## **MACHINERY'S HANDBOOK, 31ST EDITION, TEAM**

### **Editorial Advisory Board**

**Steve Heather**, an acclaimed mechanical engineer, worked in the defense, aircraft, automobile, and lighting industries for more than 30 years. More recently, he taught mechanical engineering and computer-aided design (CAD) at the college level to engineering and architectural students. He is an expert in AutoCAD®, CNC programming, multi-stage press tool design, and precision machining, as well as author of *AutoCAD® 3D Modeling* and *Engineers Precision Data Pocket Reference* and coauthor of *Beginning AutoCAD® Exercise Workbook*, *Advanced AutoCAD® Exercise Workbook*, and *AutoCAD® Pocket Reference*, all published by Industrial Press. He is an invaluable engineering advisor and contributor to material throughout the *Machinery's Handbook*, as well as a skilled technical illustrator, whose work enhances the current edition.

**David O. Kazmer** is professor of plastics engineering at the University of Massachusetts Lowell, as well as associate research professor at the University of Massachusetts Amherst. He is the recipient of 19 recognition awards, including the Ishii-Toshiba Design for Manufacturing Award, an inventor with over 20 patents, and author of more than 200 publications and vital text in the *Machinery's Handbook*. His academic work is motivated by industry experiences, most recently as director of research and development at Dynisco HotRunners. His teaching and research encompass process development, product and machine design, and design methodologies, including polymer processing, design for manufacturing, optimization, simulation, process control, and technology strategy. His ongoing research has contributed to development of new manufacturing processes with improved real-time control and robust design tools.

**Howard Kuhn** most recently served as adjunct professor at the University of Pittsburgh, Swanson School of Engineering, where he taught courses in manufacturing, additive manufacturing, product realization, and engineering entrepreneurship and performed research on additive manufacturing. He currently is a technical advisor to America Makes (National Additive Manufacturing Innovation Institute), where he previously was acting deputy director. Specializing in advanced technology implementation, he has engaged in the design and application of multiple additive manufacturing technologies for major government clients and private industry. He has developed undergraduate and graduate courses in engineering design, failure analysis, deformation processing, and powder and mechanical metallurgy; conducts tailored training courses on additive manufacturing for government agencies, trade organizations, and companies; and contributed authoritative revisions to this edition.

**Jennifer Marrs** has worked as a mechanical engineer for more than 20 years. An accredited Professional Engineer, she earned a master of science degree in mechanical engineering at Northeastern University, holds a patent, and is a registered US patent agent. Her areas of expertise include manufacturing engineering, design and analysis of machinery, tool and fixture design, machinery safety, fluid systems, industry standards, and intellectual property issues. She has worked with companies of all sizes and ran a successful consulting practice for nearly a decade. She is the author of the Industrial Press text *Machine Designers Reference*, as well as key technical material in the *Machinery's Handbook*.

### **Contributors**

**Viktor P. Astakhov** earned his Ph.D. in mechanical engineering from Tula State Polytechnic University, Tula–Moscow, USSR–Russia, in 1983. He was awarded a DSci designation (Dr. Habilitation, Docteur d'État) in 1991 and the title “State Professor of Ukraine” in 1991 for outstanding service rendered during his teaching career and the profound impact his work had on science and technology. An internationally recognized educator, researcher, and mechanical engineer, he has won a number of prestigious awards. In 2011, he was elected to the SME College of Fellows, and, in 2018, he became a member of the European Union

**MACHINERY'S HANDBOOK, 31ST EDITION, TEAM**

Academy of Science. As a professor, he has supervised graduate students at Michigan State University. He currently serves as a research professor at St. Petersburg State Polytechnic University in Russia, as well as the tool research and application manager of the General Motors Business Unit of PSMI.

**Vukota Boljanovic** received his B.S., M.S., and Ph.D. in mechanical engineering and has more than 45 years of experience in applied engineering in the aircraft and automotive industries, including serving as vice president for research and development with a major aircraft company. He has taught aerospace engineering, among other subjects, and has performed extensive research in development and manufacturing engineering, including the impact of design modification on tools, dies, and processes selection; aircraft assembly; and inspection. He is the author of numerous technical papers and books, including the Industrial Press titles *Applied Mathematical and Physical Formulas*, *Metal Shaping Processes*, *Sheet Metal Forming Processes* and *Die Design*, and *Sheet Metal Stamping Die Designs*, and has been widely recognized by both academia and industry for his contributions to manufacturing.

**Charles “Wes” Cross** has been a weld engineer for more than 25 years. He holds a degree in weld engineering from Le Tourneau University in Longview, Texas, and has held many positions in local American Welding Society (AWS) chapters. His industry experience encompasses weld applications, quality control programs, shop supervision, and weld program implementation and maintenance. He is an expert in weld processes and adhering to ASME, AWS, and NAVSEA standards and codes, as well as an AWS Certified Welding Inspector and Certified Welding Educator. He recently established All Welding Services, a consulting company for weld shops and weld code programs, working with companies around the world.

**Brad Dulin** is a senior metrologist and has worked in the research and development in aerospace, biomedical, and other technical fields for more than 30 years. He has collaborated with such technological giants as Hughes Helicopters and Space and Communications divisions, the Jet Propulsion Laboratory, and Raytheon, as well as technology companies worldwide. He has served as a metrology consultant with BAE for the Kuwait Air Force and, most recently, as operations manager for the Kuwait Green Energy Company. He currently lives in Kuwait and is collaborating on the development of advanced hydrogen/solar-based alternative energy solutions.

**Arief Era** is a graduate of Columbia University, where he received his master's degree in mechanical engineering. As a structural analysis engineer, he worked on various commercial aircrafts for the Boeing Company. At Consolidated Edison of New York in the Gas Engineering department, he has developed fittings, valves, and piping systems for gas delivery while performing root cause analysis for field failures. More recently, he has led the Maps and Records Team for the gas delivery infrastructure of Manhattan. His experience and extensive work on developing, refining, and working with industry standard and related technical information has been crucial to the current edition of the *Handbook*.

**Charles Gillis** has over 24 years of machine design experience. He received his bachelor of science degree from Worcester Polytechnic Institute and a master's degree in mechanical engineering from Northeastern University. Currently serving as a mechanical design engineer for the Gillette Company, designing automated machinery for manufacturing blade and razor products, he has been training practicing engineers in geometric dimensioning and tolerancing, print reading, and related mechanical analysis, design, and documentation topics for the last decade. A licensed Professional Engineer in Massachusetts, he holds a Geometric Dimensioning and Tolerancing Professional Certificate—Senior Level (GDTP-S) from ASME. In addition to authoring the bestselling *Hammer's Blueprint Reading Basics, 4th Edition*, he also contributed to the Industrial Press titles *Machine Designers Reference* and *The CAM Design and Manufacturing Handbook*.

**Edmund Isakov** earned his Ph.D. in technical sciences at the Novocherkassk Polytechnic Institute (Soviet Union). He is known for his work in research, development and applications of cutting tools for milling, turning, and boring. During nearly two decades at Kennametal, he became a noted authority on the technical analysis of cutting tools and processes. He holds 7 U.S. patents and 10 U.S.S.R Inventor's Certificates pertaining to carbide and diamond

**MACHINERY'S HANDBOOK, 31ST EDITION, TEAM**

tools. A senior member of SME, he has authored numerous articles and papers, as well as the Industrial Press titles *Cutting Data for Turning of Steel*, *Engineering Formulas for Metal-cutting*, and *International System of Units (SI)*.

**Melissa Klingenberg** holds a master's degree in manufacturing systems engineering and a Ph.D. in materials engineering. She has more than 25 years of experience in inorganic finishing operations, specializing in development, technology evaluation, and implementation of innovative coatings and surface finishing processes to improve engineering properties and address environmental issues. Known for research in wear-resistant coatings and replacement technologies for defense applications, she has co-authored many publications. A research and development engineer at Pennsylvania State University's Applied Research Laboratory, she also has served as AESF Foundation president and on the AESF Council, Emerging Technologies Committee, NASF Research Board, and Sur/Fin Technical Committee, and as organizer and chair for the Surface Engineering for Defense and Aerospace Applications Conference. While a principal advising engineer at Concurrent Technologies Corporation, she received the 2015 National Association for Surface Finishing's Scientific Achievement Award.

**Kathleen McKenzie** is an educator, writer, editor, and copy editor specializing in science and mathematics. With a bachelor's degree in chemistry and a master's in mathematics, she has been a career mathematics educator—primarily at Binghamton University, SUNY, where she teaches undergraduate calculus. She has worked for major publishers and composition houses nationwide, and has helped develop and add materially to a number of best-selling Industrial Press texts. Among these, she contributed to *Technical Shop Mathematics*, and served as development editor on *The Handbook of PVC Pipe Design and Construction*. In the last and particularly the current edition of the *Machinery's Handbook*, she helped make significant revisions in the mathematics and measuring units sections, as well as refining other key topics.

**Merwan Mehta** is a professor in the College of Engineering and Technology at East Carolina University in Greenville, North Carolina. He has taught engineering economics at the undergraduate and graduate levels since 2004. Prior to joining academia, he spent more than 20 years in the manufacturing industry as a partner in business, vice president, project director, manager, industrial and manufacturing engineer, and machine tool design engineer. A Certified Manufacturing Engineer and Certified Six Sigma Black Belt, he conducts workshops internationally on various engineering and operational excellence topics and has served as an examiner for the Missouri Quality Award, based on the Baldrige Criteria. His *Applied Engineering Economics Using Excel* is a top Industrial Press text.

**David R. Quinonez** has over 25 years of experience in welding, welding inspection, and nondestructive testing. His impressive experience in nondestructive testing began with nuclear submarines and aircraft carriers. Subsequent positions included nondestructive testing (NDT) and welding inspection on Rolls-Royce gas turbine engines, F-22 stealth fighter airframes, missile defense, commercial/military rockets, pipeline, and structural steel for private sector and public works projects. He is a Certified Welding Inspector performing visual welding inspection, dimensional verification, and NDT. His Level II certifications include UT, MT, and PT; past certifications have included Level I IRT, ET, and ASNT Level III MT and PT. He is the author of the highly instructive Industrial Press title *1,001 Questions & Answers for the CWI Exam: Welding Metallurgy and Visual Inspection Study Guide*.

**Peter Smid** is a professional consultant, educator and speaker, with many years of practical, hands-on experience. He consults to manufacturing industry and educational institutions on use of CAD/CAM software, CNC technology, part programming, advanced machining, tooling, and setup. His comprehensive industrial background in CNC programming, machining, and company-oriented training has assisted hundreds of companies, and he has developed and delivered thousands of customized educational and industrial programs to instructors, students, manufacturing companies, private sector organizations, and others. He is author of numerous, definitive articles and publications on the subject of CNC and CAD/CAM, with six titles for Industrial Press, including the *CNC Programming Handbook* and the CNC section of the *Handbook*.

## PREFACE

In continuous publication since 1914, *Machinery's Handbook* has served as the principal reference work in metalworking, engineering, design, and manufacturing facilities, and in technical schools, colleges, and universities throughout the world for more than a century. Throughout this period, the *Handbook* editors have strived to create a comprehensive and practical resource, combining the most basic and crucial aspects of sophisticated manufacturing practice. The *Handbook* is an invaluable tool, to be used in much the same way as other tools, to design, make, repair, and maintain products of highest quality, at the lowest cost, and in the shortest time possible.

The essential basics, material of proven and everlasting worth, always must be included, if the *Handbook* is to continue to serve the needs of the manufacturing and mechanical engineering community. Yet it is difficult to select suitable material from the vast supply of data related to these traditional yet rapidly evolving fields. An ongoing challenge is to provide valuable information for design and production departments in manufacturing plants and workshops of all sizes, as well as for product and system designers, job shops, hobbyists, and instructors and students in general, trade, technical, and engineering schools. The editorial team relies on conversations and written communications with users of the *Handbook* and experts in technical fields for guidance on topics to be introduced, revised, lengthened, shortened, or omitted.

The original *Handbook* was designed to fit inside a standard toolbox. At the request of users, in 1997, the large print or "desktop" edition of the *Handbook* was introduced. The large print edition is identical to the traditional toolbox edition, only its size is increased by 140 percent, making it an easier-to-read reference. (Note that the type is standard reference size, not a larger font designed for visually impaired readers.) Other than size, there is no difference between the toolbox and large print editions.

In 1998, Christopher McCauley developed and launched the first *Machinery's Handbook CD-ROM*, containing the complete content of the printed book, with added indexes and hundreds of pages of archival material restored from earlier editions. Continued as the *Machinery's Handbook 31st Digital Edition*, this versatile format offers rapid searching and navigation aids in the form of clickable links and cross references that take you quickly to pages referenced. The growing family of *Machinery's Handbook* products also includes the *Guide, Pocket Companion*, and attractive combination packages.

Longtime users of the *Handbook* will note many changes in recent editions, but an enduring goal of the editors is to make this encyclopedic reference easier to use. The *Handbook* continues to incorporate time-saving thumb tabs, much requested by users. In addition to the front table of contents, sectional contents beginning each major section, introduced in the 25th edition, also have proven useful to readers. In the 31st edition, these sectional contents have been expanded to provide even more detailed navigation aids.

Overall, this edition has been edited, updated, and reset. Incorporating thousands of individual changes and more than 250 new and revised tables and figures, it has expanded by nearly 100 pages, to 2,992 pages. Among major revisions of existing content and new material are the following:

First and foremost, hundreds of specific references and pieces of key information based on the most current ANSI, ASME, and ASTM standards have been updated throughout the *Handbook*. Of all the reasons to purchase the 31st edition, these timely updates make this a must-have resource.

To examine other improvements starting at page 1, while the core concepts of *MATHEMATICS* remain unchanged, this baseline material has benefited from reorganization, expansion, and elucidation by subject experts and educators to reflect current terminology and teaching. Among other formula additions in the *Handbook*, new calculations for *Tolerance Analysis and Assignment* can be found on page 684. Also see *MEASURING UNITS*, on page 2827, for added information on International System of Units (SI), related, base, and derived units, names, and prefixes.

Expert revisions have been made throughout *MECHANICS AND STRENGTH OF MATERIALS*, beginning on page 156, regarding forces, strength, testing, and related analysis. The subsection *PROPERTIES OF BODIES* is now more specifically defined as *RIGID BODY PARAMETERS*.

PREFACE

The *PLASTICS* section, beginning on page 555, has received important updates, with new information on material characteristics, properties, and costs; calculations for elasticity, stress, strain, loads, and temperature effects; manufacturing and machining processes; design considerations; use of plastics for prototyping; and additive manufacturing (AM).

*Metal Additive Manufacturing*, beginning on page 1555, has been redone, with illustrations and tables and updated text addressing the ongoing evolution of this dynamic field; key trends and recent developments in materials, processes and workflow, production considerations, and finishing; comparisons of AM costs, efficiencies, and capabilities with conventional processes for producing parts; and applicable ASTM and ISO standards. The related topic of *POWDER METALLURGY*, beginning on page 1522, also has received updates and added dimensional information.

A new *CORROSION* section on page 548 discusses forms, causes, and methods of prevention; galvanic series, compatibility, and coupling; and common effects and mitigation methods. Other surface-related information includes updates in *FINISHING OPERATIONS*, starting on page 1632, on electropolishing, passivation, and plating, and added *Sheet Metal Mill Finishes* on page 1448. Related sheet metal additions include *Blanking Pressure* on page 1413, *Three-Roll Bending* on page 1423, and *Sheet Metal Gauge Sizes* on page 1453.

In *MACHINING OPERATIONS*, see page 1154 for new material on boring and indexable boring bars. The new *NONTRADITIONAL MACHINING AND CUTTING* section on page 1344 describes mechanical erosion and electro-thermal processes. And in *CNC NUMERICAL CONTROL PROGRAMMING*, the topic *CAD/CAM*, on page 1390, has been reintroduced and revised.

*IRON AND STEEL CASTING* has been renamed *METAL CASTING, MOLDING, AND EXTRUSION*, and this section, starting on page 1480, has been rewritten and expanded. Look for new information on working with iron, steel, and nonferrous casting metals; industry casting and molding processes; heating, pouring, flow, and fluidity; heat transfer, solidification, and cooling; and materials, applications, casting defects, design considerations, and computer modeling.

The *SOLDERING AND BRAZING* and *WELDING* sections also have received important updates, including new and revised figures and tables, and an expanded section on *Non-destructive Testing*, on page 1627.

*O-RINGS*, on page 2666, has been rewritten and expanded, with 13 tables and details of standards, designations, selection, clearance gap, cramping, face seals, glands, grooves, installation, lubrication, squeeze, stretch, and equations.

