the norms of academic convention and the socializing forces that govern professorial work; an alternative set of conventions that might more appropriately govern teacher educators' work; and, a vision of what such a reorientation might mean in practice. We then draw on this framework to explore how the self-study of teacher education scholarship and practice, as a genre, has positioned itself to challenge the status quo of academic convention for schools, departments, and faculties of education.

A Framework for Rethinking the Evaluation of Teacher Educators' Work

Conventional Assumption:	Research is more highly valued than any other activity.
Alternative Assumption:	Academic activities associated with Teaching (including research) are highly valued.
Meaning in Practice:	A broadened definition of research and scholarship would include "self-study" of teacher education practices, and the contexts and processes of everyday teacher education work would become valued possibilities for inquiry.
Conventional Assumption:	Research productivity is the best indicator of faculty worth.
Alternative Assumption:	Faculty contribution is optimum when individually determined and negotiated.
Meaning in Practice:	Individual freedom to choose the nature and direction of work without fear of reprisal is as important as redefining what counts as research.
Conventional Assumption:	Quantity matters more than quality.
Alternative Assumption:	Numerical assessments are poor indicators of work quality (let alone scholarship).
Meaning in Practice:	Systematic efforts to challenge the over-reliance on measured accountability and productivity are imperative; quality is worth more than quantity.

Conventional Assumption:	Status quo practices and approaches to scholarship are preferable.
Alternative Assumption:	Non-conventional approaches to research, such as self-study, and challenges to status quo concepts, especially when directly linked to educational realities and practice, go further in advancing knowledge and developing critical and creative thinkers.
Meaning in Practice:	Collective efforts are required to promote and conduct alternative paradigm research; being on the margins fosters views alternative to the status quo.

Conventional Assumption:	The purpose of research is to develop scientific knowledge and abstracted theories.
Alternative Assumption:	The purpose of research is also to inform practice; in teacher education, theory and practice merge.
Meaning in Practice:	Collective efforts to promote and conduct research are rooted in and aimed at informing personal/professional practice.

Conventional Assumption:	Research and publishing in exclusively scholarly venues have an impact on knowledge development and society.
Alternative Assumption:	Wider accessibility of research findings to the public and to schools has a better chance of impact.
Meaning in Practice:	Greater emphasis is placed on diversity in communication forms and venues; opportunities to create alternative research texts.

Conventional Assumption:	Research and teaching are dichotomous activities.
Alternative Assumption:	Within the field of teaching and teacher education, research and teaching are inter-related and mutually informing.
Meaning in Practice:	Teaching and other elements of practice are considered as sites of research.

Conventional Assumption:	The good of the institution is more important than the good of its members.
Alternative Assumption:	Happy and healthy individuals make a good institution; individuals come first.
Meaning in Practice:	Consistent attention to staff development, well-being, and renewal through an ethic of care and community are essential.

Conventional Assumption:	Teaching and service activities do little to advance the reputation of the institution.
Alternative Assumption:	More emphasis on equitable valuing of activities is likely to enhance an institution's reputation among prospective students and faculty.
Meaning in Practice:	Attention is paid to institutional ethos and development of norms of collegiality, community, and mutual respect and care.
Conventional Assumption:	Prevailing hierarchies are maintained through differential treatment of faculty members based on seniority, status, race, class, and gender.
Alternative Assumption:	Equitable treatment of individuals and the valuing of diverse perspectives enrich individual and institutional quality of life.
Meaning in Practice:	A serious and extensive re-examination of the values, goals, policies, and practices of the reward system is required.

Self-study as a Challenge to the Status Quo of Academic Convention

The very existence of self-study of teacher education practices research on the academic and scholarly landscape is evidence of its challenge to the status quo. This is work directed by individuals and collaboratives who are intent on changing practices and programs. The dimensions of such status quo challenges articulated through self-study include: individual and collective teacher education practices (considering matters of relationality, pedagogy, and ideology, for instance); curricular and programmatic influences associated with teacher preparation programs (considering orientation, context, philosophy and purpose, for example); and, indeed, many of the researching practices and methodologies embodied in self-study. Vicki Kubler LaBoskey (2001) describes the self-study of teacher education practices as a methodology borne out of the concerns of teacher educators for the learning of preservice teachers and their students. Further, she explains how self-study has earned the designation of "scholarship of teacher education". As a methodology, practice, and scholarship, self-study challenges status quo conceptions of both knowledge and research. In conservative-minded institutions value is attached to those individuals who uphold, through their work, the dominant ideology of the institution (or other institutions that are deemed leaders, are widely acclaimed, or that the home institution aspires to emulate). Basically, this means that research should follow the scientific doctrines of positivism and meet criteria of objectivity, measurement and quantification, predictability, and generalizability, and be presented in relatively detached, impersonal ways. Self-study research is antithetical to all of these principles.

Universities tend to base their status and reputations on the construction of academic, discipline-based knowledge that is judged by standards of abstraction and obscurity. Self-study research, by its "up-close and personal" nature and by its focus on the self and immediacy of practice, flies in the face of these standards. As such, it is part of a political agenda, on the part of teacher educators, to challenge traditional conceptions of what counts as knowledge and research. Self-study work that is true to its nature and spirit leaves no holds barred, no processes sanctioned, and no topic sacred. Judged according to long-held conventional academic standards, self-study research is methodologically, epistemologically, and politically radical. Yet, as a movement, consisting of geographically dispersed clusters of like minded practitioner-researchers, the self-study of teacher education practices has established itself as a powerful mechanism for changing the way Education is viewed in the university, redefining teacher education as a field of study within schools of education, and for improving schools. According to Zeichner (1999, p. 12), "The self-study genre of research in teacher education is the one clear example of where research has had an important influence on practice in teacher education."

The self-study of teacher education practices, as a group, represents an example of how, through collective will, action, organization and solidarity, self-study has found its place on the teacher education landscape as a principled, scholarly practice that has begun to shift understandings about what counts as acceptable academic scholarship. Moreover, it certainly appears that this work is achieving the fundamental goals put forward by LaBoskey (2001). Whether this is so across the board, in the various institutions represented by self-study researchers, we have no empirical evidence. And, we imagine, self-study researchers hold a minority perspective.

What is clear, from the evidence presented elsewhere in this Handbook and in other publications (see, e.g., Cole, Elijah, & Knowles, 1998; Hamilton, 1998; Knowles & Cole, 1996; Pinnegar & Russell, 1996; Russell & Korthagen, 1995) as well as hundreds of research and professional conference presentations, is that the teacher educators involved in self-study research are highly committed to the improvement of their own practice, the reforming of courses and programs of study, and teacher certification. Still, apart from the public representations of this work in the various venues mentioned (which may or may not be accessed, read, acknowledged or even understood by peers in other disciplines within one's home institution), the benefits of self-study are largely hidden from view (although the publication of this volume may have some modest influence). In addition, it is our perception that there is a majority of North American teacher educators in the field who do not understand self-study, subscribe to it, acknowledge its benefits, or understand the possibilities of its various processes, let alone think about it as a legitimate scholarly activity.

One of the important future tasks of self-study researchers, therefore, is to take their work to new heights, to new places and to new audiences. Primarily this means going public and being political in ways that go beyond the immediate agenda of self-study aimed at improving practice. It means being an advocate

for educational change in a broad sense with self-study as one significant part of and mechanism for that broader agenda. It means taking principled actions informed by disciplined and sound approaches to knowing.

It is our hope that teacher education may be transformed and that the status of self-study as a meaningful way of coming to know will be firmly accepted within the circles of university research and practice. So it is that, through a disciplined research and publishing agenda, self-study of teacher education practices scholars will continue to:

- take care to explicate goals, intentions, and processes of individual and collective self-study work so that appropriate scholarly and institutional appraisals can be made about the value of such work;
- work toward maintaining the integrity of self-study research through explicit adherence to sound methodological standards (broadly defined);
- make clear the epistemological and methodological issues associated with self-study work by focusing on its unique strengths rather than on its dichotomous relationship with more traditional research approaches; and,
- focus self-study work on issues, matters, processes, and problems that also have value to others, and make explicit how self-study work contributes to the broader understanding and improvement of teacher education.

As a movement, the self-study of teacher education practices, as an organized body of like-minded scholar-teachers, has grown enormously in just over a decade since its inception (not to suggest that, prior to this, individuals did not orient themselves in similar ways). This has been in large part due to an explicit commitment to developing a sense of community among its members. This Handbook is a testimony to the strength and diversity of the community that has developed and how, through community, the field of self-study has gained a collective voice that rings loud and clear across the teacher education landscape. This kind of presence will only strengthen as self-study of teacher education practices scholars continue to:

- facilitate the work of colleagues and graduate students who wish to initiate their own self-study research and, when appropriate, join with them in collaborative self-study work;
- maintain and build on various networking efforts already established by self-study researchers so that those who are at the boundaries of self-study and more traditional research practices can enter the conversations;
- work towards establishing "centers" of self-study in local institutional contexts; and,
- continue "community building" activities such as national and international meetings and conferences, newsletters, and electronic mail networking.

For all of these reasons and through all of these ways self-study has established itself as a *bone fide* field of study in the Education community and has laid the foundation for shifting understandings in the academy about the nature and significance of teacher educators' work. Perhaps one of the biggest challenges

now facing self-study scholars is building on this foundation at an institutional level. Most of the self-study pioneers and founders of the movement are now senior scholars, well established in their academic careers with all of the privileges associated with that status (having said this we acknowledge that, among that founding group, are a number who were denied tenure at one institution and had to search for a more hospitable academic home). These scholars are now in a position to work within their institutions to influence the future of a new generation of self-study of teacher education practices scholars and scholarship. As senior academics, it falls upon their shoulders to:

- engage other faculty and administrators in conversations about the integral value and place of self-study in ongoing professional, program, and institutional health and development;
- make self-study processes (and work) a central component of ongoing course, teaching, and program evaluation;
- increase the scope of activities of self-study work by writing for "popular" audiences as well as scholarly and professional ones;
- become part of publishing, tenure and promotion, and grant agency decision-making groups where and when possible; and,
- become politically savvy, active, and expressive with regard to focused energies on academy and school reform through self-study.

HUMANISTIC RESEARCH IN SELF-STUDY: A HISTORY OF TRANSFORMATION*

Jerome S. Allender
Temple University, University of Kansas, U.S.A.

Abstract

A complex exploration of many influences goes into understanding the role of humanistic research methods in self-study. To begin, two historical developments must be considered. Early examples of self-study appeared in the transformation of humanistic practices as they entered into mainstream education over much of the last century. Overlapping this transformation, the expansion of qualitative research methods, initiated in the 1980s, brought along its own humanistic concerns. Together, they formed an awareness of the self's importance in the research process. With this foundation, the self-study of teacher education practices came onto the scene in the 1990s bringing with it other influences including the recognized value of reflective teaching and the impetus felt by many classroom teachers of all stripes to study their own teaching practices as a source of empowerment. This chapter sorts through these multiple influences toward the creation of a coherent picture of how humanistic research and the self-study of teaching and teacher education practices are interconnected. One thread interwoven throughout this chapter is the need for teacher educators to be honest with themselves. The essential humanistic self-study question is: Is my teaching consistent with what I expect of the teachers I am educating?

An exploration of the relationship of humanistic research and self-study methods has revealed overlapping connections that I was unaware of before embarking on this inquiry. Initially, it was hard to picture a history of humanistic research because what was accepted as scholarly investigation in academia did not coincide with the development of the concerns and methods of humanistic

---

*Chapter Consultant: Mary Lynn Hamilton, University of Kansas, U.S.A.

education – even though these concerns have been addressed and these methods have been practiced in many different forms in schools world wide for over a century (Allender, 1982; Cremin, 1961). And, from reflecting on the self-study community since its beginnings in the early nineties, another somewhat parallel oversimplification made it seem that all self-study in teacher education practices is essentially humanistic. Identifying research as humanistic, however, typically creates discomfort for all of us who hope that our research will be considered respectable. Zeichner's (1999) discussion of new scholarship in teacher education notwithstanding, any researcher who opens an inquiry into questions related to humanistic research and/or self-study is sure to encounter resistance. Inquiries, focused on self, particularly one's own, have to be defended as belonging within the pale of educational research methods that count, and more fundamentally in my view, the resistance is provoked by central humanistic concepts.

To facilitate my understanding of the connections, I began by unraveling them. Three challenging tasks emerged by asking what was there to figure out? The first of these entailed exploring the history of humanistic education. Essential elements of self-study were embedded in this history. The second task meant tracing the expanded importance of qualitative methods that had given the occasion for Zeichner's idea of new scholarship to arise. Embedded here were the elements of humanistic research, though usually not explicitly conceptualized as such. Finally, with these foundations in place, the task of reviewing the self-study literature was possible. However, instead of solely investigating where humanistic research plays a role in self-study, the story that unfolds reveals the influence of humanistic research and self-study on each other is a two-way street.

The premise of humanistic education is that the importance of fulfilling the needs of each student precedes the demands of the curriculum and our prescribed methods of teaching. Though the individual's needs and those of society are both urgent, a humanistic educator does not doubt which has the higher priority. Nor, is there any doubt that this goal requires regular attention to the teacher-student and student-student relationships. The assumptions that embrace humanistic research aren't exactly the same, but they are parallel. All who participate in humanistic inquiries must benefit from the process, and here too such a goal cannot be achieved without attention to interpersonal relationships, between all of the stakeholders.

My first insights directed me to the problem of understanding better how self-study is built into the foundations of humanistic education. With this challenge in mind, it was possible to clarify how self-study is essentially humanistic, and where it is not. Beginning with a discussion of Dewey (1938) where he too was concerned about resistance, it was not difficult to identify in the humanistic education literature, many investigations based on elements related to the study of self. During the sixties and early seventies, especially, the expression of humanistic education in its most recent heyday found its way into the mainstream with the support of two well-known psychologists, Maslow (1968) and Rogers (1969). Their theories stemming from the field of psychotherapy were derived from a fundamental focus on self. Furthermore, the element of interpersonal relationship

that is an equally important focus in therapy can be used to understand the integral role that collaboration plays in self-study.

These American psychologists were bolstered by the work of others emanating from England and New Zealand. Probably the most radical humanistic school ever, England's Summerhill, at least in terms of the notoriety it achieved, was guided by a psychoanalytic perspective (Neill, 1960). Most prescient about the methods of self-study that were to appear in the future was *Teacher* by Ashton-Warner (1963) where she described teaching Maori children in New Zealand. The year's best book on education" according to *Time Magazine* was an autobiography – often focused on her personal problems of educating other teachers. In the decades that followed, many of the studies that will be discussed show the influence of this earlier work.

A bigger problem was knowing that there is no specific body of literature called humanistic research. To meet this challenge, I had to remind myself that humanistic concerns were a major influence, during the last twenty-five-or-so years, on the expansion of qualitative methodologies in educational research. A turning point was the publication of *Human Inquiry: A Sourcebook of New Paradigm Research* by Reason and Rowan (1981) which recognized the influence of humanistic psychology on these "new" methods. They also recognized that the methods were not so new; the story is much more about their eclipse behind what had become an orthodoxy of traditional research methods. In the field of humanistic psychology itself, their book was foreshadowed in the late sixties by Bugental (1967).

By the early nineties, Shulman, in the forward of *Imagery in Teaching and Learning: An Autobiography of Research in Four World Views* (Allender, 1991), was able to say,

> A funny thing had happened to the mainstream of educational research. It had meandered. Previously taboo subjects were now becoming commonplace. Naturalistic research had become the norm. Studies of the investigator's own teaching were legitimate. Qualitative methods were even seen as squeezing out the older quantitative approaches, much to the dismay of some traditionalists. … Allender's humanistic educational inquiries were no longer beyond the pale. (pp. xii–xiii)

I had drawn upon the wide range of alternative research methods that by then had become, if not yet totally commonplace, practical tools for educational research. For me, they were the nascent canon of humanistic research. I return now to reviewing this literature, and its new developments for the purpose of understanding its role in self-study.

A limited perspective at the outset of this inquiry had interfered with recognizing the value of unraveling the connections. The early forms of scholarly research from which humanistic education evolved were supported only by a parochial canon that fit, of course, its own assumptions. At this point, Shulman not only saw alternative research methods in place, he was also aware that they could be

used as a tool for self-study. I believe that this renewed focus on alternative research methods created the context within which the more recent field of self-study of teacher education practices evolved. With this new starting point, it is possible to reframe humanistic educational research processes as having a complex relationship with the current methods of self-study. What I see is a picture of the similarities between humanistic research and self-study that can shed light on each other – benefiting the interests of both.

What follows first is a history of humanistic education and the underlying roots of self-study. Next, the discussion turns to understanding how the changes in and expansion of educational research methods over the last quarter century have essentially defined humanistic research. Finally, a sample of literature from the field of self-study is examined. The conclusion is a complex image of relationships among the three sources of knowledge and experience: humanistic education, humanistic research, and self-study.

Humanistic Education

A modern vision of humanistic education was created in the years just before and after the turn of the twentieth century. Ironically, its success was marked in 1938 with the publication of Dewey's *Experience and Education* in response to the excesses of progressive education that were expressed in his name. The book begins with, "Mankind likes to think in terms of extreme opposites. It is given to formulating its beliefs in terms of *Either-Ors*, between which it recognizes no intermediate possibilities" (p. 1). But the intention was not to negotiate a compromise. He wanted his readers to understand the question, "What does freedom mean and what are the conditions under which it is capable of realization?" (p. 10). He understood from his experience as a student and a teacher that humanizing education required an interactive relationship with students that attends to the continuity of experience in the classroom. Twenty years later, this book was my introduction to humanistic education.

These excesses represent the other side of the resistance that is commonly encountered when one wants to humanize education. The tension between humanistic and traditional education is the locus of Dewey's concern. Advocates of traditional education fear that students will not learn what they need to learn in order to fit successfully into society. Advocates of humanistic education have broader fears. In the nexus, interpersonal interaction and the possibility of continuity are maximized. Progressive educators in Dewey's day reacted to resistance by differentiating themselves even further from traditional educators. A common reaction to resistance is to push harder against one's enemies, but educationally and particularly in the classroom it is usually counterproductive. Worse yet, it wasn't consistent with Dewey's proposal. He envisioned shifting the balance from an emphasis on the curriculum to a more interactive relationship with the teacher that would maintain each student's prior experience in the foreground. Not so much a compromise, it is a means for the teacher and the students to negotiate a successful path in the classroom each day. It is a matter

of functionally integrating humanistic methods into everyday teaching without losing sight of both the students' and the teacher's needs. Building on the two, there is a continuity of experience for both the students and the teacher.

The resistance to humanistic education can be better seen as a tension between the stakeholders who are in charge (or so we all wish) of designing and those stakeholders who are in charge of carrying out education. In my experience, no teacher today, and likely most others involved in the realm of education, is without an interest in finding some ways to express humanistic concerns in the classroom. Cremin (1961) in his chronicle of progressive education and its demise in the fifties argued persuasively that, "Dewey's forecast of a day when *progressive* education would eventually be accepted as *good* education had now finally come to pass" (p. 328, italics in the original). By way of explaining the demise, he meant that the basic values had been sufficiently incorporated into conventional wisdom so as not to require a radical organization for their support. Raising a radical flag associates one with extremism, and it becomes an unnecessary sore point when the general culture is not quite so contrary to one's personal philosophy. For all the problems a teacher faces over privileging a student's needs, the obstacles are now nowhere near as great as they were before mid-century. The cultural upheaval of the sixties reduced them further even though those extremes were left far behind. The current infatuation with high-stakes testing is an anathema to humanistic education, but the arena in which the fight occurs today is clearly more conducive to creative reactions and reframing than in an earlier era.

I do not mean to minimize the difficulty and the threat in front of us; rather, it is my intent to emphasize the need to avoid either-or thinking by keeping the complexity of the problem in view. The tension among stakeholders parallels the tensions more readily accepted in the relationship between teacher and students. It is this that most needs to be the center of our ongoing attention. With both students and teachers in mind, the intent is more about supporting every teacher in finding ways to be as humanistic in the classroom as he or she chooses. Ideally, it is a matter of finding ways that are consistent with personal beliefs and hunches about what will most benefit students. A knotty problem is to recognize that students must be treated individually and with an understanding of the larger political context and what will be tolerated. Additionally, teachers must work at not compromising their integrity, visions, and hopes. I have found it worthwhile work, hard, yet more often rewarding than not.

This work involves being different than other teachers. In my development as a humanistic educator, my heroes gave me the courage to consciously develop a unique teacher personality. Among them, there were psychologists, a philosopher, and teachers turned writers who I credit: Bruner (1966), Maslow (1968), Rogers (1969), Greene (1967), Ashton-Warner (1963), Holt (1964), Kohl (1967), and Neill (1960). There were others, but the influence of these people remains vivid; they are likely to be familiar, particularly those who are alive and still writing today.

Looking back over their writings, the roots of self-study come to light. Rogers

(1969) was a key figure. Some of the language he used suggested a fiery radical: "I have a negative reaction to teaching. Why? I think it raises all the wrong questions. As soon as we focus on teaching the question arises, what shall we teach?" (p. 103). As a young professor, dedicated to not teaching the way I was taught, I was attracted to his words. This stance, however, represented his priority, not his practical politics. His emphasis was on the development of the student self, and his examples showed that he hoped not to alienate students. Focusing on "the facilitation of learning as the aim of education" (p. 105), as a method for moving away from traditional notions of teaching, he had three guiding principles. They required a teacher to feel real in his or her actions; to prize, accept, and trust students; and to have empathic understanding. It was difficult to miss how his goals could be attained without a deeper understanding of the teacher self. To complicate the task, he didn't specify how one learns to empathize or how realness related to trusting students. So, once a teacher took this advice to heart, as I did, it was intrinsically the beginning of self-study work.

The picture of early self-study enlarges when the work of my other heroes is explored. Bruner (1966) is not remembered as a humanistic psychologist, he wasn't one, but his views were radical in the context of the hegemony of behaviorism. Instead of stimuli and reinforcements he proposed that curiosity, the drive to achieve competence, and identification with those with whom we are emotionally attached are the prime factors in learning. These ideas helped to catalyze a more reflective kind of teacher. On the other hand, Maslow (1968), provided leadership for the creation of the field of humanistic psychology, and contributed a focus that connected all learning with personal growth. His discussion of the greater role that safety had over challenge for creating an effective learning environment for students influenced changes in theories of learning and teaching.

Greene (1967), in the field of education, as a philosopher, envisioned an even larger perspective in her book, *Existential Encounters for Teachers*. Like Bruner, she was not clearly identified with humanistic education, but her thinking was integral to the issues. At the end of her introduction, she says, "This book … offers encounters to those who can take the risks of becoming and to those who affirm the responsibility of creating themselves as teachers. The possibilities are limitless; each person must choose his (sic) own" (p. 18). Together, these scholars offered a clear call to study the teacher's self.

Others wrote stories. Ashton-Warner (1963) created a touching recollection of her experience teaching Maori children, native inhabitants of New Zealand. She found radical ways to change traditional European methods of teaching so that she could provide a meaningful education for students whom appeared to be unreachable. Her very successful book, *Teacher*, obviously struck a chord with teachers from many different cultural contexts. This was the common element in autobiographical accounts published during the sixties.

Holt (1964) and Kohl (1967) described their experiences with stories about teaching failing and disenfranchised children. In a book of diary entries, Holt begins by asking why children fail and answers, "They fail because they are

afraid, bored, and confused" (p. xiii). This shifts the responsibility for change to the teacher. Neill (1960), the brazen headmaster of Summerhill, an English school spanning elementary and secondary classrooms offered the most radical story about failing students. Neill's story provided clear evidence that a school could succeed while centering its vision on the development of self in society. Interestingly, while the teaching strategies appeared relatively commonplace, the involvement of every member of the community in the democratic process was quite innovative. The teachers at Summerhill looked to themselves, not to their students, for the faults in the educational process.

Bolstered by the theoreticians, the stories advanced by Holt, Kohl, and Neill were as much reflections on their own learning and development as they were about the students' learning and development. It was important for teachers and students to be consciously aware of their actions as well as the interpersonal dynamics in the classroom. Those who wrote about their teaching under the pressure of these insights, though not necessarily articulated explicitly, galvanized many other teachers to act on them. The insights also anticipated the relationship of humanistic research and self-study that would become mutually helpful methods for expanding our understanding of teaching and learning. From this view, these interactions best describe the roots of self-study of teacher and teacher education practice.

Humanistic Education Enters the Mainstream

In the decade that followed more attention was given to problems that emerged when attempting to the balance traditional and humanistic emphases in education. At this time there were some gains as well as a recognition of limitations. The loss was less attention to self, which was replaced by writing *about* education, not so much living it. Kozol (1972), in his book, *Free Schools*, recognized the effort it takes to maintain the spirit of a humanistic school. These schools, also identified as alternative, open, progressive, confluent, or humanistic, were easier to begin than to maintain because they required ongoing changes to establish a stable structure.

The seventies opened with a lengthy critique of American education, *Crisis in the Classroom* by Silberman (1970) that included ideas for building successful alternatives to traditional schools. He supported a school model based on reforms in primary English education that occurred during the sixties and popularized by Featherstone (1971) and Weber (1971). What Featherstone called "the primary school revolution in Britain" was characterized by informal learning, an integration of the curriculum, and an emphasis on learning to think over rote learning.

A trend to publish textbooks about humanistic education arose. Leading the way was *Toward Humanistic Education* by Weinstein and Fantini (1970). This text provided a model for introducing emotional learning into the classroom with a, "a curriculum of affect." Based on their experiences directing an experimental school project, the methods they presented gave guidance for interweaving intellectual and emotional classroom activities. Another text (Miller, 1976)

proposed a variety of models to choose from, organized in terms of four types: developmental, group orientation, consciousness expansion, and self-concept. My colleagues and I (Silberman, Allender, & Yanoff, 1972; Silberman, Allender, & Yanoff, 1976) added to the genre. We presented a "psychology of open teaching and learning," with readings and commentaries that covered many of the sixties' writers, classroom activities and projects. We wanted teachers to account for a wide range of factors related to the structure of everyday classroom learning. The themes also highlighted the need for teachers to involve and intellectually and emotionally guide their students. In the development of active teaching roles and learning how to facilitate groupwork, we introduced our primary aim: to challenge teachers to create both freedom *and* limitations.

Neither the topic of student self or teacher self were addressed. Toward the end of the decade, however, the Association of Humanistic Education was formed. An article by Combs (1979) in the *Journal of Humanistic Education* captured the concerns of the times: "Humanistic Education: Need or Nonsense?" Though sensitive to the legitimate criticisms that abounded, he reiterated the larger goals of society that humanizing schools addresses. Because learning is a personal human experience, Combs argued that it is essential for students to develop their inner life. This signaled a return to a focus on self, at least the student self.

Early Examples of Self-Study in a Humanistic Context

In 1973, my closest colleague, Donna Allender, and I discovered a humanistic school in Thailand, where the teachers engaged in a primitive form of self-study. The school combined an open-school model taken from the West, by Saisuree Chuktikul (who was educated in America during the sixties and dean of education at Chulalongkorn University at the time), with the ancient tradition of a temple courtyard form of teaching and learning. To say the least, our horizons were greatly expanded (published years later in connection with subsequent research from our travels, Allender & Allender, 1988). In interviews and conversations, the teachers talked about finding their work to be an exciting challenge that helped them discover what it meant to be a teacher. Granted, this was an isolated experience, but being so far from our own culture, it revealed a kind of general truth about how it is possible to humanize education within tradition, ancient as it was.

And on one other personal note, out of all the books about teaching from this decade, there is my most unforgettable one *P.S. Your Not Listening* by Craig (1972). In the genre of earlier autobiographies, it is a tale of a teacher using some of new ideas, primarily not to humanize, but to survive teaching children with grave emotional difficulties. The title came from a student's note and it revealed great progress in an ability to learn, not a grammar error. This delightful story based on a willingness to probe deeply into oneself as a teacher while the study of the teacher self was not yet largely accepted, still entered the literature.

In the years that have followed, the focus on humanistic education faded into

the background. Although the philosophy did not disappear, for there are free and progressive schools that survived, few schools identify themselves as humanistic. More typically, these schools are referred to as alternative programs. At universities occasionally some colleagues in the teacher education programs identify themselves as affiliated with the humanistic philosophy. In the world of educational research, the influence of the humanistic philosophy accounts for the focus on understanding reflective teaching, developing constructivist and critical theory, and supporting teacher research. Humanistic concerns are a part of many educational reforms.

There have been, now and then, though, publications that touch directly upon humanistic education and the roots of self-study. One example is *Totto-chan: The Little Girl at the Window*, an autobiography by Kuroyanagi (1982) as a young student in Japan. Her school, Tomoe, only existed briefly in the 1930s and early 1940s and was similar to Summerhill in the amount of freedom given to its students. This memoir reveals a school with an open setting existing within a rigidly structured culture. That such a school could exist in Japan, particularly seventy years ago, argues for a more general applicability of humanistic educational practices than is typically imagined. If the Japanese children could successfully handle such a high degree of freedom in the classroom, what might we extrapolate about schools and education in other cultures?

Indeed, Kuroyanagi's stories point to a *different kind* of structure within which children make many independent choices related to their learning. Though the book was written from a child's point of view, it reveals some of the ways in which the teachers were required to examine their behaviors and choices regarding how they facilitated daily lessons. Different than Neill's Summerhill, the emphasis at Tomoe on everyday classroom events rather than school politics. Mr. Kobayashi, the headmaster, focused on how the teachers guided the children's learning. He expected both teachers and students to be reflective and insightful about teaching and learning.

In *Growing Minds: On Becoming a Teacher*, Kohl (1984) focused on his teaching experiences in several American classrooms and demonstrated the practical applications of humanistic education. Teaching in traditionally minded schools, he bent the norms to better connect with each individual student. As one of the best examples of an early teacher self-study, this text is more than a set of stories about teaching children and how they learned. He reflects on his teaching and shows insight into the errors he made, the ways he rethought, and the ways he changed his instruction. Moreover, the advice he gave himself provides powerful help to others.

Because Kohl's work so well resembles the narrative research that goes into the self-studies of teaching that are done today, and because, his book is aimed at helping others learn to teach, it is a good segue to the next section. It is possible to bring in other work from the past to analyze in terms of how there are humanistic elements that relate to self-study in recent years. But, since the end of the eighties, it requires stretching the argument that there is a body of literature that really qualifies as belonging to the field of humanistic education.

Cremin is not alive today to give us a fresh analysis, but the one he made in 1961 still seems to hold. The fact that Roger's book, *Freedom to Learn*, first published in 1969 has reappeared in two subsequent editions (Rogers, 1983; Rogers & Freiberg, 1994) should not be ignored. Humanistic concerns had continued to become ever more present in many educational settings, and with these concerns came a beginning understanding of the relevance and importance of self-study of teacher education practice.

It is apt to recognize that the influence of humanistic education is alive and well, but mainly as it is tacitly interconnected with a wide array of pressing concerns. A striking example is, *We Make the Road by Walking*, by Horten and Freire (1990). From a recorded dialogue, insights are revealed into how humanistic concerns and practices entered integrally into their work on the politics of education. From there, it's not difficult to see that the relationship of self-study and humanistic research take us into the politics of research. What we have seen is that the focus on humanistic education has been transformed. In the next section, we will see that these humanistic concerns also deserve credit for the methodological upheavals that have occurred in the social sciences, the ones that have given us now a new, greater expanse of methods for doing educational research.

Humanistic Research

Paralleling the radical educational changes taking place in the sixties, traditional views of research began losing their dominant hold on academic scholarship. These changes, like those that took place for children in schools, were not always explicitly associated with humanism. In retrospect, though, what influenced them clearly represented this spirit. It was also not obvious that the changes were part of a radical movement, but the long-range effects proved to be so.

Thus, the foundations of self-study began to develop, as did other postmodern concerns, not by design but as a result of an ever increasing dissatisfaction with the limits of what had become traditional research methods over the first half of the twentieth century. More than anything else, these methods lacked the sense of the individual. Polanyi, as someone who understood where a humanistic point of view might be needed, expressed his dissatisfaction in his first edition of *Personal Knowledge* appearing in 1958, followed soon by the second in 1962. This was the same year that the first edition of *The Structure of Scientific Revolutions* by Kuhn was published (though its second not until 1970). While interest grew n the wake of these influential texts, more traditional academics bristled at the relativity that had been introduced into the concept of research; their objections now had to account for the constructed view of reality that had been introduced into the canon.

In a cartoon, they would be pictured as a smart double whammy. Polanyi (1962), a distinguished scientist and philosopher, boldly challenged modernistic thinking: "Theories of the scientific method which try to explain the establishment of scientific truth by any purely objective formal procedure are doomed to

failure" (p. 135). He explored and argued for the role that person, passion, and subjectivity must necessarily play in the research process. And, Kuhn, who at that moment in time, was really just an upstart scientist, "within sight of the end of my dissertation" and only a philosopher "from a long-standing avocational interest" (v, from the preface of the second edition, 1970) worked at unhinging the roots of the scientific method by pointing out how its starting points were a creative fabric woven out of evolving assumptions and blind spots that made it practical to do. Their arguments together had a stunning effect that conjured up the threat and dangers of a morass of relativity. All of a sudden, what was Einstein's exciting good news about relativity landed in every researcher's backyard with unsettling implications.

It is not likely that Polanyi and Kuhn's arguments were motivated by a conscious identification with humanism or that they resulted from what we would today call the self-study of practice. However, it was their own unsettled feelings about traditional research methods that led them to step outside the confined thinking and practice of science of the times. They gave credence to these feelings, these intuitions, that revealed their trust of self-knowledge and their willingness to risk challenging the scientific community. Out of this trust and risk emerged a fertile field within which postmodernism took root. It was not long before Berger and Luckmann (1966) published *The Social Construction of Reality: A Treatise in the Sociology of Knowledge*. Their writing had its own set of roots, but it was brought to fruition in this fertile field where all of science was under reconstruction.

These revolutionary philosophical ruminations also encouraged many educational researchers to rethink their ideas. For example, the role that an idiosyncratic student or a particular classroom had in scholarly inquiry and imagining how research methods might treat this obscured focus emerged for consideration. The possibility of leaving the laboratory and entering classrooms as a way of investigating teaching and learning processes opened up as research opportunities. Smith and Geoffrey (1968), a university professor and a seventh grade teacher, broke the new ground by using ethnographic observations, what they called classroom microethnography, to study the, "problem of how a middle-class teacher copes with a group of lower-class youngsters" (p. 1). Jackson, a young professor at the University of Chicago, having already collaborated with Getzels on *Creativity and Intelligence* (Getzels & Jackson, 1962), which anticipated the existence of multiple intelligences by decades, dared to visit classrooms, make informal notes, compare his observations with a body of literature, and then write, *Life in Classrooms* (1968). The book rocked the world of educational research. The method didn't look like science; the human elements of teachers and students were meant to touch the reader, yet it was scholarly and it made sense.

Conceptually, these studies represented the roots of self-study. In the context within which they occurred, though, the concrete idea was still distant. What they offered in the short run was relevant knowledge for education students. That was an accomplishment. We must not forget that these studies happened

in a world where formal experiments were a demanding norm for educational research. Yet, Jackson (1968) was hopeful:

> If observational studies of classrooms increase, new ways of talking about teaching are also bound to emerge. It is doubtful, however, that these different descriptive languages will readily congeal into anything like a unified theory of teaching. Instead, we are likely to see the emergence of several critical perspectives from which to view classroom events. Each perspective, it may be hoped, will provide the practitioner and the researcher with a unique strategy of inquiry with which to examine educational affairs. (p. 176)

He was prescient. Now, this kind of thinking is commonplace. However, its challenging appearance on that horizon was seen as a brazen humanistic act. There was still a long road ahead to the adventurous self-study of teaching and teacher education practices, but Jackson had done the kind of research that would serve as an initial model for reflection and eventually self-reflection in the years to come.

The Slow Transformation of Educational Research Methods

Compared to the enthusiastic pace of educational experimentation, actual changes in educational research methods crept along only slowly. Until the eighties an encouraging climate for risk-taking did not exist. A sample of work from this period reveals the breadth of changes that gave humanistic research a practical arena where it was feasible to overcome the ubiquitous resistance to change. There was not a body of research literature that bore the name humanistic. Rather, it was this academic climate that outlined research methods for humanistic educators to use in their ongoing inquiries. Moreover, labeling research humanistic was likely to make sure that it would not find a publisher. Recognizing how much research methods have changed since that time does provide some optimism.

The single most compelling and influential text, I believe, was *In a Different Voice* by Gilligan (1982). It did not as much represent a practical change in the everyday methods of doing research as it did blatantly uncover the travesties of the results of traditional research studies. The need to challenge entrenched assumptions was its paramount message, particularly with regard to the ways in which girls and woman develop, learn, and might best be taught. The implication was that traditional research methods embody these entrenched assumptions and cause the results of investigations to be not only incomplete but also misleading. From an even wider perspective, aiming at the whole of the behavioral sciences, Fiske and Shweder (1986) took on a *Metatheory in Social Science*. This edited volume encompassed the range of difference, and some of the far edges. Investigators were guided by discussions that broadened traditional methods to incorporate more radical views and insisted that there were divergent rationalities that have the power to cancel out each other's fix on reality. The

implication is to watch out for intractable problems where without reframing, there can be no ordinary solution. Doing good research cannot avoid the evolution of its context.

Yet, it is still possible to return to a more ordinary line of thinking. Around the same time, the second edition of an introduction to qualitative research methods text by Bogdan and Taylor (the first edition, in 1975) was published. In place of its lonely appearance in the seventies, the second edition (now the authors are reversed, Taylor and Bogdan, 1984) found a more welcome audience, and the new subtitle, *The Search for Meanings*, signaled room for humanism and self-study. They called upon phenomenology to serve as a central theory upon which to ground research methodology:

> The phenomenologist views human behavior, what people say and do, as a product of how people define their world. The task of the phenomenologist … is to capture this process of interpretation … to see things from other people's point of view. (pp. 8–9)

The text served to provide the practical means for confronting the issues that people like Gilligan, and Fiske and Shweder raised, because the value of the full range of views, each individual self, was recognized.

The roots of self-study had a place to take hold in this environment, even though the lack of adherence to tradition was often regarded tentatively and with suspicion. It was particularly fruitful that the need for self-study, in the sense of having researchers help practitioners evaluate their process and accomplishments, led to the development of action research methods that thrived best as qualitative inquiries. With Dewey and Lewin as a theoretical foundation, Argyris, Putnam and Smith (1985) developed an extensive philosophical and practical text that laid out how researchers could be both investigators and change agents at the same time. With qualitative research methods, the overarching strategy was to understand other people's points of view, and for everyone involved in the research process to understand each other's differing points of view, in ways that could be used to achieve common objectives more successfully. Today, there are times when the term action research is used as a comparable way of conceptualizing self-study; looking back, it is closer to the mark to say that methods were developing that could easily incorporate humanistic concerns and readily facilitate self-study, for both classroom teachers and teacher educators.

The importance of collaboration enters here. There are different levels of involvement, but by-and-large, action research means that investigators and practitioners are carrying out an investigation as a joint project: "The key characteristic of action research … is collaboration, which allows for mutual understanding and consensus, democratic decision making, and common action" (Oja & Smulyan, 1989, p. 12). Furthermore, the motivation and responsibility for such studies can come as much from the university professor as it does from classroom practitioners. Oja and Smulyan recognized that it can be equally

important for teachers to assume the role of researcher at times in order to fully carry out the responsibility of teaching. It is in the mix of interpersonal relationships in action research, key in any such humanistic endeavor, that the benefits of teacher research are likely to be realized. Simultaneous with the establishment of an environment that supported elements of humanistic research, the basic methods of self-study were appearing too. What is clear is that the study of self is not intrinsically something one does alone. It is not impossible, and it can be fruitful at times, but aloneness is not the mark of the self-study process.

Two other developments during the eighties furthered the practical application of the emerging theoretical research climate. The more prominent development was the writing of narrative within the realm of qualitative research techniques. Sarbin (1986) brought together an array of approaches to writing narrative framed in a theory that viewed story writing as a root metaphor, among others, for psychological research. This root metaphor created the context within which the narrative study of experience, beyond the field of anthropology, was meaningful as a scholarly tool. The concept proposed an effort to find some acceptance of each other's stories as a means toward achieving common understanding.

Furthermore, the text paid specific attention to self-narrative. This was essential to the self-study of teaching and teacher education practice because removing the self from the research process had become the traditional sine qua non of quality research. Probably, no other methodological development was as essential to the practice of self-study of teaching. The acceptance of narrative, and particularly self-narrative, added a dimension to the research process that provided a method for self-study while countering the fear of not having an "appropriate" disinterest as an investigator. The tone was set for examining oneself and one's practice as a source of useful scholarly information.

The second development directly addressed the illusion that a researcher could be truly disinterested. Geertz (1988) studied the writing of four early theorists in anthropology only to find that their work and their personalities were inextricably entwined. Some years earlier in the *Journal of Humanistic Psychology*, Riebel (1982), analyzing the work of Freud and Adler, had already suggested that theory building is close to self-portrait. *The Self in Social Inquiry* (Berg & Smith,1988) introduced the academic world to avenues where the clear presence of self is a desirable advantage. It can serve not only to ameliorate distortion, but it can also be a source of insight that is not readily available. Wisely, they said, "Instead of affirming which method is right, serious social science asks us to investigate ourselves while we are investigating others, so that we know about tradeoffs being made as we apply the methods we have chosen" (p. 9). Their advice cogently served to underpin the concept of self-study.

A seemingly trivial example of the resistance to the presence of self in academic research revolves around the perceived danger of using the pronoun "I" in academic writing. The fear of not maintaining disinterest is about the loss of objectivity. There has been a long-standing pressure on investigators not to admit the influence of the researcher's self; it was tantamount to admitting that

research was tainted. Over time, the willingness to accept the active role that the researcher self necessarily plays in the process slowly crept into the literature.

This willingness empowered scholars to challenge the use of "I" as a distancing tool between quantitative research and many aspects of qualitative research. This distance has shortened over the years. The continued resistance to self-study is explained by the remaining distance, the shortening of the distance, in contrast, explains the power that humanism regained as well as the support for self-study that has been found.

At this point in the discussion, I present my own self-study ethnography following the concerns and guidelines discussed by Bullough and Pinnegar (2001). By inserting the autoethnography here, I provide an example of self-study to clarify, for myself and the reader, how humanistic research was used in the writing of this chapter.

Self-study Autoethnography

Not surprisingly, the insights gained in the writing so far are not the same as those I had back when the changes were first occurring, and they, too, add to an understanding of the humanistic conditions out of which self-study grew. During this period, the *Review of Educational Research* published, "Educational Research: A Personal and a Social Process" (Allender, 1986). Though not about self-study, and only indirectly about humanistic research, the review was concerned with issues surrounding objectivity and subjectivity and the complexities that were emerging. My motivation for writing related to a dissatisfaction with traditional methodology, a fascination with the idea of a research paradigm, and a hope for the evolution of a new one. I concluded, "As our system of research moves farther from equilibrium, we could fear that chaos will result, or maybe we can expect more meaningful, new mainstream, higher order educational research methods to evolve" (p. 189). The review caused few ripples, but it did act as one of the many markers that times were changing. Its publication was an affirmation that I was on the right track.

It was *Human Inquiry: A Sourcebook of New Paradigm Research* (Reason & Rowan, 1981), influenced by humanistic thinkers that catalyzed my thinking. From an array of authors, this edited volume provided the details, both philosophical and methodological, that were needed to develop the practical application of a new paradigm (with the possibility of more than one) to pressing research problems. With forty chapters, they argued for the inclusion of democratic processes, attention to feminist concerns, new ways of using traditional methods like interviewing, and altogether new ways of approaching research stemming from creative invention and design. Prevailing concepts of validity were challenged, and an examination of how personal influences effect the identification of problems, the analysis of data, and the interpretation of the analysis were highlighted. The variety of discussions offered choices from a range of strategies, including collaborative, dialogical, heuristic, participative, and action research. More relevant to this chapter, some of their examples actually

required self-study: investigating how personality influences the course of research, tailoring methods to enhance questioning oneself and even researching to improve one's practice.

Particularly exciting were several chapters written by Reason, Rowan, and Whitehead that each included theoretical discussions based on Jungian concepts. These chapters addressed my quest to learn more about what establishes the basic assumptions that scientists use to form the rules of scholarly research. Their work led me to an earlier consideration of Jungian psychological types in *Methodological Approaches to Social Science* by Mitroff and Kilmann (1978). Through a lens that exposed archetypal roots, Mitroff and Kilmann began their inquiry by reviewing several methods of classifying scientists and ended up proposing a grid built on two axes. The grid was used to identify modes of mental functioning. On the vertical axis, the poles ranged by degree from thinking (T) to feeling (F). On the horizontal axis, the modes of perception ranged by degree from, sensing (S) to intuition (I). In one of the four quadrants that these axes formed, lay the justification for the kind of research I wanted to do.

I followed a hunch that the quadrants would greatly increase my theoretical understanding of the new developments in the larger world of social science research. The quadrants were used to identify four types of scientists. The first three were familiar, actually functioning in the academic world: (1) the analytical scientist (S/T), defining the traditional researcher, (2) the conceptual theorist (T/I), resembling scholars who interpret text, and (3) the conceptual humanist (I/F), appearing very similar to action researchers because of the priority on effecting change. The fourth quadrant was dubbed the particular humanist (F/S), but its characteristics didn't look like anyone doing educational research.

The types were not intended to directly coincide with the actual daily practice of research. Daily work has more overlap and nuance. However, defining these types provided an understanding of the assumptions underlying the methods of research that were in practice – at least in case of the first three. But in the fourth, I found a theoretical basis to support my ideas. It incorporated the value of experiential data because it premised sensing, not intuition, as one of its starting points. Yet, there was a clear priority also given to the role of feelings. Mitroff and Kilmann (1978) concluded that this science could "not be afraid to display an ever-present, underlying emotional basis beneath an apparently impersonal, logical, and rational surface ... [nor] longer afford to deny its emotional foundations" (p. 104). In opposition to the traditional view, they pictured the particular humanist finding nonrationality as important as rationality and interestedness replacing disinterestedness. Unique results were as valuable as generalized ones. And fundamentally, they saw, "emotional commitment as an instrumental condition for the achievement of rationality" (p. 102).

The problem was the quadrant seemed to be an empty set. At the time, I didn't know that it would lead to what I would call humanistic research. I didn't know that it was providing me with the groundwork for self-study research, and I certainly was unaware of the relationship between the two that is becoming clearer as the writing of this chapter unfolds. I also didn't see anyone else willing

to take this radical stand. Many others were taking radical stands, introducing and doing all kinds of innovative research, but not this one. For me, there were significant aspects of personal and social processes missing.

In addition, the eighties required attention to matters that unsuspectedly unraveled another thread related to my quest. During this same period, I participated in an anti-nuclear support group involving a dozen elementary, secondary, and university teachers. Monthly we met to share our work, our lives, and our despair. We sought personal empowerment in the face of a threat of global destruction.

While this was not a scholarly work group, it was here that I learned about and experienced activities related to a book by Elbow (1986), *Embracing Contraries: Explorations in Learning and Teaching*. Central to the book was a description of the believing game. Elbow, an English professor, was frustrated with the quality of his classroom discussions and wanted students to listen better and to respond more attentively to each other in his classroom. From his analysis, the problem stemmed from an academic milieu based on a methodology of doubt. His students had long been trained throughout their schooling to listen mainly for the faults in others' thinking – leaving little room to understand how the opinions, observations, and knowledge of others could conceivably make sense. Out of this frustration, coupled with a careful analysis of academic thinking, he proposed a *methodology of belief* that could be used to balance the overriding presence of the normal scholarly methodology of doubt. What a stunning revelation! The emphasis was on balance; his intention was not to ignore the value of doubt, but to provide a tool that improved upon helping people hear and understand each other. Today, we can even more easily see that it is an essential approach to understanding the Other.

Because this idea grew out of experience in academic classrooms, I realized that practitioners were working near or in the quadrant I thought was an empty set – only that they didn't consider themselves researchers. This kind of work required sensing experience. It necessarily combined attention to both feelings and intellect, and it seemed basic to successful collaborative work. In our teacher support group, we played the believing game to open our minds and practice to finding connections with the thinking and feelings of our enemies, politically in our own country and those of the Soviet Union with whom we were engaged in a frightening war of nuclear threats. Little extrapolation was needed to envision investigative methods that would focus on understanding oneself as a requirement for understanding others.

An Autobiography of Research in Four World Views

The final chapter of my insights during this time was the publication of a book: *Imagery in Teaching and Learning: An Autobiography of Research in Four World Views* (Allender, 1991) that culminated after a ten year research process. One pilot study led to another, turning into four major studies that developed out of 366 experience experiments. The theoretical perspective developed throughout

the research process with my theory and practice constantly influencing each other. The story explored about the everyday ebb and flow of research experiences and led to a workable concept of humanistic research.

The project started out as a quasi-experimental study of mental imagery techniques for facilitating elementary school classroom lessons in spelling, vocabulary, and arithmetic. This expanded to offering a broader range of content and giving feedback to teachers to help them make desired changes in their style of teaching using imagery techniques. The obstacle was a failure to meet acceptable methodological standards for publication. While the teachers and I focused on best teaching practice, the informality of the work was judged insufficient to warrant publication. Originally planned with a quasi-experimental design, the new second design coincided with the prevalent conception of action research methods. At the time of their completion, the efforts of neither were deemed successful in academic terms.

After three years in elementary school classrooms, three graduate students and I initiated in-depth collaborative studies of our own imagery processes using similar learning tasks. For example, learning a multiplication table of the squares of 12 to 25. Our methods were now decidedly qualitative. The research was highly idiosyncratic and very much a self-study of our practices, which was, of course, suspect. Two years later, our knowledge of imagery process had grown considerably; almost as expected, there was still no publication in sight. It was gratifying to me that the graduate students had the sense to move on to their dissertations in the field of mental imagery, with the necessary methodological tradeoffs that were expected of them.

I suspended concern for publication to follow up on what the graduate students and I had learned – by involving more people. Another busy year was added to the project. Graduate students participating in a seminar entitled, "Learning about Learning with Mental Imagery" were asked to read the literature and try out ideas that intrigued them through short studies, what I called experience experiments, of their own imagery processes. The seminar focused on the enhancement of practical, personal skills in any area of cognitive and affective learning the students chose.

By this time, the article on research as a personal and social process had appeared (Allender, 1986), and it led to discussion in the seminar about innovative research methods that could be used for their short studies. I did not require a standard methodology, but I did draw their attention to intrapersonal and interpersonal processes. Uncharacteristically, I did "impose" thoughts about incorporating a methodology of belief on them. From the students' research reports, it was clear that our discussions had a significant impact on their work. Yet once again, similar to the mental set I had about Elbow's teaching, I assumed that what we had accomplished did not count as respectable academic research. In spite of my thinking that our learning in the seminar was terrific and finding their reactions not categorically different than the elementary school students years earlier, I limited my vision and chalked it all up to good teaching.

I was yet to notice the possibility of analyzing the large number of pilot

studies, 155 experience experiments that had been completed by these 25 students. It had been a grand effort that taught me far beyond what I had set out to learn, but finally, I reluctantly decided that the original project I had set out to accomplish and the subsequent variations had led to a dead end. The research, in my mind, would never be completed.

In *Imagery in Teaching and Learning*, I said, "This dead end marks the moment of insight" (p. 25). Redesigning the methods was never about replicating the research with tighter controls or any kind of tightening up the designs. The main thrust of the continued efforts was to maintain the interactive processes that were considered fundamental to learning what the teachers, their students, the graduate students, and I wanted to learn. Realizing this pushed me to reconceptualize the data that had been collected over seven years. A total of 366 pilot studies, based on my journal entries and those written by the graduate students, were recognized as experience experiments – each one representing a small informal study, a data point, that warranted analysis together with the others. They were organized into four separate studies that were aligned with Mitroff and Kilmann's (1978) four quadrants, one for each. Three fit easily. Though none of these studies used purely one method or another, overlapping in their use of each other's methodological techniques, it was not difficult to see their differences primarily following, in turn, the tenets of quantitative, action, and qualitative research. The analyses and interpretations were guided by the assumptions that Mitroff and Kilmann had set forth for each kind of research. In the book, they were later titled (1) A Search for Truth, (2) A Search for Change, and (3) A Search for Meaning.

The experience experiments carried out in the mental imagery seminar were fit into the fourth quadrant, renamed, humanistic research. It fit closely enough. Mitroff and Kilmann couldn't say practically what defined this kind of research, since it was an idea in the making, and I approached the analysis with the mix of tenets that had been emerging. A check was made for how all the people who had a stake in the work, students, teachers, and researchers, had faired in pursuit of their goals. A lens was created to weave the many disparate concepts: self, other, intellect, emotion, belief, doubt, empathy, and collaboration. It had to be both a personal and social process, theoretically and really. The results squeezed very tightly into a tiny nutshell tell how reality and fantasy have an interconnected intimate bearing on every kind of everyday learning. The fourth study became, (4) A Search for Connection, because so much was woven together.

What should have been obvious, but for the blinders that were still in place, is that self-study is an essential element of humanistic research. So much of the work involved learning about one's own skills as they related to those that were being studied and taught to others. In some way, the need for self-study was taken for granted; its intrinsic importance wasn't recognized. Even the subtitle of the book, *An Autobiography of Research in Four World Views*, was meant mainly to frame the chapters, not to highlight the importance of studying the self. In addition to an exploration of imagery in teaching and learning, only now do I really understand how the project was as much a study of my researcher self.

Humanistic research assumes that the universe itself is an undivided whole. Saying this points to a second assumption that humanistic research follows a different kind of logic than other types of research – we have to be less unnerved when irrationality, paradox, and the hard-to-believe appear on the scene. There is no harm in using the methods from other types of research, but the main concern is how people are faring in the process. A big part of this is learning about self and Other. A less important part is about publishing, but succeeding in academia has to be part of the picture too. Just like students successfully completing their dissertations, the concerns and choices involve tradeoffs. I find these different worlds not so far from each other. It is not that some research is humanistic and that some is not. Rather, one dimension shifts from low to high and another dimension shifts from within the pale to outside the pale. The big question relevant to every researcher, and addressed in the next section, is how do "I" express my humanistic concerns?

Humanistic Research in Self-Study

With apologies and appreciation for Margery Williams, author of The Velveteen Rabbit, where the rabbit learns from a toy horse how to become real, I begin with a mythical story.

Sometime around the end the second millennium of the Common Era, two Trojan horses came behind the walls and inside the halls of academia. The name of the first was, Reflective Teaching. The second was, Qualitative Methods. Inside each was a hidden humanistic spirit. Of the pair, the first tended to be feminine, while the second to be more masculine. From a close union of these two spirits, the more feminine horse also carried within it an embryo of a Baby Trojan Horse. When it was born, it was named, Teacher Research. But behold! Hidden inside the foal were educational researchers, not unlike the soldiers within the yet more ancient Trojan Horse, thousands of years before the Common Era, prepared to do battle with the gatekeepers of academia. Shortly after Teacher Research was born – with a bit of fanfare – they popped out too. Not inanimate horses. Not spirits. They were Real People, and wondrous. Their quest was to be as honest with themselves as they expected of the apprentice teachers to whom they were giving guidance.

The story came to mind in response to my curiosity about the seemingly sudden appearance of self-study on the academic scene. Unlike earlier developments, the self-study of teacher education practices popped out practically whole as a functioning entity in 1993, in the form of a special interest group, on the program of the international meetings of the American Educational Research Association (AERA) (Hamilton & Pinnegar, 1998a). The beginning efforts of humanistic research (and humanistic education) were more like those of outsiders who were bombarding the ramparts trying to enter. In contrast, researchers engaged in self-study were more like intruders who had already ensconced themselves inside the ramparts. Considering this, more figural than my thoughts were my feelings – that the beginnings of self-study were better described as

subversion. Because the ranks were comprised of a full range of successfully practicing educational researchers, the only thing other academics could do was imagine expelling them. It was too late for the gatekeepers of the standards to simply reject them. How, I asked myself, did this occur?

With subversion on my mind came the image of the Trojan Horse, and then I quickly saw there was more than one. Many of the members (reputed to be nearly 300) of this sizeable special interest group who joined in its first year were already energetically applying the concepts of reflective teaching and qualitative methods to their classroom practices and educational research – and thus, the first two Trojan Horses were imagined. Still, there was a gap. I realized that something was missing that helped turn reflective teaching and qualitative research into an organized emphasis on self-study. It was teacher research, another burgeoning special interest group that more truly embodied the idea of studying one's own practice. Because the direct connection between self-study and teacher research was obscured, I concluded that a third Trojan Horse was needed. The ranks of self-study did not identify themselves as teacher researchers, but certainly the latter group lent support to boldly explore where few educational researchers had previously gone.

As to the genesis of Real People, it relates to the fact that over the last ten years, I personally became familiar with the self-study researchers whose work is reviewed in this section. My humanistic perspective encouraged me to tap this personal knowledge as well in the process of interpreting their studies – and thus, they became the Real People in the unfolding drama.

The mythical story was written to organize my thinking and hopefully serve as a useful outline for the reader. First, there is a bit of prehistory. This is followed by the stories of the three Trojan Horses: Reflective Teaching, Qualitative Research, and Teacher Research. The final section, Real People, moves the center of the discussion into the first years of the third millennium.

The Lighthall Group

Around 1990, not unlike the humanistic spirit that had been surviving, even thriving throughout the last century, the unnamed idea (not quite a concept) of self-study appeared. To be expected, there was no reference to it in the index to the then current *Handbook of Research on Teacher Education* (Houston, 1990). Some years later, however, Hamilton and Pinnegar (1998a) reported evidence of individuals and groups that were already engaged in this research before its formal appearance on the program of the AERA meetings in 1993. Since I am one of the researchers cited, my experience can be tapped to embellish on the complexity of their discussion.

In 1991, my colleague, Fred Lighthall, invited me to participate in a group that would focus on the personal relevance of each member's research. Though we met only infrequently, connections over time proved to be a helpful support for this attention to self. Our discussions were lively. We encouraged each other to explore what we each were learning from the process and product of our

daily research and how it related to our own practice. We gave support when it seemed that a lack of confidence was figural; we gave and accepted significant challenge when there was a sense of incongruence between intending and doing.

A highlight was the publication by a group member of *Teaching: Making Sense of an Uncertain Craft* where McDonald (1992) mined his teaching for insights that might be of value to him and others. Here, a high school teacher turned teacher educator, reflecting on daily journal entries, educational literature, and three great teacher heroes, wrote with an open-ended certainty about the necessary awareness of the unpredictability of what happens when we teach. We saw that there was much to learn from a personal perspective. The problem was similar to my earlier teacher support group experience in the eighties: the group didn't recognize that our meetings were an integral part of the research process. It seemed to be just interesting talk. We simply didn't comprehend the greater implications of our ongoing collaboration.

The Formation of a Special Interest Group

Most of us became members of the self-study community that was formed in 1993, as did the others whom Hamilton and Pinnegar (1998a) identified. Many more opportunities for interaction and collaboration were available. Along with the others, we had named ourselves: The Self-Study of Teacher Education Practices, a Special Interest Group of AERA.

Some relevant publications soon came under the rubric, and some did not. *Teachers Who Teach Teachers: Reflections on Teacher Education* (Russell & Korthagen, 1995), a collection of studies closely related to self-study, was not identified with the new concept except for an occasional reference to the idea and to its appearance on the AERA program. In the same year, though, a special issue of *Teacher Education Quarterly* was published, *Self-Study and Living Educational Theory* (Jones, 1995). Included were Hamilton and Pinnegar's earlier research with their colleagues, Guilfoyle and Placier, as well as a study by Russell, and each was commented on by Whitehead, and as a whole by Korthagen. Elsewhere, Whitehead (1993) did not make an explicit connection with his challenging concept of teachers and teacher educators creating their own "living educational theories," even though his analysis was based on a detailed self-study of his development as an educational researcher. Finally, with the publication of yet another collection of studies edited by Hamilton (1998), *Reconceptualizing Teaching Practice: Self-Study in Teacher Education*, based on earlier research and the *Proceedings of the First International Conference on Self-Study of Teacher Education Practices* (Richards & Russell, 1996), the concept of self-study established itself, at least, as a worthy contender for the canons of educational research.

Reflective Teaching as a Trojan Horse

Evidence for the first Trojan Horse, Reflective Teaching, emerged from an overview of *Teachers Who Teach Teachers* by Russell and Korthagen (1995).

Many of the chapters stemmed from thinking and research on reflective teaching. From having attended conference sessions presented by many of these authors and regular informal conversations, I knew the value they placed on teachers learning to be reflective about their practice of teaching. In general, due to the far-reaching impact of *The Reflective Practitioner* (Schön, 1983) and *Educating the Reflective Practitioner* (Schön, 1987), reflective teaching was by this time integrated into the curriculum of many, if not most, teacher education programs. This was apparent (unlike self-study) in the *Handbook of Research on Teacher Education* (Houston, 1990) as well as a plethora of other publications (e.g., Clift, Houston, & Pugach, 1990; Henderson, 1992; Valli, 1992). Furthermore, in the chapter by Cole and Knowles (1995), they tellingly concluded that, "personal studies of professional practice are a form of reflective inquiry similar to the kind of reflective practice widely advocated for teachers" (p. 147).

At the outset, self-study was mistakenly assumed to be tied only to the expansion of alternative educational research methods. I noticed ties to reflective teaching were not primarily focused on research. In important ways, reflective teaching grew out of dissatisfaction with scholarly investigations. If anything, it was an antidote to inadequate information, sometimes misinformation that for years had been arrogantly foisted on classroom teachers. The act of reflection encouraged the expression of humanistic concerns and concomitant action. The message to teachers was that from their own observations, thoughts and voices, a multitude of answers were available, though not always transparent, for confronting daily classroom problems.

In *Teachers Who Teach Teachers*, teacher educators/educational researchers turned the need for reflecting on practice on themselves. Placier says, "For me, one aspect of becoming a teacher educator has been to recover my memory of my beginning-teacher self in order to understand my students' point of view. My graduate education distanced me from that long-ago self" (Guilfoyle, Hamilton, Pinnegar, & Placier, 1995, p. 44). In another chapter, Pinnegar says, "Could I teach in ways I was telling future teachers they should? I wondered whether what I learned in university coursework and what I had been teaching my students would survive in reflections on [my] teaching practice" (1995, p. 56).

The argument is not meant to diminish the significance of the expanding concepts of qualitative research and how they embraced humanistic concerns. It is more a matter of understanding the complex foundations of self-study. So, here we see the meaning of the first Trojan Horse: The practice of reflective teaching was an essential element in the creation of the conditions for the birth of self-study. The concepts provided a theoretical framework that suggested and offered its potential as a canonical basis for the radical intruder. Reflective teaching acted as a vehicle (pun intended) for the first Trojan Horse to enter within the walls of academia without causing a battle at the front gate – bringing within its humanistic spirit.

Qualitative Methods as a Second Trojan Horse

An overview of *Reconceptualizing Teaching Practice* by Hamilton (1998, with Pinnegar, Russell, Loughran, and LaBoskey) published a few years later, told a

different story. In contrast, its focus on methodology conjured up the image of a second Trojan Horse; Qualitative Methods. Foreshadowed in the conclusion to the earlier book, Korthagen and Russell (1995) point out their, "amazement at the type of research on teacher education that seemed to be acceptable to the research community at the beginning of the 1990s" (p. 187). And indeed, in the *Handbook of Qualitative Research* published in 1994 (Denzin & Lincoln), there is a reference (even if only one) to self-study in the index. Here, Reason (1994, who with Rowan in 1981 had acknowledged the humanistic roots of new paradigm research) found connections between action research – whose history goes back to Lewinian theory in the middle of the twentieth century – and the concept of self-study. But the amazement goes far beyond action research.

Most startling were discussions that privileged possibilities that had been for years impossible to imagine: heuristic research that found a place for an investigator's intense personal involvement (Moustakas, 1990), arts-based research that brought elements of the humanities, and consequently subjectivity, blatantly within the concept of scholarship (Eisner, 1991), and suggestions that fiction might provide more useful knowledge in some contexts than sanctioned data-based analyses (Wolf, 1992). Eisner and Peshkin (1990) presented provocative discussions of the changing meanings of subjectivity, validity, and generaliziblity; they conveyed an excitement attached to the potential of these new alternative methods. And, these heightened emotions were balanced by more staid presentations in *the Handbook of Qualitative Research* – firming up the place of qualitative investigations in the canons of educational research. With the latter, what greater gift could there be than a Trojan Horse that seemed to bring some needed stability to the academic turmoil that had been brewing since the sixties, even if everyone probably suspected the humanistic spirit within?

As much as anything *Reconceptualizing Teaching Practice* (Hamilton, 1998) is a collage of lenses. A wide range of alternative research techniques is used to probe the investigator's teacher self and how it is manifested in practice. All of the studies can be referred to as reflective teaching, but the figural emphasis is focused on the choice of research methods. The studies, overlapping in their approaches to educational inquiry, incorporate the techniques of action, autobiographical, anthropological, and arts-based research. The broad application of critical theory has a place, as does the more specific use of portfolios. Psychological self-analyses and similar techniques are used to interrogate the interpersonal dynamics of collaborative work. Even philosophical analyses are included with a focus, in one case, on practical argument and, in another case, on confronting paradox. Each chapter, of course, is a unique mix created to achieve the goals of the investigator(s). And, though some traditional aspects of research appear now and then, for the most part, the studies are marked by what Hamilton and Pinnegar (1998b) in the introduction characterize as openness, collaboration, and reframing.

As a whole, the book had a remarkable fit with the current methods of qualitative research, and this fit eased the acceptance of self-studies. In discussions, there were murmurs of concern about the centrality of self and its problematic place in the research process. Significantly, Hamilton and Pinnegar (1998a)

concluded that self-study went beyond the boundaries of qualitative research: "More than a qualitative approach to a situation, self-study scholars attempt to embrace ... uncertainty and reject calls for validity and reliability as they are traditionally known. The multilayered, critically-imbued, reality-laden world is the text of the self-study scholars ..." (p. 235). And, "One of the research by-products of self-study is the way in which it pushes the boundaries of what counts as research" (p. 240). In my mind, the use of the words "traditionally" and "by-product" was overly cautious, but however these conclusions were expressed, they still expressed their unsettling challenge to the canons. Considering the breadth of the studies that were reported in the first self-study conference Proceedings (1996), bolstered by the those reported in the *Proceedings of the Second International Conference of the Self-Study of Teacher Education Practices* (Cole & Finley, 1998), clearly another, larger-than-usual, humanistic spirit was now inside the walls.

On the one hand, this humanistic spirit that is integral to self-study signifies an epistemological shift, paradigmatic in scope, in the locus of knowing. The source of scholarly knowledge in the modern view resided in an objective reality. In postmodern times, it has moved into a community of scholars because of a belief in a constructed reality. I believe, however, that it never resided solely within the community; rather, knowledge is always a balance between the conclusions of self and community inquiries. Being aware not to discount the value of collaborative inquiry, a humanistic view of self-study research suggests that the balance has shifted more to self – as the most trustworthy source of knowledge.

On the other hand, luckily, such a grandiose contrary epistemological view is not essential to the everyday practical application of the methods of self-study. Even though the larger-than-usual humanistic spirit exists, how it is expressed is a matter of personal preference. There are other factors to consider; the willingness to be reckless is one extreme, how much concern there is for staying within the bounds of an academic comfort zone is another. Whitehead's (1993) autobiographical study of his trials and travails in becoming an educational researcher is about taking sizeable professional risks. McDonald's (1992) autobiographical study is about bending the self-study methods to fit within norms of conventional academic scholarship. Both are valuable. The special self-study issue of *Teacher Education Quarterly* (Jones, 1995) bridged some of the space in-between. Similar to Whitehead, at times these studies documented personal struggles involved in becoming better teachers, teacher educators, and educational researchers. But they also probed the everyday practice of teaching in ways that invited a larger audience. So it is for all self-study: every investigator has to choose how to express his or her humanistic concerns. These concerns are fundamentally a part of the methodology, yet surviving is too. Humanistic actions take place in a context that includes the needs and values of a host of others.

Teacher Research as a Baby Trojan Horse

More factors came to light when the scope of everyday practical applications was furthered widened to include the activities related to another AERA Special

Interest Group: Teacher as Researcher. This too is self-study, though not usually in the same purview. The two fields have been developing pretty much in tandem, sharing similar goals, yet oddly they are quite independent of each other. While there is substantial overlap, we seem to be disconnected. It is these thoughts that inspired the invention of a third Trojan Horse, a Baby one, called Teacher Research. Because the body of published research is considerably smaller than it is for reflective teaching and qualitative methods, it might seem that this further figment of my imagination goes too far. However, it becomes real in its own unique way. Of special interest is how the practice of classroom teacher research informs teacher educator self-study. The knowledge base, though less extensive, offers some insights. It is noteworthy that the work is guided primarily by the methods of action research. Plus, it is curious why there are many classroom teachers attracted to this avenue of professional development. What's this all about? There is a gift in Teacher Research that needs to be examined.

It is not as if classroom teachers have never before engaged in the study of their own teaching – only that it was now identified as a special kind of inquiry. Formal studies aside, between the mid-seventies until I retired 25 years later, students in my teacher education courses were routinely asked in connection with short assignments to provide examples from the study of their teaching practice. This is a big sample, and I found that students rarely complained. For the most part, the work generated involvement and excitement. It was a good way for me as a teacher to connect theory and practice.

Had the activity been theorized, I might have noticed what Kincheloe (1991) pointed out: teachers researching their own practice are following a path toward empowerment. This is not to say that their quest starts out as a humanistic concern. Unlike McDonald (1992) who conceptualizes teaching as an uncertain craft, Kincheloe finds that teachers are often motivated by a quest for certainty. Many yearn for the proper methods to guide what they imagine is "real research" (Jungck, 1996). But the advice that gets through to teachers is about the more fluid methods of action research (Burnaford, Fischer, & Hobson, 1996; Kincheloe, 1991; Winter, 1989), and the evidence provided is comparable to the positive results I experienced. What we see is an intrinsic interest in the study of one's own teaching, which I believe is another aspect of a humanistic spirit being expressed.

Empowerment and humanism are both part of a complicated weave, much like Horten and Freire (1990) discussed. Though critical theory is the primary foundation of Kincheloe's discussion, it is to Dewey he turns to sort out the distance that alienates practitioners from the value of scholarly knowledge: "The limitations, Dewey maintained, of the hierarchical workplace prevent the non-elite from gaining access to the methods of social inquiry" (Kincheloe, 1991, p. 3). In other words, what teachers are searching for is a sense of agency in face of the difficult process of learning how to teach successfully and well in their own eyes. With little extrapolation, we can see that the search is no different for teacher educators who are applying the methods of self-study. Only, in this case, the elite to be confronted are embodied in the limitations of canonical research

methods (including even some aspects of qualitative methodology) and those colleagues who hold them too dearly for fear of breaking with tradition. Furthermore, it is telling that action research was one of the historical roots that led to the field of teacher research just as Hamilton and Pinnegar (1998a) say they did for self-study. From this perspective, I suggest that the development of reflective teaching and qualitative methods only framed the context within which self-study could be nurtured, while the more intrinsic impetus felt by teachers of all stripes urged the actual birth of self-study.

The similarity of teacher research and the self-study of teacher education practices are found in their common concern for interpersonal processes that are so much a part of action research. What separates the two is the greater attention to intrapersonal processes that self-study requires. For example, a recent concise guide to action research for classroom teachers (Mills, 2003) does not mention self-study; even though, the breadth of methodological concerns has broadened over previous texts, his own and others. Different than earlier texts, it draws attention to self-reflection and humanistic concerns, though unsurprisingly; the latter is not named as such. Yet, while targeted for classroom teachers, the book has equal merit for teacher educators who are engaged in self-study. In the story of the Trojan Horses, I describe self-study researchers as the progeny of Teacher Research. More accurately, from this complex mix of connections and disconnections we see that this is not so. Metaphorically, however, understanding self-study is richer for imagining that it was born out of the common motivations that many teachers have for studying themselves.

Real People

Today, at the beginning of the twenty-first century, who actually are the Real People? They are the members of the self-study community who have appeared in the discussion so far, those who will find their way in before the end of the chapter, and many others, unreferenced, who regularly contribute valuable efforts to this common endeavor. And, they are especially the people who have attended one or more of the four conferences of the International Self-Study of Teacher Education Practices held every two years since 1996. In addition to the first two Proceedings that have been cited for the conferences in 1996 (Richards & Russell) and 1998 (Cole & Finley), two more proceedings have been published to document the research presented in 2000 (Loughran & Russell) and 2002 (Kosnik, Freese, & Samaras). But, it is equally important to know that all four conferences, with the participants in residence, were held at the Herstmonceux Castle in East Sussex, England. In sum, the Real People brought themselves into being with their conference presentations, here and elsewhere, their many writings, and the days that were spent working closely together at the Herstmonceux Castle that is now a tradition every even year.

Stemming from the presentations at the conference in 2000, another collection of studies was published: *Improving Teacher Education Practices through Self-Study*, (Loughran and Russell, 2002). Again, the emphasis on reflective practice

was widely evident, while the application of creative qualitative methods further expanded the previous range of possibilities. But also evident were innovative approaches to familiar concepts and some new ones that connected self-studies with other fields of study. Highlighted were the ongoing actions of teacher educators that provided role models for their students – who together were learning to teach. The work of partnerships revealed unexplored nuances for differentiating collaborative teaching and collaborative analysis. Teacher research in classrooms was integrated with teacher educator self-study. And, terms that had received little attention in self-study research before became more figural: social justice, educational reform, reflective communities, critical friends, and self-analysis.

Loughran (2002) well summarized the implications of this new body of research: "For teacher education to become better equipped to respond to the expectations placed before it, there is a realization that there must be change by teacher educators themselves before there can be genuine educational change" (p. 242). For Loughran, the need to change finds its source in dissatisfaction, but I believe it is more about a desire to grow that we are witnessing – which is fundamental to the humanistic spirit that has been evolving.

From having attended all four of the Castle conferences, I have concluded that the collegial climate at the Castle conferences is unusual for the informal norms that support innovative presentations and regular opportunities for inter-active discussion. Careful listening while trying to understand colleagues' points of view ranks as high in importance as the quality of the research. Though not every participant may know Elbow's (1986) concepts of methodological belief and doubt, a typical response to research outcomes often demonstrates an intuitive ability to balance these approaches. Not that the norms for academic presentations are totally dissimilar for other special interest groups of AERA, true sometimes even at the international meetings of AERA in general, nor are the meetings of the self-study community at AERA since 1993 to be discounted, but the humanistic character of the communication at the Castle is strikingly ebullient. What adds greatly over the course of the four-day conference is living in the same dormitory, eating our meals together, and meeting at the end of each day for conversation and laughs in the pub. The members of the community clearly agree, however tacitly, to hold the value of interpersonal relationship in high regard.

Coda: Reflecting on Honesty

Rereading *Opening the Classroom Door*, aptly subtitled for this discussion, *Teacher, Researcher, Learner* (Loughran & Northfield, 1996) in preparation for writing this chapter, produced a lingering feeling that there is still something missing in the description of the humanistic elements of self-study. Northfield, a long-time teacher educator, decided to go back for a year to teach mathematics and science in a secondary school – as a self-study in an effort to improve his ability to teach teachers. The book is a wonder of a collaboration between John

Loughran, who writes the running discussion of the experience, Jeff Northfield, who supplies the targeted journal entries, and a colleague, Carol Jones, who interviews the students.

In this endeavor, the three teacher educators and a host of students work together with great honesty to get on with the task of teaching and learning. For all that, it is a model of self-study methods and an understanding of how self-study means more than how "I" improve my practice, its greater message, at least where my interest fits in, is how the humanity of each of the characters in this classroom drama gives the work something powerful to say to the others of us who were not there. When I finished reading, I knew it was all about doing what was needed to attain a new level of honesty for Jeff Northfield in pursuit of teaching high school students in a manner that is congruent with his teaching about teaching. No less were the efforts of the collaborating investigators and the high school students to be worthy of his courage to walk his talk by being honest themselves. I've discovered the underlying motivation for why teacher educators want to do self-study. It's about honesty – teacher educators asking of themselves to put in practice what they ask of their students. Northfield's strength is in the eloquence of its expression.

Yet, his is not a unique quest in the self-study community. Striving for honesty seems to be an underlying characteristic of much of the research. It's most apparent when teacher educators go back to the classroom. For example, Russell (1995), similar to Northfield, returned to the classroom to teach high school science for a semester. Differently, he also invited students from a physics methods class to observe him teaching physics "whenever their schedules permitted" (p. 86) and other physics teachers in the school as well. In the end, he says, "Both my teaching and my research have been inspired by new perspectives on the process of becoming a science teacher, and on the process of becoming a better teacher educator" (p. 93).

There are also other means of expressing honesty than returning to the classroom. Samaras (2002) in *Self-Study for Teacher Educators: Crafting a Pedagogy for Educational Change* interweaves her history of becoming a teacher and then a teacher educator – with a redevelopment of Vygotskian theory (and connections with Dewey, taking us back to the beginning of this chapter) and reflections on her more recent experiences in the role of a teacher educator. The struggle to make all these parts and pieces congruent is palpable. I wonder if every self-study, with a little effort, could be undertaken and benefit from a similar strategy.

The drive to be honest with students and myself found its expression in *Teacher Self: The Practice of Humanistic Education* (Allender, 2001). Students were asked to collaborate in my self-study by contributing stories about their learning in the Art and Science of Teaching – based on experiences that occurred in class during the semester. The task was to weave our stories together so that we could understand the same classroom events from both the teacher's and the students' points of view. Judging from the reactions of the student authors and some of their classmates who ended up as characters in the narratives, the final

stories succeeded in catching the feeling and spirit of what really happened. It was rewarding that the project had become a tool for us to reflect on my teaching, their learning, and their teaching in their field experiences.

Something else emerged however. In an effort to make sure that they would be able to tell really good stories, I found myself planning my teaching with this goal in mind. For a moment, a question of ethics arose – it seemed dishonest. But then I realized what better way is there to plan? In retrospect, the honesty sought for was about providing an exciting learning environment, one that was as exciting as I expected them to offer their students.