In *UNIFIED SCREW THREADS*, the latest *Standard Series and Selected Combination* tables, beginning on page 1951, incorporate numerous updates. *TRANSMISSION CHAINS*, on page 2616, has been revised, with meticulous updates to the *Horsepower Ratings for Roller Chains* tables, based on the latest standards. There are the countless other changes in tables, figures, calculations, and text resulting from the *Handbook* team's extensive review of current industry standards. As in previous editions, we continue to include expanded, parallel US Customary and metric figures. Where possible, formulas are presented with equivalent metric expressions (some in bold).

Addition of new and revised *Handbook* topics often requires removal of older topics to gain space. Materials removed from the print book generally appear in the *Digital Edition*, which contains added material not in the current print edition. Included in the *Digital Edition* are mathematical tables on topics such as logarithms and trigonometry; material on cement and concrete, adhesives and sealants, coloring and etching metals, forge shop equipment, silent chain, worm and other gears, keys and keyways; and many other extracts from past editions that may be of use and interest.

Absent in the 31st print edition is a conversion table that previously appeared on page 3 on fractional and decimal inch to millimeter conversion; the same information can be found in tables in the *MEASURING UNITS* section, which starts on page 2831. Other material moved to the *Digital Edition* includes tabular data, such as constants involving uses of  $\pi$ , moments of inertia and section moduli for shafts, and an older screw thread table on European systems, as well as a short section on *Bakelite*, and *Change Gears for Helical Milling*. Users requiring this information, or wishing to comment on these or other topics moved to the *Digital Edition*, are urged to contact the editors.

## PREFACE

The editors are greatly indebted to readers who call attention to possible errors and defects in the *Handbook*, offer suggestions for including new or revised material, or have technical questions about the content and applicability to manufacturing problems encountered in the shop. Such dialog helps identify topics that require clarification or expansion. Queries involving *Handbook* material usually entail an in-depth review of the topic in question, frequently resulting in improved or new material. We also welcome new contributors to each edition, joining the long line of erudite industry experts who have made the *Handbook* what it is today, and we invite topical experts to contact the editors.

Our perpetual goal is to increase the usefulness of the *Handbook* as much as possible. We welcome your input and look forward to hearing from you.

### Acknowledgments and Special Thanks

*Machinery's Handbook* is indebted to the whole mechanical field for the data contained in this master reference work. On behalf of the *Handbook* editors past and present, we wish to express our appreciation to all who have assisted in furnishing data and contributed ideas, corrections, and other commentary on the *Handbook*. Most importantly, we thank the thousands of readers who have contacted us over the years with constructive criticism and suggestions regarding *Handbook* topics and presentation. Your comments on this edition, as well as past and future ones, are invaluable.

Many of the American National Standards Institute (ANSI) standards that deal with mechanical engineering, extracts from which are included in the *Handbook*, are published by the American Society of Mechanical Engineers (ASME). The editors thank ASME for its exceptional collaboration in helping identify and bring essential data up to date, according to the latest, definitive, industry standards. Information concerning other standards and nomenclature also is included in the *Handbook*. Official standards and related publications are copyrighted by the issuing organizations; contact them directly for further information regarding current editions of standards and to purchase copies.

On the following pages are brief biographies for the *Machinery's Handbook, 31st Edition* team—an impressive roster of Editorial Advisory Board members and contributors. These esteemed colleagues have played a crucial role in guiding content decisions and advising on specific engineering questions and content challenges. Their lifelong educational and industry experience, impressive technical knowledge and expertise, and meticulous research have immeasurably enhanced the content of this edition.

We also wish to thank those behind the scenes, our tremendous editorial and production team, without whom this edition would not be possible: the incomparable Jason Hughes, Abigail Parker, Billie Rothstein, and the rest of the remarkable team at Scribe; math maven Dan McKinney; eagle-eyed editorial team members Teresa Barendsfeld, Cara Chamberlain, Gerald Murray, Julia Phelps, and Deborah Ring; and our masterful printing and binding partners at Thomson Press.

In addition, longtime editor, mastermind, and retired leader of the *Handbook* team Christopher McCauley is recognized for his extensive additions to essential content over multiple editions. Accordingly, he has been added to the masthead of illustrious authors of the *Handbook*.

The *Handbook* is indebted to many others in industry organizations and associations, educational institutions, commercial enterprises, and private practice. In this context, we cannot thank everyone who has written in, helped resolve a question, or has otherwise spent valuable time and effort assisting us improve past and present editions. Therefore, we have added a "Handbook Hall of Fame" to our website, where we can acknowledge and acclaim the most important participants in the community surrounding this legendary product. Again, we encourage you to send us your thoughts and feedback, and to share with us how the *Machinery's Handbook* product family supports and enhances your involvement in this endlessly fascinating field.

**Laura Brengelman**  
Editor

## TABLE OF CONTENTS

<b>PREFACE</b>	vii
<b>ACKNOWLEDGMENTS AND SPECIAL THANKS</b>	ix
<b>MACHINERY'S HANDBOOK TEAM</b>	x
<b>MATHEMATICS</b>	1
• REAL NUMBERS AND THEIR OPERATIONS • ALGEBRA • GEOMETRY • TRIGONOMETRY: SOLUTION OF TRIANGLES • MATRICES • CALCULUS • STATISTICAL ANALYSIS OF MANUFACTURING DATA • ENGINEERING ECONOMICS	
<b>MECHANICS AND STRENGTH OF MATERIALS</b>	154
• MECHANICS • VELOCITY, ACCELERATION, WORK, AND ENERGY • STRENGTH OF MATERIALS • RIGID BODY PARAMETERS • BEAMS • COLUMNS • PLATES, SHELLS, AND CYLINDERS • SHAFTS • SPRINGS • DISC SPRINGS

## REAL NUMBERS AND THEIR OPERATIONS

## Real Numbers

Most mathematical computation is performed in the *real number system*. The universal set of the “reals” includes the subsets: *naturals*, *whole numbers*, *integers*, *rationals*, and *irrationals*. The naturals (also called *counting numbers*):  $\{1, 2, 3, \dots\}$  are included in the whole numbers:  $\{0, 1, 2, 3, \dots\}$ , which are included in the integers (or signed whole numbers):  $\{\dots, -2, -1, 0, 1, 2, \dots\}$ . And all of these subsets are included in the rationals.

Rational numbers, including integers, can be written in fraction form. Since all fractions can be divided numerator by denominator, their decimal form either terminates or repeats. Examples of rational numbers:  $-4/1$ ,  $3/5 = 0.6$ ,  $1/3 = 0.333\dots$

The only set in the real numbers larger than the naturals that does not contain any of the other sets is the irrationals. These are *not* expressible as ratios. An irrational number's decimal representation does not terminate and it has no pattern of repetition. Examples of irrational numbers are roots that cannot be simplified, such as  $\sqrt{6}$  and  $\sqrt[3]{70}$ , as well as quantities like  $\pi$  and the natural log base  $e$ . The entire real number set is the union of the rationals and the irrationals.

**Properties of Real Numbers.**—Though often obvious and followed almost automatically, the properties of real numbers are critical to mathematical reasoning. These properties justify various steps in solving algebraic problems, such as those in this Handbook. Equivalence properties (symmetry, reflexivity, transitivity) and operational properties of numbers are summarized here.

*Equivalence Properties:* The properties of equivalence relations are the basis of equation solving.

Reflexive:  $a = a$ .

Symmetric: If  $a = b$ , then  $b = a$ .

Transitive: If  $a = b$  and  $b = c$ , then  $a = c$ .

Substitution: If  $a = b$ , then  $a$  may be replaced by  $b$  in any equation or expression.

*Operational Properties:* These concern addition, subtraction, multiplication, and division, as summarized in the table below.

<i>Property</i>	<i>Addition</i>	<i>Multiplication</i>
Commutative:	$a + b = b + a$	$a \times b = b \times a$
Associative:	$(a + b) + c = a + (b + c)$	$(a \times b) \times c = a \times (b \times c)$
Identity:	$a + 0 = 0 + a = a$	$1 \times a = a \times 1 = a$
Inverse:	$a + (-a) = 0$	$a \times 1/a = 1$

*Other Properties:*

Distributive of multiplication over addition:  $a \times (b + c) = (a \times b) + (a \times c)$   $(a + b) \times c = (a \times c) + (b \times c)$

Zero property of multiplication: If  $a \times b = 0$ , then either  $a = 0$  or  $b = 0$

Zero property of division: If  $a/b = 0$ , then  $a = 0$  ( $b \neq 0$ )

**Integers (Signed Numbers).**—Positive whole numbers extend to the right of zero on the number line. Negative whole numbers extend to the left of zero. Together with zero, these make up the *integers* (sometimes called *signed numbers*):  $\{\dots, -2, -1, 0, 1, 2, \dots\}$ .

The sciences (as well as economics and other fields) deal with negative as well as non-negative quantities. Temperature is an obvious example; so is land altitude, which can be

above, at, or below sea level. Angles can be negative, too, as explained in *TRIGONOMETRY*. Calculators facilitate computation that involves integers (signed numbers). Knowing the rules of integer operations prevents errors that might occur when a calculator is used.

**Absolute Value:** A number's absolute value, sometimes called its *magnitude*, is the number's distance from zero on the number line. Whether a number is positive or negative, its absolute value is positive. For example, the absolute value of both 5 and -5 is 5. The absolute value of  $n$  is notated  $|n|$ ; thus,  $|5| = 5$  and  $|-5| = 5$ . Absolute value helps explain the rules of signed number addition and subtraction.

**Real Number Line:** The real number line is generally shown with only the integers marked off (though all numbers are included). A number line is useful for conveying how signed numbers are added or subtracted.

**Operations on Signed Numbers:** The following rules of operations apply to rational and irrational numbers as well. For simplicity, only integers are given as examples.

**Addition and Subtraction:** Adding a negative number is equivalent to subtracting its absolute value. When a larger number is subtracted from a smaller number, the result is negative. The rules for adding and subtracting integers are illustrated with an example using four values: 7, 11, -7, and -11. The following examples illustrate the rules:

*Examples, Addition*

$$7 + 11 = 18$$

$$7 + (-11) = 7 - 11 = -4$$

$$(-7) + 11 = 11 + (-7) = 11 - 7 = 4$$

$$(-7) + (-11) = -18$$

*Examples, Subtraction*

$$7 - 11 = -4$$

$$7 - (-11) = 7 + 11 = 18$$

$$(-7) - (-11) = (-7) + 11 = 11 + (-7) = 11 - 7 = 4$$

$$-7 - 11 = -18$$

**Multiplication and Division:** Multiplication or division of numbers with the same sign results in a positive answer. Opposite signed numbers result in negative answers when multiplied or divided. The following examples illustrate the rules:

*Examples, Multiplication*

$$5 \times 2 = 10$$

$$5 \times (-2) = -10$$

$$(-5) \times 2 = -10$$

$$(-5) \times (-2) = 10$$

*Examples, Division*

$$12 \div 3 = 4$$

$$(-12) \div 3 = -4$$

$$(12) \div (-3) = -4$$

$$(-12) \div (-3) = 4$$

**Order of Operations.**—Mathematical operations are performed on numbers in a particular order, commonly referred to as PEMDAS, which stands for “**P**arentheses, **E**xponents, **M**ultiplication, **D**ivision, **A**ddition, **S**ubtraction.” First, when there are no parentheses or other grouping symbols, multiplication and division are done before addition and subtraction. Then, proceeding from left to right, the addition and subtraction are done in the order they appear. For example:

$$100 - 26 + 7 \times 2 - 100 \div 4 = 100 - 26 + 14 - 25 = 74 + 14 - 25 = 88 - 25 = 63$$

Parentheses ( ) and brackets [ ]—called *grouping symbols*—indicate if addition and subtraction are to occur before multiplication and division. The operations are performed from the innermost to the outermost grouping symbols. For example:

$$[6 \times (15 - 7)] \div 2 = [6 \times 8] \div 2 = 48 \div 2 = 24$$

Exponents are a multiplication operation, but unless parentheses or brackets are present, exponents are applied before multiplication. For example:

$$4 \times 9^2 = 4 \times 81 = 324$$

Also, when parentheses are present next to a multiplication, the  $\times$  can be omitted:

$$5(8 - 3) = 5(5) = 25$$

As explained in *Fractions*, the horizontal line in a fraction implies division. The top number (called the *numerator*) is divided by the bottom number (called the *denominator*). For example,

$$\frac{50}{10} = 50 \div 10 = 5$$

In formulas, the multiplication sign ( $\times$ ) may be omitted (when letters—called variables—are multiplied) or replaced by parentheses, which serve the same purpose.

$$A \times B = AB, \quad 6 \times 4 = (6)(4), \quad 8 \times a = 8a$$

A multiplication dot ( $\cdot$ ) is also sometimes used.

### Fractions

Rational numbers can be written as *common fractions* or as *decimal fractions*. Common fractions are written as  $\frac{a}{b}$  or  $a/b$ , where  $a$  (the numerator) and  $b$  (the denominator) are integers (but  $b$  cannot be 0, since division by zero is not defined). The denominator represents the number of equal parts that a whole quantity is broken into. The numerator is the number of these parts under consideration. For example,  $\frac{2}{5}$  indicates the whole of something is broken into 5 equal parts, and 2 of these parts are being considered. Any integer is a fraction with a denominator of 1. For example,  $\frac{6}{1} = 6$ .

The implied operation in a fraction is division. Thus,  $\frac{a}{b}$  means  $a \div b$ .

**Multiple:** A multiple of a number  $n$  is the result of multiplying  $n$  by positive integer 1, 2, 3, . . . Thus, the multiples of 3 are 3, 6, 9, 12, . . . The *least common multiple* (LCM) of two or more numbers is the smallest multiple the numbers have in common. In the example below, the first few multiples of 6 and 20 are shown, with the LCM indicated in bold:

6: 6, 12, 18, 24, 30, 36, 42, 48, 54, **60**, 66, . . .

20: 20, 40, **60**, 80, . . .

Thus, 60 is the LCM of 6 and 20.

**Factor:** An integer  $a$  is a factor of  $n$  if there is no remainder when  $n$  is divided by  $a$ . That is, if the result of  $n \div a$  is an integer. For example, 3 is a factor of 12 because  $12/3 = 4$ . The greatest common factor (GCF) of two or more numbers is the largest of their common factors. Thus, the common factors of 12 and 18 are 2, 3, and 6; 6 is the GCF.

**Unit Fraction:** A fraction having the same numerator and denominator is the unit fraction, 1 (or "one whole"). For example,  $\frac{2}{2}$ ,  $\frac{4}{4}$ ,  $\frac{8}{8}$ ,  $\frac{16}{16}$ ,  $\frac{32}{32}$ , and  $\frac{64}{64}$  all equal 1.

**Proper Fraction:** A fraction whose numerator is less than its denominator.  $\frac{1}{4}$ ,  $\frac{1}{2}$ , and  $\frac{47}{64}$  are examples of proper fractions. The value of any proper fraction is less than 1.

**Improper Fraction:** A fraction whose numerator is greater than its denominator.  $\frac{3}{2}$ ,  $\frac{5}{4}$ , and  $-\frac{17}{8}$  are examples of improper fractions. The absolute value of any improper fraction is greater than 1.

**Reducible Fraction:** A reducible fraction is a common fraction in which numerator and denominator have a common factor and so can be reduced to lowest terms by dividing both numerator and denominator by this common factor. For example, in the fraction  $\frac{12}{18}$ , the numerator and denominator have a GCF of 6. Thus,  $\frac{12}{18}$  reduces to  $\frac{2}{3}$  by dividing each part of the fraction by 6. A fraction such as  $\frac{16}{21}$  cannot be reduced, since 16 and 21 do not have a common factor.

**Mixed Number:** A mixed number is a combination of a whole number and a proper fraction. The implied operation between them is addition. For example,  $4\frac{2}{9}$  means  $4 + \frac{2}{9}$ . A mixed number is converted to an improper fraction by multiplying the whole number part with the denominator and adding the numerator to obtain the numerator of the final fraction; the denominator remains the same.