Humanistic research requires a creative investigative structure that frames the inquiry, even as the structure shifts in the process. It is a framework that invites and stimulates reflection. When the goal is self-study, it is by definition teacher research with its built-in concerns for empowerment. In the process, there is the opportunity for everyone to have an expressive voice. Above all, the work is about people, before ideas, each and every one of us. All manner of theory may be tapped, but people are more important than the theories. The concern for evidence is central, but not so much that the voice of a lone self is stifled. The goal is to connect idealism, practicality, and people in an interconnected web of respect moving in every direction. Humanistic research is about connection and so is the self-study of teaching and teacher education practices.

THE SIGNIFICANCE OF RACE AND SOCIAL CLASS FOR SELF-STUDY AND THE PROFESSIONAL KNOWLEDGE BASE OF TEACHER EDUCATION*

Enora Brown
DePaul University

Abstract

Race and social class are pivotal in structuring inequity in the educational system, defining the content of official knowledge, establishing pedagogical policies and practices, and shaping relational dynamics in educational contexts. The question arises: Do race and social class have substantive relevance for teacher practice and the process of self-study in education? The purpose of this chapter is to explore the significance of race and social class meanings in educators' practical and intersubjective experiences, and to examine the contributions of self-study theory and research to understanding race and social class in educators' pedagogical, curricular, and programmatic endeavors. A critical social-constructivist perspective is presented to examine teachers' attitudes and expectations. It is grounded in the normalization of inequity and derived from historical, racial and social class meanings that have become internal to the self-as-educator in local practice. This chapter addresses the unique contributions that self-study's research paradigm and foundational principles make to investigating and reframing beliefs, assumptions and practices, and analyzes the knowledge produced from educators' disciplined self-study inquiries on race and social class. Recommendations from these inquiries are presented with implications for educators' personal and professional growth, for transformations in the foundational knowledge-base in teacher education, and for institutional change in education.

The dynamics of race and social class have played a pivotal role in structuring

J. John Loughran et al. (eds.), International Handbook of Self-Study of Teaching and Teacher Education Practices, 517–574.

the educational system and in defining the form and content of officially sanctioned knowledge within educational institutions. Issues of race and social class have implications for the ways in which our schools are organized, the explicit and tacit goals that are embodied in our curricula, the ways in which we teach, and the ways in which we strive to improve our role as professional educators. Critical historical analyses of the American educational system reveal that the societal dynamics of race and social class undergird the legalized structure and funding of public education and account for huge disparities in the quality of education (Darling-Hammond, 1995; Lipman, 1998; Anyon, 1997; Kohl, 1991).

Theoretical and textual analyses reveal that the construction of racial and social class meanings undergird the legitimation of particular forms of pedagogy and discipline-based knowledge, while marginalizing other forms and sources of knowledge (Apple, 1985; Collins, 1990; Zinn, 1980/1990; Loewen, 1995; Morrison, 2001). Concomitantly, decades of studies document that teachers' attitudes and expectations are unwittingly laced with racial and social class meanings that intersubjectively shape their relationships with students (Griffith & London, 1980; Gottlieb, 1964) and inform the professional policies and practices that are institutionalized in educational contexts (Ladson-Billings, 1994; Foster, 1997; Irvine, 1990). In effect, qualitative and quantitative studies indicate that race and social class meanings pervade the institutional structure, the discourse of curricular texts, and the professional relationships and interpersonal dynamics within primary and secondary schools and higher education.

In light of the profound and pervasive impact that racial and social class meanings and corresponding social inequities have had on the structure and the teaching-learning processes within the American educational system, the question emerges as to whether race and social class have any substantive relevance for teaching practices and for the process of self-study in education. In other words, are the issues of race and social class present in our practice as educators? Do the issues of race and social class have any significance for teachers' daily activities in their classrooms, for teacher education programs, and ultimately for the ethical work of teacher educators' collaborative self-studies? Are race and social class issues tangential to the self-study process? Are there ways in which involvement in the self-study of teacher education practices may shed light on the function of race and social class issues in the professional practices of teachers, in programmatic or institutional policies and practices, and thereby enhance the field of teacher education? These questions frame this chapter's focus on race, social class, and the disciplined inquiry of self-study.

This chapter will examine the significance of race and social class issues in educators' daily practices and experiences of teachers and students as they shape the educational process. A rich body of early empirical research on teacher attitudes and expectations provides insights into the presence of race and social class issues in educators' practices that may be the subject of self-reflective inquiry. Second, this chapter will examine the contributions that self-study theory and practice make to our understanding of race and social class issues in

professional practice and to our efforts as educators to transform teacher educa-tion. Analysis of selected self-study studies reveals some important ways in which this work on issues of race and social class can inform educators' professional practices and the field of teacher education.

Section I, Conceptual Issues: Race, Social Class, and the Self provides an historical perspective on the concepts of race, social class, and the self to provide some context for understanding the embedded nature of the attitudes and beliefs that pervade educational policies, teachers' practices, and educators' self-reflec-tive inquiries. I present a critical social-constructivist view of the self (Elliott, 2001; Holland & Lave, 2000) because it locates self-development in the context of sociohistorical and cultural relationships as well as current local practices. This section addresses the ways in which race and class constructs are inscribed on the self and therefore operate in teachers' professional, pedagogical practice.

Section II – Teacher Attitudes and Expectations in Educational Practice focuses on the manifestations of race and social class in educational practice. In this section I explore the patterns of racial and class attitudes in the teaching practices of teachers that emerge when they work with a diversity of students in classrooms and other educational contexts.

Section III – Self-Study, Race and Social Class addresses the goodness of fit between self-study as a research perspective, its foundational theoretical prin-ciples (Dewey, 1933; Schön, 1983), and educators' inquiries into the significance of race and social class in education. This section will also pose questions related to each of the foundational principles that support educators in identifying "puzzles of practice" regarding race and social class in education.

Section IV – Self-Study Research presents an overview of the self-study research that has explicitly addressed the issues of race, social class, and ethnicity in teachers' educational practice, as well as in their endeavors to develop and transform curricula and program design. This section considers the invaluable contributions that collaborative, self-study inquiries have made to the process of discovering, producing local knowledge about, and reframing issues of race and social class in education. This section concludes with a discussion of recom-mendations drawn from the bodies of research discussed, and conclusions about possible future directions for Self-Study with regard to inquiries into the issues of race and social class in educational praxis.

I wrote this chapter based on the *critical social constructivist* view that, "… the organization of society penetrates to the emotional core of the lives of its members" (Elliott, 2001, p. 48), and that history is made in persons and made by persons in the context of local practice. As such, people are fashioned by history (Holland & Lave, 2001). Three premises flow from this perspective: 1) the *sociohistorical and cultural dynamics* of race and class hierarchies in society (i.e., enduring struggles) inform the policies and local practices within educational and other institutions (Holland & Lave, 2001); 2) the historically constituted societal dynamics and meanings of race and class shape the *social and psychologi-cal dimensions of the self* in the context of lived experience (Elliott, 2001); and, 3) the self, embodied with social meanings, brings this *history-in-person* to bear

on her/his practice as an active participant in constructing, reproducing or transforming meanings that constitute institutional social relationships (Elliott, 2001; Holland & Lave, 2001). From the critical social constructivist perspective, the societal meanings constructed in the broader society around race and social class are inherently woven into our beliefs, values, analytic lens, and teaching practices, whether explored or unexplored.

Self-study is uniquely suited to contribute to an understanding of race and social class issues in education. Grounded in the theoretical works of Dewey (1933) and Schön (1983), self-study embodies the idea that educators' self-reflective thought is an integral part of teaching practices, and that educators can research their own practices (Loughran, 2002). Self-study is a research paradigm that promotes educators' identification of the problems of practice that emerge in their work, fosters an examination of the values, beliefs, and assumptions that inform their educative decisions and actions. It encourages collaborative investigations that incorporate multiple perspectives and reframe prior conceptions regarding the problems of practice that face them. From an emic perspective, or insider's view, self-study creates practitioner-derived knowledge that may have relevance not only for the teacher researchers directly involved in the self-study process, but for other educators faced with similar questions in their teaching-learning endeavors.

Through self-study, educators may examine *the context*, that is, the historical and current social relations of race and class inequity that inform teacher attitudes and expectations and frame racial and class dimensions of the self. We may also gain insight into tacit and explicit meanings that inform and shape our work as educators, our curricular designs, our pedagogical practices, and our self-reflective inquiries. Furthermore, we may gain insight into the values, policies, and professional practices that define the structure and curricular content of teacher education and shape the racial and class attitudes reflected in teachers' practices and conceptions of self-reflective teaching (Zeichner, 1996). The depth and breadth of self-reflective inquiries may be enhanced by both an understanding of the functions of race and class issues in the structural formation and maintenance of educational institutions, policies and practices, and by an understanding of the raced and classed meanings that constitute dimensions of the self as educator. Through self-understandings, we may sharpen the lens through which we see and problematize our puzzles of practice (Munby & Russell, 1995) and facilitate our role as teacher educators committed to promoting our own and others' self-studies, and enliven and transform teacher education programs through the rigor of critical self-inquiry. It is from this perspective that the issues of race and social class need to be explored in self-study processes of educators.

Section 1: Conceptual Issues: Race, Social Class and the Self

This section presents the focal concepts of race and social class as they emerged in the views of the modern world and the dominant Western ideology and

normalized inequities in public education. This section presents a perspective that illustrates a depth and breadth of race and class issues in society, in a way that issues of subjugation are not relegated to the good or bad will of individuals. The historical origins provide a context for understanding the embedded beliefs and dynamics of race and social class issues that may emerge in teachers' practices, frame educational policies and practices, and inform the questions, blindspots, and insights that are a part of educators' self-reflective inquiries. Historically, social relations of power and privilege in the western world have been configured around phenotypic, economic, and biological differences as if they were natural hierarchies of humans' inborn qualities and characteristics.

Concepts of Race and Social Class

Stephen Gould notes the impact of the concept of race and its use as a basis for the oppression of others:

> We pass through this world but once. Few tragedies can be more extensive than the stunting of life, few injustices deeper than the denial of an opportunity to strive or even to hope, by a limit imposed from without, but falsely identified as lying within. (Gould, 1981/1996, p. 61)

Gould addresses the travesty that occurs when one group imposes external limitations on another group, *as if* they are inherent, internal limitations based on differences in skin color, with the inevitable result that the disenfranchised are denied their human rights, life opportunities, and hope. Thus, when the *social* categories of race and social class are used as markers of *inherent* difference, they have a profound impact on social life and on the intersubjective experiences of individuals and groups in their daily interactions. Even in the classroom, bell hooks notes that the voices and knowledge of some are privileged over those of others on the basis of these differences. She states: "… Race, sex, and class privilege empower some students more than others, granting "authority" to some voices more than to others" (1994, p. 185). What are the constructs of social class and race, and what is the significance of their use as human classificatory systems?

The Constructs of Social Class and Race

Social class is a hierarchical ranking of individuals and groups based on their relative position in the process of production in society and ownership of human and other resources that create, distribute, and expand wealth. In classical Marxian terms, the working class is located at the bottom of the economic ladder and sells its labor to live, the ruling class is located at the top of the ladder and owns the means to buy others' labor for profit, and the middle class are those individual entrepreneurs and members of the professional, educated elite. Classed society emerged over time as surplus resources were accumulated in the human struggle to produce the means for survival. Throughout the periods

of slavery, feudalism, and capitalism, societal arrangement into social classes manifested the private ownership and maintenance of wealth accumulated over generations. In sociological theory, there have been other definitions of social class that include attributes such as educational level, social and cultural habits/tastes, occupation, status, dispositions, and background (Brooker, 1999). Social class categories have been infused with differential essentialist characteristics (lazy, underserving poor) to explain or justify why one group or nation rules and another group is subjugated.

Race is a social construct, based on differences in physical characteristics, e.g., skin color, facial features, hair texture, eye color/shape, and body build (Lopez, 2000; Gould, 1981/1996; Harris, 1995). These observable differences in human adaptation have their origins in radically different climates, environments, and continental conditions under which people survived. Those people with darker skin, replete with melanin's protective barrier from the sun, lived in warm climates close to the equator. Their broad noses were adaptive to an ample intake of warm air and their short curly hair provided protection for the head in climatic heat. Those with lighter skin lived in cold climates that were farther from the equator. Their thin nostrils were adaptive to the limited intake of frigid air in cold climates north of the equator and their long straight hair was suited to the need for abundant head covering in the face of cold winds and snow. While these and other physical differences that contribute to variations in human physiognomy have no inherent meaning, the construct of race pervades our thinking and shapes social life. What social functions do the constructs of race and social class serve?

Racial categories, originating in the late 17th and early 18th century (Gould, 1981/1996; Watkins, 2001), and class categories were constructed in the context of one group's oppression of another in the territorial pursuit of natural resources and wealth. Differential characteristics were used as indicators of a group's superiority or inferiority and provided the impassioned rationale for exploitative social relationships. A rationale appeared under the banner of Biblical authority and the theological construct of the "curse of Ham" to justify European colonialism and U.S. slavery (Felder, 2002; Gould, 1981/1996, p. 102). Simultaneously, the ascendance and legal sanctioning of Whiteness as a property interest worthy of protection (Harris, 1995), occurred simultaneously, as blackness became synonymous with enslavement. Subsequently, with the emergence of wide-spread industrialization, mechanization, scientific inquiry, the release of Darwin's *Origin of the Species* in 1859, and the end of the Civil War, the societal shift from agrarian to industrial life solidified, and scientific racism and social Darwinism became the explanatory bases for racial and class oppression. Whiteness emerged as a normative social category that could only be defined in and through the construction of its deviant other, the category of Blackness. These mutually constitutive social categories served an important social function. They justified the enslavement of Blacks, the manifest destiny of westward expansion in the United States, the occupation of Native American land, the annexation of Mexico, the colonization of Puerto Rico, and ultimately the subjugation of

African Americans, Native Americans, Mexican Americans, and Puerto Ricans (Spring, 1994/2001; Takaki, 1993) by Whites. Similar patterns evident in the subjugation of the Aboriginal people of Australia, of Blacks in Brazil, and of Blacks in South Africa reflect the historical relationships specific to each nation. The discourse of slavery and colonialism simultaneously instantiated the dominance of whiteness, the entitlement of the economic aims of the ruling class, the deviancy of communities of color, and the depravity of the economically disenfranchised (Weis, Proweller, & Centrie, 1997).

In addition, as Gould notes in the following quote, the constructs of race and social class, ideologically sanctioned by religion and science, were and still are used to mutually define one's social location in the social order:

> The defenders of slavery did not need polygeny. Religion still stood above science as a primary source for the rationalization of the social order … Subsequent arguments for slavery, colonialism, racial differences, class structures, and sex roles would go forth primarily under the banner of science. (Gould, 1981/1996, p. 104)

Gould's words illustrate ways in which religion, science, and Social Darwinism justified slavery and class oppression, and were used to fabricate stories of inherent differences among the races and social classes. Similarly, supporters of Social Darwinism, based on the evolutionary concept of survival of the fittest, used this theory to explain class stratification, as if it was a natural hierarchy of human difference, comparable to the differences across the species. Gould notes that, "Social Darwinism … referred to a specific theory of class stratification within industrial societies, particularly to the idea that a permanently poor underclass consisting of genetically inferior people had precipitated down into their inevitable fate" (Gould, 1981/1996, p. 368). As such, the constructs of race and social class, in concert with their ideological explanations, function to support and maintain inequitable relations between groups in society. Thus, the social meanings imbued in the categories of race and social class grew out of history of slavery and other societal relationships that constituted contentious struggles for economic ascendancy and political domination. Hence, race and social class have meaning and function dynamically, only, as interdependent social phenomena. These same meanings that bolster inequitable arrangements in society also have significance for education, that is, for the values and beliefs that may pervade the structure of public education, inform our educational practice, and shape our self-study inquiries.

What is the significance of the history and function of race and social class? In part, history may prompt important questions about the current function of race and social class in education and the role of self-study in this process. For example, race and class meanings inform the values and beliefs that pervade the structure of public education, inform our educational practice, and potentially shape our self-study inquiries? Are there ways in which educators in the 21st century subscribe wittingly, or unwittingly to Social Darwinist views about

students based on race and class, by dismissing inequity or school failure with the dismissive argument: "Well, their failures must be indicative of their inferiority, and if they were equal, they would have done better!" Does the reproduction of these views contribute to the maintenance of social inequities in schools and other institutions? Hence, are these race and class meanings that need to be examined through self-study in our teaching practices, our programmatic work, and in the perspectives we transmit in our teacher education programs? A look at the past and current role and function of race and social class in education is illustrative.

The Constructs of Race and Social Class in Education

The social constructs of race and social class have played a profound role in the structure of and ideological justification for inequity in public education in the United States and in other countries, such as Brazil and South Africa (Anderson, 1988; Marx, 1998). For example, with the advent of industrialization in the United States, northern industrialists and southern plantation owners created disparate forms of education for the industrial education for African American ex-slaves and the classical liberal education for Whites. The separate, unequal schools, further institutionalized inequity through Black disenfranchisement, segregation, and economic subordination. These race and class-based policies divided Black and White workers and protected the economic interests of the burgeoning industrialists. This divisive system afforded marginal material and psychological privilege to White workers, i.e., racial privilege would compensate disadvantage because of social class, and relegated Black workers to manual labor. This structural inequity was solidified through a reign of terror against Blacks in the form of vigilante violence by the Ku Klux Klan and an accompanying ideological campaign of racist ideology of slavery (Anderson, 1988; Zinn, 1980/1990). Elaborations on the meanings embedded in the constructs of race emerged. Earlier images of the happy slave as "Mammy" were replaced with incendiary images of the "Black Brute", a violent brute who threatened civil society. These new images of freed Blacks who needed moral uplifting and threatened the civility of the New South justified the terror and unequal public education and reaffirmed insidious racial meanings. Comments by people of the times are illustrative. The sentiments of William Baldwin, a northern philanthropist for public education, stated:

> Time has proven that [the Negro] is best fitted to perform the heavy labor. … This will permit the southern White laborer to perform the more expert labor, and to leave the fields, the mines, and the simpler trades for the Negro. (Anderson, 1988, p. 82)

The Governor of South Carolina asserted that:

> [Blacks are] … destined by province for slavery … made evident … by the color of their skin … by the intellectual inferiority and natural improvidence

of this race … They were … unfit for self-government of any kind and in all respects, physical, moral, and political, inferior to the millions of the human race. (In Fredrickson, 1971/1987, p. 46)

The social and cultural meanings attributed to racialized, classed beings were embodied objectively in the structural inequity and subjectively in the ideological campaign. These social and cultural forms gave shape internally to Blacks' and Whites' intersubjective experiences of the superior racial self, the inferior racial other, and their concordant expressions in the mutually constitutive social practices of privileged Whites and disenfranchised Blacks.

Similar racial constructs accompanied the systematic removal of Mexican Americans, Native Americans and Puerto Rican Americans from their land. Characterized as "uncivilized" and "lazy", education became the means to "civilize" and "acculturate." The Native American students were removed from their land and sent to non-reservation boarding schools, portions of Mexico were ceded to the United States, and Mexican children were sent to English-Only schools. As their land was colonized, the Puerto Rican people were subjected to Americanization policies embedded in public education (Spring, 1994/2001). Are these images still with us today? Do they justify race and class inequities that exist in our educational system and inform our day-to-day perspective, decisions and practices as educators?

Current Patterns in Education

Historically constituted racial and class constructs accompany the current property-tax based disparities between predominantly White wealthy and predominantly poor schools in communities of color that are well documented in the literature (for example, Kohl, 1991; Anyon, 1997; Lipman, 1998, 2002; Oakes, 1985). These constructs have taken shape through the resurgent eugenics movement marked by the *Bell Curve* (Hernstein & Murray, 1994) and a return to/reaffirmation of the ideology of Social Darwinism and meritocracy to explain the race and class differences in IQ and academic achievement. The eugenics movement builds on previous/concurrent ideological paradigms of inferiority, cultural deprivation, at-risk status, and cultural difference that have evolved to explain race and class differences in achievement and fiscal allocations to schools. Hernstein and Murray argue that since the innately impaired race-class dregs of society are inevitably responsible for crime, unemployment, and out-of-wedlock births, federally financed programs for education, Affirmative Action, and other social welfare programs should be eliminated. Gould (1981/1996) and others (Steinberg, Kincheloe & Greeson, 1996), have aptly countered their argument and claim that the cognitive stratification by class and race that accounts for differential test scores and other social ills are economic in origin. Hernstein and Murray's argument of inherent inferiority, however, is foundational to current ideological campaigns that justify inequity and the race-class subjugation of certain sectors of society. Just as the Governor of South Carolina

claimed in 1935 that Blacks were "destined by province for slavery" due to their intellectual inferiority and moral ineptitude, so Hernstein and Murray (1994) resurrect and refashion this ideology to justify subjugation and inequity:

> In short, by custodial state, we have in mind a high-tech and more lavish version of the Indian reservation for some substantial minority of the nation's population, while the rest of America tries to go about its business. (In Gould, 1981/1996, p. 377)

Hernstein's and Murray's recommendations embody the racial and class constructs that converge under the ideological canopy of Social Darwinism and meritocracy, and are manifest in the national policies that emerged in 2001–2003. This ideology justifies the institutionalized stratification and punitive measures legalized in the No Child Left Behind Act. In addition, it rationalizes the massive building of prisons, the abdication and transfer of public education to the state private sector, the ever-present call for "accountability", and transfer of the responsibility for poor students' failure to the teachers, principals, parents and ultimately, to teacher education programs that inadequately prepared them as educators (Lipman, 2002).

Concomitantly, characterizations of working class African Americans and Latinos as lazy, violent, unintelligent, immoral, irresponsible, lascivious youth who are inherently drawn to criminality and are a danger to society, pervade the images presented in print media, film industry, curricular texts, and other forms of popular culture (Giroux, 1996; Rose, 1994). These images have supported a corresponding backlash and politics of resentment amongst many Whites, angered by the loss of privileges due to the special treatment afforded the undeserving poor and people of color (McCarthy, 1998). These divisive tactics and racial characterizations are reminiscent of: the architects differential curricula designed to antagonize Black and White laborers, the images in popular culture, and the ideological and legal/extralegal measures that reinforced the social order in the late 1800s. Through a historical lens, it becomes apparent that the constructs of race and social class, have played a pivotal role in the current structure of public education, in the differential curricula provided, and in the dominant ideology that pervades these policies and practices.

In sum, the constructs of race and social class have historically sustained structural inequity in education and continue to do so, with their attendant ideological justification. These social meanings ascribed to difference serve to *normalize inequity* institutionally along race and class lines as if it is an immutable part of life. Race- and class-coded meanings that inform the normalization of structural inequity are also symbolically or representationally marked in multiple textual forms, e.g., written, visual, verbal, auditory texts, and are instituted in practices of social inclusion/exclusion within and throughout institutions. These constructs pervade the culture, a system of shared meanings, and are reproduced, contested, and transformed in the context of dynamic contentious social relationships of power and privilege. They shape the dominant discourse within the

legal system (Harris, 1995), the educational system (Anderson, 1988), curricular and literary texts (Anyon, 1997; Apple & Christian-Smith, 1991), medical and physical sciences (Fernando, 1988, 1991; Kleinman, 1988), history (Loewen, 1995; Zinn, 1980/1990), and sociology and anthropology (Rosaldo, 1989), and are challenged as well as negotiated in the struggles around meaning and power. These institutional and discursive practices structurally generate, anchor, and stabilize divergent racial and social class meanings. For example, the discourse and practices surrounding the disruption of Affirmative Action, textbooks' promulgation of the myth of Columbus' discovery of America, and the academic and social penalization of homeless youth contribute to notions of the undeserving poor and the inferiority of marginalized people of color.

These meanings, however, are not limited to the realm of social institutions. As individuals participate in the discursive and curricular practices of these institutions, these meanings have an impact on their subjective experiences of self and the other as they are viewed from different standpoints in local practices. It is in the context of the pervasive role of race and social class inequity, that one should consider the ways in which the dynamics of race and social class are present in the values and daily practices of educators. In light of the historical and current dynamics of race and social class, one may ask: How are these pervasive, historical social meanings related to the self, and hence to inquiries about the self that emerge in educational self-study? How might these meanings, e.g., the normalization of inequity, be present in teachers' attitudes and expectations, and in their pedagogical, scholarly, and collegial endeavors with students and other educators? These questions inform the discussion in the next section, that addresses the significance of race and social class in the process of the construction of the self, and their subsequent expression in teachers' attitudes and expectations. The infusion of racial and class meanings in the social and psychological dimensions of human activity seem worthy of interrogation as they are symbolically manifested and articulated in educational practice. These issues have implications for the unique role of reflection in the self-study process.

Self as Social, Psychological, and Historical Being

What do these constructs of race and social class have to do with the self that is at the center of self-reflective inquiry? In this section, a critical social constructivist view of the self will be presented in an effort to draw a link between historical and current *sociocultural relationships* that structure society along race and class lines, and the construction of the *individual self* whose racial and class meanings are forged in this dynamic social context. This view contrasts with the commonly held modernist view that the self is a core entity, a private domain consisting of one's personal thoughts, feelings, values, perceptions, strivings, dreams, emotions and desires. This modernist concept describes the self as an individual project that is primarily shaped within the confines of maturational processes and individual will (Danziger, 1997; Holland, 1997). As such, social relationships are secondary, if at all operative in the process of self-formation.

Rather, concepts of the self are cultural constructs that have changed historically within varying sociocultural, economic, and political contexts, and have changed over time within the disciplinary frameworks of religion, philosophy, and psychology (Danziger, 1997; Holland 1997; McAdams, 1997).

Anthony Elliott offers an alternate view that locates self-development in the context of social, historical, and cultural relationships. This view is commensurate with the common view among self-study researchers that focuses on the self-in-context and reflections on the self in local educational practice. Thus, it should be useful to provide insight into the role of racial and class meanings that structure the social contexts in which the self-as-educator participates. While there are other views of the self (for example, Mead, 1934; Harter, 1999; Stern, 1985) that are not elaborated here, this perspective is important in that it illuminates the potential significance of race and social class in the formation and maintenance of the self, in the beliefs and values that undergird individuals' behaviors and practices, and hence, in the self-reflective process of self-study. Elliott explains that the self is shaped by both internal, psychological, private processes as well as external social, political, and public processes. As such, these processes influence our emotional lives and our (un)conscious experiences of ourselves along lines of difference, e.g., race and class. He states:

> Selfhood is personally created, interpretively elaborated, and interpersonally constructed. The self, however, is not only fashioned, as it were, from the inside out. In forging a sense of self, individuals routinely draw from social influences, and maintain their sense of self through cultural resources. Social practices, cultural conventions and political relations are a constitutive and colorful backdrop for the staging of human experience … The self is not simply 'influenced' by the external world, since the self cannot be set apart from the social, cultural, political and historical contexts in which it is embedded. Social processes in part constitute, and so in a sense are internal to, the self. Neither internal nor external frames of reference should be privileged; all forms of identity are astonishingly imaginative fabrications of the private and public, personal and political, individual and historical. (Elliott, 2001, pp. 5–6)

Here Elliott presents a critical social constructivist view that locates the self within the social context of both interpersonal and societal relationships. As he suggests, these contexts with their cultural conventions and practices shape both the conscious and unconscious psychological processes of personal meaning-making that constitute our interior lives. In this sense, social and cultural forms in the larger context are given shape internally in our psychic, subjective lives. As individuals participate in sociocultural, political, educational, and economic arenas, sociohistorical processes become internal to the self and are actively mediated by the self. From this perspective, the racial and social class meanings that are created in society, that constitute hierarchical relations between groups and that are a part of individuals' lived experiences on a daily basis, become

internalized in the process of self-formation and inform our beliefs, values, and worldview, e.g., about race and social class.

For example, when European Americans experience themselves as entitled, superior selves, and they experience others (unlike themselves) as undeserving, inferior selves, this reflects the lived social experience of privilege versus racism and the discourse of racial superiority versus inferiority that structures societal and psychic life. Individuals come to see and experience themselves and others in particular ways, based on the race and class meanings that are embedded in the interpersonal and social relationships within the dominant culture. In this sense, as Elliott explains, the subjective experiences that constitute dimensions of the self are forged out of social and psychological, public and private, individual and historical processes. Since race and social class meanings have been indelibly embedded over the past four centuries in the social and psychological landscapes, these meanings are woven daily into our self constructions, our subjective experiences of others, and our practices, whether we acknowledge them or not.

Furthermore, Elliott asserts that:

> … The self is also shaped and defined against the backdrop of such political and public forces; yet the fabrication of the self, psychologically and emotionally, is rightly understood to involve something more subjective, particularly in the ways in which desire, emotion and feeling influence the conscious and unconscious experience of sexuality, gender, race and ethnicity. (Elliott, 2001, p. 9)

While our emotional investments and other dimensions of our inner lives are embedded in social phenomena, simultaneously, Elliott finds that people interpretively mediate or influence our social experiences of sexuality, race, gender, etc. Thus, the internalized meanings from social life, e.g., entitled-rich versus undeserving-poor self, also color the lens which guide our actions, behaviors, and the psychic experience and expression of ourselves with others. In the ongoing process of self-construction, the individual draws on a myriad of sociocultural, political resources, i.e., ways of being, in order to sustain, maintain, and change dimensions of the self. From this perspective, the self is dynamically constructed through and reciprocally influences social life. Why is this important? It is important because it is this self that teaches, reflects, and engages in the thoughtful self-study inquiry that may, in turn, change educational practice.

Similarly, Holland and Lave (2001) conceptualize the formation of the self as a dialogical and historical process that occurs in the context of local practice. They emphasize the historical nature of interpersonal and societal relationships that constitute the self. As they state: "[using the concept of] 'History in person' … it is amenable to … approach history as something that is in part made in and by persons, and to approach the study of persons as historically fashioned" (Holland & Lave, 2001, p. 30). Self-formation is dialogic, meaning that the self shapes history and social relationships and in turn, history and social relationships shape the self in the context of the local arenas in which the self participates.

As such, local practice is the site where the self is constructed, and the history of enduring social struggles in society around race, class, and other issues of difference become intimate as they are imprinted into/onto the self through individuals' participation in the social world. They claim:

> … Dialogism stresses the sociality of the intimate self: just as local struggles are dialogic, the self-process is dialogic. It incorporates the others of its social world … The energy of enduring struggles – carried out for and against societal institutions and discourses that disproportionally distribute symbolic and material resources to favored racial, ethnic, class and gendered groups – has been realized in local practice and brought from there into the intimate. (Holland & Lave, 2001, p. 13)

Holland and Lave explain that individuals incorporate both past and present meanings that are unique to the societal culture in which they participate and that shape their own and others' subjective self-experience. These cultural meanings are embedded in historical and current dynamics of race and class relationships that operate at the interpersonal and societal level. Thus, for example, it is in the context of individuals' relationships with family, friends, social groups, and educational and other societal institutions that the complex process of self-construction occurs as they creatively infuse, self-author, and enact the social language, emotions, practices, behaviors, attitudes, values, and perspectives of others that they experience. Further, Holland and Lave's anthropological work suggests that the energy from enduring struggles (historical struggles) of social inequity in a given society (e.g., colonial struggles between the British and Irish, between Black South Africans and Afrikaners, between indigeneous peoples in the Americas and settlers) emerges in the midst of human interactions that occur in current local practice.

For example, the history of colonial struggles, the attendant ideological justifications for institutional racism and class marginalization, and the social constructions of the colonizer and colonized (Memmi, 1965) are embodied in current constructions of the British and Irish self, as well as in the current beliefs and practices of individuals that reaffirm or resist the underlying colonial relations. Similarly, European Americans' experience of themselves as entitled or superior is embedded in the institutional and personal history of privilege versus racism and the discourse of racial superiority versus inferiority that structures societal life. Thus, historically fashioned individuals enact the internally configured meanings derived from their personal histories and their relative position in enduring societal struggles. This concept of history-in-person acknowledges that individuals make history (self-author), are fashioned by history, and manifest that internalized history in the context of their social practice. In the midst of local practice, the specific cultural history of enduring struggles and history-in-person are realized, re-enacted, and manifested, contributing to the ongoing process of reproducing, reforming, and transforming social life and the intersubjective experiences of self and other.

Why is this social constructivist perspective of value in this examination of the significance of race and social class in educational practice and self-study? The interdisciplinary perspectives of Elliott and Holland and Lave draw on sociological, cultural-historical, psychoanalytic, and anthropological theories to examine the complex nature of the self, its construction and reconstruction, and its possibilities in the context of practice. This concept of the self provides a framework from which to explore the race and social class meanings that are inscribed on individuals through particular societal/national, cultural, institutional, and historical relationships, including teacher-student relationships. In this chapter it is posited that this concept of the self, as a historical, social, cultural, and psychological being, is at the center of self-reflective inquiry in/on teacher practice, and will thus guide our examination of the significance of race and social class in the disciplined inquiry of self-study in education. From this perspective, the race and class meanings that have become a part of the self-as-teacher show up in the local practice of our educational work, that is, in our teaching, curriculum development, and the design of our teacher education programs.

Section II extends this discussion by examining the ways in which the constructs of race and social class as internalized dimensions of the self are expressed in teacher attitudes and expectations for students. Implicit in this discussion is the understanding that the historical and current relations of inequity that have become normalized, also become internalized within the self-as-teacher. The archival research presented in the next section will lay the foundation for Section III that examines the contexts through which teacher educators have explored intersubjective issues of race and social class through self-study, have promoted similar inquiries with their students, and have found solutions to the challenges encountered.

Section II: Teacher Attitudes and Expectations

This section, guided by a critical social constructivist framework presented earlier, examines a body of empirical research that addresses teacher attitudes and expectations with regard to race and social class. This analysis is based on the view that the history of interpersonal and societal relations of inequity along racial and classed lines become internalized and expressed in educators' belief systems and pedagogical practices.

Dominant Notions of Race

As bell hooks notes:

> We are all subjects in history. We must return ourselves to a state of embodiment in order to deconstruct the way power has been traditionally orchestrated in the classroom, denying subjectivity to some groups and according it to others. By recognizing subjectivity and the limits of identity,

we disrupt that objectification that is so necessary in a culture of domination. (1994, p. 139)

It is important to acknowledge that we are all products of our personal and collective histories, so as not to continue the myth that bias does not exist or that one is capable of objective thought. Inherent in the process of being human in the context of culture, perspectives and ways of knowing may be linked to the social and psychological conditions through which the self was forged.

It is in light of this understanding that Oakes (1985) asserts that:

> … Given the circumstances of placement decisions, factors often influenced by race and class – dress, speech patterns, ways of interacting with adults, and other behaviors – often do affect subjective judgments of academic aptitude and probably academic futures, and that educators allow this to happen quite unconsciously. (Oakes, 1985, p. 13)

She identifies ways in which the observed differences across racial groups may contribute unwittingly to teachers' assumptions about and evaluations of youth in schools. For this reason, it is important to examine the forms that racial bias may take in education. Propositional data on teachers' attitudes and expectations with regard to students' racial and class background emerged in a bevy of research in the 1970s.

Educators' attitudes, expectations, and ways of defining the self and other are rooted in personal and social histories, and the material conditions of social life that frame intrafamilial, professional and societal relationships. The intersubjective meanings, whether tacit or explicit, are woven into our pedagogical actions as we as educators reaffirm and transform ourselves and others. From this perspective, the normalization of inequity that has characterized American public education may take various forms in educators' practice as we reproduce or strive to transform our ways of being in the world. This section includes the discussion of some informative qualitative and empirical research conducted by educators in their own and others' classrooms in local schools or university settings.

These methodologically divergent inquiries provide insight into the subjective experiences of teachers and their students, that is, the attitudes of Black and White teachers towards their students that grow out of the history and rationale for the current structure of education. This section also includes a discussion of the significance of the attitudes and pedagogical practices of African American and other educators of color that affirmed poor youth of color and a discussion of the work of White educators in addressing issues of racism in their pedagogical practices with pre-service teachers. The patterns reviewed suggest that traces of the historical meanings of race within the dominant culture are embedded in teachers' subjective experiences of self and other. These meanings are, in part, reaffirmed within present structural inequities.

Pygmalion in the Classroom (Rosenthal & Jacobson, 1968) was groundbreaking and conceptually laid the foundation for a body of research by Brophy and

Good (1974) that revealed the power of teacher attitudes and expectations on student achievement, that is, the impact of the intersubjective experiences of teachers and students on learning. Teachers' high expectations promoted high achievement and low expectations promoted low achievement. This research illustrated the impact of educators' expressed subjective experience of the student-as-other in practice on students' subjective experience of the self as expressed in their own practice/performance in school. It is in this context that the body of ongoing research revealed patterns in White and Black teachers' differential racial attitudes towards students and their impact upon them.

White teachers tend to display more negative attitudes toward, communicate low expectations to, and convey disapproving messages to Black children, especially males, than do Black teachers. They characterized Black boys as more deviant and their personality traits as more negative (Eaves, 1975) and more introversive, distractible, and hostile (Clifford, 1973) than White boys. On the one hand, White teachers had lower expectations for and gave less attention, praise and encouragement to gifted Black students than White students, and gifted Black boys received the least positive and most negative reactions from White teachers (Rubovits & Maehr, 1973). On the other hand, they gave more criticism (Simpson & Erickson, 1983), rejection of students' responses, and behavior-controlling comments to Black and Latino students (Hillman & Davenport, 1978). Black students had fewer favorable interactions with White teachers. Early research found that teachers' expectations varied when race and class were simultaneously examined (Friedman, 1976; Cooper, Baron, & Lowe, 1975).

Black teachers perceived Black students' abilities as average and White teachers perceived their abilities to be below average (Griffith & London, 1980). White teachers attributed higher ability to White students than Black students reading the same passage (Griffith & London, 1980) and gave lower evaluations to the spontaneous speech of Black students than to White students (Bikson, 1974). Similarly, Cazden's (1988) more recent analyses of classroom discourse revealed White and Black teachers' differential interpretations of the quality and value of African American children's oral narratives. White teachers had difficulty following the episodic stories of Black children and attributed lower achievement to Black children than to White children whose topic-centered stories were not criticized by the teachers. Black teachers acknowledged differences between the episodic and topic-centered stories, but were open to and appreciative of stories by Black and White students. They found the episodic stories of Black children engaging, made inferences about their stories that were missed by the White teachers, and characterized the children as, "highly verbal, very bright, and/or successful in school" (Cazden, 1988, p. 18).

Black and White teachers differed in their affective perceptions of Black students (Gottlieb, 1964; Washington, 1980). Black teachers viewed Black children as happy, more cooperative, ambitious, fun-loving, calm, quiet, and shy, whereas, White teachers saw Black children as more high strung, impetuous, lazy, moody, rebellious, and talkative. White teachers were more critical of Black

students and their families than Black teachers, who were more critical of the lack of equipment and overcrowded conditions (Gottlieb, 1964). Operating from a deficit model perspective, White teachers attributed challenges in teaching to the students, whereas Black teachers attributed teaching challenges to the institutional inadequacies (Gottlieb, 1964; Foster, 1990) and were more likely to engage with families through home visits (Boesel, 1968). These representations of Black youth and "tangle of pathology" attributed to Black families (Carter & Goodwin, 1994) echo those from the late 19th century and are embedded in the current dominant discourse about "cultural deficits," rather than institutional inequities and racism (Foster, 1990).

More recent studies show similar patterns in White teachers' displays of more negative attitudes towards communication of lower expectations to, and conveyance of disapproving messages to students of color than do Black teachers in K-12 (Carter & Goodwin, 1994; Metz, 1994) and advanced graduate studies (Margolis & Romero, 1998). Comparative studies reveal that race influences teachers' responses to students. In a review of research, Irvine (1990) found that African American and European American teachers had strikingly divergent achievement expectations for African American youth. These teachers also have divergent perceptions of their academic ability, motivation, personal characteristics (Tettegah, 1996), and social behavior (Rong, 1996). While race is not a factor in African American teachers' assessments of students' social behavior, White teachers rate Black students, especially males, considerably lower than White students (Rong, 1996). Furthermore, White teachers hold more negative beliefs about Black children and treat them less favorably than White children (Groulx, 2001), and teachers' negative perceptions influenced Black children's academic achievement (Irvine, 1990). Teachers also disproportionally place poor students and those of color in low versus high tracks. The differential curricula low and high tracks serve to lower or raise students' aspirations, respectively, constrict or expand their possibilities for future plans and deflate or enhance their sense of self-efficacy (Oakes, 1985; Metz, 1994). Poor Black students, especially youth of color, are counseled into vocational education and "realistic career choices", i.e., they were tracked, not counseled, into positions traditionally held by Blacks. White teachers have also conveyed to Black boys in schools that they would not make it in school (Foster, 1990, p. 5).

Based on her ethnography in a high school, Lee (1996) discusses teachers' and others' characterizations of Asian American youth as the model minority. She examines the erasure of various Asian ethnicities and differences across class and gender that result from the essentialist characterization of them as the model minority, and its divisive use by Whites in the dominant culture (McIntyre, 1997). The juxtaposition of this positive characterization of all Asian youth against the negative constructions of African American youth pits one group against the other and sets standards for proper behavior for minorities. This stereotype of Asians, Koreans, and other youth, and the apparent success of some in school was used by educators to illustrate that the school system is color-blind and fair for students of color, to blame African American students

for their failure by denying that racism existed in the color-blind context, and to erase Whiteness from the analysis of inequity in education by pitting one marginalized group against the other (Lee, 1996). The apparent success of Asian Americans justifies the ideology of meritocracy and allows others' failures to be attributed to cultural, intellectual, or other deficiencies.

By pitting one marginalized group against the other, issues of White privilege and racism are obscured, and by promulgating these comparisons of youth across racial and class lines outside of the particular historical context of each racial or ethnic group fosters essentialist notions of race and their attendant characteristics. Other qualitative analyses demonstrate that some teachers are uncomfortable with the language minority students and negatively view Latino youth (Avery & Walker, 1993; Byrnes, Kiger, & Manning, 1997). White youth received high ratings from teachers, while Mexican American and African American youth, especially the poor, received low ratings based on language-minority stereotypes. Teachers' attitudes towards immigrant children also affected the nature of their interaction during instruction (Byrnes, Kiger, & Manning, 1997).

In Katz's (1999) examination of the school failure of marginalized and alienated Latino immigrant youth, she found that the teacher-student relationship was pivotal. Teachers with images of Latino youth as criminals, gang members, thieves, or prostitutes condemned to school failure, also showed preferences for Chinese students in the school. Latino students were relegated to the bottom with African American youth, and were not considered a good investment of times for teachers, in light of their low test scores and at-risk status as ESL students. However, as other studies have suggested (Mehan, Villanueva, Hubbard, & Lintz, 1996; Davidson, 1996), teachers with high expectations and concern for students promoted student achievement. Other researchers found that students of color are more likely to be punished and expelled for offences that are virtually excused for White students (Fine, 1991; Nieto, 1992; Cardenas & First, 1985; Garibaldi, 1988). Increasingly, African American, Latino, Native American, and Asian youth are dropping out of school (Fine, 1991), as grade retention policies and school reform push students out of school (Lipman, 2002). These patterns have reinforced racial and socioeconomic stratification in society (Oakes, 1985, p. 153).

Ferguson's (2001) insightful and incisive ethnography, *Bad Boys: Public Schools in the Making of Black Masculinity*, examines the pathological characterization of Black boys in school as defiant, culpable troublemakers with attitudes, whose essentialized naughty-by-nature-maleness is interpreted as an indicator of their inherent insubordination. She analyzes the infusion of the dominant culture's interpretive adultification of African American boys and girls in school, and the intersection of race, class and gender (Rong, 1996; Dusek & Gail, 1985). In the literature (Metz, 1994; Sheets & Gay, 1996), they are characterized as non-children from deficient families-at-risk. Boys are described as willfully destructive with irrational disregard for rules and girls are portrayed as potently sexual, assertive children, who have the strength to threaten the social order.

According to this work, both girls and boys need to be controlled and morally rectified. These subjective characterizations of African American youth are embodied in White teachers' practices and school policies. Ferguson notes the disproportional number of African American boys who are in trouble, suspended and often falsely accused of transgressions based on assumptive attributions of blame or delinquency. She discusses the construction of African American boys as unsalvageable and incorrigible, their placement into categories of educability, along with the schools' implementation of increasing measures of surveillance and isolation, e.g., in the Punishment Room. As a part of the school culture, she examines teachers' emphases on rule enforcement, harsh punitive measures, and disciplinary actions taken against Black boys, e.g., for calling out an answer in class, that was ignored for other students (Ferguson, 2001, p. 94). Ferguson posits that the demonization of African Americans mirrors earlier popular images and embodies pervasive beliefs within the eugenics movement and the broader society.

This overview reveals that the racism that has been present historically amongst the general population is also presently quite common amongst teachers (Alhquist, 1991; King, 1991; McIntyre, 1997; Sleeter, 1993; Davidson, 1996). While the racism is rarely named, the twin phenomena of the privileged invisibility of whiteness and demonization of the racialized others of color are apparent in teachers' attitudes and expectations and in the pedagogical practices they employed in schools. This research provides powerful examples of the socially and historically constructed racial and class meanings that have become internal to the self-as-teacher, have been transmuted and instantiated over time through educators actions with others, and have shaped the interactive meanings and interactive dynamics that occur in the context of local educational practice (Elliott, 2001; Holland & Lave, 1997). The racial and social class meanings reflected in these teachers' practices mirror those that existed at the turn of the 20th century. They are related to current structures of inequity and to the pervasive overrepresentation of African American, Latino, and Native American children in special education (Artiles & Trent, 1994; Oakes, 1985, p. 186; Davidson, 1996), to their underrepresentation in gifted programs (Ford, 1995), and to the increasing numbers of student drop-outs amongst the poor and youth of color (Fine, 1991).

Dominant Notions of Social Class

Rist's analysis grows out of his research that reflects the profound impact of society's class stratification on the teaching-learning process and the experiences of youth that participate in it. His work illustrates the ways in which constructions of social class have been internalized in middle class teachers' subjective experiences of themselves in relation to working class youth.

> … The public school system not only mirrors the configurations of the larger society, but also significantly contributes to maintaining them. Thus

the system of public education in reality perpetuates what it is ideologically committed to eradicate – class barriers which result in inequality in the social and economic life of the citizenry. (Rist, 1970, p. 300)

Inquiries addressing the significance of teachers' attitudes and expectations for youth based on social class are not as plentiful as those on race. In some early studies, Black and White teachers' expectations for youth varied when race and class were simultaneously examined. Teachers had lower expectations for the academic performance of working class youth than they did for middle class youth (Friedman, 1976; Heller & White, 1975; Metz, 1994; Cooper, Baron, & Lowe, 1975). They exerted less effort in their teaching of poor youth (Clark & Peterson, 1986; Oakes, 1985), were more engaged with middle class youth (Good & Brophy, 1986; Rist, 1970), and blamed poor performance on the children or their families (Bullough, Knowles, & Crow, 1991). Working class students tend to be marginalized by teachers (Rist, 1970; Luttrell, 1997) and teachers in an observational study display the tendency to call on, praise more highly, and intellectually challenge students who are middle class, male, and White (Sadker & Sadker, 1984).

Rist's (1970) microethnography of Black students and teachers examined teachers' expressed social class attitudes and practices towards a group of students followed from kindergarten through second grade. The study revealed clear differences in teachers' organization of classrooms, expectations for and responses to students, and treatment of children based on social class. First, teachers anticipated the relative success of each student based on their construction of the ideal student. They developed caste-like groupings in classrooms, with children assigned to work tables based on dress, other physical characteristics (Luttrell, 1997), interactional behavior, and their use of what is called Standard American English versus African American English Vernacular (AAEV). Second, students identified as slow learners versus fast learners received differential treatment from teachers. Slow learners were taught infrequently by teachers and received more control-oriented and fewer supportive comments from teachers. Over the course of the year, the gap in students' work completion widened. Third, students responded in the classes by treating each other differently on the basis of social class. While high-status children sought solidarity and closeness with the teacher, low-status children were ridiculed, withdrew and resorted to in-group hostility and dropped out of school (Luttrell, 1997).

Brantlinger's (1993) more recent ethnography examines the politics of social class in school. Through extensive interviews of wealthy and impoverished high school students, she chronicles the social sorting, labeling, and tracking of working class students, and their predominance in special education classes. In addition, students report that teachers display negative affect and attitudes towards poor students and dispense degrading and more severe punishment for their infractions than for wealthier students. Brantlinger examines the ways in which the middle class teachers and parents negotiate and rationalize social class inequity and school advantage for middle class versus working class students, as well as, the ways in which teachers' varied social class positions shaped

their perspectives about students (Brantlinger, 2003). Teachers' condescension has accompanied their low expectations of working class youth (MacLeod, 1995). In this context, low-income students were less successful academically and expressed feelings of disillusionment about school. The failure of poor students, especially those of color, was attributed to their own deficiencies, e.g., lack of effort, poor choices, their families' failure to value education (Lipman, 1998; Luttrell, 1997; Hall, 2001). Earlier, Anyon's (1981) study revealed major differences in teachers' conceptions of working class youth versus those in the middle and upper classes, in their expectations and goals for these students. Teachers provided busy work for poor youth based on their depictions of them as lazy and unknowledgeable, while they provided upper class youth with opportunities to think for themselves and immerse themselves in the world of ideas, based on their view of them as better people.

These inquiries suggest that teachers' attitudes embody racial and class meanings grounded in history and current social relationships. While the myths of social mobility, the melting pot, and the absence of social classes are pervasive, it is apparent that the attitudes and practices of middle class teachers across racial lines reflect the historically constituted valorization of the middle/upper class and marginalization of the working class youth, especially those of color. These studies illustrate the ways in which the social class meanings that have become internal to the self-as-teacher are reflected in their educational practice, inform their notions of the self-as-middle-class and the other-as-working-class, and shape their relations with and intersubjective experiences of poor students (Elliott, 2001; Holland & Lave, 1997). These attitudes frame educators' relative valuations of students, inform their pedagogical practices and school policies, promotes students' failure and self-devaluation, and contribute to the naturalized reproduction of inequity in education. Teachers' attributions and expectations of poor students were similar to those for students of color, and they were infused with Oscar Lewis' deficit model notion of a culture of poverty, which located the reproduction of cycles of poverty in the personal habits and dispositions of the poor and their families. This model blamed the poor for their condition and attributed poverty to a self-imposed cycle of deprivation, while obscuring the economic, social, and educational factors that structured and justified poverty (Lewis, 1961). As such, this area is ripe for inquiry and has implications for the knowledge base that constitutes teacher education.

Resistance to Dominant Notions of Race and Class

Are all educators unconditionally bound to reproduce inequitable race-class dynamics in schools as a result of the historical construction of the self? Is every aspect of the educational system from K-12 through higher education, inevitably bound to be plagued by the reproduction of structural and ideological inequities? While the inquiries discussed above reveal dominant notions of race and social class amongst teachers and within schools, from its inception public education has been a site for educators and others to struggle for equity and democracy.

There are teachers who are quite cognizant of race and class inequities in education, who value and advocate for poor youth and students of color, who interrogate their own behaviors and tacit beliefs, and who are invested in fostering preservice teachers' commitment to equity through teacher education programs (Dlamini, 2002). Narrative, ethnographic and other qualitative inquiries illustrate the impact of teachers' high expectations for youth on their academic achievement. Foster (1997), Ladson-Billings (1994), and Irvine (1990) have done extensive work on the perspectives of successful, exemplary African American teachers in predominantly African American schools.

Their work highlights the significance of cultural synchronization and of focal teacher attitudes that foster learning. In these studies, successful teachers valued, felt committed to and responsible for the education of the African American youth. They also sought to promote students' positive identity and to succeed in the context of societal racism and inequity in schools. Furthermore, these teachers knew their subject matter well and expected and demanded much of the students in learning. These middle class teachers struggled against institutional racism in school funding, salaries, materials, and curricula, and fostered pride, social consciousness, and achievement in their students across class lines (Foster, 1997). Exemplary teachers' culturally relevant pedagogy was anchored in the belief that their students were capable of success (Ladson-Billings, 1994). The teachers commitment to and belief in Black children helped students succeed (Foster, 1997). This belief emerges as a crucial element in the academic achievement of all students (Irvine, 2002; Bartolome, 1994; Mehan *et al.*, 1996; Davidson, 1996; Rist, 1970).

A plethora of multicultural and anti-racist curricula range from pluralist inclusions of multi-racial/ethnic images in curricular experiences to interrogations of societal relations of power throughout the disciplines within universities (Sleeter, 2001; Giroux, 2001). The emergence of these curricula are an indication of the understanding that some educators have about the pervasive, and often subtle, nature of racism that resides in the classroom texts. These educators recognize the need to confront and contest institutionalized racism by teaching against the grain (Katz, 1999, p. 817).

There are some teacher educators who have examined racism, dominant constructions of Whiteness and the impact of color-blindness on pre-service teachers' orientation to students and learning. These inquiries are based on the understanding that whiteness has emerged as a normative, color/raceless category that is imbued with laudable human characteristics in contradistinction to the deviant nature of its constructed other, e.g., Blackness. As such, whiteness has been rendered an invisible racial category, based on the coterminous ascendance of the dominance of whiteness-subjugation of blackness, and of the institutionalization of racial privilege-normalization of inequity. Using narratives and autoethnographies, they facilitate student teachers' examinations of their constructions of Whiteness, of the social relations of power embedded in these constructions, and of the implications for their teaching practices (McIntyre, 1997; Sleeter, 1993) as well as the implications of unexamined notions of the self

and other in educative relations with White students and youth of color (Sleeter, 2001; McIntyre, 1997). These works explore the ways that student teachers examine their classed and raced positionalities, construct notions of White-as-victim (New & Petronicolos, 2001), tend to simultaneously minimize the marginalized history of Blacks, disavow their own inherited privilege (Brown, 2002), and reify meritocratic ideology. Through collaborative inquiries, the preservice teachers seek to become better teachers by avoiding traditional stereotypes, to disrupt dominant discourse, and to confront racism in their classrooms. McIntyre (1997) notes the importance of student teachers' reflective teaching practices in order to prevent them from succumbing to the uncritical acceptance of myths and stereotypes. These and other studies chronicle teacher educators' efforts to prepare teachers to interrupt the normalization of inequity and to reframe the meaning of Whiteness to one linked to emancipatory educational practice.

Cochran-Smith's (2000) self-reflective inquiry is exemplary in its examination of the impact of racism on the pedagogical process for pre-service teachers and teacher educators. She provides invaluable insights into the challenges faced in unlearning racism as it pervades curricular choices, classroom dynamics amongst students and teachers, structure of teacher educator programs, student support services, and the tacit assumptions, beliefs, and values of educators who are committed to social justice. In *Blind Vision: Unlearning Racism in Teacher Education*, she discusses the unanticipated criticisms by students of the teacher education program, designed to combat racism and other forms of oppression.

Grounded in an understanding of the limitations of outsider versus insider knowledge, she grapples with the interpretive perspectives of students of color versus her own as a White teacher, and her White students' assertions of color-blindness. Faced with this challenge, she embarks through narrative on a probing, collaborative self-reflective inquiry into the assumptions and beliefs that framed her own teaching and the teacher education program. Her inquiry was based on the premise that teaching practices, curricula, and teacher education are forged in the context of a racialized (and class and gender stratified society), and thus, must be read as racial text (class and gendered text). This racial text includes both explicit curricular experiences and hidden curriculum embedded in implicit values and assumptions and in the omissions, modifications, and inclusions of particular forms of knowledge (Castenell & Pinar, 1993; Cochran-Smith, 2000). Hence, Cochran-Smith reads between the lines to scrutinize the implicit messages conveyed through her curricula. While she finds major consistencies between her beliefs and practice, the tacit message about pedagogy for language and literacy conveys that, "... pedagogy developed primarily from research and writing by and about White mainstream persons was the pedagogy that was best for everyone" (Cochran-Smith, 2000, p. 178). She explains that "blind vision", i.e., seeing/not seeing, learning/unlearning, and failure are inherent in the intentional work of unlearning racism, and that reading the racial text is crucial for teacher educators' and preservice teachers' vision in practice.

Blind Vision is a pivotal self-reflective inquiry that is explicitly grounded in the sociocultural and historical dynamics of society. Cochran-Smith's self-study

reflects an understanding of the visible and invisible racial and class meanings that are inscribed onto the self-as-teacher, become a part of one's implicit values, beliefs and educative practice, and dynamically shape the curriculum, students' learning experiences, and the processes of program development and design. It is in the context of this research that one poses the question as to the role of self-study in addressing the questions of race and social class in teacher education. The overview of research on teacher attitudes is indicative of the societal meanings that become inscribed onto the self in the form of attitudes and dispositions that are enacted in educators' professional practice. The next section addresses the unique role of self-study in examining the issues of race and social class in teacher practice.

Section III: Why Self Study?

The research on teacher attitudes and expectations documents the powerful influence of the dynamics of race and social class on the interactive teacher-student relationships and subjective experiences that emerge from educators' practice in schools and other educational contexts. Given this compelling archival data, why should self-study take up the issues of race and social class in education? Is the theory and practice of self-study conducive in a particular way to the examination of race and class meanings in teacher education and classroom practice? What contributions may self-study make to educators' understanding of the significance of race and social class in our educative practice, program development, and to the field of teacher education as a whole? These are the central questions that are addressed in Section III. The answers lie in the unique qualities that characterize self-study as a research paradigm and in the principles that undergird the disciplined practice of self-reflective inquiry.

Self-Study: Research Paradigm

The previously addressed body of research has made a significant contribution to the field by demonstrating that race and social class are integral to the educative process, from teaching practice to program development to policy making. For the most part, this research has been based on propositional knowledge and has been conducted by researchers whose questions, hypotheses, and methods were conceived outside of the teaching-learning process that is under investigation. Conducted from an etic perspective, that is, from an outsider's point of view, this research from the outside-in does not incorporate the rich data, perspective, questions, or analysis that are derived from inquiries that emerge at the point of practice. Research conducted from an etic perspective is designed to produce generalizable knowledge and objective data for public dissemination, and is privileged as the official knowledge that sets the standards for teacher education and practice. However, this research paradigm does not critique the perspective or underlying assumptions and beliefs that frame the

research design, model, and outcomes, nor does it take advantage of the questions, perspectives, insights, and knowledge of those who are participants in the educational site under investigation.

In contrast, the process of self-study is grounded in, relies on, and utilizes the local questions, issues, perspectives, and insights of those who reside at the educational site of inquiry. As a research paradigm, self-study promotes the creation of knowledge from an emic perspective, that is, from the vantage point of the insider, whose perspective is derived from direct involvement in the teaching-learning process that is being examined. The production of knowledge from an insider's view, from the inside-out, has value not only in the immediate context from which it arose, but also in the public sphere for other practitioners faced with similar issues of concern. In this case, the insider develops her/his own questions, methods of inquiry, and interpretive analysis of the results, and determines their relative value for professional practice as well as the need to revise or reframe the questions of inquiry. This research paradigm is more qualitative and interpretive in nature, acknowledges and reveres the fact that bias, a particular standpoint or perspective is inherent in any and all research inquiries, questions, or analyses. It acknowledges the inherent bias, perspective, or standpoint in emic research that provide differential insights and complements the knowledge produced from other self-study inquiries, as well as knowledge produced through other research paradigms. It disavows the "blind application of a universal description" or set of criteria to judge the sameness or the validity of one's lived experience (Parker, 1997). At the point of practice, self-reflective inquiries generate questions, reveal patterns of interaction, and introduce new areas of study that go unnoticed by outside observers. As such, self-study repositions the expertise, validity, and authority of knowledge production and theory generation from outside to inside sources (Cochran-Smith & Lytle, 1993).

Self-study provides a unique opportunity to examine issues of race and social class in education as they emerge in the context of educators' daily interactions. These self-reflective inquiries may validate and create nuanced understandings of existing forms of knowledge. They may also raise different questions from those posed by outsiders, and may promote new knowledge, or ways of understanding and negotiating race and social class in education. There are three important ways in which the self-study paradigm may bring new insights and knowledge to teacher education, and thus may contribute to educators' understanding of race and social class.

First, it is at the nexus, the point of practice in school classrooms and teacher education programs, that self-study interrogates the beliefs, values, motivations, and assumptions that undergird teachers' behaviors and actions. Through informed and critical inquiry, educators may explore the personal and social source(s) of the problems that they encounter in teaching. That is, they may originate in educators' own system of beliefs as well as in the institutional relationships and policies that frame their practice. Second, self-study begins with the reflective self at the center, in an effort to examine/reflect on the social and psychological factors that contribute to, inform, and may enhance one's

practice and pedagogical outcomes. With self at the center of inquiry, this paradigm acknowledges the pivotal role of the self in creating, changing, and mediating social meaning at the point of practice (Holland & Lave, 1997). Grounded in the daily reflective activity of teachers, self-study may generate insights and theoretical propositions that grow out of the practical experience of teaching, and simultaneously provide guidance and lessons learned that may inform the broader professional community of educators. Third, this knowledge and research from an emic perspective not only validates the work of those in the field, but raises and poses questions and solutions that can only emerge in the midst of thoughtful, reflective, and interactive teaching-learning processes.

The self-study research paradigm is uniquely positioned to facilitate educators' inquiries into the issues of race and social class. As such, the body of knowledge produced through self-study makes a major contribution to teacher education by conceptually decentering propositional, positivist knowledge as the official canon, and by augmenting and complementing the source and content of knowledge that should inform educational theory and practice. From this perspective, self-study's focus on educators' self-reflective inquiry at the point of practice and construction of inside-out versus outside-in knowledge may promote substantive changes in teacher education and support democratic, transformative efforts to provide a quality education for all students.

Foundational Concepts

Attending to the issues of race and social class is both difficult and challenging. However, some of the foundational principles of self-study drawn from the work of Dewey (1933) and Schön (1983) are instructive in facilitating educators who traverse this terrain. This section will discuss ways in which the Deweyian concepts of reflective thought, the requisite dispositions that accompany reflection, i.e., openness, wholeheartedness, and responsibility, and explicit and implicit knowledge, and Schön's concept of reframing in reflective practice facilitate educators' efforts to raise and address issues of race and class in teaching and other educational endeavors. Each principle is accompanied by a number of questions that may support educators in identifying the puzzles of practice related to race and social class in educational contexts and illustrate the significance of race and social class in self-reflective inquiry.

First, the disciplined inquiry of self-study is theoretically grounded in the belief that self-reflection (Dewey, 1933; Schön, 1983) is integral to and constitutive of the dynamic process of teaching and professional practice in education. As initially conceptualized by Dewey in *How We Think* (1933), reflective thought is a way of being that draws on the intellectual and emotional dimensions of educators to address and resolve problems that emerge in the process of our teaching. By reflecting on one's own practice, educators have the potential to render conscious those unconscious ideas, thoughts, feelings, and sentiments that are embedded in and unwittingly guide their teaching practice. This reflection can reveal the meaning, significance, and value of actions and events that would

have been missed or trivialized without the insights provided through thoughtful retrospective examination. In this sense, reflection can emancipate teaching from the depths of routinized, impulse-driven action that lacks foresight, planning, and the capacity to achieve one's desired educative aims in practice (Dewey, 1933). Reflective teaching can transform education, by revising the traditional dominant goals of scientific inquiry – to understand and explain phenomena – and placing them in the service of the change process for personal growth and social transformation (Parker, 1997).

Embracing this tenet is important in an discussion of the issues of race and social class in self-study. The pervasive history of racial and social class inequity and the attendant meanings that normalize structural hierarchies, also shape our self and other perceptions in the midst of daily educative practice. Reflexivity potentially opens up the possibility for educators to unearth, investigate and gain understanding of routinized ways of operating that go undetected and carry strong racial and social class meanings. This tenet should assist us as educators in positing the questions: Is our attention or inattention to issues of race and social class indicative of the routinized nature of our practice? Are there puzzles of practice that have normalized inequity in ways that mirror social and institutional dynamics? How might others' perspectives and insights help in our identification of issues in our pedagogy or curricular work that embody racial and social class meanings that reaffirm inequity?

Second, the emancipatory capacity of reflective thought that Dewey discusses is based on the attitudes of open-mindedness, wholeheartedness, and responsibility. An open-minded disposition may enable educators to embrace points of view that diverge from her/his own, may reveal the limitations in one's own thinking, expose one to new ways of defining the problems identified or challenges encountered, and push the boundaries of thought and practice beyond the prejudices, partisanship, and other habits that constrain professional growth and change. By subjecting one's beliefs and conclusions to rigorous, public interrogation, one may increase the validity of one's claims (Parker, 1997, p. 48). Wholeheartedness, on the other hand, embodies the commitment of one's intellectual, emotional and social being to reflective thought that grows out of the volitional decision to investigate a problem of choice that emerges in pedagogical practice. Finally, the attitude of responsibility provides the ethical anchor for teachers' reflective thinking. By owning and acknowledging the beliefs, values, and actions that constitute their teaching activities, and summarily taking responsibility for the impact of their belief systems and professional practices on students' growth, educators may insure the integrity of their actions and a greater congruence between word and deed.

These principles have significance for educators when considering the institutionalized normalization of inequity in schools, curricula, and in our pedagogical practices. They provide guidance and an orienting framework for the ethical and dispositional considerations that shape investigations into conscious and unconscious aspects of the educators' professional practice. These principles reflect the

seriousness of the work of educators at the personal and social level. As Parker states:

> Reflective teaching involves a "willingness to engage in constant self-appraisal and development", which "implies flexibility, rigorous analysis and social awareness" (Pollard & Tann, 1994, p. 9). Drawing on Dewey's blueprint, reflective teaching opposes "routine action" which is guided by "tradition, habit and authority and by institutional definitions and expectations" (Pollard and Tann, 1994, p. 9). Consequently, a reflective teacher has need of personal qualities of open-mindedness in entertaining the claims of a range of views or theories, responsibility in the readiness to submit to the authority of rationality and wholeheartedness of commitment. (In Parker, 1997, p. 31 from Pollard & Tann, 1994, pp. 13–15)

Hence, educators should ask: Are we open to examine our prejudices, partisanship, and other habits around race and social class that reaffirm inequity in education, and constrain the professional growth and change of teacher educators, as well as pre-service teachers? Are the intellectual and emotional choices that we make about topics of inquiry fully volitional or are they also socially constructed? Does the ethical responsibility or obligation to address issues of race and social class jeopardize our choices and siphon off the productive energy of volitional self-reflective inquiries? Do we own, acknowledge, and accept responsibility for our belief systems, our professional practice and their consequent outcomes for our students' emotional and intellectual growth and their future role as teachers?

Third, Dewey asserts that reflective thought and the process of understanding one's actions and their underlying principles are enhanced by making the distinction between implicit and explicit knowledge, that is, between the conscious and unconscious processes that inform and frame our assumptions and practice, our interpretations of our own and others' actions and motivations, which may create and obscure blind spots in our problem-posing, our reflective thinking, and ultimately, in our efforts to improve our work as educators. On the one hand, By examining our tacit knowledge and bringing it to consciousness (Dewey, 1933), we access unexplored attitudes and motives, which introduce new understandings, unanticipated insights, and fresh interpretations that may inform, guide, and enhance our practice in creative and productive ways. On the other hand, it is through conscious thought and intentional action we may leverage our thinking, detect faulty reasoning and misconceptions, and wrestle with the complexity and perplexity of the problem at hand.

The issue of tacit knowledge, unexplored beliefs, values, and assumptions is a salient one in considering race and social class issues. Our values, social position, theoretical orientation, and previous practice contribute to the problems of practice that we construct and that are revealed, as well as those that are dissolved or are undetected (Parker, 1997). A case is point is the normalization of inequity in education and society that renders invisible the race and class

issues around school tracking, student achievement, and teachers' practices that need to be revealed in order to further democratize education. Educators may ask: Are we willing to explore the blind spots that exist in our attention/ inattention to the significance of race and social class in our pedagogical practice? Are we willing to interrogate the ways in which we promote certain race and class meanings in our daily practice with youth, pre-service teachers, other colleagues? Are we willing to examine our own attitudes and expectations as educators and investigate the hidden curriculum in texts, or to question normal-ized practices in schools that sustain inequity? Are we willing to consider what it means to be an educator if we sidestep these aspects of our work? Are we diligent in examining the significance of our tacit and explicit curricular and pedagogical decisions, beliefs and attitudes, and actions about race and social class as teacher educators, and in fostering such inquiries amongst pre-service teachers? Reflective self-studies that broach these questions may "provide rich information about the ways in which teachers' perspectives are rooted in the variety of personal, familial, religious, political and cultural experiences they bring to teaching" (Zeichner & Gore, 1990, p. 234).

A fourth principle, drawn from Schön's (1983) work, that undergirds self-study is that of reframing. In this work, Schön delineates the twin concepts of reflection-in-action and reflection-on-action, which entail a retrospective view of one's problems in practice or reflection, theorizing, and hypothesizing about an issue in the crucible of engaged activity. The dual process allows us to reframe or see differently the things under review. As Loughran states: "Reframing is seeing a situation through others' eyes ... If all the problems to be investigated are solely from the teacher educator's perspective, then a myriad of teaching and learning perspectives would, sadly, be ignored" (2002, p. 243). He highlights the importance of the understanding our practice from multiple vantage points, and the importance of making "the tacit explicit, meaningful, and useful" (2002, p. 38). Thus, by attending to our knowledge-in-action or making our tacit knowledge conscious, we may be able to critique, reaffirm, or change those formerly unexamined, routine actions in order to improve our practice. The reflective process with its consequent reframing of problematic issues is thus a generative or creative one, in which new modes of thought and action may emerge. Hence the question: Are we willing to reframe our approach, orientation towards, and patterns of omission/exclusion/inclusion of race and social class with regard to self-reflective practice and the larger body of teacher education research to which it contributes?

The theoretical tenets from Dewey and Schön inform the conceptual frame-work and principles of the disciplined inquiry embodied in self-study. While reflective thought (Dewey, 1933) is a foundational aspect of self-study, there are other dimensions of this process of contemplating and changing the actions and beliefs that undergird one's teaching practice. In self-study, reflective thought is not an isolated, arbitrary, or occasional incident. Rather, it is systematized into an ongoing process or cyclical series of self-reflective inquiries through which

educators continually revise, build on and transform their practice. The systematic self-reflective process that constitutes self-study focuses on an issue chosen by the educator and is guided by the overarching principles of openness, collaboration, and reframing. From this perspective, the questions arise: How can systematic and collaborative self-study facilitate our inquiries into the racial and social class meanings that infuse our pedagogical practice, curricula, and program development? Are educators willing to rigorously pursue an understanding of themselves in practice with others over the long haul, that is, to regularly pursue the tacit issues related to race and class that may go unexamined?

In self-study, educators choose the puzzles of practice (Munby & Russell, 1995) or problems that grow out of disjunctures between our beliefs and actions. The investment in the choice of study and desire to improve one's practice fosters successive, reflective studies of one's practice. Self-study is based on the principle of educators' openness to a range of perspectives and willingness to go public with their inquiry, expressed through collaboration with others in examining the issues, actions, and beliefs under review. The principles of choice, openness, and collaboration sustain and extend the dispositional attitudes that accompany Dewey's concept of reflective thought. Educators may ask: Are we willing to go public as we identify and strive to solve the puzzles of practice that emerge around racial and social class issues?

Self-study extends Schön's concept of reframing, a process by which the tacit knowledge, insights and understanding garnered from the reflective, collaborative process of self-study contribute to the individual educator's ability to revamp or reframe her/his own ongoing practice and reexamine, reify, or revise one's underlying beliefs and values. For self-study, the process of reframing goes beyond the individual's reinterpretation of one's own pedagogical praxis. The knowledge constructed in the process of the self-reflective inquiry may enhance one's self-understanding as an educator and contribute to the ever-growing body of research that is available to other educators as they examine, reframe, and theorize their own professional practice. The shared insights and research findings generated from self-study should also inform the requisite knowledge base for teacher education, and the practice of self-reflective inquiry should be foundational or intrinsic to teacher education programs, such that both the archival data and research-in-progress synergistically transform/reframe the collective body of knowledge for teacher educators and for pre-service teachers. Hence this question is posed: How may we use self-study inquiry to identify and reframe our intersubjective experiences, our pedagogical practice and curricula, and the nature of teacher education within and across educational institutions?

The theoretical concepts and history of the ideas embedded in the conceptualization of self-study provide a profound opportunity to examine the issues of race and social class in teachers' pedagogical practice and confront both the challenges and possibilities of such inquiries. Each of the principles prompts questions that may facilitate educators' inquiry into issues of race and social class. Attention to these principles may assist educators in disrupting patterns of routinized behavior, bias/discrimination, blindspots, or race- and class-coded

beliefs. Each of these patterns may account for the inclusion and/or exclusion of race-class issues in self-study. They also suggest that there are both challenges and possibilities incurred from going public, engaging in collaborative inquiry, reframing our ways of thinking, and embracing issues that heretofore have not emerged volitionally in self-study.

However, it is in the going public that validates the creation of practitioner-derived knowledge from the inside-out (Cochran-Smith & Lytle, 1993), in identifying and solving the challenges in teaching. Strides may be made by sharing the questions and knowledge from the point of practice that, ultimately, serve to support other educators, to contribute to developing theory, and to enhance the knowledge-base for teacher education. Self-study is grounded in Dewey's democratic tradition and commitment to enhancing social consciousness. Zeichner and Liston's (1996) discussion of different perspectives on self-reflective teaching indicates that self-study may be taken up with different foci and goals: "some striving to rise above institutional, political, and cultural complexities of social life and the challenges of personal change, while others embrace the democratic principles of equity and social justice and the benefits derived from collaborative inquiry towards social change. While the generic tradition that stands above social and institutional contexts may be more comfortable for educators' self-reflective inquiries, the risk, of course, is that preservice teachers and teacher educators will unwittingly or knowingly teach and design programs as if they are unfettered by the history of relationships and ideological perspectives that pervade our intersubjective experiences of each other and the larger social order" (Vavrus & Archibald, 1998). In fact, "emancipation is the moral imperative of reflective teaching" which is a process that goes beyond personal, decontextualized self-critical reflection to inform our practical judgment (Parker, 1997). Rather, reflective teaching should identify and engage the ideological and social forces that frame our ways of being in the world and foster our active participation in social practices that remove the obstacles and enhance the liberatory aspects of our work.

Self-study provides the opportunity and possibility for educators' growth and change, through one's willingness to be vulnerable and open, flexible and creative, thoughtful and committed. These qualities are necessary ingredients for preservice teachers and teacher educators to examine the overt and muted forms that race and class may take in the policies and practices of our educational institutions, in our ways of thinking, and in our daily practice (Loughran & Russell, 2002).

Section IV: Self-study Research

In this section I examine the self-study research in light of the issues of race and class. Then I present examples drawn from the two edited texts of Hamilton (1998b) and Loughran and Russell (2002) that illustrate the ways that these researchers address issues of race, social class, and culture where they surface in their classrooms, in their collaborative work with colleagues, in program and

curricular design, and in the policies and practices promoted in their institutions. As such, these researchers embrace the principles presented above, accept the challenge to interrogate uncomfortable issues, and seek to make sense of these issues for themselves, preservice teachers, and other educators.

From its inception, self-study has promoted honest self-inquiry, collaborative interchange and critique with colleagues, and examination of the meanings and assumptions embedded in our practice as they coincide with or contradict our beliefs and values. Cochran-Smith highlights the imperative to investigate and be responsible for our long-held assumptions that grow out of social life and in turn, shape social life:

> … Our responsibility as teachers and teacher educators is to struggle with others … to interrogate the racist [and social class] assumptions that may be deeply embedded in our own courses and curricula, to own our own complicity in maintaining existing systems of privilege and oppression, and to grapple with our own failures to produces the kinds of changes we advocate. (Cochran-Smith, 2000, p. 158)

Similarly, Lisa Delpit notes that: "We all interpret behaviors, information, and situations through our own cultural lenses; these lenses operate involuntarily, below the level of conscious awareness, making it seem that our own view is simply 'the way it is'" (Delpit, 1995, p. 151). Self-study provides a tool for educators to reframe our long-held view that this is "the way it is" and allows us to grapple with our failures in order to promote both personal and social change. As such, self-study privileges the complexity and messiness of lived experience. A question to ask becomes how have the issues of race and social class been addressed in self-study inquiries and what may they contribute to teacher education? In the next few pages I present a series of examples that I have categorized by topics relevant to the issues of race and class.

Institutional Change and Social Justice Curricula

Two exemplary self-studies, one by Hamilton (2002) and the other by Vavrus and Archibald (1998), examine the challenges and possibilities faced in educators' explicit advocacy for a social justice curriculum in teacher education, with attention to the issues of race, class, and gender. First, Hamilton's (2002) self-study addresses some veiled forms of racism that emerge at the programmatic and personal level within teacher education programs. As the Director of the Teacher Education Division (TED), she is leading the School of Education in its redesign of the TED Program, based on the major theme of social justice. While this thematic focus grew out of collaborative work with faculty and apparent agreement of the Curriculum Committee to redesign the program on this basis, serious reservations surfaced about the explicit use of the term "social justice", state legislators' reactions, and relevance of this theme for a small section

of the student population. As a result, the Committee voted to table the incorporation of social justice as a major programmatic theme. This surprising disjuncture was the focus of the self-study exploring possible sources of the Committee's resistance as "an act of racism", resistance to the Director's leadership, or a measured response to the state's emergent right-wing educational policies. Hamilton states as she ponders the dilemma:

> Again I questioned and wondered, "How could this happen? How could we table the issue of social justice?" We had all read the same literature. We had listened to each other's views. How did this disjoint occur? Were we not listening to each other? (p. 181)

The self-study that resulted from this query was an incisive, multilevel inquiry that involved a careful examination of the department's track record in opposing state policies and the faculty's work culminating in support for the social justice theme, as well as a search for indicators of departmental politics or faculty displeasure with the Director's leadership. A discourse of racism emerged as faculty questioned the value of an education in social justice for white students, i.e., prospective educators who would be teaching in the suburbs and not in an urban area. Ultimately, the topic was never discussed again and the Division was dismantled, only to be replaced by the previous structure. This self-study poses questions, both theoretical and practical, about the power of white privilege, role of white scholars (and others) in recognizing and challenging structures of inequity that are manifest institutionally and in the professional lives of educators. It reveals the common misconception that issues of equity, power, and privilege have relevance for the few whites who may work with the poor and people of color. It suggests that multicultural education should prepare "us" to work with "them," not to disrupt the views and perspectives in all educational sites that disenfranchise some and privilege others. This self-study reveals the counterintuitive notion that the issues of racism and class inequity are as important, if not more so, for those teachers who are going to teach in their suburban communities. If not educated in these issues, the children they educate will become the adults of tomorrow, who will either play a role in reproducing or contesting the inequitable societal relations of power and privilege that characterize the educational system. This study provides insightful revelations about the varied forms that racism and resistance to social equity may take in academia as faculty strive to develop curricula in teacher education programs, and about the nature of the social and political dynamics that emerge around pivotal ideological differences related to issues of race and social justice in education.