Examples:

$$5\frac{2}{3} = 5 + \frac{2}{3} = \frac{15}{3} + \frac{2}{3} = \frac{17}{3} \qquad 9\frac{1}{2} = 9 + \frac{1}{2} = \frac{18}{2} + \frac{1}{2} = \frac{19}{2}$$

To convert mixed numbers to improper fractions, multiply the whole number by the denominator and add the numerator to obtain the new numerator. The denominator remains the same. For example,

$$2\frac{1}{2} = \frac{2 \times 2 + 1}{2} = \frac{5}{2}$$

$$3\frac{7}{16} = \frac{3 \times 16 + 7}{16} = \frac{55}{16}$$

An improper fraction is converted to its mixed number form by dividing the numerator by denominator and placing the remainder over the denominator. Sometimes the fraction part can be reduced, as the second example shows.

$$\frac{17}{8} = 17 \div 8 = 2\frac{1}{8}$$

$$\frac{26}{16} = 26 \div 16 = 1\frac{10}{16} = 1\frac{5}{8}$$

**Equivalent Fractions:** A fraction raised to its equivalent form ("higher terms") by multiplying numerator and denominator by the same number (that is, by multiplying by a form of 1). For example,  $\frac{1}{4} \times \frac{4}{4} = \frac{4}{16}$  and  $\frac{3}{8} \times \frac{4}{4} = \frac{12}{32}$ .

Any integer  $n$  can be expressed as a fraction with a chosen denominator value of  $m$  by simply writing  $n$  as  $n/1$  and multiplying by  $m/m$ .

**Example:** To express 4 as an equivalent fraction with a denominator of 16, write  $\frac{4}{1} \times \frac{16}{16} = \frac{64}{16}$

**Reciprocal:** The reciprocal of any number  $a$  other than 0 is  $1/a$ . (0 has no reciprocal, since  $1/0$  is undefined.) The reciprocal also is called the *multiplicative inverse*, since  $a \times 1/a = 1$ . For example, the reciprocal of 8 is  $1/8$ ; the reciprocal of  $4/7$  is  $7/4$ .

**Least Common Denominator:** Fractions cannot be added or subtracted without a common denominator. For example,  $\frac{2}{5} + \frac{1}{5} = \frac{2+1}{5} = \frac{3}{5}$ , a simple computation, since the denominator in the answer is the same denominator seen in the fractions. In general,  $\frac{a}{c} + \frac{b}{c} = \frac{a+b}{c}$ . But fractions with different denominators cannot be added or subtracted until they are converted to *equivalent forms* that have common denominators. This is done by raising the fractions to higher terms (as explained previously). While any common multiple serves as a common denominator, it is preferable to use the *least common multiple* (LCM) of the denominator, referred to as the *least common denominator* (LCD). For example, 36 is the LCD of  $\frac{2}{9}$  and  $\frac{5}{6}$ , since the LCM of 9 and 6 is 36. Raising each fraction to its equivalent form having a denominator of 36 is shown:

$$\frac{2}{9} \times \frac{4}{4} = \frac{8}{36} \quad \text{and} \quad \frac{5}{6} \times \frac{6}{6} = \frac{30}{36}$$

**Example:** In the case of  $\frac{9}{11}$  and  $\frac{7}{10}$  the LCD is the product of the denominators,  $11 \times 10 = 110$ . Raising each fraction to its equivalent form is shown:

$$\frac{9}{11} \times \frac{10}{10} = \frac{90}{110} \quad \text{and} \quad \frac{7}{10} \times \frac{11}{11} = \frac{77}{110}$$

### Adding and Subtracting Fractions and Mixed Numbers

**To Add or Subtract Common Fractions:** 1) Convert each fraction to terms of the least common denominator; 2) add or subtract numerators; 3) if answer is an improper fraction, change it to a mixed number; and 4) reduce fraction part if necessary.

*Example, Addition of  
 Common Fractions*

$$\begin{array}{r} \frac{1}{4} \quad \text{LCD} = 16 \quad \frac{1}{4} \times \frac{4}{4} = \frac{4}{16} \\ \frac{3}{16} \quad \frac{3}{16} \times \frac{1}{1} = \frac{3}{16} \\ + \frac{7}{8} \quad + \frac{7}{8} \times \frac{2}{2} = + \frac{14}{16} \\ \hline \frac{21}{16} \end{array}$$

*Example, Subtraction of  
 Common Fractions*

$$\begin{array}{r} \frac{15}{16} \quad \text{LCD} = 48 \quad \frac{15}{16} \times \frac{3}{3} = \frac{45}{48} \\ - \frac{7}{12} \quad - \frac{7}{12} \times \frac{4}{4} = - \frac{28}{48} \\ \hline \frac{17}{48} \end{array}$$

**To Add Mixed Numbers:** Two methods for adding mixed numbers are shown below the explanations.

First method: 1) Raise fraction parts to the higher terms of the LCD; 2) add whole number parts and fraction parts separately; 3) if result has an improper fraction, convert it to a mixed number and add the whole number parts.

Second method: 1) Convert mixed numbers to improper fractions; 2) raise resulting fractions to the higher terms of the LCD; 3) add fractions as usual and convert back to a mixed number; reduce, if needed.

*Examples, Addition of Mixed Numbers*

*Method 1*

$$\begin{array}{r} 2\frac{1}{2} \quad 2\frac{1}{2} \times \frac{16}{16} = 2\frac{16}{32} \\ 4\frac{1}{4} \rightarrow 4\frac{1}{4} \times \frac{8}{8} = 4\frac{8}{32} \\ + \frac{15}{32} \quad + \frac{15}{32} \times \frac{1}{1} = + \frac{15}{32} \\ \hline 7\frac{39}{32} = 7 + 1\frac{7}{32} = 8\frac{7}{32} \end{array}$$

*Method 2*

$$\begin{array}{r} 2\frac{1}{2} \quad \frac{5}{2} = \frac{5}{2} \times \frac{16}{16} = \frac{80}{32} \\ 4\frac{1}{4} \rightarrow \frac{17}{4} = \frac{17}{4} \times \frac{8}{8} = \frac{136}{32} \\ + 1\frac{15}{32} \quad + \frac{47}{32} = \frac{47}{32} \times \frac{1}{1} = + \frac{47}{32} \\ \hline \frac{263}{32} = 8\frac{7}{32} \end{array}$$

**To Subtract Mixed Numbers:** The methods are similar to those for adding, except the fraction part may need to "borrow" from the whole number. The examples show the details.

1) Convert fraction parts to equivalent fractions with LCD; 2) subtract whole number and fraction parts separately, *unless* the first fraction's numerator is *smaller* than the second. In that case, proceed as shown in the second and third examples below, borrowing 1 in the form of a fraction and then subtracting.

*Examples, Subtraction of Mixed Numbers*

*Example 1*

$$\begin{array}{r} 12\frac{4}{5} \\ - 4\frac{1}{5} \\ \hline 8\frac{3}{5} \end{array}$$

*Example 2*

$$\begin{array}{r} 43\frac{14}{15} = 43\frac{14}{15} \\ - 19\frac{3}{5} = -19\frac{9}{15} \\ \hline 24\frac{5}{15} = 24\frac{1}{3} \end{array}$$

*Example 3*

$$\begin{array}{r} 20 = 19 + 1 = 19\frac{2}{2} \\ - 7\frac{1}{2} = -7\frac{1}{2} = -7\frac{1}{2} \\ \hline 12\frac{1}{2} \end{array}$$

*Example 4*

$$\begin{array}{r} 8\frac{2}{9} = 7 + 1\frac{2}{9} = 7\frac{11}{9} \\ - 1\frac{4}{9} = -1\frac{4}{9} = -1\frac{4}{9} \\ \hline 6\frac{7}{9} \end{array}$$

**Multiplying Fractions and Mixed Numbers**

**To Multiply Common Fractions:** 1) Multiply numerators; 2) multiply denominators; and 3) convert improper fractions to mixed numbers, if necessary.

**To Multiply Mixed Numbers:** 1) Convert mixed numbers to improper fractions; 2) multiply numerators; 3) multiply denominators; and 4) convert improper fractions to mixed numbers, if necessary.

*Examples, Multiplication of Fractions*

$$\frac{2}{3} \times \frac{8}{15} = \frac{2 \times 8}{3 \times 15} = \frac{16}{45} \qquad 4\frac{2}{5} \times 1\frac{1}{3} = \frac{22}{5} \times \frac{4}{3} = \frac{22 \times 4}{5 \times 3} = \frac{88}{15}$$

**Dividing Fractions and Mixed Numbers**

*To Divide Common Fractions:* 1) Take the reciprocal of the dividing fraction; 2) multiply the numerators and denominators; and 3) convert improper fractions to mixed numbers, if necessary.

*To Divide Mixed Numbers:* 1) Convert the mixed numbers to improper fractions; 2) take the reciprocal of the dividing fraction; 3) multiply numerators and denominators; and 4) convert improper fractions to mixed numbers, if necessary.

*Examples, Division of Fractions*

$$\frac{2}{7} \div \frac{5}{21} = \frac{2}{7} \times \frac{21}{5} = \frac{2 \times 21}{7 \times 5} = \frac{42}{35} = \frac{6}{5} \qquad 3\frac{1}{3} \div 2\frac{4}{5} = \frac{10}{3} \div \frac{14}{5} = \frac{10}{3} \times \frac{5}{14} = \frac{50}{42} = \frac{25}{21}$$

**Decimal Numbers.**—Decimal fractions are fractional parts of a whole whose implied denominators are multiples of 10. A decimal fraction of 0.1 has a value of 1/10, 0.01 has a value of 1/100, 0.001 has a value of 1/1000, and so on. Thus, the value of the digit in the first place right of the decimal point is expressed in tenths, a digit two places to the right is expressed in hundredths, a digit three places to the right is expressed in thousandths, and so on. Because the denominator is implied, the number to the right of the decimal point indicates the numerator of the decimal fraction. For example, 0.125 is equivalent to 125/1000.

In industry, most decimal fractions are expressed in terms of thousandths rather than tenths or hundredths. For example, a decimal fraction of 0.2 is written as 0.200 and read as “200 thousandths” rather than “2 tenths”; a value of 0.75 is written as 0.750, and read as “750 thousandths” rather than “75 hundredths.” In the case of four place decimals, the values are expressed in terms of ten-thousandths. So a value of 0.1875 is read as “1875 ten-thousandths.”

Just as a mixed number is the sum of a whole number and a fraction, a decimal number greater than 1 has a whole and a decimal part. For example, 10.125 = 10<sup>125/1000</sup>, which is read as “10 and 125 thousandths.”

*Adding or Subtracting Decimal Numbers:* To add or subtract decimal numbers, align the decimal points and add or subtract the digits as usual. The decimal point in the answer is aligned with the decimal points in the numbers added or subtracted.

*Examples, Adding Decimal Fractions*

$$\begin{array}{r} 0.125 \\ 1.0625 \\ 2.50 \\ + 0.1875 \\ \hline 3.8750 \end{array} \qquad \begin{array}{r} 1.750 \\ 0.875 \\ 0.125 \\ + 2.0005 \\ \hline 4.7505 \end{array}$$

*Examples, Subtracting Decimal Fractions*

$$\begin{array}{r} 1.750 \\ - 0.250 \\ \hline 1.500 \end{array} \qquad \begin{array}{r} 2.625 \\ - 1.125 \\ \hline 1.500 \end{array}$$

*Multiplying Decimal Numbers:* In setting up decimal multiplication, the decimal points do not have to be aligned. Long multiplication is done as usual, but the decimal point in the answer is placed so that the number of digits on its right is the same as the total number of digits on the right of the numbers multiplied.

*Examples, Decimal Number Multiplication*

$24.035$	three decimal places	$6.002$	three decimal places
$\times 0.08$	two decimal places	$\times 41.3$	one decimal place
$1.92280$	five decimal places	$18006$	
		$60020$	
		$+ 2400800$	
		$247.8826$	four decimal places

**Dividing Decimal Numbers:** There are several types of decimal division problems: (1) a whole number divided by a decimal number; (2) a decimal number divided by a whole number; and (3) a decimal number divided by a decimal number. For all situations, if the divisor is a decimal, its decimal point must first be moved right to make it a whole number, and the dividend's decimal likewise moved, before the operation is performed. Examples of each type are:  $18 \div 0.3 = 180 \div 3 = 60$ ;  $1.8 \div 3 = 0.6$ ;  $1.8 \div 0.003 = 1800 \div 3 = 600$ .

**Ratio and Proportion.**—A ratio of quantities  $a$  to  $b$  is written  $a:b$  or as a fraction  $a/b$ . For example, the ratio of 12 to 3 is written 12:3 or 12/3. Ratios, like fractions, can be reduced: 12:3 is 4:1. The *inverse* (or reciprocal) ratio of  $a:b$  is  $b:a$ . Thus, the inverse ratio of 12:3 is 3:12.

When two or more ratios are multiplied, the ratio obtained is called a *compound ratio*. The compound ratio of  $a:b$ ,  $c:d$ , and  $e:f$  is the ratio  $ace:bdf$ . For example, the compound ratio of 8:2, 9:3, and 10:5 is  $8 \times 9 \times 10 : 2 \times 3 \times 5$ , or 720:30.

An equality of ratios,  $ab = cd$ , is called a *proportion*, which can be written as  $a:b::c:d$ , read as "a is to b as c is to d." Thus, 6:3::10:5 because 6/3 and 10/5 both reduce to 2/1 or 2. In a proportion  $a:b::c:d$ , the first and last terms (which can be variables or numbers) are called the *extremes*, and the second and third are the *means*.

Note that if  $ab = cd$ , then the rules of algebra show that  $ad = bc$ . Thus, the proportion  $a:b::c:d$  is equivalent to  $a \times d = b \times c$ . So the proportion 6:3::10:5 is equivalent to  $6 \times 5 = 3 \times 10$ .

Often, some part of a proportion is an unknown. For example, in the proportion 2:3:: $n$ :4 (2 is to 3 as  $n$  is to 4),  $n$  is found by setting up a proportion. According to the basic rules of algebra, 2:3:: $n$ :4 means  $(2)(4) = 3n$ , and hence,  $8 = 3n$ , so  $n = 8/3$ . A full discussion of the rules for solving equations can be found in **ALGEBRA**.

If the second and third terms in a proportion are the same, that term is the *mean proportional* of the other two. Thus, in the proportion 8:4::4:2, 4 is the mean proportional of 8 and 2. The mean proportional of any two numbers may be found by multiplying them and extracting the square root of the product. Thus, the mean proportional of 3 and 12 is 6, because  $3 \times 12 = 36$ , which is  $6^2$ .

**Example 1, Involving Proportion:** If it takes 18 days to assemble 4 lathes, how many days would it take to assemble 14 lathes?

**Solution:** Let  $x$  be the number of days to be found. The proportion is written 4:18 :: 14: $x$ , where  $x$  is the number of days to be found. Setting this up as an equation and solving:

$$\frac{4}{18} = \frac{14}{x}$$

$$x = \frac{18 \times 14}{4} = 63 \text{ days}$$

**Example 2, Involving Direct (Simple) Proportion:** 10 linear meters (32.81 feet) of bar stock are required as blanks for 100 clamping bolts. What total length  $x$  of stock, in meters and feet, is required for 912 bolts?

**Solution:** The setup to solve the proportional meters-to-bolts problem comes from the way this proportion is read: "10 meters is to 100 bolts as how many meters is to 912 bolts." It is solved accordingly:

$$10 : 100 :: x : 912, \text{ that is, } \frac{10}{100} = \frac{x}{912} \quad \text{Solving for } x: \quad x = \frac{10 \times 912}{100} = \frac{9120}{100} = 91.2 \text{ meters}$$

Likewise, the setup to solve the feet-to-bolts problem comes from reading it as: "32.81 feet is to 100 bolts as how many feet is to 912 bolts." Thus:

$$32.81 : 100 :: x : 912, \text{ that is, } \frac{32.81}{100} = \frac{x}{912} \quad \text{Solving for } x: \quad x = \frac{32.81 \times 912}{100} = \frac{29,922.72}{100} = 299.2 \text{ feet}$$

**Inverse Proportion:** Quantities with an inversely proportional relationship behave in such a way that as one increases the other decreases. For example, a factory employing 270 workers completes a given number of automotive components weekly, the number of working hours being 44 per week. If the hours are reduced, then more workers will be required to do the same amount of work. How many employees would be required for the same production if the working hours were reduced to 40 per week?

The hours per week is inversely proportional to the number of workers; fewer hours per worker means more workers are required. Letting  $x$  be the number of workers needed when time is reduced, the inverse proportion is written:

$$270 : x :: 40 : 44$$

Thus

$$\frac{270}{x} = \frac{40}{44} \quad \text{and} \quad x = \frac{270 \times 44}{40} = 297 \text{ workers}$$

**Problems Involving Both Direct and Inverse Proportions:** If two groups of data are related by both direct (simple) and inverse proportions among the various quantities, a simple mathematical relation may be used to solve the problem as follows:

$$\frac{\text{Product of all directly proportional items in first group}}{\text{Product of all inversely proportional items in first group}} = \frac{\text{Product of all directly proportional items in second group}}{\text{Product of all inversely proportional items in second group}}$$

**Example:** If a worker capable of turning 65 studs in a 10-hour day is paid \$13.50 per hour, how much per hour should a worker be paid who turns 72 studs in a 9-hour day if compensated in the same proportion as the first worker?