The second self-study, by Vavrus and Archibald (1998) examines the challenges faced in their efforts to include social justice issues in the curriculum and to promote faculty accountability on the issues of race, class, and gender. As director of a three-college consortium in education, Vavrus found that faculty had little ownership or familiarity with their mission statements and little understanding of the social and political context that framed education and the

teaching-learning process, and were thus bound by documents that reduced education to technical requirements. Aided by the structure and requirements of the national accreditation process, this realization led Vavrus to push the faculty to examine their syllabi, their collective goals as educators, and possibilities for restructuring the curriculum. This process was one of struggle, in which many faculty resisted the imperative to create an emancipatory educational program that fostered equity and exposed injustice towards providing a quality education and life for all youth, especially those subjugated by race and class. Though faculty resisted self-reflexive engagement, political consciousness, and examination of the curriculum's reproduction of the dominant ideology, ultimately, a conceptual model for the School was developed from a critical social, multicultural perspective.

In contrast to this process of advocacy for social justice in education at one institution, Vavrus found himself in a position to reaffirm/validate a social justice perspective at another institution in which faculty were clearly committed to emancipatory education, but had not yet articulated this widely-held view in a written conceptual framework. Again, under the aegis of national accreditation and amidst faculty concerns about the loss of autonomy and creativity, he embarked on the perilous path of convincing them to concretize the beliefs and values that inform their pedagogy into themes that undergird their curricula: Democracy for Schooling, Multicultural and Anti-bias Perspective, and Developmentally Appropriate Teaching and Learning. Through self-study of his experiences with faculty at two institutions, Vavrus recognizes the overriding necessity of having a common vision amongst faculty in order for him or any educator to foster an emancipatory education that is stable and has longevity, whether he is there as a catalyst or not. In essence, the personal investment and commitment of faculty in the values and ethics of equality and social justice were a prerequisite for real institutional transformation. As a part of this self-study, Archibald discusses the value of personal essays in documenting, assessing, and reflecting on the work that occurs in the context of fostering institutional change. As such, personal essays provide insight for the writer and for the reading audience without the scolding voice.

The self-studies, by Hamilton and, Vavrus and Archibald, illuminate the difficulties and hence the possibilities of transforming educators' consciousness and deconstructing long-held beliefs and practices in education so that the curriculum and pedagogical practices through which pre-service teachers learn, will also prepare them to advocate for and provide an education for all youth, across race, class and gender lines. They highlight the importance of forging a common vision amongst teacher educators involved in the process of developing emancipatory educational policies and practices, and of sustaining the power of participants' personal investment throughout the difficult process of programmatic and institutional change.

Development of Multicultural Curricula

There are also important self-studies that focus on classroom experiences and curricular changes in the education of pre-service teachers. LaBoskey, Davies-

Samway, and Garcia (1998) discuss the absence of any professional preparation for most educators in institutions of higher education (IHE), the need for teacher educators to understand adult learning processes and related teaching strategies, and the need for universities and colleges to ensure teacher educators' effectiveness in their work with students. In an effort to fill the void, the authors formed an action research team, as members of the Bay Area Teacher Educators (BATE) engaged in collaborative self-study as it impacts on professional development and school reform. LaBoskey's and Garcia's self studies focused explicitly on issues of race, social class, gender, and culture. LaBoskey redesigned the multicultural component of a course through consultation and work with the action research team and feedback from students and faculty at her university. She designed specific, text and conversation-based mini-lessons that addressed the issues of racism, sexism, and social class for her students, in lieu of a general research project on diverse populations. This allowed for more curricular content and deeper examination and discussion of issues that underlie race, class, and gender differences. LaBoskey and her students saw this as a lifelong growth producing educational process that could continually prepare them to "engage authentically in any challenging conversations that may arise" (LaBoskey, Davies-Samway, & Garcia, 1998, p. 158). Their work highlights the ways in which collaborative work with colleagues within and across institutions may deepen and broaden teacher educators' pedagogical practices and scholarly inquiry, and enhance the intellectual, emotional, social and ethical components of discursive learning processes amongst students.

Garcia's self-study occurs in the context of her work with fellow colleagues in restructuring the curriculum in order to prepare pre-service teachers to teach in linguistically and culturally diverse classrooms. Her inquiry was designed to explore students' thinking about the relationship between social justice and cultural knowledge as a part of the process of becoming teachers. While the programmatic changes made a difference, the students' narrative reflections revealed that their learning occurred on a basic level, and that more substantive, in-depth, transformative thinking would be more likely to occur if the learning process continued throughout the first year of teaching. This inquiry fostered Garcia's growth and changes in her educative practices, and a commitment to provide staff development that would promote self-reflective inquiry as teacher educators. Catalyzed by group participation, these collaborative self-studies prompted change and motivated teacher educators' to clarify the central issues in their self-studies. They illustrate the importance of professional development, that is, educators having an opportunity to think about, reflect on, and discuss their practices with colleagues in order to foster change and educational reform. As such, professional development offers the opportunity for colleagues to consider social, cultural, political, and economic issues that frame their work as educators, to process the significance of their own experiences and those of pre-service teachers in rethinking the curriculum, and to reflect collaboratively with colleagues on the multiple sources of theoretical and practical knowledge that will best prepare teachers to be educators for social justice. Garcia's work reveals

the importance of educators engaging in sustained, collaborative, professional development processes with colleagues in developing social justice and other curricula. These opportunities for intellectual and practical sharing and inquiry may have a substantive impact on curricular development and on the bodies of knowledge from which educators may draw in their teaching.

Significance of Race and Teacher Educator-Student Interactions

My own self-study (Brown, 2002) examines curricular issues that undergird students' reactions to the issues of race, class and gender in their self-narratives. In my study, I explored the myth of the invisibility of race in the context of human development courses for European American pre-service teachers whose narrative constructions of the self were virtually devoid of discussions of race as a dimension of identity. This phenomenon contrasts with my own experience as an African American woman, for whom the issues of race and social class were outstanding in my self-other conceptions. I engaged in a self-study inquiry to examine the source of the difference in perspective, by redesigning the curriculum, i.e., texts, materials, and written assignments to foster students' critical examination of the role of race and social class in their identificatory constructions of the self and their role as educators. I collaborated with the pre-service teachers in analyzing their narrative self constructions, which revealed interesting patterns. Students who were already aware of issues of socially constructed difference in some form, e.g. gender, religion, etc. in their own lives, were more open to and initially more aware of the significance of race in their own and others lives, as well as its importance in the teaching-learning process.

Through the analysis, pre-service educators began to consider the ways in which they might make a difference in their own classrooms and in the daily interactions in their lives across multiple contexts. This self-study resulted a greater understanding of the relationship between individuals' lived experience and their position in the social order along racial and class lines, as they inform their ideological perspectives and openness to change and transformation in education. It also underscored the importance of placing these issues at the center of teacher education, rather than as tangential, marginal issues, that are subject to dismissal or deletion. My self-study reveals the impact of teacher educators' and students' personal/social histories, ideological formulations, constructions of identity in the process of conceptualizing and living the curriculum. It reveals the significance of race and social class in the dynamic process of teaching and learning, curricular design and revision, and educators'/students' growth and change.

Tidwell's (2002) self-study focuses on the challenges of addressing the individual needs of students in the context of the university's norms and standards. As an educator who values the individual and is committed to incorporating her/his culture and unique ways of knowing into the program curriculum, Tidwell examined ways of fostering student success within the structure and culture of the university, through case studies of her own interactive relations

with students. With attention to the unique qualities and educational needs of each student, she reflects on her relationship with one African American undergrad male, Martin, one European American graduate female, Karen, and one Chinese national female doctoral student, Ruby. To do that, she poses the question: How do I interact with students at the individual level? Interlaced with a focus on the individual are issues of race, ethnicity, academic standing, and the teacher's perceived role as educator with each student. First, Tidwell wrestles with equity and other issues surrounding her work with the sole African American student in her class, who worked full-time and had difficulty investing in the course or her instructional meetings with him. She examines her frustrated efforts to help Martin succeed, her perception of his inability to develop a sense of community with others or to function successfully as a student, and her interpretation of his late assignments and spotty class attendance, that culminated in his withdrawal from the class at mid-term. She considers the faux choices she provided for him and considers her attribution of his failure and her unsuccessful teaching experience to his inadequacies/choices.

Second, Tidwell examines her supervisory relationship with the self-sufficient, competent European American student, whose family of educators provided synchronous preparation for her participation in the culture of schooling. As a graduate student, Karen was an engaging, comfortable supervisor for others and a competent advisee for supervising faculty. She required different/less instructional guidance in her practicum and her competence prompted Tidwell to reexamine her concept and experience of what it meant to be an effective teacher educator. Lastly, Tidwell describes her work with the bilingual, Chinese national doctoral student. She guides Ruby through the process of refining her dissertation research design and topic, and facilitates the student's growth by balancing her academic rigor with passion for her dissertation topic. Each of these case studies has implications for Tidwell's concept and practice as a teacher educator. Her unsuccessful work with Martin raised questions about whether the university could be shaped for all students, her somewhat augmented role with Karen raised questions about her needs as an instructor and her valuation of students, while her successful work with Ruby reaffirmed the importance of her ability as a teacher educator to inform, direct, and facilitate students' work.

Her self-reflective inquiry into each experience allowed her to consider her ability to assume differential, natural educative roles with students that address and value their individual needs and dispositions, as well as her own. While this self-study does not focus explicitly on race, class, or ethnicity, these issues may have contributed to the intersubjective experience and the dynamics that emerged between teacher educator and student, and may also be embedded in her implicit characterizations of black, white, and Asian students that are presented in these case studies. These case studies provide fertile ground for further inquiry. Tidwell's self-study reveals the significance of student differences in teacher educators' sense of self-as-educator and the implicit role of race, ethnicity, and social class on the dynamics of the teacher-student relationship that unfold in teaching and advising endeavors.

Teemant, Harris, Cutri, Squires, and Gibb (2000) focus on collaboration as they engage in the self-study process of examining literature that may facilitate white teachers' work with culturally and linguistically diverse student populations. With the assistance of other professionals with expertise in working with other special populations, the educators found that they needed to learn about the needs and abilities of the culturally and linguistically diverse students and develop a common understanding across these groups in order for educators to advocate properly for them. This initial work laid the groundwork for the educators to develop a conceptual framework, the Inclusive Pedagogy, which was based on collaboration and included guiding principles, essential policy, critical learning domains, and classroom strategies. They engaged in ongoing refinement of the Inclusive Pedagogy Framework by instituting questions for students' inquiry rather than directive statements. This was done in order to have an enduring impact on students' thinking and culminated in the educators' use of the Inclusive Pedagogy to remove pre-service teachers' work with special populations from the margins of teacher education and to recenter it as an integral part of the curriculum. The structure and content of the Inclusive Pedagogy that Teemant and her colleagues developed was the direct result of a collaborative process of inquiry and refinement of their work. Teemant's and colleagues' work reveals the importance of collaborative work, of providing curricula for white educators' work with diverse populations, and of collaborating with students in refining a curriculum and in recentering issues of diversity in teacher education.

Pre-Service Teachers' Biases and Insights

Race and social class meanings play a dynamic role in the structure of inequity that exists in educational institutions, in the source and content of official knowledge that infuses educational programs and in the values, attitudes, beliefs, and expectations embedded in teachers' practices. At the institutional, curricular, and pedagogical levels, race and class meanings are created that reproduce or contest social inequity. Once created they positively or negatively contribute to the overarching goals and purpose of education. Racism and class bias are expressed in multiple ways through the individual and institutionalized decisions and educators' practices, and are reinforced in teacher education when the curricula and pre-service teachers beliefs, values, and assumptions are left unexamined. Self-study inquiries that grapple with these challenges for pre-service teachers disrupt the normalization of inequity by supporting pre-service teachers self-reflective inquiries and providing rigorous, thoughtful curricular experiences that unveil the individual and collective problems of practice that occur in education.

The following four self-studies published in the Proceedings of the Second (1998) and Third (2000) International Conference on Self-Study of Teacher Education Practices, by Johnston (2000), Guidry and Corbett-Whittier (2000), Anderson (2000), and Hamilton (1998a) address the issues of racial and other

biases amongst white preservice teachers as they relate to their preparation to teach amongst racially and linguistically diverse populations. The importance of educators honoring different perspectives and bodies of knowledge constructed by those who are marginalized in educational settings and in the dominant culture is also explored.

Johnston (2000), along with Thomas, another colleague, worked with African American, Asian, and Latina students as part of a self-study to examine her own teaching with regard to issues of diversity, equity, and social justice in her social studies methods course. They value the students' perspectives as an important tool for them to understand the complexity of these issues and to develop the teacher development programs as a community of practice that relies on and finds support from the input and ideas of classroom teachers, faculty, and master's student interns. In an effort to address the concern over the years of students of color that the teacher education program did not address their needs, Johnston and Thomas sought feedback from them as cultural consultants, whose input could provide insight into teacher education and dynamics within the Professional Development School project.

Through discursive analyses of audio-taped conversational interviews with the students, the educators gained insights into students' experiences of racism and instructors' and students' attitudes and behaviors, raised questions about PDS principles along with suggestions for program courses, and considered possibilities for program outcomes. The cyclical nature of this action research project produced knowledge that promoted changes in the educators' teaching, fostered the study of literature on multicultural education, race studies, action research, post-structural feminism, and prompted further inquiry into institutional, individual, and societal change, and assumptions about race and inequity. Through this collaborative self-study, Johnston became more sensitive to the different opinions and perspectives amongst African American students and other racial groups, and the importance of not essentializing racial and ethnic groups. She also attended more closely to the comments of students of color during class and sought their feedback in evaluating the value and impact of classroom experiences and her position on issues that arose in class with regard to race and social justice. Student feedback allowed Johnston to become acutely aware of the impact of differential power relations in the classroom between teacher and student on their willingness to talk and aware of the crucial importance of students of color having an opportunity to talk amongst themselves as they faced the daily challenges of racial discourse and inequity. This self-study revealed the value of educators' seeking the input of students or colleagues who are more likely to provide different, discordant, or marginalized perspectives to illuminate issues of race and social justice. It reveals the power of educators' willingness to be open to critique and input, flexible in considering new ideas, and vulnerable to others' insights about their work around issues of racial and cultural diversity in curriculum.

Similarly, Guidry and Corbett-Whittier (2000) engaged in a self-study to examine and challenge stereotypes and racial and religious biases that surface

in their classes with pre-service teachers. Guidry examined the racial stereotypes and biases about people of color that she and her white students brought to the learning environment and informed their teaching. Based on her experience in schools with poor youth of color, she knew the importance of addressing the issues of race, class and gender with students who were preparing to become teachers. Through journal entries, class discussions, and readings, Guidry and her students expressed their fears and assumptions about the residents in poor communities of color, began to examine racist ideas embedded in teaching behaviors and to deconstruct their beliefs about helping children of color to succeed. Corbett-Whittier examined her biases and stereotypes about a student in her class from the religious right, and found that as she interacted with him her resolve against his views intensified. However, as she challenged this student to examine his beliefs and assumptions, she prompted him to pursue other resources to insure that his beliefs were well-founded, even though he maintained his perspective. Through this experience, Corbett-Whittier recognized the value of knowledge and her relationship to it, as she sought not to change the student's beliefs, but to insure that his beliefs were truly his own. Both Guidry and Corbett-Whittier engaged with students in self-study to reflect on and deconstruct their own and their students' beliefs and biases about race and religion that affect the teaching and the learning processes. Guidry's and Corbett-Whittier's self-study highlights the value of collaborative work with students in identifying and challenging racial stereotypes and biases in the classroom, in an effort to promote students' critical examinations of their views.

Anderson's (2000) self-study focuses on the goal of incorporating the Aboriginal worldview into his own as well as the teaching practice of his candidate teachers. Recognizing that western thinking, the dominant culture's worldview, pervades society in Ontario, Canada, he made a conscious effort in educating pre-service teachers to use teaching methods and principles from traditional Anishainabe teachings that were created by the First Nation's peoples. He visited the classrooms of teacher candidates to examine the ways in which his teaching of the ideas from the Medicine Wheel and Seven Grandfathers had influenced their practice, and considered ways to further enhance the impact of his work with them. Anderson's commitment to this work grew out of his observations that Aboriginal students in schools were becoming increasingly uncomfortable and anxious about the mandated standardized curriculum and testing, that rising numbers of young teachers were working in classrooms with Aboriginal students, despite their limited knowledge about and experience with these children, and that Aboriginal youth were being further marginalized and alienated in schools as they faced the rigid curriculum and teachers' preoccupation with its implementation. Attuned to these impingements on the learning and growth of the children, his goal was to to help young teachers place their concerns for rigid, disciplinary curriculum implementation (Anderson, 2000).

Towards this end, Anderson instilled in his teacher candidates the view that teaching entails more than following a curriculum by focusing on four areas within his Teaching Circle: language, stories, community, and intentionality.

With regard to language, he worked with teacher candidates to deconstruct the differential meanings in English and Aboriginal languages to demonstrate the ways in which English excluded, degraded, and fostered bias towards the First Nation's children. He also highlighted the significance of the children having the opportunity on a daily basis to tell stories about their experiences. These stories fostered confident, respectful communication amongst students and teacher and provided rich information for teachers to expand and develop their curriculum in ways that were connected to the lives of the students. Based on the view that schools are a community of learners, he encouraged teacher candidates to create an inclusive, inviting, relevant, and accepting environment for the students. Candidates had the task of learning more about the children's neighborhoods, about the life and experiences of an individual student, and of examining and practicing ways to improve their own teaching practice. Finally, intentionality was central to the process of candidates' examining and improving their practice. They were encouraged to carefully examine the materials presented to the students, and to insure that their interactions and activities were respectful and inviting to the Aboriginal youth. This self-study highlighted the importance of other people's knowledge, valuing difference, and deconstructing normal teacher practice as cornerstones of the educational process. Anderson's self-study reveals the critical role played by educators' consciousness of the marginalization of students from oppressed groups, and by their ethical responsibility for the self-affirmative educational experiences for these students. It also reveals the power of educators' willingness to learn about, and pedagogically incorporate and validate knowledge about linguistic and cultural practices that accompany the subjugation of marginalized groups.

Hamilton's (1998a) self-study grew out of her concern that many preservice teachers were not prepared to work with diverse populations, not aware of the personal beliefs and values that undergird their views about race, diversity, and culture, and not receiving educational experiences that would prepare them for diversity in the classroom. She highlighted the pivotal role that differences in culture and belief systems have on white teachers' interpretations, understandings, assumptions, and attributions about students from other racial and ethnic groups in the classroom. She discussed the importance of educators becoming conscious of the underlying beliefs and tacit assumptions that inform their decisions and unwittingly reinforced inequity in schools.

Through journal entries, autobiographies, narratives, readings and bi-weekly discussions, Hamilton guided a group of primarily white students through the process of exploring and critically examining her/their beliefs, assumptions, and expectations about diversity, and of seeing themselves and others in new ways. Throughout this process, one pattern that emerged was the Tinkerbell Tenet of Teaching, that is, the tendency for students and educators to think that things would happen or work out based on the sheer strength or power of their beliefs. The Tinkerbell Tenet had significance for Hamilton also, as she addressed the frustrations that emerged from her efforts to foster new ways of thinking amongst the students, and the realizations that grew out of her reflective reexamination

of the origins of students' thinking within the context of an educational institution that had failed to prepare them adequately for diversity. While the narratives, autobiographies, and group discussions were useful in preparing students for their work as teachers in diverse settings, this self-study revealed that the curriculum and other dimensions of the teacher education program needed to address the issues of racial, ethnic, and cultural difference in order to support preservice teachers in examining their beliefs, and in reflecting on and improving their practice with students across racial and cultural contexts. As such, this self-study laid the groundwork for further inquiries into the needs of teacher education programs. Hamilton's self-study reveals the importance of teacher educators' self-understanding and empathy in providing insights into the dilemmas that students face and blindspots encountered in tackling issues of race and social justice. It also reveals the power of various narrative forms of inquiry that provide rich data about the realistic and unrealistic expectations that educators have about the power of their ideas and the nature of social change in practice.

Cultural Difference and Adjustments in the Dominant Culture

Cultural differences is a focal theme of a number of other self-studies, including those by Oda (1998), Johnson and Allen (1996), Butler, Herndon, Kumar, Oda, and Wong (1998), and Garcia and Litton (1996). In different ways, each self-reflective inquiry addresses the challenges faced and stigmatization experienced by teacher educators or students whose immigrant status or ethnic and linguistic background marginalized them in the broader culture. The teacher educators discuss the ways in which these experiences have shaped their philosophies of education, their efforts to support ethnically and linguistically diverse students, their efforts to develop and implement curricula that broadens the multicultural lens and promotes equity amongst pre-service teachers.

Oda explores the significance of her Asian-American cultural background on her personal experiences and professional role as a teacher educator, and considers ways in which she may assist her students in addressing issues of multiculturalism in the classroom. As one of few university faculty of color, Oda reflects on the influences of Japanese-American culture and explicit cultural values, e.g., reverence for family, attaining an education, hard work, frugality, honesty, interpersonal harmony, and dignity on her thinking, decision-making, behaviors, and professional practice. She discusses the challenges she faced in seeking harmony and dignity in childhood amidst struggles to survive difficult, conflictual interactions with others, and as an adult, while serving as a principal with a predominantly white staff. As an educator, Oda examines her "culturally-informed" capacity to promote harmony, manage conflict, assuage students' guilt about the Americans' internment of the Japanese during World War II, and promote dignity and fairness amongst students, through questionnaire responses from pre-service teachers. Students speak of her soft-spoken, respectful, humble, tolerant, accepting, reverent manner and Oda posits that these qualities are grounded in Japanese culture and serve to avoid conflict amongst others. She reveres these

qualities as elements that facilitate the discussion and examination of multicultural issues in teacher education and potentially defuse contentious issues that may arise.

Interesting questions emerge from Oda's self-study in light of Stacy Lee's analysis and ethnography of Asian Americans as the model minority (addressed earlier in this chapter). Lee's analysis poses important questions about essentialist characterizations of Asian Americans that construct them as a homogeneous group devoid of national origin (e.g., China, Korea, Japan), and position them as exemplars of success and assimilation for other marginalized groups, despite fundamental differences within and across their histories of inequity in the Western world. These characterizations promote the belief that certain qualities are natural and inherent in different racial, ethnic, or social class groupings. As such, they can inform educators' receptivity to and expectations of students along these lines of difference and obscure the white privilege and racism in these characterizations. Oda's study has implications for the impact of these generalized cultural ascriptions that are placed on marginalized groups. Her work invites further discussion and inquiry into the ways in which these cultural ascriptions, e.g., the Asian as model minority, pit marginalized groups against each other and inadvertently reaffirm structural inequity. Her self-study reveals the cultural nature of educative practice and provides insights into students' differential receptivity to certain ethnic groups and "cultural" ways of being.

Johnson and Allen (1996) examine the process of widening the multicultural lens and strengthening the diversity of issues among their predominantly white, privileged, pre-service teachers by providing a service learning opportunity for them to tutor homeless youth and other poor youth of color, with whom they had little, if any, previous experience interacting. Their goal was to promote teachers' understanding of difference and social inequity across racial and class lines, to create the conditions for them to be aware of and reexamine their assumptions and unearth their biases, as well as reconsider their beliefs and views about marginalized youth. Ultimately, Johnson and Allen wanted their preservice teachers to better understand their students' real life experiences. Moreover, they sought to develop cultural knowledge and learning and an awareness of issues of social justice. Through student interviews and surveys, observations, journals, portfolios, and other written documents, the preservice teachers began to have new perceptions about their students and to question their initial assumptions and judgments about them. Through reflection, dialogue, discussion of course texts, and the interface between preservice teachers and the educators' knowledge, preservice teachers developed new insights and inquiries that promoted changes in their interactions with their students. Johnson and Allen's self-study documents the possibilities for transformative education based on the creation of a democratic space for a community-of-learners to think reflectively, share experiences, examine perceptions, and to construct new understandings that grow out of and inform their educational practices. It highlights the value of creating curricular experiences that will enhance white, middle class pre-service teachers' understanding of the life experiences of students

marginalized along race and class lines, and enhance their self-understanding through an examination of underlying beliefs and assumptions about race and class. It illustrates the possibilities that exist for teacher educators to promote pre-service teachers' self-reflection, transformative thinking and ethical practice in educational settings.

The collaborative self-study conducted by Butler, Herndon, Kumar, Oda, and Wong (1998) focuses on their range of experiences primarily as immigrants to the United States, that have informed their understanding and practices as teacher educators. Four of the five educators were members of families that immigrated voluntarily to the U.S. in optimistic search of economic and educational advancement, career success, or escape from religious persecution. However, they were confronted with racism and discrimination, social ostracism, struggles over their identity, tension between their cultural heritage and the press to assimilate into a new culture, become bilingual, and to endure the pain and loss that accompanies marginalization. Through narrative analyses of familial historical journals, diaries, autobiographical writings, and other written records, the educators sought an understanding of the relationship between their immigrant experience and their pedagogy. These early experiences had an indelible impact on the educators and provided a foundation from which they could support current preservice teachers in the process of understanding and accepting others through an understanding and acceptance of themselves. Recognizing the multifaceted challenges of immigrating to the U.S. from their own experience, these teacher educators shared their experiences and cultivated strong relationships with ethnically diverse students in order to promote academic success. They also attended to the internal struggles that students may contend with around issues of identity, bilingualism, and self perception, while encouraging them to cherish the material and subjective expressions of their cultural heritage, and examine the attitudes, beliefs, and perspectives of others. As such, the immigrant experiences of the teacher educators played a pivotal role in their teaching philosophy and in their efforts to support students and change important aspects of teacher education. Butler and colleagues' self-study reveals the pivotal and powerful role of their cultural experiences as immigrants with racism and nationalism on their collaborative design and implementation of curricula for disenfranchised groups. It highlights the instrumental role of the personal/social histories in framing educators' insights about ways to support students and to develop educational experiences that promote equity in teacher education programs.

In a joint self-study, Garcia and Litton (1996) draw on their immigrant experiences and commitment to social justice and equity to examine the impact of their courses on preservice teachers efforts to promote social change in schools. Through their own personal narratives and ongoing dialogues with each other, Garcia and Litton examine the impact of economic, social, and political inequity on the lives of poor Mexican and Filipino youth, and others that are marginalized along ethnic and linguistic lines. Based on their experiences, they expressed commitment to a critical examination of educational structures that promoted

social inequity, to critical self-reflection that promotes personal and professional efficacy, and to the view that teachers are instruments of social change. Garcia and Litton draw from their own self-reflective inquiries and the theoretical works of Freire, Bruner, and Ricoeur in their courses, to guide students in self-analysis that fosters personal transformation, promotes individual agency, and enhances their professional efficacy in creating social change in education. Garcia and Litton's self-study reveals the incisive role that teacher educators' immigrant background may have on their philosophy of education, their understanding of the challenges facing poor immigrant youth, their commitment to critical analysis of social inequity and to advocacy as educators for social justice.

Each of the self-studies has addressed the impact of race, ethnicity, and/or social class as they concretely inform the practice, the structure, and the content of teacher education. On the basis of the problems of practice, these educators collaboratively examined their practice, interrogated their own belief systems and values, and explored the assumptions that informed their relationships with their preservice teachers and other colleagues. In the course of their self-reflective inquiries, the teacher educators drew on their personal and social histories to understand and change their own practice. With self at the center, the educators interrogated to varying degrees, their own views on race, ethnicity or social class, and embraced the responsibility to make a difference in their own work or in the curriculum and structure of teacher education.

These self studies serve as models for others to investigate their teaching, to examine/anticipate faculty or institutional resistance to issues of race and diversity, to institute social justice curricula, to foster pre-service teachers' reexamination of racial and class perspectives in classroom interactions and curricula, to promote self-reflective inquiry around challenging issues, to value and utilize the perspectives of marginalized students in understanding issues of race and class, and to document the need for major changes in teacher education. Ultimately, self-studies have the capacity to render visible what has been invisible or devalued in the traditional production of empirical knowledge that is not anchored in the complex, collaborative investigation of the self as educator in social practice. While the self-studies discussed in this chapter make a considerable contribution to the body of knowledge for teachers, they represent a small percentage of self-reflective inquiries that address race or social class. It is in this light that some recommendations emerge.

Recommendations and Conclusion

The normalization of inequity is an important aspect of the dynamics of race and social class that should be interrogated as a part of the ongoing work of educators. In part, this requires that both teacher educators and pre-service educators attend to both the tacit and explicit understandings in order to examine their own work. In the previously presented body of self-study research, the researchers attended to, raised questions about, and were invested in the process of understanding and transforming their own and others' practice. Hence,

the recognition of the blind spots of our work is a cornerstone of our inquiries into race and social class. It is from this perspective that the lessons learned from this body of research foster recommendations that may facilitate broader inquiries in this area. These recommendations grow out of the unique contributions that self-study inquiries make to the broad body of knowledge in teacher education. These contributions are unique because they could only emerge from a research paradigm that privileges an emic perspective, validates the knowledge constructed in local educative practice, upholds foundations principles that foster critical examination and transformative practice, and valorizes systematic self-reflection designed to enhance/reframe personal and social educational policies and practices.

First, it is important for educators to examine their own personal and social history, in light of the culture and race-class dynamics of society. This should provide a context for educators' understanding of their subjective experiences and the multiple venues available for change. The studies conducted by Anderson (2000) Oda (1998), Brown (2002), Johnston (Johnston, 2000), Guidry and Corbett-Whittier (2000) illustrate the kinds of questions that may emerge from one's own experience and provide insight into the racial, cultural and class meanings that pervade their teaching. This recommendation is reminiscent of Dewey's (1933) advocacy for wholeheartedness and commitment to engage the often difficult tacit or explicit problems of practice that emerge. As teacher educators engage in inquiries into their own conscious and unconscious views about race and class, their explorations may support pre-service teachers in comparable, collaborative explorations (Loughran, 1996). This may support pre-service teachers and other teacher educators in their efforts to contest race and class inequities. It is through this examination of one's own experience that educators can interrogate and alter their own curricula, and interactions with students, and collaboratively promote pre-service teachers' inquiry into their own self-development and educative practice.

Second, it is important for teacher educators to understand that charting the waters of race and social class in one's own practice and the examination of one's values and beliefs is challenging, emotion-laden, and disruptive of seeing things the way they were. In light of the collective histories of race and social class, and the current manifestations of inequitable relationships, there are attitudes and feelings that emerge in relations with others that create dissonance in the process. In this view, self-study as a wholehearted process that draws on many dimensions of the self, including social, emotional, and intellectual, should be acknowledged and encouraged. The work of Hamilton (2000), Brown (2000), Tidwell (2002), and others are reflective of the disjuncture that emerges upon encountering resistance from others or in unearthing some dimension of one's own beliefs and values. This understanding is also crucial in light of the work that teacher educators do with student teachers in facilitating their own self-reflective inquiries.

Through the experience of the self-study inquiry, teacher educators come to learn not to expect seismic shifts in attitudes in a semester or quarter, in light

of the structural and ideological moorings that undergird students' attitudes about race and social class. This understanding is important to thwart educators' experience of burn-out, unrealistic expectations, or disappointment at the absence of immediate change. This may foster a deeper understanding of the change process and the ways in which resistance to new ways of thinking may be negotiated. Self-studies by Vavrus and Archibald (1998), Tidwell (2002), Brown (2002), and Hamilton (2002) illustrate this point. As these and other teacher educators interrogated issues of white privilege or promoted social justice curricula, they experienced both explicit and tacit forms of resistance to their efforts, spurning further self-reflective inquiries about their own behavior. They were faced with opposition to their efforts in promoting social justice curricula and program development as were Hamilton, Vavrus, and Archibald or in their engagement with students in new ways of thinking, as were Tidwell and Brown. These experiences prompted some understanding of what one is up against and what it takes to negotiate the differences over the long haul. This is of particular importance for teacher educators' participation in systematic, sustained self-reflective inquiries into one's own work on race and class, and the perspectives of others in the process.

Third, teacher educators' work with pre-service teachers and other colleagues is crucial. In part, it is apparent that the normalization of inequity renders the dynamics of race and social class invisible to those who are privileged and not faced on a daily basis with the injustices of inequity, or not provided with an education that fosters an understanding of our collective history. Thus, considerable work needs to be done to educate pre-service teachers to the significance of race and social class in the structure of education and in the complex process of self-formation. LaBoskey's work with Garcia and Davies-Samway (1998) as well as her work with students is illustrative of the understandings that were gained on issues of race, social class and gender.

In addition, LaBoskey and her colleagues engaged collaboratively in their own reading. This is an important issue for teacher educators and preservice teachers. In order, however, for teacher educators to provide the guidance or frame experiences that may facilitate students' and their own understanding, it is important for teacher educators to read and be familiar with the sociocultural and historical contexts that frame race and class dynamics in society. This enriched the experiences for the teacher educators and promoted a course of study that would enhance students' understanding. This will assist in deconstructing notions of colorblindness and meritocracy, which if left unexamined reinforce racial and class bias amongst teachers.

Fourth, as a part of the process of examining and revising our own practices, teacher educators need to examine the race-class meanings embedded in curricular texts and consider alternate or complementary texts for students that disrupt particular racial and class meanings. Students involved in the process of questioning their own assumptions, as well as others in visual and written discourse are in a better position to challenge those assumptions in other contexts. This will facilitate students in reexamining notions of the self and other in social context.

Educators may insure that curricula provide balanced, accurate history that reflects inequity and struggles for democracy in education and larger society. This will provide students with a context for understanding themselves and social processes for change. It will also disrupt the discursive reproduction of inequity reflected in visual and print curricular texts.

For European American students, this may facilitate their inquiries into constructions of their own whiteness as it relates to the constructions of other racial categories, and into the emancipatory possibilities embodied in redefining notions of race and promoting equity. The work of Vavrus and Archibald (1998), Hamilton (1998a), Garcia and Litton (1998), Teemant and her colleagues (2000), Guidry and Corbett-Whittier (2000), and Brown (2002) are illustrative. Through self-study and direct efforts to institute curricular change, they provided a forum for students to think differently, pose new questions, and to engage as pre-service teachers in unique ways. For these teacher educators, self-reflective inquiry spurned insights, prompted pivotal questions about the nature of the curricula, and engaged colleagues and students in an effort to change.

These efforts entail the promotion of equity within classrooms and institutions, by prompting them to think differently, to reflect, and to act differently in the world, both inside and outside of the classroom. This may have implications for curriculum development, clinical experiences in schools, collaborative reflective inquiries amongst student and teacher educator, as well as, the cultivation of relationships that will support self-examination and an investment in growth and change at the individual and social level.

Sixth, teacher educators should investigate their own expectations and attitudes towards students of color and white students to assess differences in one's perspective that may provide insights and understandings for further inquiry. One may consider how these attitudes and expectations may contain historical meanings (history-in-person) about race or social class that are carried over into the classroom and contribute to the particular dynamics that unfold. This is apparent in Johnston's (Johnston, 2000) inquiry, in which she seeks out the perspectives and insights of their Asian, African American, and Latina students. Similarly, Anderson (2000), who is attuned himself to the needs of his students and the shortcomings of the educational program, utilizes the insights to provide a more appropriate curricula. Hamilton's (1998a) concerns about pre-service students' lack of preparation to work with diverse populations fostered an ongoing process of shared experiences via narrative, journals, between teacher educator and students. These insights would be invaluable for pre-service teachers and other educators' self-reflective inquiries.

There are a number of self-studies that attend to educators' and students' immigrant experiences and cultural differences amongst students and faculty. Studies by Butler and colleagues (1998), Oda (1998), Garcia and Litton (1996) emerge from educators' self-reflective inquiries into their own cultural experiences as a way of responding to the interests and needs of students. Investigating these issues fosters support for the educative relationship, changes in the curriculum, and ongoing methods to respond to the needs of immigrant youth who are

marginalized in schools. These teacher educators' commitment to social justice grows out of their own experiences and supports their work with students. Such collaborative engagements may promote equity in the classroom, as educators' tacit knowledge becomes conscious and subject to change in the context of practice with students. As Johnston (2000) illustrates in her work, consultation with students provides insights and alternate perspectives to lend to the issues at hand.

Seventh, an examination of institutional and personal histories should be integral to teacher education, as an invaluable resource for educators' inquiries into the self and one's professional practice. In part, this entails teacher educators' investigating the ways in which the normalization of equity expresses itself in the context of higher education and conducting similar inquiries in K-12 schools. These inquiries may lead to valuable insights about one's own practice, institutional policies and practices, and the possibilities for change. This is important in order to understand the social sources of inequities that may mediate the means of intervention in self reflective inquiries.

Hamilton's (2002) and Vavrus and Archibald's (1998) understanding of the institutional history in which they operate, proves to be important in making sense of the obstacles encountered and the possible means for changing the course of action. Understanding their own and some aspects of the histories of participants was important in order to step beyond the individual and investigate institutional practices and patterns. This understanding is vital for teacher educators and preservice teachers who will face challenges in the public school systems and other educational contexts. Race and social class cannot be relegated to remaking the individual, but inherently must entail some institutional change, in light of the structural and ideological roots of inequity.

Eighth, teacher educators should examine the implications of their self-reflective inquiries for developing theory that guides practice. It is important to acknowledge and enhance the inexorable link between theory and practice, and to understand that all practice is theory driven. The theories derived from the educators' practice and the subsequent questions posed to address emergent issues, are indispensable for guiding our work and in enhancing the canonical knowledge that exists. This insight for pre-service teachers may be an invaluable tool in promoting change in their own self-studies as well as in the educational institutions of which they are a part. This was apparent in the Teemant's self-study with colleagues (2000), in their development of the Inclusive Curricula, in Anderson's (2000) developing work with the Aboriginal children, and in the questions posed by Hamilton (2002) about the forms and expressions of resistance to social justice.

Ninth, teacher educators may pose the question: "Why have I not attended to in my own professional practice regarding race and social class? Is this a blind spot?" Here, the theoretical underpinnings of self-study and the questions that emerge from those principles provide ways to interrogate our own thinking and reflect on our own practice. These questions are important in order to understand what has been omitted and why. This increases the possibility that

the puzzles of practice that emerge will be drawn from tacit as well as explicit challenges in classrooms or institutions. Teacher educators may consider the unexamined areas of their own practice with regards to race and social class, that do not automatically surface as a problem of practice. In light of the pervasive, yet often hidden meanings embedded in our practice, there may be much there for self-reflective inquiry. Importantly, teacher educators' support of pre-service teachers engaging in similar self-reflective inquiries that pose the same questions will be invaluable in institutionalizing self-reflective practice and in forging inquiries into the challenges that are directly tied to equity and social justice.

The final overarching recommendation is central in charting the future paths of direction of self-reflective inquiries that address issues of race and social class and the implications of the directional choices made for teacher education. Ultimately, it is incumbent upon teacher educators to take the issues of race and class seriously and to embrace the challenges, difficulties and rewards that grow out of our understanding of the race and class dimensions of ourselves-as-educators. One may ask, "Why?" This recommendation hearkens back to the initial questions posed at the beginning of this chapter regarding the place of race and social class issues in the foundational knowledge of teacher education, the worth of their systematic investigation in self-study, and the light that self-study inquiries may shed on the function of race and social class in education. In summation, what may be concluded from this chapter?

First, the dynamics of race and class structure hierarchical relationships in the educational system and inform the content and process of policies and practices in educational institutions. In the context of relationships forged in local practice, race and class meanings also become/are dimensions of the self that emerge in the attitudes and pedagogical practices of educators on a daily basis. As meanings that are constitutive of the self, race and social class are integral to the process appropriately named *self*-study, and hence, worthy of their inquiry. From this perspective, self-study inquiries that address race and social class and the particular knowledge that they produce should be foundational in any teacher education program, because these programs serve individuals whose prospective selves-as-educators utilize the race and class meanings that frame their lived experience and that inform their professional insights and practices in any educational setting. The omission of these particular self-meanings in reflective inquiry may skew the perspective of and knowledge produced from the educator's investigation into one's own practice in context. It also distorts the quality of and cumulative significance of knowledge produced that represents the official/unofficial knowledge-base in teacher education. To systematically omit these issues in self-study and in teacher education is to deny their existence and ultimately to reaffirm the normalization of inequity at the individual and institutional level.

Second, self-study has already shed light on the professional practices of teachers, and on programmatic and institutional policies and practices and has made important contributions as the studies in this chapter illustrate. It is only

through serious self-reflective inquiry, in contrast with etic forms of research, that we could have: gained an understanding of the significance of our personal/social histories for educative practice; learned of and managed the emotional and intellectual terrain traversed in our investigations of race and social class; and, documented and experienced the unexpected gains proffered from collaborative work with colleagues and students. It is through self-reflective inquiries carried out by educators whose dispositions embrace an open-minded, wholehearted, responsible approach to the teaching-learning process that we have gained an understanding of the race and class meanings that are embedded in their self-constructions and relationships with students, in the curricular texts and educational programs designed, and in educators' forms of resistance to social justice and transformative curricular design. It is through these self-studies that we may continue to gain insights into the particular ways in which the normalization of inequity manifests itself throughout the educational system, gain an understanding of probable means of intervention, based on the unique histories of the persons and institutions with which we are involved, and gain a profound understanding of the theoretical implications that this local work has for educational practice and hence, for teacher education.

Third, this chapter was designed to examine the significance of race and social class in practical and intersubjective experiences of educators and students in the educative process and to examine the contributions of self-study to our professional practices and policies and to the field of teacher education. The self-study inquiries presented in this chapter reify and augment other bodies of knowledge that document the significance of race and social class in teacher educators' and pre-service teachers' attitudes and professional practice, in the ideological formations that guide educators' design of the content and process of official teacher education knowledge, both of which contribute either to the disruption or maintenance of race and class inequity. Educators have derived the lessons learned from the range of puzzles of practice on issues of race and social class in accord with their personal and collaborative investment in and willingness to understand these issues as they are manifested in multiple forms. As educators, our ability to come to terms with race and social class in our self-reflective inquiries and to make a concerted effort to traverse uncharted or here-to-fore prohibitive territory will fundamentally contribute to the democratic transformation of education at both the personal and institutional level. They are worthy of our attention. They are worthy of our personal and social investment.

KNOWLEDGE, NARRATIVE AND SELF-STUDY*

D. Jean Clandinin[a] **and Michael Connelly**[b]
[a] *University of Alberta;* [b] *OISE, University of Toronto*

Abstract

In this chapter we explore the ideas of knowledge and narrative in self-studies. Questions of how narrative self-studies allow insight into participant knowledge are addressed. Two sets of assumptions guide the exploration: first, a distinction between teacher knowledge and knowledge for teachers; and, second, a notion of narrative inquiry. We first distinguish between a view of knowledge as something teachers possess and a view of knowledge as coming from experience and as learned and expressed in practice. We then distinguish between knowledge as a state of mind and knowledge as a narrative, historical, phenomenon embedded in a teacher's actions in classroom studies. Working with these distinctions, we review self-studies of the living of teacher knowledge in practice. We conceptualize a range of self-studies of teacher knowledge as narrative by imagining studies positioned along a continuum between the personal and the social. We position studies along a personal-social continuum with studies emphasizing the personal to studies emphasizing the social. For each study we show why it is a self-study of narrative teacher knowledge. In the next section we link each of the self-studies to professional knowledge. Finally we outline what we see as the potential and risks of self-study in narrative teacher knowledge. We argue that self-knowledge is, in the end, not important but stress that as means it is all important. Self-study is important not for what it shows about the self but because of its potential to reveal knowledge of the educational landscape.

In this chapter we explore the ideas of knowledge and narrative in self-studies. In particular we are interested in how narrative self-studies open up understandings about participant knowledge. Our review is guided by two sets of notions,

---

one on narrative inquiry and the other on knowledge. For us, narrative inquiry is a multi-dimensional exploration of experience involving temporality (past, present and future), interaction (personal and social), and location (place). For knowledge we distinguish between teacher knowledge and knowledge for teachers. The former is critical to our notions of narrative and self-study. Interested readers will find more in-depth discussions of these two notions in Clandinin and Connelly (2000) and Connelly and Clandinin (1999).

We begin with an excerpt from a classroom study in one elementary school. The excerpt, drawn from a narrative inquiry written by Ross (2002), opens a space for exploring the interconnections between teacher knowledge and narrative in self-study research. Ross's study took place in an urban elementary school classroom taught by Ms. O'Neil.

Ross's study was a three year in-classroom study of one teachers' practice. Ross was in the classroom two-three days a week, active as a teacher assistant and ultimately became a colleague and friend with Ms. O'Neil. The overall purpose of the study was to understand mathematics education reform at a classroom level set within the context of overall policy changes in the officially mandated mathematics curriculum. This excerpt from the midst of Ross's study occurred in November.

> After reading orally to the children for a few minutes, Ms. O'Neil closes the book and lays it on the two-drawer filing cabinet between us. I sense, and I imagine the children do as well, that we are shifting gears now, moving into something different.
>
> Ms. O'Neil takes the three steps to the center of the carpet, standing at the edge of it, just in front of the chalkboard. She simultaneously says to the children, "Turn your bodies in this direction," as she physically shows them what she means, facing the chalkboard. "And look here." She shows them the paper she has taped on the chalkboard.
>
> Turning to face them, she doesn't miss a beat. "I was saying to Vicki [the researcher] what a nice job you did yesterday at the assembly. I know we didn't have a lot of time to prepare, but you said some very important things about peace and about war."
>
> "Tomorrow is Remembrance Day." And with this she begins the math lesson by removing the piece of tape that is holding the fold in place, and the paper opens to show the hidden writing.
>
> Her, now familiar, elementary school lettering is done with a fat, smelly red marker. She uses the same type of marker that every autumn I have to buy just to feel the comfort of the ritual, the confirmation of myself. With these markers, Ms. O'Neil has drawn two red poppies with green centers, one on each of the top corners of the chart paper.
>
> Remembrance Day Math:

1. In 1914 Canada's population was seven and a half million people. Write this number.
2. If Canada's population today is 30,000,000, how much has our population increased since 1914?
3. How many years passed between the end of World War I (1918) and the beginning of World War II (1939)?
4. How many years ago did the Second World War end?
5. Copy this chart neatly into your math book.

War	WWI	WWII	Korean War	Gulf War
Participant	628,736	1,081,865	26,791	4,074
Died	66,573	44,927	516	0
Wounded	138,166	53,145	1,558	0
Prisoners	2,818	8,217	33	0

We begin at the top of the first page; we read and discuss the assignment. As we talk about 1914 and Remembrance Day Math, it becomes apparent to me by the children's remarks that they recognize this date as the beginning of World War I. Hannan raises her hand, and when asked, tells Ms. O'Neil and the class about something she had seen on television about an old soldier who was worried that people didn't remember what they had done. Other students comment about the veterans that have been on television. After this conversation, Ms. O'Neil brings the children's attention back to question 1. Again, she asks the class the question. "How would we write the number seven and a half million people?" She points to the written words on the chart paper.

Then we moved to question 2. Adam suggests that subtraction is the way to solve the problem. Naomi explains that she would subtract the seven and a half million from question 1 from the thirty million in question 2. Some students comment about how much Canada's population has grown.

The students are able to quickly set up a subtraction problem for question 3. I have often seen the class do this type of problem when reading books or around an important date. For example, when Ms. O'Neil is introducing a new book to the children, she might say to them that this book was written in 1975. How long ago was that? Or on Mozart's birthday, she asks the class, if he was born on January 27, 1756, how old would he be today?

Question 4 ties in with current events. This year marks the fiftieth anniversary of the end of World War II. Many children, some with their arms waving in the air and others who don't bother, call out the answer. Norville, however, is singled out by Ms. O'Neil. "Norville, thank you for remembering to raise your hand. How many years ago did World War II end?" Norville smiles broadly (the rest of the class is quiet) and gives the answer.

Pulling on an exaggerated frown, Ms. O'Neil says, "Now, Room 34, this is where I will be very grouchy. I want you to be neat when you copy this

chart into your math books. What do I mean by that?" A number of hands reach up. There are two or three suggestions about keeping writing and columns neat. In the end, Ms. O'Neil asks, "What do I use to make my lines straight?"

Kelly, with a wide smile on her face, answers, "A ruler!" Ms. O'Neil elaborates on this. She shows the students how to line the ruler and use the pencil along the line. She demonstrates how some students' lines go crooked when they think they can draw straight lines without using their rulers.

Time is an element coming into play in the lesson. The children were late coming in, and they will need to leave at 11:00 for International Language Classes. (Ross, 2002, pp. 16–19)

In this excerpt we see a classroom in operation. We see a teacher in the midst of a school year, early November, teaching a mathematics lesson. She links the mathematics lesson, problem solving involving addition and subtraction, to current events around a celebration in most Canadian schools. There is a link to the subject matter of social studies with the focus on the Canadian population and recent wars. The lesson is teacher directed with a common class assignment in which all of the children participate, first as a whole group and later alone as they record the answers in their notebooks. An account of this part of the lesson is not excerpted above. The classroom routines for learning are set up and recognizable such as raising hands before speaking, turning bodies to face the chalkboard, and the expectation of copying work into their notebooks. We know something of the milieu of the classroom, that is, that there is a chalkboard, a teacher and children. The temporal flow of the day is noted as well as the urgency of keeping within the ordered blocks of time. In this way we can see a lesson as taught, a teacher teaching, students learning although it is not explicit what they are learning, a particular aspect of subject matter.

We also see a researcher trying to locate herself in the midst of the many lives in the classroom as she undertakes a study of a teacher's knowledge. As she studies the curriculum being made in the classroom she learns something of herself as child, as teacher, as researcher.

In our terms, the telling of this classroom lesson opens up the multidimensional quality of narrative inquiry. In particular, we see the teacher in interaction in a particular place. We glimpse, but do not see in depth, temporality in this excerpt. We see something of the personal practical knowledge of the teacher, the professional knowledge landscape within which she lives, and the unfolding story of who she is as a teacher. We do not yet see the children's stories as their lives meet together with this particular subject matter. We see only glimpses of Ross's life being composed as she studies this classroom in a relational way. Ross's study details much of this and, as we work our way through this chapter, we will bring forward other aspects. In this chapter we set out to explore the meanings of knowledge, narrative and self-study and how they are interwoven. We return to Ross's study throughout the chapter to try to make sense of our

conceptualization and the other studies that we review. As more narrative qualities of Ross's work unfold the self-study quality became increasingly apparent. Just as narrative inquiry takes time, self-study takes time.

Coming to Terms in Studies of Teacher Knowledge

Research on teacher knowledge, teachers' knowledge, knowledge of teachers and teaching has grown steadily over the past twenty years or so. However, the term teacher knowledge often blurs the distinctions among these terms. A distinction (Connelly & Clandinin, 2000) we see as critical to understanding self-studies of teacher knowledge is the distinction between teacher knowledge and knowledge for teachers. In the view of knowledge for teachers, knowledge is seen as something teachers possess, something that they acquire from researchers, policy makers, and curriculum developers. Teachers are seen to hold knowledge as possession and they are seen to be more or less skilled in using this possessed object in their practice. Research falling within a view of knowledge for teachers is research designed to produce knowledge that can be given to teachers. When knowledge is seen as a possession, research can be undertaken to see how much knowledge teachers have, the content of their knowledge, and how skilled they are at using their knowledge. While self-study research could proceed from a view of knowledge for teachers, most often such a view of knowledge is expressed in studies on teachers.

A second view of teacher knowledge is of knowledge that comes from experience, is learned in context, and is expressed in practice. Teachers' practice is their knowledge in action. In our own work we explored this idea of teacher knowledge by conceptualizing such knowledge as personal practical knowledge (Connelly & Clandinin, 1985). We drew on Polanyi's (1958) argument that knowledge has a subjective, personal character. For us, personal practical knowledge is a resolution of the subjective and objective in the person, namely the personal (Connelly & Clandinin, 1988). By personal we do not mean idiosyncratic or private, but something that has both a personal and cultural origin and quality. Our conceptualization of personal practical knowledge drew on Dewey's ideas (1938) that knowledge and knowing are dialectical combinations of subject and object and of the cultural and the individual. Johnson (1987), also a Deweyan scholar, argued that knowledge is embodied and expressed socially.

Polanyi (1959) describes two kinds of human knowledge. "What is usually described as knowledge, as set out in written words or maps, or mathematical formulae, is only one kind of knowledge" (p. 12). This kind of knowledge is akin to what we see as knowledge for teachers, something one can acquire as possession. Polanyi terms this kind of knowledge "explicit knowledge" (p. 12). He describes a second kind of knowledge as "unformulated knowledge, such as we have of something we are in the act of doing" (p. 12). For Polanyi, this is "tacit knowledge" (p. 12). These epistemological notions are central to our understanding of teacher knowledge as experiential, as personal, as having a subjective

quality and a pre-cognitive bodily basis that is expressed as tacit professional/
cultural knowledge.

Other researchers share similar views of teacher knowledge. Hollingsworth
(1994) developed a view of knowledge as relational knowledge. Schön's (1983)
view of knowledge-in-action fits within this second view of teacher knowledge.
Schön writes about, "the spontaneous, intuitive performance of the actions of
everyday life" (1995, p. 6) as knowledge that is, "tacit, implicit in our patterns
of action and in our feel for the stuff with which we are dealing" (p. 6). For
Schön, the "workaday life of the professional practitioner reveals, in its recogni-
tions, judgments and skills, a pattern of tacit knowing-in-action" (p. 6). Elbaz's
(1983) ideas of practical knowledge as oriented in 5 ways and as structured and
held as rules of practice, practical principles and images is also a view of teacher
knowledge as distinct from knowledge for teachers.

Coming to Terms with what Counts as Narrative in Teacher Knowledge

"Teacher knowledge" and "narrative" are used in such a diversity of ways that
it is difficult to meaningfully make use of the words outside of particular contexts.
Their generic meaning is difficult, if not impossible, to specify. Adler and Van
Doren (1972) made a distinction between words and terms, arguing that terms
are words that take on meaning through context of usage. Words, they held, are
like empty vessels waiting to be filled with meaning to become terms. Meaning
is found in terms. We have already commented on a range of possibilities for
the word "teacher knowledge" and have, as described above, come to terms by
making a distinction between teacher knowledge and knowledge for teachers.
Much the same can be said for narrative, a word that was barely used in the
educational literature until the 1980's and which is now so ubiquitous as to have
entered the general educational language with studies claiming to be narrative
in character without defining narrative or referencing particular narrative inquiry
traditions.

Curiously, then, narrative entered the educational literature as a term and has
lost meaning as it became a common word. Samaras (2002), for example, in her
book *Self-Study for Teacher Educators* declares her work to be a form of narrative
inquiry. She writes in the Preface, "As I moved from my training in quantitative
research to a narrative inquiry style and began to write not only for others but
also for myself, I gained new insights about my teaching" (p. xiii). What does
she mean by a "narrative inquiry style"? Early in the book there is a longish
section titled My Educational Biography (pp. 8–20) and about a third of the
way into the book she observes, "Impressed by the work of Bullough (1994a,
1994b) and Cole and Knowles (1995) on education-related life history
approaches, I have adapted it in my teaching" (p. 46). Bruner (1966, 1985, 1987a)
is cited for his work on cognitive psychology and especially for his writing on
Vygotsky but not for his work on narrative (1987b, 1990). It appears that she
means first person accounts, perhaps autobiographical and perhaps fitting a

notion of life history. For Samaras the word narrative inquiry appears to refer to a rather general cluster of non-quantitative ways of thinking and doing things.

Our purpose here is to demonstrate the state of usage of the word narrative in the educational literature and to support the need for the distinctions we offer. We are not criticizing Samaras's work; a careful analysis might reveal a solid definable study. Our point is that not much can be made of Samaras's work as a narrative inquiry even though it is said to be such. Similar comments apply to other studies either using the word narrative or claiming to be narrative inquiry studies. This observation is behind our effort to clarify aspects of our usage of narrative in this chapter.

For purposes of this chapter we make a distinction between narrative as teacher knowledge and narrative as representing states of mind and taken to be teacher knowledge. An analysis of Freeman's (1996) "*To take them at their word: Language data and the study of teachers' knowledge*" illustrates our meaning. Freeman criticized narrative research on teacher knowledge by arguing that researchers collected information on what teachers said and used that as a proxy for what teachers did. He wrote that, "To date, research on teachers' knowledge has assumed, perhaps intuitively, that words can represent thought" (p. 734) and have thus focussed on language as a way into understanding "the inner worlds of teachers" (p. 733). He believes that people working in this tradition have used what he calls a "representational" (p. 734) approach to language in which, "language data is treated as data or information first and as language second" (p. 734). Freeman went on to argue that work on narrative and story, especially work coming under the rubric of "personal practical knowledge", where he relied heavily on our own work, was, as he said, "still to stick to the contents of the mind" (p. 741). The work did not, he said, "alter the basic assumptions about language. Advocates of narrative continue to emphasize a representation of teacher's worlds through language data, although the form of these representations change from decisions to stories" (pp. 741–742).

The thrust of Freeman's argument is that in the shift from research on teacher decision making to research on teacher knowledge, particularly as thought of in terms of personal practical knowledge and studied in terms of narrative, the notion that what teachers said reflected what was in their minds and, therefore, what they did, had not changed. From the point of view of this chapter Freeman's point is that narrative continued a methodological tradition of using teachers' spoken statements as a proxy for representing what they thought and did.

Freeman has almost completely misread the literature on narrative teacher knowledge.[1] In general, this literature focuses on what people do, not on what they say they do. To the extent that some research is linguistic and language-based Freeman's argument is compelling. However, he misread much of the work by assuming a language base the research did not have. Clandinin's (1986) work, cited by Freeman, for example, is almost entirely a study of classroom practice with virtually no tape recordings and other use of teacher language. Elbaz's (1983) study, also highlighted in Freeman's critique, is more akin to his balanced representational and presentational modes in which Elbaz both

observed a teacher's classroom and relied on interview. Reliance on interview is the methodological basis of Freeman's critique.

We shall return to Ross's study, as well as other classroom studies, to illustrate what we mean by teacher knowledge as narrative. As these studies are read, a reader will notice little to no sense of narrative as representing states of mind as suggested by Freeman. Rather, knowledge will be seen to be an historical phenomenon embedded in the classroom studies, in the teacher's actions.

Coming to Terms with what Counts as Self-study in Teacher Knowledge Research

Given our view of what counts as teacher knowledge, the question of what counts as self-study of teacher knowledge is important to define. While there can be a range of kinds of research that fits under the broad heading of self-study, the boundaries of self-study of teacher knowledge follow from our definitions of teacher knowledge. If teacher knowledge is defined as knowledge that is experiential, personal, practical, narrative knowledge, then what counts as a self-study of that kind of knowledge?

We turned to Dewey's ideas of experience and inquiry as a way to bound the area of self-study of teacher knowledge. As Schön wrote:

> In the domain of practice, we see what John Dewey called inquiry: thought intertwined with action – reflection in and on action – which proceeds from doubt to the resolution of doubt, to the generation of new doubt. For Dewey, doubt lies not in the mind but in the situation. Inquiry begins with situations that are problematic – that are confusing, uncertain, or conflicted, and block the free flow of action (Schön, 1995, p. 9).

This notion of Deweyan inquiry in practice gives us a way into defining how we might think about self-study of teacher knowledge. Self-studies of teacher knowledge must somehow be located in practice if we are to study the situated, embodied nature of teacher knowledge. Self-study must somehow give an account of the living of teacher knowledge in action, rather than merely the verbal (whether written or spoken) accounts of action. What this means for us is that self-studies of teacher knowledge must somehow lie closer to practice, to be studies of practice, studies of what we call personal practical knowledge.

This is not to say that all self-studies need to be situated in the living of practice but for us, the boundary around what counts as self-studies of narrative teacher knowledge is a boundary that encircles the living of teacher knowledge in practice. It is, as Dewey might have said, undertaken in particular situations of practice.

The Ross Study as an Exemplar of Self-study of Narrative Teacher Knowledge

Returning to the Ross study we note that it is framed within a view of teacher knowledge as experiential, as learned in context, and as expressed in practice.

The knowledge under study in Ross's work is both Ms. Ross's knowledge and Ms. McNeil's. In the excerpt we are situated in Ms. McNeil's classroom but our view of the ongoing life there is mediated through Ms. Ross's presence, through her knowing of practice. We see Ms. McNeil's knowledge in action – her knowing of Canadian history, her knowing of mathematics, her knowing of class routines, and her knowing of the cycle of the school day. We also see Ms. Ross's knowledge in action as she links her knowing of an autumn ritual to the marker Ms. McNeil uses and as she links her knowing of the temporal organization of the school day to what she observes in the school day. The excerpt does not allow us to learn much of either the experiential background of Ms. McNeil and Ms. Ross for we catch them both in the midst. We need to read much more of the study to learn the details of their narratives of experience but still, even in the excerpt, it is clear that this is a study emerging from a view of teacher knowledge as experiential, as contextual, as expressed in practice.

Ross's study is one kind of self-study. It is not the only kind of self-study but we shall say more about that later. It is inquiry in the sense that Dewey wrote of inquiry. It begins with the tensions and problems a person encounters in practice as they attempt to live their experiential knowledge in practice.

Ross's study is a study of teacher knowledge as narrative knowledge. We see Ms. McNeil and Ms. Ross as they live their narrative knowledge in practice not as they use language to try to represent their knowledge in practice. We see the living of their knowledge as they work together with the children on the mathematics lesson, as they bring their knowing of the Canadian social context together with their knowing of the children with whom they engage. They live their knowing in their practice.

A Range of Self-studies in Teacher Knowledge as Narrative

Our structure for organizing the literature follows from our notions of narrative inquiry and knowledge, indicated above. One way to think about the kinds of self-studies that fit within a view of teacher knowledge as narrative is to imagine studies positioned along a kind of continuum between the personal and the social. Thinking of teacher knowledge as both personal and social comes from our Deweyan view of experience as having both personal and social dimensions. In this review of the literature of self-studies in teacher knowledge as narrative, we position studies along a personal-social dimension with studies emphasizing the personal to studies emphasizing the social.

We imagine various points on the continuum and below we offer a description of each point and review relevant studies[2] that fit within the self-study of teacher knowledge as narrative. As we positioned self-studies along our imagined continuum, we realized that individual studies slid up and down the continuum. Some aspects of the study might be more personal; other aspects might be more social. We see this below in both Kennedy's (1992) and Collins's (2002) studies.

1. The first kind of self-study is work that engages someone in studying himself

or herself in order to learn something about their own teaching. This kind of self-study emphasizes the personal and is closest to the personal on our imagined personal-social continuum. The most frequently seen self-study work here is the autobiographical work sometimes represented in narrative texts. An example of such a self-study would be the research of Kennedy (1992). In her study *Narrative Journeys: A Mother/Teacher's Story*, Kennedy studied her practices as a teacher returning to teach after many years at home with her children. She tells the first part of her study as a recollection of her stories of teaching prior to having children. The data for this first part of the study were her remembered stories and artifacts from her early teaching. The second part of the study was based on field notes, journal entries and artifacts kept as an ongoing record of the first 6 months of her return to teaching after 20 years away. The self-study was situated in such a way that it was a study of Kennedy, a study positioned at the personal end of the personal – social continuum but with more social aspects in the second part of the study. Her intent was to learn something about her own teaching, to try to understand something about how her teacher knowledge had shifted over the years.

Another intensely personal self-reflective study is Collins's (2002) *A Return to the Garden – Re-Interpreting Personal Stories: A Hermeneutic Narrative Inquiry into My Experience of Learning*. There are several qualities of this study important to building an understanding of the potential of self-study. At one level, the study is carefully bounded and defined. It is a study of Collins' learning focussed specifically on that aspect of narrative inquiry she calls restorying. Drawing on Clandinin and Connelly (2000), Bruner (1990) and Gadamer (1976, 1994) she undertook what she called "hermeneutic narrative inquiry". The study is built around a series of reflective returns to important learning events in her life. Methodologically, she used dialogue with participants, and the experience of taking and retaking a graduate course, to create situations that facilitated the hermeneutic process. The narrating and re-narrating of her experiences constituted a form of continuous learning. She advanced the idea of "learning recovery rate" which she understood as the ease and speed with which she could revisit and reinterpret experience. For Collins this was a measure of personal flexibility and, therefore, of the ability to learn. Her written text is filled with descriptions of situations and of imaginative, metaphoric image-filled reconstructions of those situations. Collins is a practicing teacher and completed her work by exploring ways that a hermeneutic self-study influenced her teaching.

He's (2002) *A River Forever Flowing: Cross-Cultural Lives and Identities in the Multicultural Landscape* contrasts with Kennedy's and Collins's self-studies in that He is concerned to understand the formation of personal identity of Chinese women intellectuals who grew up in the Chinese Cultural Revolution and subsequently emigrated to North America. Like Collins, she reconstructs the narrative histories of selected participants but with more of an eye to understanding women in similar situations as opposed to a personal account. For instance, part of her writing is devoted to the demographics of Chinese immigration to

North America and the justification of the study in terms of world-wide intercultural movement. Furthermore, though a reader understands the text as He's personal narrative, she used a methodology she called "composite autobiography" in which she masked the identity of the participants, including herself, by mixing aspects of participant life stories. As a result the text has an odd postmodern quality in which the reader is asked to relate to the participant narratives as one would to individual people while, at the same time, being told that the characters are composites. The tone of the text is strongly personal and it would be easy for readers to identify with each character as if she were a person. Postmodern questions arise about the necessary subterfuges to maintain anonymity in a situation where the lack of anonymity can have political consequences unfamiliar to most North American readers. Does this text qualify as a self-study? Without the methodological asides on composite autobiography, the study is clearly a self reflective study of identity formation in cross-cultural and multicultural life settings. Taking the methodology of composite autobiography into account, the study is still seen to be self reflective, since only three people are involved, but the personal connections of the reflections to individuals are tempered and the text takes on a more generic quality with respect to its topic of identity formation.

Conle's (in press) *Texts, Tensions, Sub-texts and Applied Agendas: My Quest for Cultural Pluralism in a Decade of Writing* illustrates another kind of self-study. Beginning with what she called her quest for cultural pluralism, by which she meant her quest both to understand the idea of cultural pluralism and to understand how she might lead such a life, Conle analyzed ten years of her published scholarship in which various multicultural themes were explored in her teaching. The practical, professional, consequence of the inquiry are not directly explored. Rather, somewhat in keeping with He's study of identity, Conle's concern is both to understand cultural pluralism in her own life and, though this is not made explicitly clear, to develop a concept in general as it emerges from a personal life of living at the boundaries (she is German born but spent her life in Canada).

Let us summarize this set of studies that fall on the personal end of a personal-social continuum in terms of our working distinctions. All are clearly studies of teacher knowledge. None deal with what teachers should know to accommodate the curriculum, meet social conditions, or respond to professional directions; that is, none are studies of knowledge for teachers. Furthermore, none of the studies fall under Freeman's notion of narrative inquirers setting out to represent a state of mind. Each study is an account of the authors' knowledge that, in contrast to being a mental state, is a composite construction drawn from a large temporal and social span in the author's life.

Kennedy offers an account of how her knowledge of children, schooling and teaching have shifted over the years; Collins gives a fluid, growing, account of her knowledge of herself as a learner; He offers an understanding of her cross-cultural identity development seen in terms of a lifetime of development; and Conle gives an historical, developmental, sense of her understanding of cultural

pluralism. While Freeman would say that each person offers a representation of her state of mind on her respective topic – Kennedy on her teacher knowledge, Collins on her learning, He on her identity and Conle on her sense of cultural pluralism – the knowledge expressed in each study is both historical and developmental and is to be understood as such – Kennedy with changing knowledge, Collins with hermeneutic growth and learning, He with cross-cultural blending of historical forces captured in the metaphor of the river, and Conle as a chronology of thought on cultural pluralism. None of these statements on knowledge fit easily, or even at all, under notions of knowledge as something definable and existing in the mind or, as Freeman would have it, perhaps, as others would have it, in a book of knowledge. Narrative knowledge, to be understood as such, needs to be read in terms of the inquiries that gave rise to it and how each person speaks of it: developmentally, historically, socially.

2. A second point on the personal-social continuum that moves somewhat away from the personal toward the social are self-studies where someone studies themselves in relation to their practices (students, contexts, subject matters and so on) in order to learn something about themselves and to change some aspect of their practices. A study such as the one by Conle (2000) is an example of such a study. Conle sets out to study her own practice in a preservice teacher education class. She is attempting to have her students use narrative inquiry as a way to learn to teach. Her intentions were to promote in-depth understandings of 'others'; to encourage greater personal involvement; and to shift the emphasis from received knowing to "an exploration of practical professional knowledge" (p. 55). In teaching her class she began to study her own practice in order to learn something about herself and her teaching in this new way. The focus for her is on the kinds of curriculum spaces she was creating for her students and how the students learned within those spaces. But she undertook to study not only the students but how they were experiencing the curriculum she was creating, that is, she was studying herself as curriculum maker.

Another study that fits within this second point on the continuum between the personal and the social is a study undertaken by Elbaz (2001). In her self-study, Elbaz wanted to understand the place of, "narrative and storytelling in a situation of conflict and diversity" (p. 134) in Israel. Telling a story of teaching a pre-service teacher education course where students of diverse religions and lifestyles come together to inquire into coexistence, Elbaz describes a conflict that occurred between Arab and Jewish students. The conflict arose when students encountered an art display while on a break from class. The art display showed caricatures depicting historical violence between Arabic and Jewish nations. They were created by an Arabic artist and beneath each caricature the artist had included a caption that could not be translated to Hebrew. Seeing the anger the caricatures/captions brought forth in the students, Elbaz opened up a space, when the students returned to class, for them to talk about their feelings in relation to the art display. As the conversation ended Elbaz had the sense that, "although time was limited every student who wished to speak was able

to do so, with little or no interruption or discussion … and people seemed rather subdued as they left the room" (p. 137). After class Elbaz engaged in further discussion about the art display with a student who was from the class but had not left the display to return to class after the break. In their discussion, Elbaz came to understand the moment of conflict differently. She wrote, "I begin to see the value of engaging with conflict, of persisting in a difficult discussion with another person until some understanding (not necessarily agreement) is reached" (p. 138). Later as Elbaz reflected on the events of the day she wrote a narrative account of her experiences. Writing this account, Elbaz began to reimagine the final assignment for the course. She wanted the assignment to become something that would help the students learn to restory their experiences and "to figure out how to achieve coexistence" (p. 138). Elbaz describes diverse students' final projects and how they engaged in different ways to explore issues of diversity and coexistence.

In this paper Elbaz is clearly focussed on a self-study of herself as she encounters a problem in practice and works through an inquiry into her practice. It is a study of her teaching and learning from a self-study of her teaching. She is studying herself in relation to her practice and in that self-study comes to understand something of how she might teach so that students could learn how to know the "other".

Ollerenshaw and Lyons (2002) undertake a similar task to Elbaz's, although in this case, there is both the teacher educator and the student teacher engaged in a self-study. Their paper, aptly titled "Make that relationship: A professor and a pre-service teacher's story about relationship building and culturally responsive teaching", is a self-study of the experiences of a Santee pre-service teacher and a university professor. The study tells of Ollerenshaw who taught a pre-service science education course on a Reservation in the United States and of her learning from, and with, Delberta Lyons. In the research undertaken in the context of the pre-service teaching, Ollerenshaw moves to the Reservation to live in a Teacherage. She teaches and lives in that space. Ollerenshaw describes her work to establish a teaching/learning context that would enable the constructivist science teaching she wanted to do. In the self-study, Ollerenshaw and Lyons attend particularly to tensions such as the one that occurred around Ollerenshaw's use of a poster that was seen by some as a "stealing" of the culture. Lyons visits Ollerenshaw outside of school hours in order to help Ollerenshaw understand more of the way her teaching both interrupts and fits within the plot line of the story of learning to teach on the Reservation. The paper is a rich telling of their personal practical knowledge situated on their professional knowledge landscapes. As the year unfolds and as Lyons and Ollerenshaw come to know of each other and of teaching science, they both study themselves. In the conclusion Ollerenshaw writes,

Many educators have come to the Reservation school with good intentions to tell Umoho people what and how to teach Umoho children. Now another, well-intentioned, white teacher had come to the Reservation Teacherage to train indigenous pre-service teachers. (p. 19)

In their paper they both learn something of who they are as a science teacher and a science teacher educator. They use the Teacherage and what happened there as a way to think about who they are. As they wrote, "We both related to the Teacherage as a place to create a new identity" (p. 26).

Another study where we see the focus on educators studying themselves in relation to their teaching practices is the project undertaken by Hinchman and Oyler (2000). They say, "[we] explore our work as teacher educators, an effort to reconstruct a stance for ourselves in relation to our students" (p. 495). Both of them were involved in pre-service teacher education but were teaching different classes. As they told stories of their teaching over the time of teaching their curriculum methods courses, they kept a real time dialogue journal. They write that they, "started these conversations, and excavations of our teaching vaguely satisfied that we were not prescriptive methods instructors" (p. 501). However, as they studied their journal entries, they realized that their,

> conversations have caused us to push against this facile and familiar framing of ourselves. We noticed our instrumentalist struggles to find better assignments, more sophisticated approaches to construction of cohesive unit plans, and more efficient uses of class time. With some surprise, we saw our words and read of our craving for the exact certainty we rejected as unreasonable from our students. Our desire for coherence was no less obvious than theirs. (p. 501)

What they realized, as they studied themselves in relation to their teaching, was something about themselves. They realized that they,

> composed a story that featured students as less sophisticated others and us as more privileged intellectual workers. But, the source of our privilege was the cohesion in the story we told. As grounding we used the same exclusive 'what the research shows', 'what made sense to me, when I was a teacher', or even worse, 'what makes sense to me now that I haven't been in a classroom for a while and have had time to think about it'. In an eerie echo of our students' pleas, we were intent on grabbing hold of our practices and finding the ones that worked in most situations. (p. 502)

Miller Marsh (2002) also engaged in a study of her own practices as an early childhood teacher educator. She undertook this study in order to learn more about her practices as someone situated between the competing discourses of a child-centered discourse and a social-cultural discourse. She saw that her student teachers were also situated in this place between two discourses and understood that both she and they were shaped by living within both discourse communities. She wrote that studying her own teaching, "caused me to reflect even more deeply on my own struggles with identity as the instructor of the course" (p. 454). Prompted by responses and feedback from her students and struggling to help them understand their identities, she used children's literature to help them see the various ways discourse shaped identities. She wrote that, "as a teacher

educator I continue to struggle with making visible to myself and to the prospective and practicing teachers with whom I work how theory informs my pedagogy and shapes my identities as 'teacher'" (p. 454).

To summarize this second set of studies from the point of view of narrative and knowledge it is to be noted that the points made relative to the first set of studies carry forward and apply. These are studies of teacher knowledge, not studies of knowledge for teachers. Each study is a self reflective exploration of the author's knowledge in relation to a particular action setting used by the author for study purposes: Conle with teaching preservice teachers, Elbaz in her Jewish/Arab seminar on conflict and diversity, Ollerenshaw and Lyons in a collaborative teacher educator and student teacher self-study, Hinchman and Oyler in a collaborative study of themselves in relation to their preservice students, and Miller Marsh in a study of her preservice teaching practices. As with the first set of studies, none of these purport to represent the author's state of mind. Each gives a complex historical and social/relational account of the teacher knowledge under study. Thus, the first set of studies which are historically self-reflective for the author, and the second set of studies which, while historically reflective, deliberately engage a practical work situation, share similar features on teacher knowledge and narrative.

3. A third point on the personal-social continuum is the kind of self-study where a researcher sets out to study something else and in the process of doing so learns something about themselves. Some might argue that all research is a kind of self-study. The researcher is always a shaping force in an inquiry. Another way of stating this is to note that an inquirer is one of the terms of an inquiry. We do not intend to include all research in narrative teacher knowledge as self-study. Though not necessarily designed as self-study, work included in this section has a self-study component. Depending on the researcher stance, that is, depending on the relational aspect of the inquiry stance, the researcher may learn about themselves in relational ways, as for example in the Ross study. Ross sets out to study a teacher's personal practical knowledge and in the process of living alongside the teacher, she learns something of her own personal practical knowledge. It is in the process of the inquiring and in the interpreting of her field texts that she learns about herself.

Hollingsworth (1994) began a study intended to look at beginning teachers' experiences of teaching reading and writing in urban settings. She designed the study using a conversational research methodology clearly intended as one in which the beginning teachers would share their narrative knowledge of teaching reading and writing. However, in the process she learned something about her own practices as a researcher and a teacher educator.

> Very early on in our conversations, I saw that – for us to remain a group – I would have to learn a different way, as a teacher-educator, to think epistemologically and act pedagogically. When we initially convened, I had planned for and hoped that our after-dinner conversation would lead to specific talk and research about learning to teach reading and writing ... I

had been a reading instructor in the teachers' preservice programs and had just completed a study of their cognitive change in learning to teach reading within one program (Hollingsworth, 1989b). I knew that they had learned and could demonstrate adequate knowledge about reading theory and practice. I was now interested in a follow-up study into how teachers were applying what they'd learned in their courses to their classrooms, and how I could continue to offer support for their efforts. Under the guise of 'researcher' and 'helpful' facilitator, I could still operate in an expert-novice mode, where I assumed I knew what questions to ask about teaching literacy in urban environments and how to evaluate the answers. However, these teachers did not let me hide my questions or their responses behind my privilege as 'teacher-educator' (Hollingsworth, 1994, p. 17).

Hollingsworth's study is a self-study in which she unexpectedly learned something of her own practices as a researcher and teacher educator. She began with quite different intentions and appears surprised when she finds that she is not able to progress in the way she intended. As she describes the process, she learned about herself and began to shift her practices in the process of the study.

This kind of self-study is similar to the experience described by Goodfellow (2000). This study, a narrative inquiry, is focussed on the experiences of one cooperating teacher, Julie, as she worked with a student teacher, Mandy, in Mandy's final teacher education practicum. Through research conversations with Goodfellow, Julie reflected on and learned from her own teaching practices and beliefs as she tried to make sense of the tensions she was experiencing as cooperating teacher. Goodfellow's research intentions were to try to understand more fully the experience of being a cooperating teacher. There was no initial self-study intent but rather an intent to study something else, the experience of a cooperating teacher. However, as Goodfellow notes, in the process of trying to make sense of Julie's experiences, Goodfellow awakens to how, "professional practice does not occur in a vacuum or within the hearts and minds of individual practitioners but in the relational climate within which practice occurs" (p. 40). It is in studying the other that Goodfellow begins to recognize her own complicity in the stories Julie is telling of her experience. However, Goodfellow stops short of speaking of how she, herself, was changed as a result of the study. She does note the part she plays in the tertiary institution.