**Solution:** The first group of data in this problem consists of the number of hours worked, the hourly wage of the first worker, and the number of studs produced per day; the second group contains similar data for the second worker, except the hourly wage is unknown, so it is indicated by  $x$ .

The labor cost per stud, as may be seen, is directly proportional to the number of hours worked and the hourly wage. These quantities, therefore, are used in the numerators of the fractions in the formula. The labor cost per stud is inversely proportional to the number of studs produced per day. (The greater the number of studs produced in a given time the less the cost per stud.) The numbers of studs per day, therefore, are placed in the denominators of the fractions in the formula. Thus,

$$\frac{(10)(13.50)}{65} = \frac{9x}{72}$$

$$x = \frac{(10)(13.50)(72)}{(65)(9)} = \$16.62 \text{ per hour}$$

**Percentage.**—A percentage is a ratio expressed as a part of 100. For example, if out of 100 manufactured parts, 12 do not pass inspection, then 12 percent (12 of the 100) are rejected. The symbol % indicates percentage.

The percent of gain (or loss) with respect to a base (original) quantity is found by dividing the amount of gain (or loss) by the base quantity and multiplying the quotient by 100. For example, if a quantity of steel is bought for \$2000 and sold for \$2500, the profit is  $\$500/2000 \times 100$ , or 25 percent of the invested amount.

**Example:** Out of a total output of 280 castings a day, 30 castings are, on average, rejected. What is the percentage of bad castings?

$$\frac{30}{280} \times 100 = 10.71 \text{ percent}$$

**Percent Change:** Any increase or decrease in some measured quantity can be expressed as a *percent change* using the formula:  $\frac{\text{final} - \text{original amount}}{\text{original}} \times 100 = \text{percent change}$ . If in the

previous example, production increased from 280 to 300, then the percent change would be:

$$\frac{\text{final} - \text{original amount}}{\text{original}} \times 100 = \frac{300 - 280}{280} \times 100 = \frac{20}{280} \times 100 = 7.14\%.$$

The denominator is always the original amount. Percent change also can be negative. If production decreased from 280 to 245, the percent change would be:

$$\frac{245 - 280}{280} \times 100 = \frac{-35}{280} \times 100 = -12.5\%.$$

### Powers and Roots

**Powers:** The *square* or *second power* of a number (or quantity) is the product of that number multiplied by itself. Thus, the square of 9 is  $9 \times 9$ . The square of a number is indicated by the *exponent*<sup>2</sup>, thus:  $9^2 = 9 \times 9 = 81$ .

The *cube* or *third power* of a number  $n$  is the product  $n \times n \times n$ , or  $n^3$ . Thus, the cube of 4 is  $4 \times 4 \times 4 = 64$ , and is written  $4^3$ .

In general, the  $n$ th power of  $a$  is written  $a^n$ , where  $a$  is the *base* and  $n$  is the *exponent*.

**Roots:** The *square root* of a given number is the positive number which, when multiplied by itself, will produce the given number. The square root of 16 (written  $\sqrt{16}$ ) is 4 because  $4 \times 4 = 16$ . The other root of 16 is  $-4$ , but the use of the square root symbol indicates the positive (principal) square root only.

Similarly, the *cube root* of a given number is the number which, when used as a factor three times, will produce the given number. Thus, the cube root of 64 (written  $\sqrt[3]{64}$ ) is 4 because  $4 \times 4 \times 4 = 64$ .

In general, the  $n$ th root of  $a$  is written as  $\sqrt[n]{a}$  or  $a^{1/n}$ .

#### Properties of Exponents

$$a^n a^m = a^{n+m} \quad \frac{a^n}{a^m} = a^{(n-m)} \quad (a^m)^n = a^{mn} \quad (ab)^m = a^m b^m$$

$$\left(\frac{a}{b}\right)^n = \frac{a^n}{b^n} \quad a^{m/n} = (a^{1/n})^m \text{ or } (a^m)^{1/n} \quad a^{-n} = \frac{1}{a^n} \quad \frac{1}{a^{-n}} = a^n$$

$$a^0 = 1 \quad (a \neq 0) \quad a^{1/n} = \sqrt[n]{a} \quad a^{m/n} = (\sqrt[n]{a})^m = \left(\sqrt[n]{a^m}\right) \text{ unless } a < 0, \text{ and } m \text{ and } n \text{ are both even}$$

**Examples:**

$$3^1 3^2 = 3^{1+2} = 3^3 = 27$$

$$(x)(x^3) = x^{(1+3)} = x^4$$

$$\frac{5^4}{5^2} = 5^{4-2} = 5^2 = 25$$

$$\frac{x^9}{x^6} = x^{(9-6)} = x^3$$

$$(2^4)^2 = 2^{(4)(2)} = 2^8 = 256$$

$$(x^3)^3 = x^{(3)(3)} = x^9$$

$$(9x)^2 = 9^2 x^2 = 81x^2$$

$$(ab^4)^2 = a^2 b^8$$

$$32^{3/5} = (32^{1/5})^3 = (\sqrt[5]{32})^3 = 2^3 = 8$$

$$4^{-3} = \frac{1}{4^3} = \frac{1}{64}$$

$$\frac{1}{2^{-5}} = 2^5 = 32$$

$$9x^0 = 9(1) = 9$$

Using logarithms can greatly facilitate the process of raising a number to a power or extracting its root. As shown in *Logarithms* on page 36, this is especially true if the power is not an integer. For example, the square root of 137.1 can only be found with a degree of accuracy through logarithms, a scientific calculator, or Taylor series polynomials.

**Scientific Notation.**—Calculations involving both large and small magnitude numbers are facilitated by *scientific notation*. In this system, a number is expressed by two factors: (1) an integer from 1 to 9, possibly followed by a decimal, and (2) a power of 10. Large numbers in standard form are converted to scientific notation as shown in the following examples:

$$50,000 = 5 \times 10^4 \qquad 273.15 = 2.7315 \times 10^2$$

In the example, 50,000 becomes  $5 \times 10^4$  because the positive exponent on 10 is the number of places to the right that the decimal point moves so that the first factor falls between 1 and 10. Numbers less than 1 are converted to scientific notation as shown in the following examples:

$$0.840 = 8.40 \times 10^{-1} \qquad 0.0000001 = 1 \times 10^{-7}$$

The negative exponent shows the number of places to the left that the decimal point moves, so that the first factor falls between 1 and 10.

Science and engineering quantities—which are often quite large or small—lend themselves to representation in scientific notation. For instance, *Avogadro's number*, which is the number of particles in one mole of a substance, is  $6.024 \times 10^{23}$ . The metric (SI) pressure unit of 1 pascal (Pa) is equivalent to 0.0000986923 atmosphere (atm) or 0.0001450377 pound/square inch (psi). In scientific notation, these figures are  $9.86923 \times 10^{-6}$  atm and  $1.450377 \times 10^{-4}$  psi, respectively.

*Engineering notation* is a version of scientific notation in which the exponent of 10 is always a multiple of 3. (See *MEASURING UNITS* on page 2827 for a table of this system.)

*Multiplication in Scientific Notation:* The procedure is as follows:

- 1) Multiply the first factors of the numbers to obtain the first factor of the product.
- 2) Add the exponents of the factors of 10 to obtain the product's factor of 10. Thus:

$$(4.31 \times 10^{-2}) \times (9.01 \times 10) = (4.31 \times 9.01) \times 10^{-2+1} = 38.8331 \times 10^{-1}$$

$$(5.98 \times 10^4) \times (4.37 \times 10^3) = (5.98 \times 4.37) \times 10^{4+3} = 26.1326 \times 10^7$$

3) Write the final in conventional scientific notation, as explained in the previous section. So, for the two examples:

$38.8331 \times 10^{-1} = 3.88331 \times 10^0 = 3.88331$ , because  $10^0 = 1$ , and  $26.1326 \times 10^7 = 2.61326 \times 10^8$ .

When multiplying several numbers written in this notation, the procedure is the same. Thus,  $(4.02 \times 10^{-3}) \times (3.987 \times 10) \times (4.863 \times 10^5) = (4.02 \times 3.987 \times 4.863) \times 10^{(-3+1+5)} = 77.94 \times 10^3 = 7.79 \times 10^4$ , rounding off the first factor to two decimal places.

*Division in Scientific Notation:* The procedure is as follows:

1) Divide the first factor of the dividend (the first number) by the first factor of the divisor (the second number) to get the first factor of the quotient.

- 2) Subtract the exponents of the factors of 10 to obtain the product's factor of 10:

$$(4.31 \times 10^{-2}) \div (9.0125 \times 10) =$$

$$(4.31 \div 9.0125) \times (10^{-2-1}) = 0.4782 \times 10^{-3} = 4.782 \times 10^{-4}$$

It can be seen that this system of notation is helpful where several numbers of different magnitudes are to be multiplied and divided.

*Example:* Find the solution of  $\frac{250 \times 4698 \times 0.00039}{43678 \times 0.002 \times 0.0147}$

*Solution:* Changing all these numbers to powers of 10 notation and performing the operations indicated:

$$\begin{aligned} & \frac{(2.5 \times 10^2) \times (4.698 \times 10^3) \times (3.9 \times 10^{-4})}{(4.3678 \times 10^4) \times (2 \times 10^{-3}) \times (1.47 \times 10^{-2})} \\ &= \frac{(2.5 \times 4.698 \times 3.9)(10^{2+3-4})}{(4.3678 \times 2 \times 1.47)(10^{4-3-2})} = \frac{45.8055 \times 10}{12.8413 \times 10^{-1}} \\ &= 3.5670 \times 10^{1-(-1)} = 3.5670 \times 10^2 = 356.70 \text{ (rounded)} \end{aligned}$$

**Factorial Notation.**—A factorial is a mathematical shortcut denoted by the symbol ! following a number (for example, 3! is “three factorial”).  $n!$  is found by multiplying together all the positive integers less than or equal to the factorial number  $n$ . Zero factorial (0!) is defined as 1. For example:  $3! = 1 \times 2 \times 3 = 6$ ;  $4! = 1 \times 2 \times 3 \times 4 = 24$ ;  $7! = 1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 = 5040$ ; etc. Factorial notation is used in certain areas, including probability and analysis. The following two topics (permutations and combinations) relate to probability and statistics.

**Permutation.**—A permutation is an arrangement of objects of a set into a sequence or order. In mathematics, the number of arrangements of  $n$  objects is given by  $n!$ . For example, 4 objects can be arranged  $4!$  ways, that is,  $4 \times 3 \times 2 \times 1 = 24$  ways. The number of ways  $r$  objects can be arranged (that is, ordered) from a set of  $n$  is given by the *permutation*

$$\text{formula } {}_n P_r = \frac{n!}{(n-r)!}$$

*Example:* How many ways can the letters X, Y, and Z be arranged?

*Solution:* Three objects ( $r = 3$ ) out of a set of 3 ( $n = 3$ ) are being arranged. The numbers of possible arrangements for the three letters are  $3!(3-3)! = (3 \times 2 \times 1)/1 = 6$ . Listing them is not difficult, since there are so few: XYZ, XZY, YXZ, YZX, ZXY, ZYX.

*Example:* There are 10 people participating in a foot race. How many arrangements of first, second, and third place winners are there?

*Solution:* Here  $r$  is 3 and  $n$  is 10. The number of possible arrangements of winners are:

$${}_{10} P_3 = \frac{10!}{(10-3)!} = \frac{10!}{7!} = 10 \times 9 \times 8 = 720$$

**Combination.**—This is the number of ways  $r$  objects can be chosen from  $n$  in a way that order does not matter. It is expressed as “ $n$  choose  $r$ .” There are fewer combinations than permutations of  $r$  objects out of  $n$ , since it does not matter in what order the three objects are chosen. So in a combination, choosing ABC is the same as choosing ACB or BAC and so on. The formula is  ${}_n C_r = \frac{n!}{(n-r)!r!}$

*Example:* How many possible sets of 6 numbers can be picked with no regard for order from the numbers 1 to 52?

*Solution:* Here  $r$  is 6 and  $n$  is 52. So the possible number of combinations is:

$${}_{52} C_6 = \frac{52!}{(52-6)!6!} = \frac{52!}{46!6!} = \frac{52 \times 51 \times 50 \times 49 \times 48 \times 47}{1 \times 2 \times 3 \times 4 \times 5 \times 6} = 20,358,520$$

**Prime Factorization of Numbers.**—Tables of prime numbers and factors of numbers are particularly useful for calculations involving change-gear ratios for compound gearing, dividing heads, gear-generating machines, and mechanical designs having gear trains.

*Definition:*  $p$  is a *factor* of a number  $n$  if the division  $n/p$  leaves no remainder. Thus, any number  $n$  has factors of itself and 1, because  $n/n = 1$  and  $n/1 = n$ . Other factors of a number are found as follows:

2 is a factor of any even number. Thus,  $28 = 2 \times 14$ , and  $210 = 2 \times 105$ .

3 is a factor of any number where the sum of its digits is divisible by 3. Thus, 3 is a factor of 1869, because  $1 + 8 + 6 + 9 = 24$ , and  $24 \div 3 = 8$ .

4 is a factor of any number in which the last two digits are a number divisible by 4. Thus, 1844 has a factor 4, because  $44 \div 4 = 11$ . 761 does not have a factor of 4, since 61 is not divisible by 4.

5 is a factor of any number that has a ones digit that is either 0 or 5.

A *prime number* is one that has no factors except itself and 1. Thus, 2, 3, 5, 7, 11, etc. are prime numbers. 2 is the only even prime number. A factor which itself is a prime number is called a *prime factor*. All numbers can be expressed as a product of their prime factors.

It can be determined if 7 is a factor of a number according to this process: Remove the last digit from the number, double it, and subtract it from the remaining number. If the result is divisible by 7 (e.g., 14, 7, 0, -7, etc.), then the number is divisible by 7.

The *prime factorization* of a number is done by expressing the number as a product of its primes. For example, the prime factors of 20 are 2 and 5; the prime factorization is  $2 \times 2 \times 5 = 20$ .

The *Prime Number and Factor Table*, starting on page 15, give the smallest prime factor of all odd numbers from 1 to 9600, and can be used for finding all the factors for numbers up to this odd number. Where no factor is given for a number in the table, the letter **P** indicates that the number is a prime number. The last page of the tables lists prime numbers from 9551 through 18691; it can be used to identify unfactorable numbers in that range.

*Example 1:* Find the factors of 833. Use the table on page 15 as illustrated below.

*Solution:* The table on page 15 indicates that 7 is the smallest prime factor of 833, shown at the row-column intersection for 833. This leaves another factor, because  $833 \div 7 = 119$ .

From To	0 100	100 200	200 300	300 400	400 500	500 600	600 700	700 800	800 900	900 1000	1000 1100	1100 1200
33	3	7	P	3	P	13	3	P	7	3	P	11

It also shows that 7 is a prime factor of 119, leaving a factor  $119 \div 7 = 17$ .

From To	0 100	100 200	200 300	300 400	400 500	500 600	600 700	700 800	800 900	900 1000	1000 1100	1100 1200
19	P	7	3	11	P	3	P	P	3	P	P	3

**P** indicates that 17 is a prime number and no other prime factors of 833 exist.

From To	0 100	100 200	200 300	300 400	400 500	500 600	600 700	700 800	800 900	900 1000	1000 1100	1100 1200
17	P	3	7	P	3	11	P	3	19	7	3	P

Hence, the prime factorization of 833 is  $7 \times 7 \times 17$ .

*Example 2:* A set of four gears is required in a mechanical design to provide an overall gear ratio of  $4104 \div 1200$ . Furthermore, no gear in the set is to have more than 120 teeth or less than 24 teeth. Determine the tooth numbers.

*Solution:* The prime factorization of 4104 is determined to be  $2 \times 2 \times 2 \times 3 \times 3 \times 57 = 4104$ . The prime factorization of 1200 is determined to be  $2 \times 2 \times 2 \times 2 \times 5 \times 5 \times 3 = 1200$ . Therefore,

$$\frac{4104}{1200} = \frac{2 \times 2 \times 2 \times 3 \times 3 \times 57}{2 \times 2 \times 2 \times 2 \times 5 \times 5 \times 3} = \frac{72 \times 57}{24 \times 50}$$

Each resulting factor represents the number of teeth that fulfill the requirement. If the factors had been combined differently, say, to give  $\frac{72 \times 57}{16 \times 75}$ , then the 16-tooth gear in the denominator would

not satisfy the requirement of having no less than 24 teeth.