Hoban (2000) also undertook a study where he set out to study something else, that is, the experiences of preservice teachers in programs organized in ways that, "divide the complexities of education into independent courses ... and attempt to deliver specialized formal knowledge in ... each course topic" (p. 166). In an attempt to change preservice teachers' experiences, Hoban developed a framework that would allow preservice teachers to see the whole picture, understanding who they are as learners and seeing relationships between teaching and learning. Hoban worked with a group of preservice teachers in his elementary science methods course using a reflective three phase (analysis, synthesis and theorizing) framework. In the analysis phase students were asked to reflect on

factors that encouraged and hindered their learning in relation to the following four categories: personal factors attributed to each student, teaching factors attributed to the instructor/lecturer, peer factors attributed to other students, and situational factors attributed to the task, setting and environment. The synthesis phase involved students in looking back over their weekly analyses and summarizing the four categories attending to both factors they experienced as encouraging and hindering their learning. In phase three, theorizing, students developed a metaphor to visually show the key factors that encouraged their learning. From these key factors, students theorized their role as teachers and imagined optimal learning environments. In order to demonstrate the students' engagement in the three phases of the reflective framework, Hoban included and summarized the work of two students who "produced the most insightful metaphors" (p. 169).

What makes this work self-study of a teacher's narrative knowledge is that Hoban then reflectively turned to his own teaching as he described how monitoring and reflecting on students' reflections helped him both know his students more deeply and to gain insights into his teaching practices. These insights, according to Hoban, encouraged him to continue to realize there is no one effective or right way to teach all students. While Hoban did not set out to study his own teacher knowledge but rather to study students' experiences using a reflective framework, he learned something about himself and his own practices as a science teacher educator.

In another paper positioned at this third point on the continuum where researchers set out to study something else and learn something about themselves in the process is a study undertaken by Day and Leitch (2001) into the, "tensions within and between the four interconnected areas of teachers' lives: the cognitive-emotional and the personal-professional" (p. 403). They focussed their work on six participants enrolled in a course on continuing professional development and school improvement. The students were either enrolled in a course in England or in Northern Ireland. The course was intended to be a space where teachers could consider how their identities were shaping and being shaped by issues in continuing professional development. While the pedagogical approaches were different in the two sites, the purpose of exploring the personal-professional, cognitive-emotional dimensions of teachers' lives was the same.

In the study of the students' experiences in the course, Day and Leitch wrote that, "we have two fundamentally different ways of knowing and understanding, which interact to construct our mental life. First, there is the rational mind, characterized by the logical, deductive mode of comprehension … Alongside this, however, is another system of knowing, the emotional mind, which is powerful, impulsive, intuitive, holistic and fast – and often illogical" (p. 406). Linking these ways of knowing to the approaches used to teach the course, Day and Leitch suggest that the approaches, "were designed to evoke emotional memories for the purpose of developing new responses on the basis that these would be likely to contribute significantly to emotional and cognitive development" (p. 406). As they studied the work of the three teachers in England they showed how the

teachers continued to apply their personal and professional values and their knowing in their teaching practices and how emotionally draining teaching had become for them in environments of increased bureaucracy and work loads. The stories of the teachers in Ireland also stressed the emotional difficulties teachers face in Northern Ireland and show how, "immense emotional investment [is a] … 'taken for granted' aspect of their work" (p. 411).

What makes this work a self-study of teacher knowledge is that Day and Leitch turned to study themselves in their contexts and included a written dialogue between themselves when they considered their emotional knowing both as teachers and researchers. In their dialogue, and in the analysis of their dialogue, they explored how they, similar to the teachers that they studied, also suppressed their emotions because they knew that showing emotions, especially at work, was unacceptable. Day and Leitch noted that it has only been in spaces where reflection was encouraged and supported that they were able to reconnect the emotions they had felt to the stories they had lived. It was in these spaces of reflection, particularly when the space was shared, that Day and Leitch recognized the, "delicate interaction between the rational (cognitive) and the non-rational (emotional) and, in particular, the powerful influencing role of the latter upon the former" (p. 414).

In another paper positioned at this third point on the continuum where researchers set out to study something else and learn something about themselves in the process is a study undertaken by Huber and Whelan (1999) into the experiences of teachers positioned on the margins of schools' "professional knowledge landscapes" (Clandinin & Connelly, 1995). As Huber and Whelan explored one teacher's, Naomi's, stories to live by, they learned how Naomi experienced a particular story of school focussed around a plotline of inclusive education. Naomi was one teacher who participated with a group of teachers in the two-year study. The teachers met monthly with Huber and Whelan to tell stories of their lives in and out of schools. Huber and Whelan learned stories of both in- and out-of-classroom places on Naomi's former school landscape. As they listened to Naomi's stories, they began to realize that Naomi had resisted falling into the story of school that was developing around what inclusive education should look like in her school. They studied Naomi's experiences of "borders and bordercrossings shaped out of the response" (p. 391) on her school landscape. However, as they listened to Naomi's stories and tried to understand her experiences of resistance, Huber and Whelan began to awaken to their own stories of resistance to stories of school. What makes this a self-study is that Huber and Whelan began the process of studying their own experiences of trying to, "sustain stories that run counter to those being scripted for us on school landscapes" (p. 396).

Phillion (2002) also undertook a study where she set out to understand the experiences of other teachers and found herself engaged in a self-study of her own experiences. Phillion wrote a research proposal designed to study the classroom experiences of immigrant teachers. Her research design took her to Pam's classroom, a teacher of West Indian background who teaches in an inner

city school in Toronto. Phillion, with her intense interest in multiculturalism, saw Pam's classroom as a place where she would learn about an immigrant teacher's experience. She held an image in her mind when she began her research of the stories that Pam would live and tell in her practice, stories which grew out of Phillion's notions of West Indian culture and the West Indian population in Canada. When she began she expected to learn about Pam. She expected Pam to live and tell the stories that Phillion already held as a kind of template of multiculturalism. However, as she worked alongside Pam in her classroom, she was surprised to find that the stories Pam lived and told were not the ones Phillion expected. It was at this juncture that Phillion came to engage in a kind of self-study. She did come to live in relation with Pam and learned about Pam's teacher knowledge in practice. But she also came to learn that her stories of others as multicultural other prevented her from seeing the stories of experience that Pam was living and telling. In her inquiry into their living in relation, Phillion tells much about what it means to live as a narrative inquirer with others. As an anonymous reviewer of this chapter pointed out, researchers often stumble from surety to doubt rather from doubt to surety. For this reviewer, this insight helps explain the unhelpfulness of much research on knowledge for teachers.

To summarize this third set of studies we note that even though the research was initially not designed as a self reflective study, all of the studies share similar teacher knowledge and narrative features with those described in the first and second sets of studies above. Perhaps because these studies primarily began in concerns and problems "out there", there is a somewhat more relational and/or interactive sense about the knowledge expressed; knowledge seen as closely interwoven and connected with the participants in the original inquiry. Ross and her participant, Ms. O'Neil, co-figure in knowledge accounts; Hollingsworth and her sense of the beginning teachers group; Huber and Whelan and their learning from and with Naomi; Goodfellow and her connections to Julie, the cooperating teacher; Hoban and his personal learning from the growth of his students; Day and Leitch who, likewise, used their participants' reflective practices to open up a self reflective process between them as authors; and Phillion who rethought her values and philosophy of multiculturalism based on a long-term collaborative relationship with Pam. As with the studies in the first two sets above, these exhibit an historical social quality in which, perhaps, the social dimension, because of the nature of the original inquiry, appears stronger for a reader than in the other studies.

Linking the Self-studies to Professional Knowledge

Self-studies of teacher knowledge become studies of professional knowledge in two ways. Personal practical knowledge is transformed into professional knowledge by narrativizing the relationship of personal practical knowledge to professional knowledge contexts. In one way, the researcher in each self-study transforms his or her personal practical knowledge into professional knowledge

as she/he restories his/her knowing within his/her particular social, cultural and institutional narratives. In a second way, each researcher in a self-study transforms his/her personal practical knowledge within the unique professional setting to resonate with others' professional knowledge in teaching. This latter transformation moves self-study research from an intensely personal focus to connect to audiences of other researchers, other teacher educators, other teachers and perhaps policy makers. In part, we selected self-studies of narrative teacher knowledge which were exemplars in linking self-study accounts of personal practical knowledge with professional knowledge. In the following sections we revisit each study to exemplify these links.

Self-studies at the Personal end of the Personal-Social Continuum

Kennedy (1992) in her autobiographical self-study first links her personal practical knowledge and her particular professional knowledge context as she restories herself as a teacher who lives in more attentive ways to children's lives after returning to teaching. She situates herself within the institutional story of school in which the particular children she taught were children on the margins, children who did not live out plotlines of achievement. But she also moved from situating her personal practical knowledge within her unique professional knowledge landscape to speak to stories of shifting social justice and of respect for children of Aboriginal heritage. Her shifting stories to live by, her shifting identity, were narrated to offer openings for other teachers who find themselves in unfamiliar school landscapes.

We see something similar as Collins stories her own processes of learning within a particular set of learning experiences. She first narrativizes the relationship of her personal practical knowledge to her professional knowledge context of graduate school and research dialogues. But she, too, as does Kennedy, offers a link to professional knowledge through a conceptualization of restorying as having a learning recovery rate. Collins develops a unique way of understanding a learning recovery rate as interwoven with each person's personal practical knowledge.

He (2002) also offers a narrativizing of her personal practical knowledge in relation to her professional knowledge contexts although it is less clear when she is speaking of her own knowing and when she is speaking of, and to, others' professional knowledge. This blurring of the two ways of narrativizing the relationship of personal practical knowledge to professional knowledge contexts is a consequence of the representation of unique individuals in composite autobiographies. Through situating personal accounts within cultural and social narratives He offers insights into the ways that Chinese immigrant women's identities are shaped within new professional landscapes.

Conle's self-study of her own scholarly writing also offers a narrativizing of her personal practical knowledge to her professional knowledge context. In part her self-study is about understanding how she might lead a life marked as a life of cultural pluralism. But she also speaks to others, as noted above, about a

concept of cultural pluralism that emerges from living a life at cultural boundaries.

Self-Studies in the Midst of the Personal-Social Continuum

Self-studies situated more centrally along the personal-social continuum also become studies of professional knowledge in similar ways. These self-studies seem less intensely personal but are self-studies where the researchers want to learn something about their own knowledge in practice, something that usually focuses on restorying their own personal practical knowledge and that might lead to shifts in their professional knowledge. However, in these self-studies, the researchers also speak to larger issues of professional knowledge.

Conle (2000) in her self-study is attempting to have her students use narrative inquiry as a way to learn to teach. She is trying to shift the way she expresses her knowledge in her teaching practice. She narrativizes the relationship of her personal practical knowledge within her professional knowledge context as she studies her attempts to shift her curriculum making. While she does not make explicit the links to professional knowledge outside her own practice, it is clear that she wants other teacher educators to raise similar questions about the kinds of spaces we create in pre-service teacher education classes.

Elbaz (2001) studies the place of narrative and storytelling in situations of conflict. Elbaz embraces the conflict that emerges among Arab and Jewish students in her class and uses the moment of conflict as an opportunity to learn more about the possible uses of narrative. In her study she situates the conflict within the larger cultural narrative of co-existence and her professional knowledge context as a place for learning how to co-exist.

Ollerenshaw and Lyons (2002) in a cross-cultural self-study of learning to teach science illustrate how two individuals transformed their personal practical knowledge into professional knowledge by giving accounts of the relational knowing they developed as they worked together, restorying their personal practical knowledge on a newly shared professional knowledge landscape, Ollerenshaw as a teacher educator and Lyons as pre-service teacher. They tell their stories in a compelling way that allow other teacher educators and pre-service teachers to resonate with their narratives of experience, a way of beginning their own restorying. They reveal, in the space between them, the understanding of culture, cultural difference, and what it means to be in relation to others who are culturally different.

Hinchman and Oyler (2000) and Miller Marsh (2002) undertake a similar kind of restorying of their personal practical knowledge within their teacher education contexts. In both self-studies, the teacher educators use their knowledge as expressed in practice as the research site. While the most focussed account is of transforming their own personal practical knowledge into professional knowledge, they also tell their accounts in ways that other teacher educators can use their work as a place to begin to shift their own personal practical knowledge. They reveal in the space between them the understanding of culture,

cultural difference, and what it means to be in relation to others who are culturally different.

Self-Studies at the Social end of the Personal-Social Continuum

Hollingsworth (1994) began with a focus on studying the experiences of beginning teachers. Early on in the process of her research, the study became a self-study of Hollingsworth as teacher educator and researcher. In the process of this shift to self-study, Hollingsworth undertakes the work of narrativizing the relationship of her personal practical knowledge to her professional knowledge context. She situates her knowledge in the context of the institutional plotline of expert-novice and begins to shift her practices. In her narration of her shifting professional knowledge, she invites others to join her in this restoried approach.

Similarly Phillion (1999) began with a focus on a professional knowledge context as she narrativized the rubbing points between her beliefs about the teaching context studied and the practices she observed her personal practical knowledge was revealed. She comes to respect teachers' ongoing multicultural work with children and to hold in abeyance judgment of teachers' practices in terms of theoretically derived categories. Huber and Whelan (1999), similar to Phillion (1999), also began with a focus on a professional knowledge context. As they narrativized Naomi's experience of resistance in a school, they began to awaken to their own personal practical knowledge of resisting imposed stories of school. They came to understand that teachers' resistance to stories of school shape their stories to live by.

Goodfellow (2002), much less directly, also transforms her personal practical knowledge into professional knowledge. In her study of a cooperating teacher's experience, she comes to realize that her part as university supervisor is implicated in the experience of the cooperating teacher. The part that is left mostly silent is the exploration of Goodfellow's personal practical knowledge. It is her shifting professional knowledge that becomes visible.

Hoban (2000) and Day and Leitch (2001) also focus their attention on the other and turn to focus on their own personal practical knowledge as they reflect on what they have learned about themselves from studying their students. Again, as with Goodfellow, we learn more about their professional knowledge than we do about their personal practical knowledge.

Knowledge, Narrative and Self-Study: Potential and Risks

The distinction between teacher knowledge and knowledge for teachers is important to keep in mind when considering the potential and risks of self-study. Knowledge for teachers originates in theory and policy matters outside of teachers and teaching. The potential and risks of addressing and, more often, assumed not to be addressing, important knowledge for teachers in teacher education programs is widely discussed and found in both an academic and a public interest literature. We have nothing to say about knowledge for teachers,

nor the literature that addresses it, in this chapter. Our concern is with teacher knowledge. We are concerned with how teachers know their professional settings: how they know children, colleagues, schooling, their subject matter, and their policy environment. We do not include "knowing themselves" or "knowing oneself" in this list because the purpose is, ultimately, professional. Research on teachers and teaching owes its justification not to self-knowledge but to teacher knowledge of the professional landscape.

Self-knowledge, in the end, is not important. As means it is all important. In our first book on knowledge, narrative and self-study we wrote (Connelly and Clandinin, 1988), "For each of us, the more we understand ourselves and can articulate reasons why we are what we are, do what we do, and are headed where we have chosen, the more meaningful our curriculum will be" (p. 11). We also wrote that, "We believe that curriculum development and curriculum planning are fundamentally questions of teacher thinking and teacher doing. We believe that it is teachers' 'personal [practical] knowledge' that determines all matters of importance relative to the planned conduct of classrooms" (p. 4). The significance of these statements that, we believe, still hold, is that the researcher's obligation, his or her responsibility, is to be concerned with what is out there. 'Looking in' must take its place as shedding light on what is out there. 'Looking in' must make for a better professional landscape.

This is where the potential of narrative self-study arises. It is possible to study another, and to study collaboratively with an other – most of our work is designed this way – but no matter the duration nor the intimacy, one can never hope to achieve the nuanced, factual, empirical, historical, field base/data base that one might achieve in enlightened narrative self-study. We do not mean a psychologist's self-study, the sort of thing Freeman, noted above, discussed where narrative researchers used inquiry to obtain an understanding of the state of mind. We do not mean that. We mean a narrative understanding with temporal and existential/social elements. Narrative knowledge, we once wrote (Connelly & Clandinin, 1985), is as multisided as the situations that one placed oneself into. Narrative knowledge, we said, is best thought of as situational crystallization of narrative histories and narrative social constructions. Particular situations draw forth and crystallize particular expressions of one's personal practical knowledge. These crystallizations are not psychological states of mind.

It is possible to achieve some of these narrative expressions in intensive, collaborative, narrative study with others. That is the goal. But well done self-study inevitably, because of the experiential base of the self knower, will transcend and be richer than similarly obtained collaborative narrative knowledge. Thus, our position is that self-study is important not for what it shows about the self but because of its potential to reveal knowledge of the educational landscape. Self-study holds the highest possible potential for improving education.

The risks are obvious. Students of self-study may stop with the self and think that self-knowledge in and of itself is enough. It is not, though it may, of course, be enough for a particular researcher's personal purposes. Though we have not done so we found ourselves tempted, while writing this chapter, to devote it to

a criticism of self-study rather than to a demonstration of its potential. These temptations grew out of our sense that too much self-study research is, as harsh critics claim, solipsistic or, as more gentle critics like Freeman claim, psychologically oriented to self understanding what is in the mind. The session happenings at publicly funded academic conferences are often the extreme end of self-study for self-satisfaction. However, we stayed with the idea of potential because we believe the potential is so great. But it is clear, from reading the literature, that the temptations of self-study to merely satisfy the self are strong. To fulfill its promise this field will need to struggle for balance between the potential and risks of knowledge, narrative and self-study.

Notes

1. A related analysis of Freeman's critique was provided by Stefinee Pinnegar, a reviewer of this chapter, as follows:

    I have not read the piece by Freeman, but I know that he is an applied linguist and one of the few who do any work in teacher education. However, that means he brings the scholarly conversation in linguistics into the arena of teacher education. I have no problem with that but what I have often found is that when scholars do this they make assumptions that discourse across the research conversations are shared when they are not or that points made in one arena apply where they do not exactly apply. He seems to me to be referring to the long debate in linguistics about the relationship between thought and language complicated more recently by both Chomsky and Saussure by the distinction between competence in language and performance of the language. Chomsky uses for analysis of sentences the "idealized" form rather than the "spoken" form. He defends this use by saying that the conception of a sentence that native speakers of a language carry in their heads is a more accurate representation of their language than the imperfect forms we find in their speech. He argues that this idealized form is how language exists in their mind for them and therefore is the "true" language they think they are speaking which makes the actual spoken form irrelevant. As I read your report of the Freeman critique I think that he has misunderstood what you are doing in terms of the language/thought debate and the competence/performance debate in the field of linguistics. Furthermore, he probably doesn't make very clear his own position in the historical debate between thought and language and competence and performance, in other words his own beliefs about the debate. Because, those debates in linguistics are philosophically like the ones in development about what contributes more "nature or nurture" and the answer is as much founded in belief as it is in empiricist research findings, his position and belief are important points in his critique and if hidden make understanding exactly what his critique is perhaps misdirected or obscure.

    This is problematic when applied to accounts of teaching practice because what we are analyzing is semiotically more complex than merely the "speech behavior" that a linguist would analyze. We are trying to make sense of the teachers' language, curriculum, behavior and interaction with students as their "language of practice" and teacher knowledge (personal practical knowledge) and so it has so many more dimensions. What you say about Ross and McNeil relates directly. What we can know about Ms. McNeil's knowledge is clouded by Ms. Ross's ability to observe Ms. McNeil's knowledge and by Ms. McNeil's visible practice that elicits from Ms. Ross possibly a small subset of her knowledge about practice generally and even as it might specifically capture Ms. McNeil's practice.

    The problematical nature of Freeman's critique is that the example is squarely positioned between the competence and performance of both Ms. Ross and Ms. McNeil – as scholars we are positioned to learn about teaching in the space between the competence and performance of both participants and mental states seem irrelevant.

2. The online and library searches for this chapter were conducted by Marilyn Huber, doctoral

candidate at the University of Alberta. Using Educational Resources Information Centre (ERIC), the Neos Library Consortium on-line catalogue system, and Educational Research Abstracts as databases, Huber did single descriptor searches for books and journal articles using "narrative," "self-study" and "teacher knowledge" as descriptors. The Neos Library Consortium on-line catalogue system produced a short list of possible books while ERIC and Educational Research Abstracts yielded thousands of articles. Scanning the abstracts identified in the latter databases, Huber recognized she needed to narrow the search to find articles more closely linked to the chapter's purpose. Huber combined the research descriptors and produced a much more specific list of articles. After she compiled the list of possible books and articles, we identified texts that appeared to be research based. We returned this list to Huber and we, and she, read and wrote summaries of each article and book.

PRACTITIONER INQUIRY, KNOWLEDGE, AND UNIVERSITY CULTURE*

Marilyn Cochran-Smith[a] **and Susan L. Lytle**[b]
[a] *Boston College;* [b] *University of Pennsylvania*

Abstract

This chapter explores the relationships among practitioner inquiry, knowledge, and the cultures of universities. The chapter uses the term, "practitioner inquiry," as a kind of conceptual umbrella to overview a number of differing forms of practitioner-based study of teaching, teacher education, and related issues. The chapter has three major parts. The first examines the discourse and terminology of practitioner inquiry, suggesting that the language used to describe it has been widely appropriated for many different contexts. The chapter argues, however, that it is not language alone that differentiates particular kinds of inquiry, nor is it ideological, political, or historical traditions alone. Rather, in order to understand the range and variation of practitioner inquiry, particular practitioner inquiry initiatives and their operating assumptions about how inquiry is related to knowledge, practice, and change must be examined. The chapter offers three different inquiry-knowledge-practice relationships as a way to sort these out. The second section of the chapter discusses the features and assumptions that most variants of practitioner inquiry share and that divide practitioner inquiry from many traditional forms of educational research. The chapter identifies the most common critiques of practitioner inquiry, particularly in relation to issues of epistemology, methodology, and politics. The final section considers the role of practitioner inquiry in the university. This section of the chapter draws on the authors' own experiences working with teacher research and other inquiry communities within the contexts of large research universities over a period of more than 15 years. It explores the ethical, political, and practical dilemmas and contradictions that are created when teacher research and its underlying premises are taken seriously over a long period of time and within the culture of the university.

Even before the emergence of research on teaching as a legitimate field of study almost 50 years ago, it has been widely assumed that scholarly research about teaching and teacher education would allow the educational community to analyze, understand, and ultimately improve teaching, learning, and schooling. Of course there have been many challenges to this assumption about what it actually means to do research on teaching and teacher education and what kinds of research could actually transform schooling. Over time, many important questions have been debated: What can be known about teaching, learning and schooling? How can it be known? Who are the appropriate knowers? How should knowledge claims be supported? What is the relationship between knowledge and the contexts in which it is developed? What kinds of knowledge are most valuable, most useful, most generalizable? What are the connections between knowledge production and knowledge use? What role do values and ideological positions play in research? What are the connections and distinctions between research and advocacy, researchers and activists? How do issues of power and politics play out in research? Whose interests are served and whose are disadvantaged by particular kinds of research? Can practitioners do "legitimate research"? What are the connections between knowledge and experience, research and practice, researchers and practitioners, knowledge generation and professional development? This chapter suggests that these and other important questions about research, knowledge, and the contexts of practice play a major role in the history of practitioner inquiry.

In this chapter we use the phrase, "practitioner inquiry," as a conceptual umbrella to describe many forms of practitioner-based study of teaching and teacher education. The chapter has three major parts. In the first, we unpack the discourse of practitioner inquiry, suggesting that the language used to describe the most fully conceptualized forms of practitioner inquiry have been widely appropriated. Thus, we make the argument that it is not language alone that differentiates particular instances of inquiry, nor is it ideological, political, or historical traditions alone. Rather, in order to understand the range and variation of practitioner inquiry, we must also examine particular practitioner inquiry initiatives and their operating assumptions about how inquiry is related to knowledge, practice, and change. Along these lines, we suggest that there are three significantly different inquiry-knowledge-practice relationships that animate the various forms and versions of practitioner inquiry that are current.

In the second section of the chapter, we look more closely at practitioner inquiry, particularly at the features and assumptions that most versions and variants share. Although there are major differences as well as more subtle nuances that distinguish among various approaches to practitioner inquiry, we suggest that there are also important assumptions that unite them. We point out that these shared assumptions also reflect the major issues that divide practitioner inquiry from more traditional forms of educational research. Along these lines, we identify and analyze the most common critiques of practitioner inquiry, revealing that most of them hinge on traditional issues of epistemology, methodology, and politics.

In the final section of the chapter, we draw on our analysis of the issues that divide and unite forms of practitioner inquiry developed in the first two sections in order to consider the role of practitioner inquiry in the university. To do so, we draw on our own experiences working with teacher research and other inquiry communities within the contexts of large research universities over a period of more than 15 years. In this section of the chapter, we trace the roots of our own interest in teacher research within the university context by developing the notion, "working the dialectic" of research and practice. Finally, we consider some of the ethical, political, and practical dilemmas and contradictions that are created when we take teacher research and its underlying premises seriously over a long period of time and within the culture of the university.

Practitioner Inquiry: Unpacking the Discourse

In the penultimate chapter of her account of the "troubling" history of educational research, Ellen Condliffe Lagemann (2000) suggests that by the 1990s, several new directions seemed to offer particular promise for promoting learning and accomplishing educational reform. These included the development of cognitive science and its application to classroom problems, the adaptation of qualitative research methods from several disciplines for the study of educational questions, acknowledgement of the central role that culture plays in all aspects of schooling, and innovative ways of creating closer links among research, practice, and policy. Lagemann highlights three new links between research and practice – teacher research, design experiments, and combining teaching with research. Along these lines, she comments that although various forms of teacher inquiry were discussed throughout the 20th century, it was during the 1980s that teacher research gained new standing because of its potential to lessen the divide between theory and practice, on the one hand, and contribute needed insider perspectives to the knowledge base about teaching and learning, on the other (Cochran-Smith & Lytle, 1993).

As Lagemann's history and other analyses (Bullough & Pinnegar, 2001; Cochran-Smith & Lytle, 1999b; Zeichner & Noffke, 2001) have made clear, then, there has been an active and ongoing conversation about teacher research and other forms of practitioner inquiry for some time now. Drawing on different intellectual traditions and emerging or re-emerging at different historical points in time, the various strands of this conversation have explored the modes, forms, methods, and purposes of practitioner inquiry in a wide array of national and international contexts. It is not surprising, then, that the language used to describe practitioner inquiry has varied considerably. In the scholarly literature and in popular usage, modifiers such as "action," "collaborative," "narrative," "pedagogical," "participatory," "autobiographical," "reflexive," and "critical" have been combined with each other, with a collection of nouns connoting systematic examination of educational problems such as "research," "inquiry," "scholarship," and "study," and with a number of terms referring to the identity

of the agents involved in the inquiry process such as "teacher," "practitioner," "teacher educator," "participant," and "self."

Roots, Relatives, and Research Traditions

It is not within the scope of this chapter to explore and analyze in detail the various roots and relatives of practitioner inquiry and the long history of research traditions out of which its multiple forms have emerged. A number of other publications have tackled this job quite ably. Both Anderson, Herr and Nihlen (1994) and Zeichner and Noffke (2001), for example, examine the roots and traditions of "practitioner research," a term they use to encompass a variety of forms and types of practitioner inquiry. In addition, others have analyzed the roots and influences on more specific forms of practitioner inquiry (Fecho & Allen, 2003; Lytle, 2000).

Anderson, Herr and Nihlen (1994) acknowledge that there is quite a variety of research traditions and social movements out of which different forms of practitioner inquiry have emerged. These have emerged at various points in time in conjunction with evolving beliefs about what counts as knowledge and as research and also in interaction with varying historical, cultural, and social forces. Anderson and colleagues suggest that the idea of practitioners doing research goes back as far as the late 19th and early 20th centuries, overlapping in a certain sense with the scientific movement in education. They identify several key traditions of practitioner research including: the work of sociologist Kurt Lewin and the group dynamics movement of the 1940s; the tradition of action research in education promoted by then Dean of Teachers College, Columbia, Stephen Corey in the 1940s; the teacher as researcher movement in Great Britain, spearheaded by Lawrence Stenhouse, John Elliot, and Clem Adelman; the participatory research movement in Latin America and other Third World countries, especially influenced by Paulo Freire who argued for emancipatory forms of praxis; the field of action science, as developed primarily by Chris Argyris, often writing with Donald Schön, that was intended to build and test organizational theory as well as alter the status quo in organizations; and, the teacher researcher movement in North America that emerged in the 1980s partly in response to the dominance of process-product research on teaching.

Zeichner and Noffke's (2001) five major traditions of practitioner research in education in the 20th century are very similar to those of Anderson and colleagues. However, they also include in their list the self-study research movement in teacher education at the higher education level and the participatory action research movement in Australia.

Other scholars have examined the roots and traditions of more specific forms of practitioner inquiry. In describing the complex roots of the large family of action research, for example, Noffke (1997), makes it clear that there are many current forms and historical streams that have influenced the professional, political, and personal purposes of these. As a social movement, however, Noffke suggests that action research is fundamentally about the "emergent meanings"

(p. 306) of action, research and their relationships. In previous work we (1999b) discuss salient influences on the teacher research movement that emerged in the U.S. in the 1980s. We suggest that the intellectual traditions and educational projects that influenced this movement include: the paradigm shift in researching, teaching and assessing writing that evolved during the 1970s and 1980s; the British teacher as researcher movement and the development of critical action research in Australia; a variety of efforts by progressive educators committed to social responsibility to construct alternative ways to solve teaching and learning problems; and, arguments that the traditional knowledge base for teaching failed to account for the knowledge generated by teachers. Bullough and Pinnegar (2001) suggest that self-study emerged from the convergence of four developments in educational research: the emergence of qualitative research methods in education with new conceptions of validity; the Reconceptualist movement in curriculum studies, which emphasized the central role of the self in teaching; growing international participation in teacher education research, bringing research methods that draw on the humanities; and, action research in its many variations that blur boundaries between research and practice.

Reading across various scholars' explications of the roots of practitioner inquiry makes clear that a number of related but also quite different intellectual traditions, social projects, and educational initiatives in various parts of the world have shaped the emergence and development of practitioner inquiry. As we noted above, multiple terms and permutations of these terms have been used to describe practitioner inquiry. These signal a wide range of meanings and purposes, but they also reflect surface as well as deeper differences – contrasting paradigms of research, different assumptions about the roles of practitioners in the production and use of knowledge, and differing conceptions of professional development for teachers, teacher educators, and other practitioners. They also reflect different emphases on individual and institutional growth and on the promotion of practitioner inquiry as a means toward the end of problem solving, technical improvement, strategic social change, and/or personal growth and development. The admixture of terms and the differing accounts of influences and relatives for practitioner inquiry are not surprising given the complex ideological, multinational, and sociocultural history of efforts by educators to document, understand, and alter practice. In addition, since each participant in the work of practitioner inquiry is somewhat differently positioned in the power structures of schools and universities, each becomes involved in practitioner inquiry to further different agendas or outcomes.

Practitioner Inquiry as Conceptual Umbrella

In this chapter, we use the term, "practitioner inquiry" as a conceptual and linguistic umbrella to refer to a wide array of educational research modes, forms, genres, and purposes. As noted above, Zeichner and Noffke (2001) and Anderson, Herr, and Nihlen (1994) have used "practitioner research" in a similar encompassing sense. We prefer "inquiry" here rather than "research" as the inclusive

term simply because, in our experience, the former is more resonant with school- and community-based teachers and other practitioners. In using "practitioner inquiry" as an umbrella, it is not our intention to suggest that the terms encompassed by the general phrase are synonymous with one another nor is it our intention to blur the important ideological, epistemological, and historical differences that exist between and among them. Rather we hope to illuminate the differences across these forms of inquiry at the same time that we clarify some of their commonalties, in particular the ways in which they collectively differ from more traditional forms of research on teaching and teacher education.

Arguably, the most common terms for practitioner inquiry that occur in the current discourse of educational research are: action research; teacher research; self study; narrative inquiry; the scholarship of teaching and learning; and, the use of teaching as a context for research. These terms are not mutually exclusive nor do they comprehensively encompass the whole of practitioner inquiry. Nonetheless, we find that they do convey the general landscape of practitioner inquiry and begin to suggest some of the intricate ethical, epistemological, and political issues involved when exploring practitioner inquiry in the context of university culture, the topic that is the focus of the third section of this chapter.

In the following paragraphs, we offer an overview of each of these as they are used in current discourse. For more extensive discussions of their roots and more nuanced explication of their epistemological and methodological assumptions, we refer readers to the literature noted above and throughout this chapter.

Action Research

Under the umbrella of practitioner inquiry in teaching and teacher education, "action research" is commonly used to describe collaborations among school-based teachers and other educators, university-based colleagues, and sometimes parents and community-based activists. Their efforts center on altering curriculum, challenging common school practices, and working for social change by engaging in a continuous process of problem posing, data gathering, analysis, and action. As noted above, the term, "action research" is used to describe projects that locate their roots in the social action traditions of Kurt Lewin and Stephen Corey in the 1940s and 1950s in the U.S. (Anderson *et al.*, 1994). More often in the current discourse, however, "action research" refers to work in the tradition of the teacher-as-researcher curriculum development movement in the U.K., which was spearheaded by Lawrence Stenhouse, John Elliott, Jean Rudduck, and others, and/or to work in the tradition of the Australian participatory and critical action research movement, led by Wilfred Carr and Stephen Kemmis, who conceptualized action research as critical and emancipatory (Noffke, 1997; Zeichner & Noffke, 2001).

Teacher Research

Although overlapping in certain ways with uses of "action research," the phrase "teacher research," is now commonly used to refer to the North American

renewal of interest in teacher inquiry that emerged in the late 1980s (Cochran-Smith & Lytle, 1999b; Lagemann, 2000) and continues to be vigorous in discussions about teacher learning, school reform, and the knowledge base for teaching. Teacher research has been conceptualized by Marilyn Cochran-Smith and Susan Lytle as the central task of teaching across the professional lifespan (Cochran-Smith & Lytle, 1993, 1999b) and by Gary Anderson and Kathryn Herr (Anderson & Herr, 1999; Anderson *et al.*, 1994) as a way to study one's own school. Generally, "teacher research" refers to the inquiries of K-12 teachers and prospective teachers, often in collaboration with university-based colleagues, who work in inquiry communities to examine their own assumptions, develop local knowledge by posing questions and gathering data, and – in some versions of teacher research – work for social justice. This often involves developing alternative ways to understand, assess, and improve teaching and learning and using inquiry to insure educational opportunity, access, and equity for all students.

Self-Study

As many of the chapters in this handbook make clear, "self-study" has been conceptualized and carried out primarily in the U.K., Australia, Canada, and the U.S. More international in focus than some other varieties of practitioner inquiry, the term, "self-study," is used almost exclusively to refer to inquiries at the higher education level by academics involved in the practice of teacher education, broadly construed. Often drawing on biographical, auto-biographical, and narrative forms of data collection and analysis, self study works from the postmodernist assumption that it is never possible to divorce the "self" from either the research process or from educational practice (Bullough & Pinnegar, 2001; Cole & Knowles, 2000). Self study has been conceptualized by Mary Lynn Hamilton, Stefinee Pinnegar, John Loughran, Vicki LaBoskey, Tom Russell, Gary Knowles, Bob Bullough, Ardra Cole, Jeff Northfield, Fred Korthagen, and other members of the AERA Self-Study Special Interest Group as a way to reinvent teacher education by continuously interrogating one's own practice and all of its underlying assumptions (see, for example, Cole & Knowles, 1995; Hamilton, 1998; Loughran & Northfield, 1998; Russell & Korthagen, 1995).

Narrative Inquiry, Autobiographical Inquiry

Closely related to and sometimes overlapping with self-study, "narrative inquiry" and/or "autobiographical inquiry" may also be located under the practitioner inquiry umbrella. The phrase, "narrative inquiry" is generally used to refer to the idea that the narratives produced through systematic reflections by prospective and experienced teachers and/or by teacher educators contain knowledge within them. At the same time, narratives are the vehicles through which much of a practitioner's knowledge is made explicit and articulated by the knower and also conveyed to others outside the immediate context of the knower. Narrative inquiry has been conceptualized by Jean Clandinin and Michael Connelly as a way to uncover and represent teachers' personal practical knowledge (Clandinin, 1986; Clandinin & Connelly, 1995, 1996) and by Nona Lyons

and Vicki LaBoskey as a way of knowing that is complementary to, but also different from, more traditional epistemologies (LaBoskey, 1994; Lyons, 1998; Lyons & LaBoskey, 2002). "Autobiographical inquiry" focuses on narratives that are autobiographical in nature as a way for educators to get at the roots of their own assumptions and deep-seated beliefs about teaching and learning (Bullough & Pinnegar, 2001). Similarly "reflexive inquiry" is conceptualized by Ardra Cole and Gary Knowles (2000) as a way for both prospective teachers and teacher educators to explore beliefs and further professional development.

The Scholarship of Teaching

Another form of inquiry that we include here under the practitioner inquiry umbrella is "the scholarship of teaching," a term originally coined by Ernest Boyer, then President of the Carnegie Foundation, as part of special report on the priorities of the professoriate (Boyer, 1990). The report was intended to forward a new and enlarged vision of scholarship in higher education that would go beyond what Boyer termed "the scholarship of discovery" (traditional research) and "the scholarship of integration" (connecting research across disciplines) to include as well "the scholarship of application" (applying knowledge to consequential problems in the real world) and "the scholarship of teaching" (transforming, transmitting, and extending knowledge in pedagogical contexts). Making a distinction between Boyer's notion, which emphasizes "scholarly teaching," Lee Shulman and his current colleagues at the Carnegie Foundation have conceptualized the notion of "the scholarship of teaching and learning." This goes beyond scholarly teaching to focus on studying, understanding, and enhancing teaching and learning across disciplinary areas and at both K-12 and higher education levels by making the scholarship of teaching public, accessible to critique by others, and exchangeable in the professional community (Hutchings, 1998; Shulman, 2001; Shulman, Lieberman, Hatch, & Lew, 1999).

Using Teaching as a Site for Research

The final mode of inquiry that we include in this discussion is research that is carried out by university-based researchers who take on the role of teacher in K-12 settings in order to conduct research on the intricate complexities involved in the problems of practice. This version of practitioner inquiry does not have such clearly identifiable nomenclature as the previous versions do. As noted above, Lagemann (2000) refers to this simply as work by researchers who are also teachers studying their own practice. The best known examples of this kind of inquiry are the work of Magdalene Lampert, Deborah Ball, and some of their colleagues and students. Lampert (1990, 2001) conceptualizes this work as a process of documenting and presenting the social and intellectual performances visitors often commented on when they observed in her fifth grade mathematics classroom. Adding to the layers of research on their own teaching, Lampert and Ball (1998) conceptualize "pedagogical inquiry" as a way for teachers to learn from other very experienced and expert teachers' records of practice.