*Example 3:* Factor 25,078 into two numbers, neither of which is larger than 200.

*Solution:* The smallest factor of 25,078 is obviously 2, leaving  $25,078 \div 2 = 12,539$  to be factored further. However, from the last table, *Prime Numbers from 9551 to 18691*, on page 23, it is seen that 12,539 is a prime number; therefore, no other factors exist. So the factorization named is not possible.

## ALGEBRA

In engineering, manufacturing, and industrial applications, physical laws govern the behavior of all quantities. Algebraic formulas (equations) are the models for these laws. They usually consist of algebraic expressions, the most common being polynomials, rational expressions, and radicals. Most of the formulas used in this Handbook contain one or more of these. This section gives a foundation for understanding the algebra indispensable to solving equations.

**Definitions.**—The vocabulary of algebra extends to all mathematics. The essential definitions are given here.

**Operation:** Addition, subtraction, multiplication, division, root-taking, raising to a power, taking a logarithm.

**Inverse Operation:** An operation that reverses another operation. Addition and subtraction are inverse operations, as are multiplication and division. Taking the  $n$ th root is the inverse of raising a number to a power. Finding an antilogarithm is the inverse of finding a logarithm.

**Constant:** A known quantity, either a number standing alone or a letter that is assumed to be given or known in an application. In  $5x + 14$ , 14 is the constant. Usually, the letters  $a$ ,  $b$ , and  $c$  are used to represent constants, as in the linear equation  $ax + by = c$ . Note:  $e$  and  $\pi$  are commonly seen constants.

**Variable:** An unknown quantity, represented by a letter such as  $n, x, y, x, t$ . Note:  $e$  and  $\pi$  are not variables.

**Exponent:** The power to which a variable or number is raised.

**Monomial:** A single variable or number or a product of numbers and variables. Examples:  $5, x, -4y^2, 12xy^2z^3$ . Exponents in monomials are whole numbers, 0, 1, 2, 3, . . . , so  $x^{-1} = 1/x$  and  $x^{1/2} = \sqrt{x}$  are not monomials.

**Coefficient:** The numerical factor in a term. Examples (in bold):  $5x, 16n, -2r$ . The coefficient of a variable standing alone is understood to be 1, for example,  $x = 1x$ ; the coefficient of  $-x$  is  $-1$ .

**Term:** Monomials are terms, but so are expressions that are not monomials:  $1/x, \sqrt{x}, 8x^{1/3}, \log x$ , and so on.

**Like Terms:** This usually refers to monomials with the same variable and exponent, and having any real number coefficients, such as  $x$  and  $7x$ ;  $2n^2$  and  $n^2/4$ ;  $2rst/5$  and  $14rst$ , and so on. Any constant  $a$  can be written as  $ax^0$ , so all constants are like terms. But  $x^{1/2}$  and  $4x^{1/2}$  also are like terms.

**Expression:** Numbers and variables with operators (addition: +, multiplication:  $\times$  or  $\cdot$ ,  $\sqrt{\quad}$  etc.).

**Equation:** Two expressions set equal to one another with the equal sign = .

**Examples:**  $5x = x^2 - 6$ ;  $\sqrt{3x} = 14$ . Solving equations for the unknown is the foundation of algebra.

**Inequality:** Two expressions set against one another by  $>$ ,  $<$ ,  $\geq$ ,  $\leq$ , or  $\neq$ .

**Evaluating Algebraic Expressions.**—An expression is *evaluated* by substituting given values of the variable. For example,  $x^2 - 2x + 7$  evaluated at  $x = -3$  is  $(-3)^2 - 2(-3) + 7 = 9 + 6 + 7 = 22$ .

Another example,  $\sqrt{1 - x^2}$  evaluated at  $x = \frac{1}{3}$  is  $\sqrt{1 - (\frac{1}{3})^2} = \sqrt{1 - \frac{1}{9}} = \sqrt{\frac{8}{9}}$ .

**Combining Like Terms.**—Like terms are added and subtracted by combining their coefficients and leaving the rest of the term as is. For example:

$$3x + x - 7x = -3x \quad 2n^2 + \frac{n^2}{4} - n^2 = \frac{5n^2}{4} \quad 2rst - 14rst + rst = -11rst$$

**Solving an Equation for an Unknown.**—Solving an equation for an unknown (say,  $x$ ) requires isolating  $x$  from the other terms. This is accomplished by applying techniques of *inverse operations*, *combining like terms*, and *factoring*, as explained throughout *ALGEBRA*, *GEOMETRY*, and *TRIGONOMETRY*.

The simplest equations contain only one or two variables, such as linear equations and other polynomials in two dimensions. Others may contain many variables, such as formulas in physics and engineering. A *formula* is an equation that determines a physical quantity based on other known quantities. An example is area of a rectangle,  $A = lw$ , where  $l$  is length and  $w$  is width in like units. Another is horsepower transmitted by belting,  $P = SVW/33,000$ , where  $S$ ,  $V$ , and  $W$  are, respectively, working stress of the belt, belt velocity, and belt width, all in appropriate units.

The following examples give an overview of equation solving with general terms  $A$ ,  $B$ ,  $C$ , and  $D$ . The same processes apply for solving polynomial and other algebraic equations for an unknown.

*Solving by Adding or Subtracting:*

$$\text{Given: } B - C = A - D$$

$$\text{To solve for A: } B - C + D = A, \text{ that is, } A = B - C + D$$

$$\text{To solve for B: } B = A - D + C$$

$$\text{To solve for C: } B = A - D + C \rightarrow B - A + D = C, \text{ that is, } C = B - A + D$$

$$\text{To solve for D: } B - C + D = A \rightarrow D = A - B + C$$

In the last two,  $C$  and  $D$  are moved first so they do not have a minus sign before them in the answer. But *keeping in mind that subtracting a term is the same as adding its negative* (see *Integers* on page 3), another way to solve for  $C$  or  $D$  is given below. The subtraction “minus  $C$ ” is treated as “negative  $C$ .” Then, multiplying through by  $-1$ , all signs change but equality is maintained, leaving  $C$ :

$$\text{Solve for C: } B - C = A - D \rightarrow -C = A - D - B \rightarrow (-1)(-C) = (-1)(A - D - B) \rightarrow C = -A + D + B$$

$$\text{Solve for D: } B - C = A - D \rightarrow B - C - A = -D \rightarrow (-1)(B - C - A) = (-1)(-D) \rightarrow -B + C + A = D, \text{ or } D = A - B + C$$

Changing the sign of each term by multiplying through by  $-1$  is a common technique.

*Solving by Multiplying or Dividing:* A variable that is a factor or a divisor within a term is isolated using division (*multiplying by the reciprocal*) or multiplication (*cross-multiplying*).

*Example:* In the equation  $\frac{AB}{C} = D$ , each variable is isolated using multiplication.

To isolate  $A$ , multiply each side by the reciprocal of  $\frac{B}{C}$ :

$$\frac{C}{B} \times \frac{AB}{C} = \frac{C}{B} \times D \rightarrow A = \frac{C}{B} \times \frac{D}{1} = \frac{CD}{B}, \text{ so } A = \frac{CD}{B}$$

To isolate  $B$ , multiply each side by the reciprocal of  $\frac{A}{C}$ :

$$\frac{C}{A} \times \frac{AB}{C} = \frac{C}{A} \times D \rightarrow B = \frac{C}{A} \times \frac{D}{1} = \frac{CD}{A}, \text{ so } B = \frac{CD}{A}$$

To isolate  $C$ , multiply each side by  $C$ :  $C \times \frac{AB}{C} = C \times D \rightarrow AB = CD$

Then divide by  $D$  (multiply by the reciprocal of  $D$ ):

$$\frac{AB}{1} \times \frac{1}{D} = \frac{CD}{1} \times \frac{1}{D} \rightarrow \frac{AB}{D} = C, \text{ so } C = \frac{AB}{D}$$

Equations with more complexity require more steps to solve for an unknown.

*Examples:*

Solve  $\frac{A+B}{C} = D$  for  $A$ :

Multiply both sides by  $C$        $\frac{A+B}{C} \cdot C = D \cdot C \rightarrow A+B = DC$

Subtract  $B$  from both sides       $A+B-B = DC-B \rightarrow A = DC-B$  or  $CD-B$

Solve  $\frac{A+B}{C} = B-D$  for  $D$ :

Add  $D$  to both sides       $\frac{A+B}{C} + D = B$

Subtract  $\frac{A+B}{C}$  from both sides       $D = B - \frac{A+B}{C}$

Solve  $\frac{A+B}{C} = B-A$  for  $A$ :

Add  $A$  to both sides       $\frac{A+B}{C} + A = B$

Multiply both sides by  $C$        $C\left(\frac{A+B}{C} + A\right) = CB$

Distribute  $C$        $A+B+CA = CB$       Like terms  $A$  and  $CA$   
are isolated from  $B$

Subtract  $B$  from both sides       $A+CA = CB-B$       Since  $A$  and  $CA$  cannot be combined,  
 $A$  must be factored out

Factor out  $A$        $A(1+C) = CB-B$

Divide both sides by  $1+C$        $A = \frac{CB-B}{1+C}$

Solving an equation for an unknown is the basic technique for working with formulas.

### Rearrangement and Transposition of Terms in Formulas

A *formula* is a rule for a calculation expressed by using letters and signs, instead of writing out the rule in words. By this means, it is possible to condense, in a small space, the essentials of long and cumbersome rules.

As an example, the formula for horsepower transmitted by belting may be written

$$P = SVW/33000$$

where  $P$  = horsepower transmitted;  $S$  = working stress of belt per inch of width in pounds;  $V$  = velocity of belt in feet per minute;  $W$  = width of belt in inches; and, 33,000 = a constant that is part of the formula for horsepower with units of hp/(lb-in<sup>2</sup>/min).

If the working stress  $S$ , velocity  $V$ , and width  $W$  are known, horsepower can be found directly from this formula by inserting the given values. For example, if  $S = 33$ ,  $V = 600$ , and  $W = 5$ . Then,

$$P = 33 \times 600 \times 5 / 33000 = 3 \text{ hp}$$

Assume that horsepower  $P$ , stress  $S$ , and velocity  $V$  are known, and that the width of belt  $W$  is to be found. The formula must then be rearranged so that the symbol  $W$  will be alone on one side of the equation. This is accomplished by isolating  $W$  by moving the other variables and the number to the other side of the equation:

$$\text{From } P = \frac{SVW}{33,000}, \text{ multiply both sides by } 33,000: \quad 33,000P = SVW$$

$$\text{Divide both sides by } SV: \quad \frac{33,000P}{SV} = W, \text{ or } W = \frac{33,000P}{SV}$$

**Algebraic Operations**

Algebraic operations rely on the symbols and properties of real numbers, reviewed below from *ARITHMETIC* and used throughout this section. Key skills include exponent use (for both powers and roots), polynomial operations, and solving equations for a variable (unknown). The same skills carry over to areas of geometry, trigonometry, and calculus, where a strong foundation in algebra is essential.

**Properties of Monomials and Exponents**

$a + \cdots + a = na$ ( $n$ terms)	$a + 0 = a$	$a + (-a) = 0$	$a \times b = ab$
$a \times a \times \cdots \times a = a^n$ ( $n$ factors)	$a^n a^m = a^{(n+m)}$	$\frac{a^n}{a^m} = a^{(n-m)}$	$(a^m)^n = a^{mn}$
$a^{m/n} = (a^{1/n})^m$	$a^{-n} = \frac{1}{a^n}$	$\frac{1}{a^{-n}} = a^n$	$a^0 = 1$ (for $a \neq 0$ )
<i>Examples:</i>			
$a + a = 2a$	$-3a - a = -4a$	$4a \times 3a = 12aa = 12a^2$	
$a^2 a^3 = a^{2+3} = a^5$		$(a^2)^3 = a^{2 \times 3} = a^6$	
$a^{-3} = \frac{1}{a^3} = \left(\frac{1}{a}\right)^3$	$(ab)^2 = a^2 b^2$	$\left(\frac{a}{b}\right)^3 = \frac{a^3}{b^3}$	$\frac{a^4}{a^3} = a^{4-3} = a$

**Properties of Radicals**

$\sqrt{a} \times \sqrt{a} = a$	$\sqrt{a} \times \sqrt{b} = \sqrt{ab}$	$\frac{\sqrt{a}}{\sqrt{b}} = \sqrt{\frac{a}{b}}$
$(\sqrt[n]{a})^n = a$	$\sqrt[n]{a^m} = (\sqrt[n]{a})^m = a^{m/n}$ , unless $a < 0$ , $m$ and $n$ are both even	
$\sqrt[n]{\frac{1}{a}} = \frac{1}{\sqrt[n]{a}} = a^{-1/n}$	$(\sqrt{a} + \sqrt{b})^2 = (\sqrt{a} + \sqrt{b})(\sqrt{a} + \sqrt{b}) = a + 2\sqrt{ab} + b$	
<i>Examples:</i>		
$\sqrt[3]{a} \times \sqrt[3]{a} \times \sqrt[3]{a} = (\sqrt[3]{a})^3 = a$	$\sqrt[3]{ab} = \sqrt[3]{a} \times \sqrt[3]{b}$	$\sqrt[3]{\frac{a}{b}} = \frac{\sqrt[3]{a}}{\sqrt[3]{b}}$
$\sqrt[3]{a^2} = (\sqrt[3]{a})^2 = a^{2/3}$	$\sqrt[3]{\frac{1}{a}} = \frac{1}{\sqrt[3]{a}} = a^{-1/3}$	$\sqrt[4]{\sqrt[3]{a}} = 4 \times \sqrt[3]{a} = \sqrt[3]{\sqrt[4]{a}} \quad (a^{1/12})^{1/3}$
$\sqrt{x} + 9\sqrt{x} - 4\sqrt{x} = (1+9-4)\sqrt{x} = 6\sqrt{x}$	$\sqrt{x^2} = x$	$\sqrt{x^3} = \sqrt{x^2} \sqrt{x} = \sqrt{x^2} \sqrt{x} = x\sqrt{x}$
$\sqrt{100x} = \sqrt{100} \sqrt{x} = 10\sqrt{x}$	$\sqrt[5]{x^3} = (\sqrt[5]{x})^3 = x^{3/5}$	$\sqrt{20x^3} = \sqrt{4 \cdot 5 \cdot x^2 \cdot x} = \sqrt{4x^2} \sqrt{5x} = 2x\sqrt{5x}$
$4\sqrt{5x}(\sqrt{x} + 3x) = \sqrt{5x} \cdot x + 12x\sqrt{5x} = 4\sqrt{5x^2} + 12x\sqrt{5x} = 4x\sqrt{5} + 12x\sqrt{5x}$		
$\sqrt[4]{\frac{36}{x^4}} = \frac{\sqrt[4]{36}}{\sqrt[4]{x^4}} = \frac{6}{x^2}$	$\sqrt{x+1}$ cannot be simplified	

### Polynomials

Polynomials in a single variable are expressions of the form  $a_n x^n + a_{n-1} x^{n-1} + a_{n-2} x^{n-2} + \cdots + a_1 x^1 + a_0$ , where  $n$  is a non-negative integer, and the coefficients  $a_n, a_{n-1}, \dots, a_0$  are real numbers (the subscripts are simply labels that correspond to the variables ( $x^n, x^{n-1}, \dots$ )).  $n$  is the *degree* (or *order*) of the polynomial;  $a_n$  is the *leading coefficient*;  $a_0$  is the *constant coefficient*. A *first-degree polynomial* has  $n = 1$ ; a *second-degree polynomial* has  $n = 2$ , and so on.

*Example:*  $\frac{x}{3} + \frac{1}{6}$  is degree 1,  $a_1 = \frac{1}{3}$  is the leading coefficient,  $a_0 = \frac{1}{6}$  is the constant coefficient.

*Example:*  $4x^2 - 7$  is degree 2,  $a_2 = 4$  is the leading coefficient,  $a_0 = -7$  is the constant coefficient.

*Example:*  $x^3 + 5x^2 - x + \frac{1}{3}$  is degree 3, and the coefficients are  $a_3 = 1, a_2 = 5, a_1 = -1$ , and  $a_0 = \frac{1}{3}$ .

A *monomial* is a single-term polynomial. For example,  $8x^5$  is degree 5 with coefficient 8. A constant is a polynomial, by the definition. Its degree is 0. For example, 19 is a 0-degree polynomial, since it can be written as  $19x^0$ . A *binomial* is a polynomial with two terms, such as  $x + 9$  and  $5 - x^2$ . A *trinomial* has three terms, such as,  $x^2 + x - 6$ .

Finally, second-degree polynomials are called *quadratic* polynomials. They are important because they model so many processes in engineering and other technical and scientific fields.

**Operations on Polynomials.**—Polynomials can be added, subtracted, or multiplied (“expanded”), with the result being another polynomial. If polynomials are divided, the result is a *rational expression*. Polynomials also may be *factored*. That is, they may be written as a product of lower-degree polynomials.

*Combining (Adding and Subtracting) Polynomials:* Two or more polynomials are added by combining like terms. For example:

$$(x^4 + 6x^3 - 3x^2 - 5x - 11) + (x^3 - 12x^2 + x + 28) = x^4 + 7x^3 - 15x^2 - 4x + 17$$

*Multiplying (Expanding) Polynomials:* Taking the product of two or more polynomials relies on the distributive property of multiplication over addition (or subtraction):  $a(b + c) = ab + ac$ , where the rules of exponents are followed (see *Properties of Monomials and Exponents* on page 27).

*Examples of simple distributive case:*

$$2x(8x^4 + 3x^2 - 6) = 2 \cdot 8x^{1+4} + 2 \cdot 3x^{1+2} - 2 \cdot 6x = 16x^5 + 6x^3 - 12x$$

*Note:* This technique also is used for multiplying other algebraic expressions, such as radical (root) and rational expressions. Such terms are not polynomials, since their exponents are other than non-negative integers.

*Examples of Distributive Property for Root and Rational Expressions:*

$$2x^{1/2}(7x + 3) = 14x^{1/2+1} + 6x^{1/2} = 14x^{3/2} + 6x^{1/2}$$

$$\frac{1}{x}(x^3 - 7x^2 + 3x) = x^{-1+3} - 7x^{-1+2} + 3x^{-1+1} = x^2 - 7x^1 + 3x^0 = x^2 - 7x + 3$$

“FOIL” is a version of the distributive property in which two binomials are multiplied. FOIL stands for **F**irst **O**uter **I**nners **L**ast, the order in which terms are multiplied. The first is  $ac$ ; outer is  $ad$ , inner is  $bc$ , and last is  $bd$ .

*FOIL multiplication:*  $(a + b)(c + d) = ac + ad + bc + bd$

*Examples:*

$$(x-6)(x+1) = x \cdot x + x \cdot 1 - 6 \cdot x - 6 \cdot 1 = x^2 + 1x - 6x - 6 = x^2 - 5x - 6$$

$$(3x^2 + 2x)(4x^3 - 5) = 3x^2 \cdot 4x^3 - 5 \cdot 3x^2 + 2x \cdot 4x^3 + 2x \cdot (-5) = 12x^5 - 15x^2 + 8x^4 - 10x$$

$$(x-1)(x+1) = x \cdot x + x \cdot 1 - 1 \cdot x - 1 \cdot 1 = x^2 + 1x - 1x - 1 = x^2 - 1 \quad (\text{the middle terms drop out})$$

$$(x+1)^2 = (x+1)(x+1) = x^2 + x + x + 1 = x^2 + 2x + 1$$

In the first and third examples, the products of the outer and inner terms are like terms, so they are combined. The third example is a *special product* (in this case, the difference of squares). The fourth is an example of raising a polynomial to an exponent.

*Raising a Polynomial to an Exponent:* Consider first  $(a+b)^2$ , which is  $(a+b)(a+b)$ , and this expands by FOIL to  $a^2 + ab + ab + b^2 = a^2 + 2ab + b^2$ . In general, an expansion like  $(a+b)^2, (a-b)^2, (a+b)^3, (a-b)^3$  is called a *binomial expansion*,  $(a+b)^n$ . For example:

$$(a+b)^n = \underbrace{(a+b)(a+b)(a+b) \cdots (a+b)}_{n \text{ factors}}$$

*Caution:* A common but *serious* mistake is distributing the exponent to each term in the parentheses:

$$(a+b)^2 = (a+b)(a+b) = a^2 + 2ab + b^2 \quad \text{NOT} \quad a^2 + b^2$$

**Factoring Polynomials.**—The result of two or more polynomials being multiplied is a higher-degree polynomial. *Factoring a polynomial* breaks it into its lesser-degree factors. This section explains how to factor a polynomial, a skill needed for solving equations and graphing functions (see *Graphs of Functions* on page 35). The categories are: dividing by a *common factor* (i.e., distributive property in reverse); factoring by *reverse FOIL* (with leading coefficient of 1 and otherwise); factoring *special products*.

*Common Factors:* Each term is divided by the *greatest common factor* (GCF) and written as shown:  $ab + ac = a(b+c)$

*Examples of GCF factoring:*

$$6x^3 + 2x^2 - 10x = 2x(3x^2 + x - 5) \quad \text{GCF}$$

$$mn + m^2n - mn^2 = mn(1 + m - n) \quad \text{GCF}$$

$$-7abc - 21bc^2 + 4bc = -bc(7a + 21c - 4) \quad \text{GCF}$$

*Note:* The variable in the GCF is the one with the lowest exponent in common to all terms. If two terms have a GCF, but the others do not, then that factor cannot be pulled out. And, if the leading coefficient is negative (third example), it is customary to factor out  $-1$  in the GCF redundant. This is so the expression in parentheses has a positive leading coefficient, which makes it easier to factor further.

*Reverse FOIL of Form  $x^2 + bx + c$ :* The basic technique is demonstrated for a second-degree trinomial with a leading coefficient of 1. The task is to factor  $x^2 + bx + c$  as  $(x + \square)(x + \square)$ , using only integers  $\{\dots, -2, -1, 0, 1, 2, \dots\}$  in the boxes.

*Example:* Consider  $x^2 + 4x + 3$ . To factor it as  $(x + \square)(x + \square)$ , the integers must have a product of  $+3$  (the last term of  $x^2 + 4x + 3$ ) and a sum of  $+4$  (the middle term). 1 and 3 are correct, as verified by FOIL:

$$x^2 + 4x + 3 = (x+1)(x+3).$$

As long as the leading coefficient is 1, reverse FOIL works. If one or both operations in the trinomial are negative, the process is the same, but some trial and error may be needed, as shown in the examples below.

*Example:* Three similar trinomials, only two are factorable:

$$x^2 + 2x - 3 = (x + 3)(x - 1), \quad \text{since } (3)(-1) = -3 \text{ and } 3 + (-1) = 2$$

$$x^2 - 2x - 3 = (x - 3)(x + 1), \quad \text{since } (-3)(1) = -3 \text{ and } -3 + 1 = -2$$

$$x^2 - 2x + 3 \quad \text{Does not factor over the real numbers, since no two integers have a product of } +3 \text{ and a sum of } -2$$

*Examples:* Factoring by reverse FOIL, along with the explanation:

$$x^2 - 8x - 20 = (x - 10)(x + 2) \quad \text{The two integers whose product is } -20 \text{ and whose sum is } -8 \text{ are } -10 \text{ and } 2.$$

$$x^2 - 21x + 20 = (x - 20)(x - 1) \quad \text{The two integers whose product is } 20 \text{ and whose sum is } -21 \text{ are } -20 \text{ and } -1.$$

Reverse *FOIL* for polynomials of Form  $ax^2 + bx + c$ : If the leading coefficient is other than 1, reverse FOIL works, but a different tactic is needed. Sometimes called "magic factoring," the procedure is shown in this example:

$$3x^2 + 13x + 12, \quad a = 3, b = 13, c = 12$$

*Step 1:*  $ac = (3)(12) = 36$

*Step 2:* Write all factor pairs of  $ac = 36$ : 1,36; 2,18; 3,12; 4,9; 6,6

*Step 3:* Choose the factor pair whose sum is  $b = 13$ : 4,9

*Step 4:* Rewrite polynomial with middle term  $13x$  as  $4x + 9x$ :  $3x^2 + 4x + 9x + 12$

*Step 5:* Group first two terms and second two terms in parentheses:  $(3x^2 + 4x) + (9x + 12)$

*Step 6:* Take the common factor out of each group:  $x(3x + 4) + 3(3x + 4)$

*Step 7:* Take the common *binomial* factor out of each large term:  $(3x + 4)(x + 3)$   
Correct factorization

*Step 8:* Check the factorization found:  $3x^2 + 9x + 4x + 12 = 3x^2 + 13x + 12$

*Special Products:* Certain binomials are factored according to formulas, which can be checked by multiplying. The *difference of squares* is perhaps the most important because it comes up so often in applications, as do many quadratic (second-degree) polynomials. It comes from multiplying the *conjugate pair* of binomials,  $(a + b)$  with  $(a - b)$  to get  $a^2 - b^2$ .

Difference of squares:  $a^2 - b^2 = (a + b)(a - b)$

Difference of cubes:  $a^3 - b^3 = (a - b)(a^2 + ab + b^2)$

Sum of cubes:  $a^3 + b^3 = (a + b)(a^2 - ab + b^2)$

Square of a sum:  $(a + b)^2 = (a + b)(a + b) = a^2 + 2ab + b^2$

Difference of a sum:  $(a - b)^2 = (a - b)(a - b) = a^2 - 2ab + b^2$

*Note:* The sum of squares  $a^2 + b^2$  is not a factorable binomial over the set of real numbers. However, it is factorable over the set of complex numbers (see *Complex Numbers* on page 59).

*Examples:* Several special product factorizations are shown:

Difference of squares:  $a^2 - b^2$       Difference of cubes:  $a^3 - b^3$       Sum of cubes:  $a^3 + b^3$

$$x^2 - 81 = (x + 9)(x - 9) \quad x^3 - 1 = (x - 1)(x^2 + x + 1) \quad x^3 + 1 = (x + 1)(x^2 - x + 1)$$

$$100 - 49x^2 = (10 + 7x)(10 - 7x) \quad 8 - x^3 = (2 - x)(4 + 2x + x^2) \quad 27 + x^3 = (3 + x)(9 - 3x + x^2)$$

Factorization of all other cases is done using the *quadratic formula*, as shown in the next section.

### Equation Solving

An equation is a statement of equality between two expressions, such as one monomial set equal to another, like  $5x = 105$ . The unknown, or variable, is frequently designated by  $x$ . Other unknowns (if any) are designated by letters also usually selected from the end of the alphabet:  $y, z, u, t$ , etc.

Equations, like expressions, have a degree. A *first-degree* equation is one in which the variable is raised to the first power, as in  $3x = 9$ . A *second-degree* equation, also called a *quadratic* equation, is one in which the highest power of the variable is two; for example,  $x^2 + 3x = 10$ .

Solving a first-degree equation requires isolating the unknown. In the example below,  $x$  is the unknown variable. To get  $x$  alone (to isolate  $x$ ), constants are combined on one side of the equation and variable terms are combined on the other. The steps are:

Given:	$10x - 14 = 8 - 2x$
Add $2x$ to both sides:	$10x - 14 + 2x = 8 - 2x + 2x$
	$12x - 14 = 8$
Add 14 to both sides:	$12x - 14 + 14 = 8 + 14$
	$12x = 22$
Divide by 12 (multiply by $1/12$ ):	$12x/12 = 22/12$
Simplify:	$x = 22/12 = 11/6$

Any answer can be checked by substituting it into the original equation to see that it satisfies it.

**Solving a System of Linear Equations.**—More involved than solving a single-variable equation is the process of solving a *system* of linear equations. A simple linear system represents two lines in the plane that behave in one of three ways: they *intersect at one point*, in which case they have a *unique solution*,  $(x, y)$ ; they intersect everywhere—that is, they are *collinear*—so all points  $(x, y)$  of one line satisfy the other; or they are *parallel* and thus intersect nowhere, hence, there is no solution.

The methods for solving a system of linear equations are *substitution* and *elimination*, as shown next.

*Substitution:* In this method, one of the variables is expressed in terms of the other variable by isolating it. This expression is then substituted into the second equation, converting it to a single-variable equation. It is solved for this variable, and the solution is substituted back into the either of the original two equations to find the value of the other variable.

*Example (Unique Solution):* Find the ordered pair  $(x, y)$  that satisfies the system of equations:

$$\begin{aligned} 2x + y &= 7 \\ x - 2y &= -4 \end{aligned}$$

First, solve either equation for one variable in terms of the other. Say, solve the second equation for  $x$ :

$$x = 2y - 4$$

Then, substitute this expression for  $x$  into the first equation and solve it for  $y$ :

$$2(2y - 4) + y = 7 \quad \rightarrow \quad 4y - 8 + y = 7 \quad \rightarrow \quad 5y = 15 \quad \rightarrow \quad y = 3$$

Finally, substitute  $y = 3$  into the second equation:  $x = 2(3) - 4 = 6 - 4 = 2$ . The solution (that is, the point at which the lines intersect) is  $(2, 3)$ .

*Example (Infinite Solutions):* Find the ordered pair  $(x, y)$  that satisfies the system of equations:

$$\begin{aligned} 7x - y &= 3 \\ 14x - 2y &= 6 \end{aligned}$$

The first equation is rearranged to  $y = 7x - 3$ . Substituting into the second equation yields:  $14x - 2(7x - 3) = 6 \rightarrow 14x - 14x + 6 = 6 \rightarrow 6 = 6$ .

If a system results in  $a = a$ , then the lines are the same, or collinear. All of the points on either line are solutions to (points on) the other line. The indication that lines are collinear is that one is a multiple of the other, term by term.

*Example (No Solution):* Parallel lines have the same slope, and so they have no point of intersection. This is seen in the substitution of one equation's variable into the other equation, giving a false statement, such as  $1 = 3$ . An example is the system  $y = -x + 4$  and  $y = -x - 1$ . Substitution of the first into the second gives  $-x + 4 = -x - 1$ , or  $4 = -1$ . This clearly is not true, hence the system has no solution.

A final way to find the solution to a linear system is to put the coefficients of the equations into the following formulas and to solve for  $x$  and  $y$ , as follows:

$$a_1x + b_1y = c_1$$

$$a_2x + b_2y = c_2$$

Then,

$$x = \frac{c_1b_2 - c_2b_1}{a_1b_2 - a_2b_1} \qquad y = \frac{a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$$

*Example:*

$$3x + 4y = 17$$

$$5x - 2y = 11$$

$$x = \frac{(17)(-2) - (11)(4)}{(3)(-2) - (5)(4)} = \frac{-34 - 44}{-6 - 20} = \frac{-78}{-26} = 3$$

The value of  $y$  can now be most easily found by inserting the value of  $x$  in one of the equations:

$$(5)(3) - 2y = 11, \quad 2y = 15 - 11 = 4, \quad y = 2$$

Checking the solution by putting these values into the original system shows that  $(3, 2)$  is the solution of this linear system.

**Solving a Second-Degree (Quadratic) Equation.**—A second-degree equation is also called a *quadratic equation*. To solve a second-degree equation is to find the  $x$  values (or points) at which the parabola intersects the  $x$ -axis. These are the *roots* or *zeros* of the parabola.

There are several ways to solve a quadratic equation for its roots. If an equation can be factored, then each factor is set equal to zero and the solution is thus found. This is according to the *zero property of multiplication*, which states that if  $AB = 0$ , then either  $A = 0$  or  $B = 0$ .

If the equation is not readily or obviously factored (or even if it is), the *quadratic formula* can be used to find the roots, as explained in the next section, *Using the Quadratic Formula*.

The simplest quadratic equation has the form  $x^2 = c$ , where  $c$  is a constant. Solving this entails simply taking the square root of both sides:

$x^2 = c$ , therefore,  $x = \sqrt{c}$  and  $-\sqrt{c}$ . For example,  $x^2 = 36$  has two solutions,  $x = 6$  and  $x = -6$ . If the quadratic has the form, like  $ax^2 = c$ , the solution is also straightforward,  $x^2 = a/c$ , and so  $x = \pm \sqrt{a/c}$ .

*Note:* The square root of a number as it stands alone is understood to be its positive root; that is, the square root of 9 is 3. But *in an equation* the solution includes both positive and negative roots. This makes sense because the equation represents a parabola, which can intersect the  $x$ -axis in two places, its two roots. The other two possibilities occur when the parabola (a quadratic function) intersects the  $x$ -axis once (touches it) or does not intersect it. All three possibilities are revealed in solutions to the quadratic equation.

Designating the roots of a quadratic equation (or any polynomial) by  $r$ ,  $x^2 = c$  can be regarded as  $x^2 = r^2$ , so  $x = r$  and  $-r$ , the roots of the parabola. Another way to rewrite  $x^2 = r^2$

is  $x^2 - r^2 = 0$ , and then factor as the difference of squares (see *Polynomials* on page 28):  $(x+r)(x-r) = 0$ , hence,  $x = -r$  and  $r$ .