Inquiry-Knowledge-Practice Relationships

The preceding paragraphs present a brief outline of some of the most commonly used terms for practitioner inquiry. In the section that follows this one, we elaborate on some of the issues that unite the various forms of practitioner inquiry as well as those that divide it from more traditional approaches to educational research. The point we wish to make here, however, is that the terms and concepts commonly used to refer to describe practitioner inquiry are evoked in widely differing circumstances and for many different purposes, some of which are quite inconsistent with the purposes of those who initially and/or most notably conceptualized and developed them.

The Protean Shape of Practitioner Inquiry

"Teacher research" and "action research" are now widely used in a diverse array of preservice teacher preparation programs and professional development projects for experienced teachers. Across these programs and projects, however, this language carries multiple and divergent meanings and is connected to agendas that are quite different from one another. The result is that "teacher research" and "action research" and some of its common permutations – "teacher inquiry," "collaborative action research," and "teacher action research" – are used to describe activities that widely diverge: one teacher's systematic documentation of successive attempts to implement accurately and consistently a pre-determined sequence of phonics instructions, on the one hand, and the work of a school-based community of urban teacher candidates and experienced teachers working collectively to do away with tracking practices and make the literature curriculum at their school more multicultural and inclusive, on the other. Along related lines, the term, "self-study" is used to describe a teacher education faculty's collaborative efforts over time to explore and expose the power relationships involved in their own practices recruiting and socializing prospective teachers, on the one hand, but also used to portray a single teacher educator's autobiographical reflections without reference to the relationship of his practice to the learning of either his own teacher education students or their current and future pupils in K-12 schools.

Our point here is twofold. First, the various terms commonly used to conceptualize practitioner inquiry often have deep roots in particular epistemological and intellectual traditions, some of which are decidedly political and radical. Nevertheless, there is little shared meaning across the education community about what it means to do teacher research, action research, or self-study in school and university settings, and thus these concepts are often instantiated in ways that are divorced from their conceptual underpinnings. Historical roots notwithstanding, then, the fact is that ideas such as action research, teacher research, and self-study have been widely appropriated and have come to mean many different things as they are attached to various research initiatives and various educational purposes, some of which are quite conservative in nature. In this sense, we (1999b) have pointed out that practitioner inquiry has a rather

protean shape and its remarkable growth over the last two decades hinges on a paradox: the increased acceptance and even (in some contexts) institutionalization of practitioner inquiry brings with it the increased possibility of the co-optation, dilution, and misinterpretation of the very roots that may have made this kind of inquiry epistemologically desirable or socially radical in the first place.

Secondly, it is not the activities within which inquiry occurs or the pedagogies to which it is attached that reveal its critical features and assumptions. For example, having teachers construct portfolios is a widely used activity in preservice teacher education programs and is also central to certain opportunities for advanced professional development, such as experienced teachers' preparation for certification by the National Board for Professional Teaching Standards. In a certain sense, it would be accurate to say that portfolios represent a widespread and significant opportunity for teachers to engage in inquiry. But just as inquiry has a protean shape, portfolios thought of as scaffolding or containers can be built upon or filled up in quite different ways. Some portfolios are more like scrapbooks than anything else, containing photos of children and classroom activities as well as samples of lesson plans and pupils' work with little critical commentary or thematic synthesis. Other portfolios contain photos and sample lesson plans but also feature multiple checklists that correspond to the required certification regulations in a particular state with the prospective teacher's statement about how he or she has demonstrated competency in each area.

Still others may contain: teachers' narratives about puzzling experiences, constructed as exemplars of teachers' ways of knowing (Lyons & LaBoskey, 2002); teachers' essays, studies, journals and oral inquiries, critically analyzing the questions addressed over time and exploring the relationships of their own learning to their students' learning and to issues of social justice (Cochran-Smith, 1999; Lytle & Cochran-Smith, 1990); or, an array of prospective teachers' work samples (Schalock, Schalock, & Girod, 1997), demonstrating teachers' growth and development by measuring pupil change on pre and post tests of knowledge in particular units or areas of study. What is contained in most of these portfolios could certainly be said to represent teachers' inquiries, and yet the differences are striking.

To sort out some of the key differences among various approaches to practitioner inquiry, we need to look beyond language, beyond method, and beyond context. We need to look instead at what is made problematic and what is assumed when practitioners engage in inquiry as well as the larger purposes, educational agendas, and social meanings to which their inquiries are attached. As we noted above, the salient differences among and across modes of practitioner inquiry do not reside in the methods or contexts in which they occur, but in the ideas and assumptions that animate them, particularly the relationships of inquiry, knowledge, and practice.

Knowledge *for* Practice

We have distinguished three sets of relationships among inquiry, knowledge and practice: inquiry as a way to implement or codify for dissemination "*knowledge-*

for-*practice*," inquiry as a way to uncover and enhance "*knowledge-in-practice*," and inquiry as a way to generate local "*knowledge-of-practice*" within inquiry communities (Cochran-Smith & Lytle, 1999a). These three derive from differing ideas about knowledge and professional practice and how these are related to one another in practitioners' work. Although competing in fundamental ways, these three conceptions co-exist in the world of educational policy, research, and practice and are invoked by differently positioned people in order to explain and justify quite different ideas and approaches to improving teaching, learning, and teacher education and to generating knowledge in these areas. The salient differences among these three relationships do not turn on clearly demarcated terminology since, as we have shown above, this is not the case. Rather, important differences are the result of different underlying assumptions.

When it is assumed that inquiry is a way to implement or codify "knowledge-for-practice," the focus is on what has commonly been referred to as "formal knowledge" (Fenstermacher, 1994a; Richardson, 1996) or general theories and research-based findings on a wide range of foundational and applied topics that together constitute the basic domains of knowledge about teaching and teacher education, widely referred to by educators as "the knowledge base." The idea here is that the work of competent practitioners reflects the state of the art – that is, that highly skilled practitioners have deep knowledge of their content areas and of the most effective strategies for implementing that knowledge to solve problems of practice. In much of the literature of research on teaching, it is assumed that formal knowledge is generated through "studies of teaching that use conventional scientific methods, quantitative and qualitative; these methods and their accompanying designs are intended to yield a commonly accepted degree of significance, validity, generalizability, and intersubjectivity" (Fenstermacher, 1994a).

The "knowledge-for-practice" relationship is evident in two strands of practitioner inquiry. Some versions of teacher research or action research that are implemented at the school-wide or school district-wide level as ways to insure that teachers faithfully and accurately implement particular instructional programs and strategies reflect this set of assumptions. Although dramatically different from the intentions of many of those who have theorized teacher and action research, the point of "inquiry" initiatives such as these is for practitioners to use "teacher research" or "action research" as vehicles for documenting and improving their implementation of strategies and approaches that have been identified as "best practices" through empirical research on high performing schools, programs, or teachers.

As Shulman (1987) and others pointed out more than a decade ago, however, the knowledge base for effective practice needs to include an array of knowledge categories and sources. He argued that one of the most important sources of the knowledge base for teaching – the wisdom of practice – was generally missing from the literature. Of particular interest was what Shulman called "pedagogical content knowledge," defined as a special combination or "amalgam" of content and pedagogy that is uniquely the province of practitioners (p. 8). Throughout

the late 1980s and 1990s, a number of research programs explored pedagogical content knowledge, especially teachers' reasoning as they transformed their personal understandings of content into representations that could be taught to students. These and other programs of research attempted to formalize what teachers needed to know about their subjects as well as what they needed to know in order to choose, construct, use and evaluate representations of subject matter in ways that were understandable to pupils and thus teachable.

Some versions of practitioner inquiry, particularly some approaches to the scholarship of teaching and/or of using teaching as a site for research, are consistent with the idea of codifying and formalizing as "*knowledge-for-practice*" the pedagogical content knowledge and other forms of knowledge that characterize the work of excellent and wise practitioners, whether at the K-12 level or the higher education level. As we commented above, this perspective is reflected in Shulman's distinction between "scholarly teaching," as conceptualized by Ernest Boyer (1990), and what has more recently been conceptualized as "the scholarship of teaching" (Hutchings, 2000; Shulman *et al.*, 1999), both of which are valued in the professional community. Shulman (2000) points out that scholarly teaching is well-grounded in the field, reflects thoughtful and well-designed examples and strategies, and models the modes of inquiry valued in the discipline. The scholarship of teaching, on the other hand, exists when the work of practitioners who are engaged in scholarly teaching is made public and available as community property so that it can be peer-reviewed, critiqued, and built on by others. Shulman suggests that the scholarship of teaching allows practitioners to treat their own courses and classrooms as "laboratories or field sites" so that they can pass on to others what they "discover, discern, and experience" and thus contribute to, "the improvement and understanding of learning and teaching" (p. 49).

Knowledge in Practice

When it is assumed that inquiry is a way to uncover and enhance "*knowledge-in-practice*," the focus is on what many people have called practical knowledge, or, what practitioners know or come to know as it is embedded in the artistry of practice, in practitioners' reflections on practice, and/or in practitioners' narrative and autobiographical probing of practice. A basic assumption here is that practice is to a great extent an uncertain and spontaneous activity, situated and constructed in response to the particularities of everyday life in schools, classrooms, and the contexts of teacher education programs. What practitioners need to know to teach well under these conditions is acquired through experience and through considered and deliberative reflection about, or inquiry into, professional and personal knowledge and experience.

The *knowledge-in-practice* conception is rooted in constructivist images of knowledge and is based on the premise, best articulated by Donald Schön, that there is knowledge implicit in action and artistry – that artistry itself is a kind of knowing (Schön, 1983, 1987). This view of professional knowledge breaks epistemologically with what Schön calls "technical rationality" wherein it is

assumed that professionals are problem-solvers (rather than problem posers), that the problems of professional practice present themselves ready-made and full-blown, and that they can be solved instrumentally through the application of research-based theory and technique.

Russell (1987) suggests that Schön's general idea of professional knowing-in-action is closely akin to what many educational researchers refer to as "practical knowledge," a term used to conceptualize and sort out varying perspectives on knowledge about teaching. The conception of practical knowledge that underlies practitioner inquiry rooted in this second set of inquiry-knowledge-practice relationships reflect this epistemological break with the knowledge-claiming conventions of formal knowledge. Refusing to make apologies for the practicality of teaching or to act as if practical work is somehow "less than," approaches to practitioner inquiry that assume a knowledge-in-practice relationship explore how practitioners invent knowledge in action, how they learn to make that knowledge explicit through deliberation and reflection, and how they link self learning with the learning of their students (Clandinin & Connelly, 1995; Grimmett & MacKinnon, 1992; Munby, 1987; Russell, 1987).

The *knowledge-in-practice* relationship is evident in a number of strands of practitioner inquiry. There are many professional development initiatives at the preservice and K-12 level, for example, wherein facilitators work with groups of teachers, functioning as supportive outsiders who push others to question their own assumptions and reconsider the bases of actions or beliefs. Richardson's notion of practical inquiry (Richardson, 1994a, 1996) as a method of staff development (Anders & Richardson, 1994; Richardson, 1994a, 1994b), for example, is based on the idea that consultants, often from a university, work collaboratively with teachers to help them see the discrepancies between their beliefs and practices. This process of teacher learning hinges on constructing and reconstructing the "practical arguments" (Fenstermacher, 1994b) that guide practice and consequently experimenting with alternative practices (Richardson, 1994b). Some versions of self-study that focus on professional development for teacher education faculty by clarifying assumptions, recognizing discrepancies between beliefs and practices, and rethinking practices based upon these interior analyses are also the lines of *knowledge-in-practice* (e.g., Hamilton, 1998; LaBoskey, Davies-Samway, & Garcia, 1998).

Other versions of self-study put more of an emphasis on autobiography and on self-understanding and self-exploration. Bullough and Pinnegar (2001) suggest that this approach to self study was particularly influenced by Ross Mooney's argument (Mooney, 1957 as cited in Bullough & Pinnegar, 2001) that who the researcher is, is central to what and how he or she studies educational issues and also by William Pinar's belief (Pinar, 1980 as cited in Bullough & Pinnegar, 2001) that understanding of education requires rigorous exploration of the roots of self understanding. These ideas about the dramatically important role of the self in uncovering and enhancing the knowledge needed to understand, conceptualize, and improve practice are central to much of the current self-study movement in teaching and teacher education.

Knowledge <u>of</u> Practice

When practitioner inquiry is understood as a way to generate local and critical "*knowledge-<u>of</u>-practice*," it is assumed that the knowledge practitioners need to teach well is generated when they work within inquiry communities and treat their own classrooms, schools, programs and courses as sites for intentional investigation. At the same time, they treat the knowledge and theory produced by others as generative material for interrogation and interpretation. In this sense, practitioners learn when they generate local knowledge <u>of</u> practice by working within the contexts of inquiry communities to theorize and construct their work and to connect it to larger social, cultural, and political issues.

The idea behind this perspective on practitioner inquiry is not that practitioners' research provides all the knowledge necessary to improve practice or that the knowledge generated by researchers who study practice from perspectives outside of their own context is of no use to practitioners. Nor is the suggestion here that using roughly the same strategies as researchers investigating topics from the outside, practitioner researchers add to the knowledge base a new body of generalizations based on their own perspectives inside practice. In other words, the assumption is <u>not</u> that practitioners are generating a new or supplementary kind of formal knowledge about practice in teaching and teacher education that can be removed from the context of its development and passed around to others. Rather, implicit in the idea of *knowledge-<u>of</u>-practice* is the assumption that through inquiry, practitioners across the professional life span can make problematic their own knowledge and practice as well as the knowledge and practice of others and thus stand in a different relationship to knowledge and action.

There are a number of strands of practitioner inquiry that work from this set of assumptions about the relationships of inquiry, knowledge, and practice. Some of this is commonly labeled action research, some teacher research, and some self-study. As we have argued throughout this chapter, however, it is not the labels that define this work nor is it the contexts within which it occurs.

Some of the practitioner inquiry from this perspective is grounded in critical social theory and aimed explicitly at social change and the creation of a more just and democratic society (e.g., Elliot, 1991; Gitlin, 1994; Gore & Zeichner, 1995; Kincheloe, 1991; Noffke, 1997; Noffke & Brennan, 1997). From this perspective, knowledge is understood to be constructed collaboratively by teachers, students, administrators, parents, community members, and academics with the end of locally developed curriculum and more equitable social relations. The emphasis is on transforming educational theory and practice toward emancipatory ends and thus raising fundamental questions about curriculum, teachers' roles, and the ends as well as the means of schooling. Kincheloe (1991) has written explicitly about the critical nature of professional practice and of teacher research as a path to empowerment while Noffke (1997, p. 306) argues that all forms of action research deal with issues of power and control and are about the relationships of action and research.

Rooted in the intersection of teacher education and language/literacy studies, another approach to practitioner inquiry that shares this third set of assumptions about the relationship of inquiry, knowledge, and practice emphasizes teacher research as an agency for school and social change. The premise of this approach is that local knowledge of teaching, learning, and schooling is generated by making classrooms, schools, and other professional contexts sites for research, working collaboratively in inquiry communities, and taking critical perspectives on the theory and research of others. This work pays particular attention to the discourse of learning communities, the conjoined efforts of teachers and students as inquirers, and the role of inquiry in the fields of literacy and curriculum. The emphasis here is on blurring the boundaries of research and practice and on conceptualizing practice as a critical and theory-building process. The larger goal is to create classrooms, schools, and professional programs where rich learning opportunities increase students' life chances as well as to alter the cultures of teaching by altering the relations of power in schools and universities.

Some of these initiatives in the education of K-12 teachers working in collaboration with university-based faculty are parallel to some inquiries and self-studies at the higher education level (e.g., Cochran-Smith, Albert *et al.*, 1999; Cole & Knowles, 1998; Zeichner, 1999; Zollers, Albert, & Cochran-Smith, 2000) wherein teacher educators rethink their own assumptions, teaching strategies, and, in many cases, missed opportunities to clarify or connect with students (Cochran-Smith, 1995; Zeichner, 1999). As Zeichner (1999) points out, self study of this kind has the potential to move us, "beyond the slogans of critical, multicultural and feminist pedagogies in teacher education and the uncritical glorification of methodologies such as case pedagogies and narrative" (p. 40) and toward interrogation and reconstruction of practice. Similarly Cole and Knowles (1998) assert that self-study fundamentally challenges the status quo of the academy.

Practitioner Inquiry and Educational Research

Despite the many different modes, forms, and types of practitioner inquiry that we note above, there are several important features that most of these modes share. We analyze several of these below. To elaborate on the assumptions and features that many modes of practitioner inquiry have in common, however, is also to point to some of the basic issues that divide practitioner inquiry, on the one hand, from more traditional forms and paradigms of educational research, on the other. Thus, in the following section, we explore the issues that both *unite* many forms of practitioner inquiry but also *divide* practitioner inquiry from more traditional modes of university-based educational research.

The Issues that Unite, The Issues that Divide

Although there are differences in emphasis and intention, there are seven general aspects of practitioner inquiry that cut across versions. These include: the practitioner as researcher, the practitioner as legitimate knower, the professional

context as inquiry site for the study of problems that arise from practice; blurred boundaries between inquiry and practice; notions of validity and generalizability different from the conventions of traditional research; systematicity in terms of documentation, data collection, and analysis; and, making the work of practice public and accessible to critique by others. We describe each of these below.

Practitioner as Researcher

One feature that every form of practitioner inquiry has in common is that the practitioner himself or herself also takes on the role of researcher. (In practitioner inquiry where the researcher takes on the role of teacher in order to do research, there is an interesting inversion with the researcher taking on the role of practitioner.) This duality of roles makes it possible for the classroom teacher, the student teacher, the school principal, the school district superintendent, the teacher educator, the professional development leader, the community college instructor, the university faculty member, the adult literacy program tutor, the fieldwork supervisor of prospective teachers, and many other educational practitioners to participate in the inquiry process as researchers. This is quite different from what is usually the case with research on K-12 teaching where practitioners are usually the topics of study, the objects of someone else's inquiry, or the informants and subjects of research conducted by those outside the situation. In some versions of practitioner inquiry, "researchers" also includes participants who are not "practitioners" in the professional sense, but are significant stakeholders in given social situations and educational contexts such as parents, community members, and families.

Although some practitioner inquiry is conducted by individuals working more or less by themselves, in most versions of practitioner inquiry, collaboration among and across participants is a key feature. These collaborations take many forms – they may be inquiry communities of new and experienced teachers across several schools working together with teacher educators to generate local knowledge; university- and school-based educators working collectively with community-based activists and parents to change the conditions of a particular school or neighborhood; faculty members from different disciplines and research paradigms working together to interrogate the assumptions and values that underlie their practices and programs; or, small groups of teachers preparing for advanced certification working with university-based facilitators to make visible, document, and critique beliefs and practices. In most forms of practitioner inquiry, the role of the local community is critical since this is the context in which knowledge is constructed and used, and it is also the context in which knowledge is initially made public and opened up to the scrutiny and consideration of others.

Knowledge, Knowers, and Knowing

Across varieties of practitioner inquiry, a second key idea is that those who work in particular educational contexts and/or who live in particular social

situations are among those who have significant knowledge and perspectives about the situation. This means that all of the participants in inquiry groups and communities are regarded as knowers, learners, and researchers. As we have pointed out elsewhere (Cochran-Smith & Lytle, 1993), from this perspective, fundamental questions about knowing, knowers, and what can be known have different answers from those that underlie traditional research on and about teaching and teacher education. From the perspective of practitioner inquiry, practitioners are assumed to be among those who have the authority to know – that is, to construct "Knowledge" (with a capital K) about teaching and learning. It is also assumed that what is worth knowing about includes practitioners' ways of knowing, or what practitioners, who are researchers in their own professional contexts, can know through systematic inquiry.

Most varieties of practitioner inquiry share the assumption that the knowledge needed to understand, analyze, and ultimately improve educational situations cannot be generated primarily outside of those contexts and then transported from "outside to inside" (Cochran-Smith & Lytle, 1993) for direct implementation and use. Rather practitioner inquiry is built on the assumption, noted above, that practitioners are knowers, that the relationships of knowledge and practice are complex and distinctly non-linear, and that the knowledge needed to improve practice is influenced by the contexts and relations of power that structure the daily work of teaching and learning. For most versions of practitioner inquiry, this does not mean that it is intended to usurp or negate the role of outside researchers who are engaged in the generation of knowledge for and about teaching, learning, and schooling. To the contrary, this knowledge is vital. But it does mean that most versions of practitioner inquiry challenge the idea that knowledge can be generated in one site and directly and unproblematically generalized and transmitted to another site. Unlike the knowledge generated by outside researchers, the knowledge generated through practitioner inquiry, which often takes the form of enhanced conceptual frameworks, altered practices, and/or reconstructed curricula, is intended primarily for application and use within the local context in which it is developed. With some of the most well-known versions of action research (Carr & Kemmis, 1986; Noffke, 1997), the whole emphasis is on action and social change and not on knowledge except as it is understood to be in the service of change. Nonetheless, some of those who have conceptualized practitioner inquiry have suggested that this local knowledge is often useful and of interest beyond the immediate context (Lytle & Cochran-Smith, 1992).

Professional Context as Inquiry Site, Professional Practice as Focus of Study

A third common feature of the many varieties of practitioner is that the professional context is taken as the site for inquiry, and problems and issues that arise from professional practice are taken as the topic or focus of study. This means that a whole variety of educational contexts at many different levels of organization become research sites – the K-12 classroom, the university teacher education program, the school-university partnership, and the adult literacy program, but

also the reading group, the multicultural education course, the correspondence of an inquiry group, the individual journal, and the teacher leadership team. Although many of these are quite common as sites for research on teaching and teacher education, it is the combination of the practitioner as researcher with the professional context as research site that is critical here.

When the practitioner is engaged in inquiry about his or her own professional context, the questions emerge from the day to day experiences of practice and, often, from discrepancies between what is intended and what occurs. In traditional research on teaching, questions generally reflect careful study of the existing theoretical and empirical literature and sometimes negotiations with those who work in the contexts where data are collected. The questions of practitioner inquiry, on the other hand, are often highly reflexive, immediate, and referenced to particular students or situations. At other times, they are more general. Embedded within the questions generated by practitioners are many other implicit questions about the relationships of concrete, particular cases to more general and abstract theories of learning and teaching. The unique feature of the questions that prompt practitioners' inquiry is that they emanate from neither theory nor practice alone but from critical reflection on the intersections of the two.

It is important to note here that most versions of practitioner inquiry do not assume that because the researcher concentrates on questions of practice, he or she is engaged in inquiry about only "practical" things or that practice is a narrow construction referring to behaviors or actions. Rather, as Cochran-Smith and Lytle (1993) have pointed out, most practitioner inquiry turns on the assumption that practice is both practical and theoretical. As McEwen (1991) suggests: "The concept of practice has become fixed in our minds as inhabiting the phenomenal world rather than the theoretical world. But to make such a division between theory and practice is to misunderstand the nature of practice" (p. 13). What this means for practitioner inquiry is that while the questions of practice are the major focus of study, these have a great deal to do with the ways practitioners theorize their own work, the assumptions and decisions they make, and the interpretations they construct about their students' learning.

Blurred Boundaries between Inquiry and Practice

The boundaries between inquiry and practice blur when the practitioner is a researcher and a knower and when the professional context is a site for the study of problems of practice. This is particularly clear in the work of many university-based faculty members who are engaged in practitioner inquiry. The vast majority of university faculty members – whether engaged in practitioner inquiry or not (and certainly most are not) – work as teachers and/or in other practitioner roles, and their performance as practitioners represents a portion of how their overall merit is measured and rewarded.

At a growing number of universities, however – and not only at those that have traditionally been regarded as research universities – research is the most valued and rewarded activity of the faculty member. Nevertheless, many of those

involved in teacher education and professional development have been unwilling to privilege the role of either practitioner or researcher (Lytle & Cochran-Smith, 1995). Rather, over the years, a growing number of teacher educators have found that the work they wanted to do in the university and in the community blurred boundaries and prompted a fundamental rethinking of the meanings of research and practice, the roles of researchers and practitioners, and the distinctions between conceptual/theoretical scholarship, on the one hand, and empirical research, on the other. As faculty members, a number of teacher educators have learned to make their professional work a strategic site for inquiry by focusing at least some of their conceptual and empirical research as well as their writing and grant-getting efforts on the work they do with others in various inquiry communities as well as on their own courses and programs. At the university level, making professional work an inquiry site means most importantly that there is not a clear demarcation between the activities of research and the activities of practice. More recently, a small number of arts and science faculty members have also begun to engage in inquiry about their own work as teachers, particularly by engaging in the scholarship of teaching and learning (Hutchings, 2000, 2002b). Many of these faculty are documenting their teaching in college courses, developing appropriate methods of assessing their students' learning, and disseminating their work in innovative digitized forms.

In the university context, blurring boundaries and roles can create enormous potential for innovative programs of research and the generation of new kinds of knowledge as well as tensions and professional dilemmas. While in the university context research is highly valued, in the context of elementary and secondary schools, this is rarely the case. In schools, the primary work of the practitioner – and certainly the most valued and rewarded work – is the work of practice. When the teacher or other school practitioner reconstructs his/her role as practitioner researcher, different kinds of tensions and problems are created, and there are often great concerns about the danger of research stealing time and energy away from the more important activity of teaching.

Most of the modes of practitioner inquiry described above share the assumption that inquiry is an integral, not separate, part of practice and that learning from practice is an essential task of practitioners across the professional lifespan. This assumption is based in part on the belief that teaching and other forms of educational practice are incredibly complex and changing. This means that seeking global solutions to problems and monolithic strategies for teaching and teacher education is not a fruitful direction. Rather, the assumption is that the boundaries between teaching and inquiry must blur so that teachers, teacher educators and other practitioners have opportunities to construct their own questions, interrogate their own assumptions and biographies, gather data of many sorts, and develop courses of action that are valid in local contexts and communities.

Validity and Generalizability

Issues about generalizability and validity have often been used to discount the value of practitioner inquiry, which is by definition usually prompted by the

questions of individuals or local groups of practitioners, and is often conducted in the context of a single classroom, course, school, or program (Cochran-Smith & Lytle, 1990). However, an important feature shared by many forms of practitioner inquiry is that notions of validity and generalizability are quite different from the traditional criteria of transferability and application of findings (often, the identification of causes and effects) to other populations and contexts.

With some forms of practitioner inquiry, notions of validity are similar to the idea of "trustworthiness," that has been forwarded as a way to evaluate the results of qualitative research (Lincoln & Guba, 1990; Mishler, 1990). In conceptualizing narrative inquiry, for example, Lyons and LaBoskey (2002), use Mishler's (1990) argument that with inquiry-guided research – including narrative inquiry – the concept of validation replaces the notion of validity. From Mishler's perspective, validation is the extent to which a particular research community, which works from, "tacit understandings of actual, situated practices of a field of inquiry" (Lyons & LaBoskey, 2002, p. 6), can rely on the concepts, methods, and inferences of an inquiry for their own theoretical and conceptual work. Following this line of reasoning, Lyons and LaBoskey suggest that for narrative inquiry, validity rests on concrete examples (or "exemplars") of actual practices presented in enough detail so that the relevant community of practitioner researchers can judge the trustworthiness and usefulness of the observations and analyses of an inquiry.

Bullough and Pinnegar's (2001) discussion of the problems of determining quality and finding suitable publication outlets for autobiographical forms of self-study research are along similar lines. Bullough and Pinnegar do not discuss validity per se but instead refer to issues of significance, quality, grounding, and authority of autobiographical self-study. They suggest that because self-study borrows from several different scholarly traditions and also introduces the subjectivity of "self" as its central aspect, criteria for assessing quality have yet to be clearly established. For assessing the quality of self-study research and determining its virtue (or "virtuosity" as they call it) – particularly that which draws heavily on narrative, autobiography, correspondence, and/or conversation – they suggest 14 guidelines. These include: resonance and connection with readers; insight and interpretation of patterns in experience; honesty and historical accuracy; narrative focus on important issues confronting educators; authenticity of voice; attention to the learning of others as well as self learning; narrative structure and character development; thorough grounding in context; originality of perspectives; intimacy and openness to insider perspectives; convincing argumentation and evidence; wholeness; interrogation of limitations; and, representation of disagreements as well as agreements.

Along somewhat different lines, Anderson, Herr and Nihlen (1994) make a distinction between practitioner inquiry that is intended to produce knowledge for dissemination in traditional outlets, on the one hand, and action research that is intended to transform educational or institutional practice, on the other. For the former, they suggest that more common notions of validity – whether derived from quantitative or qualitative research traditions – may be appropriate.

In this vein, Lampert's (1990; Lampert, 2001) work is a useful illustration. Do we want to make a statement about/imply something about goodness here? We don't do this with others. She suggests that her detailed analysis of her own and her pupil's thinking in a mathematics classroom provides "proof of possibility" that the theoretical frameworks underlying new notions of mathematics teaching and learning are useful in classrooms.

For practitioner research that is intended to be transformative, however, Anderson, Herr and Nihlen (1994) call for different ways of valuing and establishing validity than those appropriate for research intended to be traditionally disseminated. Anderson and colleagues draw on the work of Clandinin and Connelly (1995), Cunningham (1983), Lather (1986), and Watkins (1991), each of whom has conceptualized validity in interesting ways that break with traditional epistemologies and with traditional criteria for validity. Anderson and colleagues proffer a "tentative" set of new criteria for practitioner research that include democratic validity (honoring the perspectives and interests of all stakeholders), outcome validity (resolving the problems addressed), process validity (using appropriate and adequate research methods and inquiry processes), catalytic validity (deepening the understandings of all the participants), and dialogic validity (monitoring analyses through critical and reflective discussion with peers). These guidelines are consistent with Grimmett and MacKinnon's (1992) discussion of the value of teachers' "craft knowledge." They point out that in the final analysis, "the essential validity and morality of craft knowledge reside in readers' 'living' the life of particular teachers through stories, narrative, case studies, and other forms of vicarious experience" (p. 396).

Systematicity

All of the forms of practitioner inquiry listed above share the feature of systematicity and intentionality. Stenhouse's (1985) emphasis on research as "systematic" and "self critical" inquiry emphasized this idea early on. In some forms of practitioner inquiry, systematic documentation of issues related to teaching, learning, and schooling resembles the forms of documentation (observation, interviews, and document/artifact collection) used in ethnographic research, grounded theory, and other forms of qualitative and interpretive study. Many K-12 teacher researchers (Cochran-Smith & Lytle, 1999a) as well as university faculty members engaged in the scholarship of teaching and learning (Hutchings, 1998) or self-study (Hamilton, 1998), for example, keep systematic notes about classroom interactions and conversations with students and colleagues and also catalog the documents that represent students' emerging understandings, such as their written work, number work, drawing, figuring, and their approaches to problems as well as their explanations, questions, and ways of linking information and ideas. In addition, classroom performances of all kinds as well as test scores and other modes of evaluation are systematically documented.

Part of what distinguishes the inquiries of practitioners from those of outside researchers who rely on similar forms of data collection is that in addition to

documenting students' learning, practitioner researchers also systematically document their own teaching and learning – their own thinking, planning, and evaluation processes as well as their questions, interpretive frameworks, changes in views over time, issues they see as dilemmas, and themes that recur. Often practitioner researchers capture these interpretive processes by collecting multiple versions of course syllabi and class handouts, plans and materials used for class activities, class assignments and problems posed, and the texts used in teaching and learning interactions (Lytle & Cochran-Smith, 1990). In addition, teacher researchers keep extensive journals and/or make audio and videotapes of group discussions and other class interactions, students' and teachers' presentations, and talk with students (Lampert, 2001; Lampert & Ball, 1998).

Like many forms of qualitative research conducted by outside researchers, a strength of practitioner inquiry is that it usually entails multiple data sources that can be used to illuminate, confirm, but also disconfirm one another. What distinguishes this work from other qualitative forms is the systematic examination and analysis of students' learning juxtaposed and interwoven with systematic examination of the practitioners' own intentions, reactions, decisions, and interpretations. This combination makes for incredibly detailed and complex analyses of teaching and learning. Lampert's (2001) detailed analysis of teaching and learning mathematics in a fifth grade classroom where she was the teacher while also a university-based researcher as well as Russell's (1997) account of his own struggle to learn to teach provide quite different but equally persuasive evidence of the remarkable potential of practitioner researchers to analyze the links as well as the disconnects between teaching and learning that are not readily accessible to researchers based outside the contexts of practice.

Notions of what counts as data and what counts as analysis in practitioner research are often different from those of more traditional modes. Autobiographical and narrative inquiry (e.g., Cole & Knowles, 1995; Florio-Ruane, 2001; Lyons & LaBoskey, 2002), for instance, almost always treat stories as data and treat certain kinds of narratives as interpretation as well. However, practitioner inquiries also sometimes include as data sources email, letters, and other forms of correspondence as well as recorded conversations and other artifacts that illuminate and represent participant's meaning perspectives at particular moments in time (Bullough & Pinnegar, 2001; Cole & Knowles, 1994). Broader notions of what counts as data are in keeping with many postmodernist perspectives about the nature of knowledge and or human experience that are more akin to the traditions of the humanities than of the social sciences.

Those engaged in practitioner inquiry have been inventing new forms and frameworks of analysis and interpretation as well as new forms of data. As noted above, some of these may look quite unfamiliar to those who are accustomed to the traditional modes of data collection and analysis entailed in most university-based research. For example, in some forms of practitioner research, such as "oral inquiry" (Lytle & Cochran-Smith, 1990), the analysis of data sources is primarily oral and constructed in the social interactions of particular groups or

communities of practitioners. Oral inquiries represent practitioners' self-conscious and often self-critical attempts to make sense of their daily work by talking about it in planned ways. In communities convened to explore issues and practices across contexts by examining particular cases, the primary outcomes are the enriched understandings of the participants (Himley, 1991). What sets this kind of inquiry apart from other forms is that analysis is collectively constructed and emerges from the conjoined understandings of teachers and others committed to long-term highly systematic observation and documentation of learners and their sense-making (Carini & Himley, 1991). To generate analyses that account for multiple layers of context and multiple meaning perspectives, practitioners usually draw on a wide range of experiences and their whole intellectual histories in and out of their immediate contexts of practice (Cochran-Smith & Lytle, 1999a).

Publicity, Public Knowledge, and Critique

Although the focus of practitioner inquiry is, by definition, the work of practitioners in their own professional contexts, most forms of practitioner inquiry are characterized by their emphasis on making the work public and open to the critique of a larger community. Along these lines, as noted above, Stenhouse (1985) defined research as systematic inquiry "made public" to others, and much of the current North American teacher research movement is distinguished by the work of K-12 teachers, teacher educators, and others working together to generate "knowledge of practice" within inquiry communities (Cochran-Smith & Lytle, 1999a). There are two important issues involved here that turn on two related but different senses of the notion of "publicity" or "public-ness." One has to do with the critical role of peers and more distant others in scrutinizing and critiquing the analyses and interpretations of practitioner researchers in order to enhance and validate its legitimacy as knowledge about teaching, learning, and teacher education and also to build on that work in their own. The second is concerned with making practitioner knowledge public beyond the immediate local sense by disseminating it through traditional as well as innovative channels.

In self-study research, for example, which by its very title suggests an individual and self-focused approach, it is widely acknowledged that inquiry cannot be solely individual (Cochran-Smith, Dimattia *et al.*, 1999; Loughran & Northfield, 1998; Smith, 1998). Loughran and Northfield (1998) point out that without the perspectives of important "others," self-study research may become merely "rationalizing or justifying one's actions or frames of reference" (p. 7) rather than genuine grappling with the contradictions and tensions involved in the quest to improve practice and develop knowledge by better understanding personal experience. The scholarship of teaching and learning, (Hutchings, 1998; Shulman et al., 1999), puts even greater emphasis on the role in inquiry of a critical community, or what Shulman (1999) calls "the public face of scholarship" (p. 161). Shulman suggests that in order to become useful as well as credible to others, scholarship must be accessible – transformed, essentially, into community

property – which makes possible both peer scrutiny and generativity, or the building of new work on other people's work (Shulman, 2000). A hallmark of many forms of practitioner inquiry is the invention of new ways to store, retrieve, code, and disseminate practitioners' inquiries in the form of CD-ROMS, websites, and other electronic innovations (see, for example, Hutchings, 2000; Lampert & Ball, 1998) as well as new modes of public presentation and publication of this work, such as multi-voiced conversations, readers' theater, poetry, and so on.

Making practitioner inquiry accessible beyond the immediate local community raises a number of important issues related to generalizability and purpose that are touched on above. Although some descriptions of practitioner inquiry suggest that it generates practical knowledge that is quite distinct from formal knowledge, which is generalizable and widely usable (Richardson, 1996), many of the forms of practitioner inquiry are characterized by their efforts to break with the traditional epistemological distinction between formal and practical knowledge and with the traditional notion that practice is practical by developing new ways to talk about knowledge that is truly useful in describing, understanding, and altering the conditions of teaching, learning, and teacher education. We have suggested that teachers' work in inquiry communities generates knowledge of teaching that is both local and public (Cochran-Smith & Lytle, 1993; Lytle & Cochran-Smith, 1992). This local-public conception does not posit two kinds of knowledge analogous in any way to the distinction made between practical and formal knowledge. Rather, it suggests that through inquiry, teacher researchers and other practitioners generate knowledge of how teachers and their students co-construct teaching and learning in particular schools and classrooms. This kind of knowledge is useful for the individual practitioner engaged in efforts to alter and improve his or her own practice, but is also useful for the local or immediate community of inquiry where groups of practitioners build a contextualized knowledge base on teaching and learning that cuts across classrooms and contexts. This knowledge may also be useful more publicly and generally, however in that it may suggest new insights into many of the domains of research on teaching and learning, new knowledge about teacher inquiry, teachers' learning, and professional growth; and new knowledge about the relationships among teacher inquiry, knowledge, and school reform (Cochran-Smith & Lytle, 1993).

In the preceding section, we have described seven salient features shared by most forms of practitioner research. Analysis of these features not only reveals the general ways that divergent forms of practitioner inquiry are united, but also points to many of the issues that divide practitioner inquiry from more traditional university-based research. For example, the discrepancies between practitioner inquiry where roles and boundaries are blurred, on the one hand, and traditional forms of research that makes sharp demarcations between researcher and that which is being researched, on the other, are clear in many of the critiques that have emerged about practitioner inquiry over the years. We elaborate these in the following section. Then, in the final section of this chapter, we use our own work as university-based researchers promoting practitioner inquiry within the

culture of the university as an illustration of some of the concrete particulars that divide practitioner inquiry from educational research more generally.

Critiques and Commentaries on Practitioner Inquiry

At the same time that practitioner research has gained an important measure of acceptance and standing over the last quarter century (Lagemann, 2000), a number of significant critiques of practitioner inquiry have emerged from both inside and outside the movements. Many of these are by no means new criticisms. Rather, as Zeichner and Noffke (2001) point out, serious challenges to the idea that teachers could be involved in researching their own practices were leveled by university-based researchers as early as the 1950s. Some of the most prominent current criticisms of practitioner inquiry are made by scholars who have taken an interest from the disciplinary perspectives of philosophy and/or research methodology. Other critiques are rooted in critical social and economic theory and/or in understandings of pedagogy as praxis. Arguably the most dismissive critiques are tied to the preoccupation at the beginning of the 21st century with "scientifically-based" research in education (Shavelson & Towne, 2002) and with "evidence-based" or "scientifically-based" reform of many aspects of curriculum, instruction, and teacher preparation that are embedded in new legislation from the federal government.