Verifying this to be the factorization of the difference of squares is simply a matter of applying the distributive property of multiplication over addition to each term:

$$(x+r)(x-r) = xx - xr + xr - rr = x^2 - r^2$$

As previously explained, this process is called expanding by FOIL, for the **F**irst, **O**uter, **I**nner, and **L**ast terms of each binomial, which are multiplied in that order to get the product. From the zero property of multiplication,

$$(x+r)(x-r) = 0 \text{ implies } x+r=0 \text{ or } x-r=0, \text{ thus } x=-r \text{ or } x=r.$$

If a quadratic cannot be factored as a difference of squares, then factorization is approached as shown in *Factoring Polynomials* on page 29. Given a quadratic equation in the form  $ax^2 + bx + c = 0$ , first obtain the product  $ac$  from the coefficients  $a$  and  $c$ ; then determine two numbers whose product is  $ac$  and whose sum is  $b$ .

*Example:* Find the solution to  $x^2 - 5x + 6 = 0$  by factoring.

In this example,  $a = 1$ ,  $b = -5$ ,  $c = 6$  and  $ac = (1)(6) = 6$ . The factors of 6 whose sum is  $-5$  are  $-2$  and  $-3$ . The equation is factored as  $x^2 - 5x + 6 = (x-2)(x-3) = 0$ . Then by the zero property of multiplication, the roots of the equation are  $x = 2$  and  $x = 3$ . The parabola intersects the  $x$ -axis at these two values of  $x$ .

A more difficult example has a leading coefficient of  $x$  other than 1.

*Example:* Factor  $8x^2 + 22x + 5 = 0$  and find the values of  $x$  that satisfy the equation.

*Solution:* Here,  $a = 8$ ,  $b = 22$ , and  $c = 5$ . Therefore,  $ac = 8 \times 5 = 40$ , and  $ac$  is positive, so we are looking for two factors of  $ac$ , namely  $f_1$  and  $f_2$ , such that  $f_1 + f_2 = 22$ .

The possible combinations of numbers with product of 40 are 20 and 2, 8 and 5, 4 and 10, and 40 and 1. The requirements that satisfy a sum of 22 are 20 and 2, since  $20 \times 2 = 40$  and  $20 + 2 = 22$ . Hence:

$$8x^2 + 22x + 5 = 0$$

$$8x^2 + 20x + 2x + 5 = 0$$

$$4x(2x + 5) + 1(2x + 5) = 0$$

$$(2x + 5)(4x + 1) = 0$$

On the second line, the common factor of  $4x$  in the first two terms is factored out, so the common binomial factor of  $2x + 5$  is then apparent, to be factored out of the larger terms. Checking the answer is a matter of simply remultiplying the factors to produce the original expression.

Because the product of the two factors equals zero, each of the factors also equals zero. Thus,  $2x + 5 = 0$  and  $4x + 1 = 0$ . Rearranging and solving,  $x = -5/2$  or  $x = -1/4$ .

*Example:* Factor  $8x^2 + 3x - 5 = 0$  and find the solutions of the equation.

*Solution:* Here  $a = 8$ ,  $b = 3$ ,  $c = -5$ , and  $ac = 8 \times (-5) = -40$ . The required numbers must have a product of  $-40$  and a sum of 3.

As in the previous example, the possible combinations are 20 and  $-2$ ,  $-20$  and 2,  $-8$  and 5, 8 and  $-5$ , 40 and  $-1$ , and  $-40$  and 1. Only 8 and  $-5$  satisfy the requirements because  $8 \times (-5) = -40$ , and  $8 + (-5) = 3$ . Notice that  $3x$  in the first line is thus written as  $8x - 5x$  in the second line, making it possible to rearrange and simplify the expression.

$$8x^2 + 3x - 5 = 0$$

$$8x^2 + 8x - 5x - 5 = 0$$

$$8x(x + 1) - 5(x + 1) = 0$$

$$(x + 1)(8x - 5) = 0$$

Solving, for  $x + 1 = 0$ ,  $x = -1$ ; and, for  $8x - 5 = 0$ ,  $x = 5/8$ .

**Solving by Completing the Square.**—An equation of the form  $x^2 + bx + c = 0$  can be turned into the square of a sum. The steps are:

- Move constant to the right side of the equal sign:  $x^2 + bx = -c$
- Add  $(b/2)^2$  to both sides:  $x^2 + bx + (b/2)^2 = -c + (b/2)^2$
- Note the left side is the square of a sum, that is:  $(x + b/2)^2$
- The right is a new constant, call it  $d$ :  $-c + (b/2)^2 = d$
- The equation is thus converted to:  $(x + b/2)^2 = d$
- Take the positive and negative square root of both sides:  $x + \frac{b}{2} = \pm\sqrt{d}$
- Solve for  $x$ :  $x = -\frac{b}{2} \pm \sqrt{d}$

*Example:* Complete the square to solve  $x^2 + 4x - 3 = 0$ .

- $x^2 + 4x = 3$
- $x^2 + 4x + (4/2)^2 = 3 + (4/2)^2$ , that is,  $x^2 + 4x + 4 = 3 + 4$
- Left side:  $x^2 + 4x + 4 = (x + 2)^2$
- Right side:  $3 + 4 = 7$
- So,  $(x + 2)^2 = 7$
- $x + 2 = \pm\sqrt{7}$
- $x = -2 \pm\sqrt{7}$

Completing the square is more involved if the leading coefficient  $a$  is not 1. Then it is preferable to use the *quadratic formula*, which can be used for any value of  $a$  in a quadratic equation.

**Using the Quadratic Formula.**—The method of completing the square leads to the quadratic formula for finding the roots of equations with the form  $ax^2 + bx + c = 0$ :

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

*Example:* In the equation,  $x^2 + 6x + 5 = 0$ ,  $a = 1$ ,  $b = 6$ , and  $c = 5$ .

$$x = \frac{-6 \pm \sqrt{6^2 - (4)(1)(5)}}{(2)(1)} = \frac{(-6) + 4}{2} = -1 \quad \text{or} \quad \frac{(-6) - 4}{2} = -5$$

*Example:* A right triangle has a hypotenuse of 5 cm and one leg that is 1 cm longer than the other; find the lengths of the two legs.

Let  $x$  be the length of one leg and  $x + 1$  be the length of the other; then by Pythagorean theorem (see page 62),  $x^2 + (x + 1)^2 = 5^2$ . Expanding this and setting all terms equal to zero gives  $x^2 + x - 12 = 0$ . Now referring to the basic formula,  $ax^2 + bx + c = 0$ , here,  $a = 1$ ,  $b = 1$ , and  $c = -12$ . Substituting these values into the quadratic formula:

$$x = \frac{-1 \pm \sqrt{1 - (4)(1)(-12)}}{(2)(1)} = \frac{(-1) + 7}{2} = 3 \quad \text{or} \quad x = \frac{(-1) - 7}{2} = -4$$

Since only the positive value, 3, makes sense in this case, the lengths of the two sides are  $x = 3$  cm and  $x + 1 = 4$  cm.

**Solving a Cubic Equation.**—Just as quadratic equations may be simple to solve if they are of the form  $x^2 = c$ , a cubic equation of the form  $x^3 = c$  also is simple to solve. But, the given equation has the form:  $x^3 + ax + b = 0$  then one of the real roots is:

$$x = \left(-\frac{b}{2} + \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{1/3} + \left(-\frac{b}{2} - \sqrt{\frac{a^3}{27} + \frac{b^2}{4}}\right)^{1/3}$$

The equation  $x^3 + px^2 + qx + r = 0$  may be rewritten in the form  $x_1^3 + ax_1 + b = 0$  by substituting  $x_1 = \frac{x - p}{3}$  for  $x$  in the given equation.

### Functions

Functions are understood through both equations and graphs. Graphs are drawn on the  $(x, y)$ -coordinate system (or rectangular coordinate system), which is described fully in *Analytic Geometry* section of *GEOMETRY* starting on page 42.

A *function* consists of two sets (generally called  $X$  and  $Y$ ) of numbers and a *rule* that assigns (or sends) each element (usually, a real number)  $x$  in  $X$  to a *unique* element (another real number)  $y$  in  $Y$ . “ $y$  is a function of  $x$ ” is commonly expressed as  $y = f(x)$ . Countless physical processes are represented by functions. For example, displacement,  $s$ , is a function of time,  $t$ , so it is represented as  $s(t)$ . Velocity also is a function of time,  $v(t)$ .

The set  $X$  is called the *domain* of a function, which is the set of all real number values for which a function is *defined*. When the function acts on these numbers, the result is another real number  $y$ .

As an example,  $y = f(x) = 2x + 5$  is a linear function whose domain is the set of all real numbers, since when 5 is added to the product of 2 and any real number  $x$ , the result is always a real number  $y$ . Lines are first-degree polynomials; in fact, the domain of *any* polynomial is the set of reals (see *Polynomials* on page 28).

Two more examples:  $f(x) = 1/x$  is not defined at  $x = 0$ , since  $1/0$  is not a number, so its domain is the set of all real numbers except 0. Since negative numbers do not have square roots in the reals, the domain of  $f(x) = \sqrt{x}$  is the set of non-negative real numbers.

In  $y = f(x)$ ,  $x$  is called the *input* to the function. The  $y$  value resulting from  $x$  is the *output*, or *function value*. Since  $y$  depends on  $x$ , it is the *dependent variable*;  $x$  is the *independent variable*.

*Interval Notation:* Domain is often expressed in *interval notation*, indicating the portion of the number line that contains a function's valid input values. The interval notation for set of all reals is  $(-\infty, \infty)$ ; for non-negative numbers, it is  $[0, \infty)$ ; for positive numbers, it is  $(0, \infty)$ ; and for all real numbers except 0, it is  $(-\infty, 0) \cup (0, \infty)$ . The domain of a polynomial is therefore  $(-\infty, \infty)$ ; the domain of  $f(x) = 1/x$  is  $(-\infty, 0) \cup (0, \infty)$ ; and the domain of  $f(x) = \sqrt{x}$  is  $[0, \infty)$ .

**Graphs of Functions.**—The *graph* of a function is drawn through the points  $(x, y)$  on the rectangular coordinate system (see page 42) so that the curve satisfies the equation  $y = f(x)$ . A graph depicts the relationship between  $x$  and  $y$ . The graph of a function will always pass the *vertical line test*, by which any vertical line intersects the graph at most once. Thus, any line other than a vertical line is expressible in function form,  $f(x) = mx + b$ , where the slope is  $m$  and the  $y$ -intercept is  $b$ . (The several *forms* of linear equations are explained in *Equation Forms of a Line* on page 44.) A parabola is represented by a polynomial function of the form  $f(x) = ax^2 + bx + c$ . All polynomials pass the vertical line test (Fig. 1a).

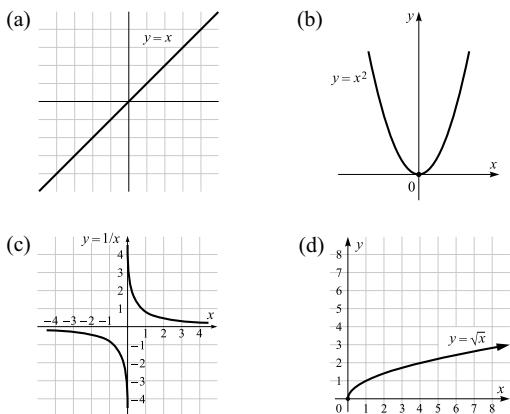

Fig. 1. (a) Passes Vertical Line Test—Represents a Function;  
(b) Fails the Test—Does Not Represent a Function.

*Sketches of Basic Functions:* Sketches of basic functions and domain interval notation are shown in Fig. 2. It is obvious that each function passes the vertical line test.

Fig. 2. (a)  $f(x) = x, D_f = (-\infty, \infty)$ ; (b)  $f(x) = x^2, D_f = (-\infty, \infty)$ ;(c)  $f(x) = \sqrt{x}, D_f = [0, \infty)$ ; (d)  $f(x) = 1/x, D_f = (-\infty, 0) \cup (0, \infty)$ .

### Logarithms

Logarithms are of value in many engineering and shop calculations because they make it possible to solve cumbersome and difficult problems that otherwise would require more complex mathematical methods. Because of this, "logs" (for short) have long been used to facilitate and shorten calculations involving multiplication, division, the extraction of roots, and obtaining powers of numbers. Since the advent of hand-held calculators, however, logarithms are rarely used to do these basic operations. The *Guide and Logarithms* in the *ADDITIONAL MATERIAL* on *Machinery's Handbook 31 CD* in the *Machinery's Handbook 31 Digital Edition* include explanations and examples of how the log tables are used for computation.

Log properties and principles are still necessary in many areas. Logarithmic growth and its inverse, exponential growth (and decay), are essential to investigating processes in technical fields and science, in general. The main principles and properties of logarithms are covered here, along with representative examples. In most cases, a calculator is used to arrive at the answers.

**Meaning of Logarithm.**—The logarithm of a given number is the exponent to which a stated base must be raised to produce the given number. A formulaic definition of logarithm is:

$$\log_b x = y \quad \text{means} \quad b^y = x$$

which is read, "The logarithm of  $x$  in base  $b$  is  $y$ ; that is,  $b$  raised to the  $y$  power equals  $x$ ."  $y$  is the logarithm and  $x$  is the *antilogarithm* ("antilog"). Base  $b$  is always greater than 1. The antilog must be positive, since a positive number  $b$  raised to any power cannot give zero or a negative number. Some examples:

$$\begin{array}{lll} \log_2 8 = y & \text{means } 2^y = 8, & \text{so } y = 3 \\ \log_b 100 = 2 & \text{means } b^2 = 100, & \text{so } b = 10 \\ \log_3 x = -1 & \text{means } 3^{-1} = x, & \text{so } x = 1/3 \end{array}$$

**Properties of Logarithms.**—The definition along with exponent rules covered previously lead to the *properties of logarithms*, given here with examples. When no base is shown, base 10 is implied. (See *Common Logarithms* on page 37.)

<i>Property</i>	<i>Example</i>
$\log_b 1 = 0$	$\log_3 1 = 0$
$\log_b b = 1$	$\log_8 8 = 1$
$\log_b (xy) = \log_b x + \log_b y$	$\log(2y) = \log 2 + \log y$
$\log_b \left(\frac{x}{y}\right) = \log_b x - \log_b y$	$\log\left(\frac{100}{3}\right) = \log 100 - \log 3$
$\log_b x^r = r \log_b x$	$\log_2 x^3 = 3 \log_2 x$
$\log_b b^r = r$	$\log_5 5^{11} = 11$

**Common Logarithms.**—There are two standard systems of logarithms: *common* (base 10) and *natural* (base  $e$ , explained below). In general,  $\log_{10} x$  is written simply as  $\log x$ . For example,  $\log 100 = 2$  because  $10^2 = 100$ .

*Examples:*  $\log 15 = 1.176$ , since  $10^{1.176} \approx 15$   
 $\log 250 = 2.397$ , since  $10^{2.397} \approx 250$   
 $\log 4000 = 3.602$ , since  $10^{3.602} \approx 4000$

The log values seen here can be found by using either log tables or a scientific calculator. Because most logarithms are irrational numbers, the values given in any example and in the tables are approximations, rounded to several decimal places. When a calculator is used, the answer should be rounded to four or five decimal places.

The whole number part of a logarithm is called the *characteristic*; the decimal portion is called the *mantissa*. In the examples above, the characteristics are 1, 2, and 3, respectively, which correspond to the power of 10 of the antilog when it is written in scientific notation:

$$\begin{aligned}\log 15 &= \log (1.5 \times 10^1) = \log 1.5 + \log 10^1 = 0.176 + \mathbf{1} \approx 1.176 \\ \log 250 &= \log (2.5 \times 10^2) = \log 2.5 + \log 10^2 = 0.397 + \mathbf{2} \approx 2.397 \\ \log 4000 &= \log (4.0 \times 10^3) = \log 4.0 + \log 10^3 = 0.602 + \mathbf{3} \approx 3.602\end{aligned}$$

The property  $\log(ab) = \log a + \log b$  has been applied; the “log  $b$ ” portion (characteristic) is quickly determined, as it is simply the power of 10 (bold). The “log  $a$ ” portion (mantissa) is read from the log table, which gives logs of numbers from 1 to 10 up to a certain number of decimal places. If the log of a number less than 1 is to be found, again, the antilog is represented in scientific notation to get to the answer, only now the characteristic is negative, so a subtraction is involved. For example:

$$\log 0.63 = \log(6.3 \times 10^{-1}) = (\log 6.3) + \log(-\mathbf{1}) = 0.799 + (-\mathbf{1}) \approx -0.201$$

**Natural Logarithms.**—In certain formulas and in some branches of mathematical analysis, use is made of the *natural* logarithm. The base of this system is given as  $e$ , which is the symbol for the irrational number that is approximately equal to 2.7182818284. (Recall that an irrational number cannot be represented by a repeating or terminating decimal.)  $e$  is the base of exponential growth phenomena such as populations and compound interest, among others. Though  $e$  was first conceptualized by John Napier (who developed logarithmic calculation) and developed further by Jacob Bernoulli, the use of  $e$  credits eighteenth-century Swiss mathematician Leonhard Euler (pronounced “oiler”), who developed mathematical analysis, in part, through his discovery of the so-called Euler identity,  $e^{i\pi} = -1$ .

It is conventional to write  $\log_e x$  as “ $\ln x$ ”; hence:

$$\ln x = y \text{ means } \log_e x = y, \text{ that is, } x = e^y$$

So, for example,  $\ln e = 1$ , since  $e^1 = e$ ;  $\ln 1 = 0$ , since  $e^0 = 1$ ;  $\ln e^3 = 3 \ln e = 3 \cdot 1 = 3$ . And, the process of finding logarithm values in base  $e$  is the same as in base 10.

*Example:* To represent  $\ln 0.239$  as a sum of natural logs:  $\ln(2.39 \times 10^{-1}) = \ln 2.39 + \ln 10^{-1} = \ln 2.39 + (-1)\ln 10$ .

Logarithms in any base can be converted to another base by the formula:  $\log_b x = \frac{\log_a x}{\log_a b}$

Logarithms of bases other than 10 and  $e$  were often converted to these bases, since the values were easy to look up on the common or natural log tables. The formula also can convert between the two most-often used bases:

$$\text{Base } e \text{ to base } 10: \quad \ln x = \frac{\log x}{\log e} \approx \frac{\log x}{0.4343} \quad \text{so} \quad \log x \approx 0.4343 \ln x$$

$$\text{Base } 10 \text{ to base } e: \quad \log x = \frac{\ln x}{\ln 10} \approx \frac{\ln x}{2.3026} \quad \text{so} \quad \ln x \approx 2.3026 \log x$$

*Example:* Convert  $\ln 4$  to  $\log 4$  using the conversion,  $\log x \approx 0.4343 \ln x$ :

$$\log 4 \approx 0.4343 \ln 4 \approx (0.4343)(1.3863) \approx 0.60207$$

*Example:* Express  $\log_2 9$  in terms of the natural logarithm:

$$\log_2 9 = \frac{\log_e 9}{\log_e 2} = \frac{\ln 9}{\ln 2} \approx 3.170$$

**Using Calculators to Solve Logarithms.**—To find a common logarithm on a scientific calculator (hand-held or online), the **log** key is used. To find a natural logarithm the **ln** key is used. Depending on the calculator used, either the number is entered before the log key is pressed, or log is entered before the number. The correct sequence can be seen if an error message results. For example,  $\log 6$  is found by this sequence on the typical scientific calculator:

*Example:* To find  $\log 6$ , press in sequence,  $\boxed{6} \boxed{\log}$  to get display

$\boxed{0.77815125038 \dots}$

To find the common antilog of a given number, the **10<sup>x</sup>** key is used. To find the natural antilog, the **e<sup>x</sup>** key is used. This kind of problem is often asked as  $\ln x = 4$ , meaning  $e^4 = x$ , so one must know the definition of  $\log_b x = y$  to get the answer by calculator.

*Example:* To find  $x$  in  $\ln x = 4$ , press in sequence,  $\boxed{4} \boxed{e^x}$  get the display

$\boxed{54.5980015003 \dots}$

On calculators without the **10<sup>x</sup>** and **e<sup>x</sup>** keys, the **x<sup>y</sup>** key enables, substituting 10 or  $e$  (2.718281 . . .) for  $x$  and the logarithm of the number sought for  $y$ . On some calculators, while the **log** and **ln** keys are used to find common and natural logarithms, the same keys in combination with the **INV**, or inverse, key are used to find the number corresponding to a given logarithm.

**Solving an Equation Using Logarithms.**—Solving exponential and logarithmic equations is possible because of the following properties of logs and exponents, which are true for any base:

If  $x = y$ , and  $x, y > 0$ , then  $\log x = \log y$ .      If  $x = y$ , then  $a^x = a^y$  for  $a > 0, a \neq 1$ .

Both statements are true in the other direction, too:

If  $\log x = \log y$ , then  $x = y$ .      If  $a^x = a^y$  then  $x = y$ .

*Example 1:* Find the square root of 754.

*Solution:* Let  $x = \sqrt{754}$ . Then  $\log x = \log \sqrt{754} = \log 754^{1/2} = \frac{1}{2} \log 754 \approx \frac{2.8774}{2} \approx 1.4387$ .

So,  $\log x \approx 1.4387$ , hence,  $x = 10^{1.4387} \approx 27.460$ . That is,  $\sqrt{754} \approx 27.460$ .

*Example 2:* Solve  $4^x = 7^{x-3}$  for  $x$ .

*Solution:*  $4^x = 7^{x-3} \xrightarrow{\text{apply property}} \log 4^x = \log 7^{x-3} \rightarrow x \log 4 = (x-3)(\log 7)$

$$\xrightarrow{\text{distribute on the right}} x \log 4 = x \log 7 - 3 \log 7 \xrightarrow{\text{by calculator}} 0.6021x = 0.8451x - 3(0.8451)$$

$$\xrightarrow{\text{proceed with algebra}} 3(0.8451) = 0.8451x - 0.6021x \rightarrow 2.5353 = 0.243x, \quad \text{so } x = 10.433$$

The technique of taking the log (either common, natural, or other) of both sides of an equation is used often to solve for unknown exponents, as happens with compounding of interest (see *ENGINEERING ECONOMICS* on page 143).

### Arithmetic Sequence

An arithmetic sequence (also called an arithmetic progression) is a sequence of numbers in which each term differs from the preceding one by a fixed amount, called the *common difference*,  $d$ . Thus, 1, 3, 5, 7, etc. is an arithmetic sequence where the difference  $d$  is 2. Here, the consecutive terms of the sequence are increasing by 2. In the sequence 13, 10, 7, 4, etc., the difference is  $-3$ , and the sequence is decreasing. In any arithmetic progression (or portion of one):

$a$  = first term of the sequence, also called the  $a_1$  term

$l$  = last term considered, also called  $a_n$  for the  $n$ th term

$n$  = number of terms

$d$  = common difference

$S_n$  = sum of  $n$  terms

The formula for the last term is  $l = a + (n - 1)d$ , or  $a_n = a_1 + (n - 1)d$ . The sum of an arithmetic sequence with  $n$  terms is  $S_n = \frac{n(a + l)}{2}$  or  $\frac{n(a_1 + a_n)}{2}$ .

In these formulas,  $d$  is positive when the progression is increasing and negative when it is decreasing. When any three of the preceding five quantities are given, the other two can be found by the formulas in the table *Arithmetic Sequence Formulas* on page 40. Often, however, the desired quantity can be determined by working with the information given.

*Example 1:* In a given arithmetic progression, the first term is 5 and the last term 40, and the difference between terms is 7. To find the sum of the progression, first the number of terms has to be found. This is done by considering the difference between the first and last:  $40 - 5 = 35$ . Dividing this by the difference between terms gives the number of intervals between the terms:  $35 \div 7 = 5$ . Finally, adding 1 gives the number of terms in the sequence:  $n = 5 + 1 = 6$ . The sum of the sequence is:

$$S = \frac{n}{2} (a + l) = \frac{6}{2} (5 + 40) = 3(45) = 135$$

### Geometric Sequence

A geometric sequence or progression is a sequence of numbers in which each term is derived by multiplying the preceding term by a constant multiplier called the *ratio*. When this ratio is greater than 1, the progression is increasing; when less than 1, it is decreasing. Thus, the sequence 2, 6, 18, 54, etc. is an increasing geometric sequence with a ratio of 3, and the sequence 24, 12, 6, etc. is a decreasing sequence with a ratio of  $1/2$ .

In any geometric progression (or part of progression):

$a$  = first term of the sequence

$l$  = last (or  $n$ th) term of the sequence

$n$  = number of terms

$r$  = ratio of the progression

$S_n$  = sum of  $n$  terms

The general formulas for the  $n$ th term:  $l = ar^{n-1}$  and  $S = \frac{rl - a}{r - 1}$

When any three of the preceding five quantities are given, the other two can be found by the formulas in the table *Geometric Sequence Formulas* on page 41. Geometric progressions are used for finding the successive speeds in machine tool drives, and in interest calculations.

*Example 2:* The lowest speed of a lathe is 20 rpm. The highest speed is 225 rpm. There are 18 speeds. Find the ratio between successive speeds.

$$\text{Ratio } r = n - 1 \sqrt[n-1]{\frac{l}{a}} = 17 \sqrt[17]{\frac{225}{20}} = 17 \sqrt[17]{11.25} = 1.153$$

**Arithmetic Sequence Formulas**

To Find	Given	Use Formula
<i>a</i>	<i>d l n</i>	$a = l - (n - 1)d$
	<i>d n S</i>	$a = \frac{S}{n} - \frac{n-1}{2} \times d$
	<i>d l S</i>	$a = \frac{d \pm \frac{1}{2} \sqrt{(2l + d)^2 - 8dS}}{2}$
	<i>l n S</i>	$a = \frac{2S}{n} - l$
<i>d</i>	<i>a l n</i>	$d = \frac{l - a}{n - 1}$
	<i>a n S</i>	$d = \frac{2S - 2an}{n(n - 1)}$

	<i>l n r</i>	$S = \frac{l(r^n - 1)}{(r-1)r^{n-1}}$

## GEOMETRY

Geometry is the branch of mathematics that studies the features of two- and three-dimensional figures. (The word “geometry” means “measure of the earth.”) This branch can be separated into *pure geometry* and *analytic geometry*. Pure geometry is concerned with the propositions of shape, size, and relative position of figures, as well as their constructions. Analytic geometry studies geometry using the coordinate system, relying heavily on algebraic principles. The results of geometry apply to many areas of industry.

The first part of this section, addressing analytic geometry, may be considered a continuation of the material in *ALGEBRA*, which begins on page 24. The rest of the section focuses on pure geometry, particularly the formulas for figure dimensions and figure construction; these are based on the concepts introduced by the Greek mathematician Euclid, in the fourth century BCE. Included are examples showing how measures of diameter, perimeter, area, surface area, volume, angle, and more are determined. In the case of angle measure, use of trigonometry is often necessary. Explanations of trigonometric relations are found in the next section, *TRIGONOMETRY*, beginning on page 94.

## Analytic Geometry

Analytic geometry uses algebra to model geometric objects, such as points, lines, and circles, on the rectangular coordinate system.

**Rectangular Coordinate System.**—The *rectangular coordinate system* (also called the *xy-plane* or the *Cartesian plane*) is a grid formed by intersecting two real number lines at right angles (Fig. 1a). The horizontal *x-axis* (labeled *X*) intersects the vertical *y-axis* (labeled *Y*) at the point (0, 0), the *origin*. Any point *P* on the plane can be so identified by its *x-coordinate* and its *y-coordinate* in the *ordered pair* (*x*, *y*).

The four quadrants formed by the *x-* and *y-*axes are numbered counterclockwise (see Fig. 1a). In Quadrant 1, both *x* and *y* coordinates are positive; in Quadrant 2, the *x* is negative and *y* is positive; in Quadrant 3, both coordinates are negative; and in Quadrant 4, the *x-coordinate* is positive and the *y* negative. Several representative points are pictured in Fig. 1b.

Fig. 1. (a) Rectangular Coordinate System;

(b) Examples of Points in Each Quadrant.

The rectangular coordinate system is used to illustrate ideas in algebra, analytic geometry, and trigonometry.

**Slope of a Line.**—The *slope* of the line passing through any two points ( $x_1, y_1$ ) and ( $x_2, y_2$ ) in the plane is given by  $m = \frac{\Delta y}{\Delta x} = \frac{y_2 - y_1}{x_2 - x_1}$ , where  $\Delta$  represents difference. Fig. 2a shows a line with a positive slope, Fig. 2b a line with a negative slope. A horizontal line (Fig. 2c)

has a no slope, since  $\Delta y = 0$ . Hence,  $m = 0/\Delta x = 0$ . Between any two points on a vertical line,  $\Delta x = 0$  (Fig. 2d). So,  $m = \Delta y/0$ , which is undefined.

Fig. 2. Lines with (a) Positive Slope,  $m > 0$ ; (b) Negative Slope,  $m < 0$ ; (c) No Slope,  $m = 0$ ; (d) Undefined Slope.

**Lines and Line Segments.**—A *line* in the plane is the shortest path between two known points, extending indefinitely in both directions. “Line  $AB$ ” is notated  $\overleftrightarrow{AB}$ . A *line segment* is the portion of the line between  $A$  and  $B$ . The line segment  $AB$  is notated  $\overline{AB}$ ; its length is indicated without the bar, as  $AB$ . The distinction between the actual line and its length is helpful to keep in mind when referring to the formulas for distance, midpoint, and the other concepts in this section.

**Distance Between Two Points:** The distance  $d$  between two points  $A$  and  $B$  is the length of the line segment connecting them. The formula comes from the Pythagorean theorem, which says that the sum of the squares of the leg measures is the square of the hypotenuse. As labeled in Fig. 3, the legs are lengths  $x_2 - x_1$  and  $y_2 - y_1$ , and the hypotenuse is the distance  $d$  between these points. Its formula is:

$$d(A, B) = AB = \sqrt{(x_2 - x_1)^2 + (y_2 - y_1)^2}$$

Fig. 3. Distance between points  $A$  and  $B$ .

The order in which  $x$  and  $y$  are subtracted actually does not matter, since the squared difference is the same.

**Example 1:** Find  $AB$ , the distance between points  $A(4, 5)$  and  $B(7, 8)$ .

**Solution:** The length of line segment  $AB$  is:

$$d = \sqrt{(7-4)^2 + (8-5)^2} = \sqrt{3^2 + 3^2} = \sqrt{18} = 3\sqrt{2}$$

**Midpoint of a Line Segment:** The midpoint  $M(x, y)$  of line segment  $AB$  is found by the coordinate formulas (Fig. 4a):

$$x = \frac{x_1 + x_2}{2} \quad \text{and} \quad y = \frac{y_1 + y_2}{2}$$

**Internal Division of a Line Segment:** Point  $P$  divides line segment  $AB$  (Fig. 4b) in the ratio  $m:n$ . That is,  $P$  is such a point that  $AP:PB$  as  $m:n$ . Then, the coordinates of  $P$  are given by:

$$x = \frac{mx_1 + nx_2}{m + n} \quad \text{and} \quad y = \frac{my_1 + ny_2}{m + n}$$

If the desired point is the *midpoint* of  $AB$ , then  $m = n = 1$ , and the coordinates of  $P$  are:

$$x = \frac{x_1 + x_2}{2} \quad \text{and} \quad y = \frac{y_1 + y_2}{2}$$

*Example 2:* Find the coordinates of a point  $P$  that divides the line segment defined by  $A(0, 0)$  and  $B(8, 6)$  at a ratio of 5:3.

$$\text{Solution: } x = \frac{5 \times 0 + 3 \times 8}{5 + 3} = \frac{24}{8} = 3 \quad y = \frac{(5)(0) + (3)(6)}{5 + 3} = \frac{18}{8} = 2.25$$

*External Division of a Line Segment:* If the line segment  $AB$  is extended to point  $Q$  (Fig. 4c), and  $Q$  is such a point that  $AQ:QB$  as  $m:n$ , then the coordinates of  $Q$  are given by:

$$x = \frac{mx_1 - nx_2}{m - n} \quad \text{and} \quad y = \frac{my_1 - ny_2}{m - n}$$

Fig. 4. Divisions of Line Segment  $AB$ :  
(a) Midpoint  $M$ ; (b) Internal Division Point  $P$ ; (c) External Division Point  $Q$ .

**Equation Forms of a Line.**—Given any two known points, a linear equation can be expressed in either *point-slope* or *slope-intercept* form.

*Point-Slope Form:* Consider that  $m = \frac{y_2 - y_1}{x_2 - x_1}$  for any two points  $(x, y)$  on a line. If the known point  $(x_2, y_2)$  is replaced with an arbitrary (not specified) point  $(x, y)$ , the slope becomes  $m = \frac{y - y_1}{x - x_1}$ , which rearranges to  $y - y_1 = m(x - x_1)$ . This is the *point-slope form* of the line. If  $x_1 = y_1 = 0$  (that is, the line passes through the origin  $(0, 0)$ ), then the equation becomes  $y - 0 = m(x - 0)$ , or  $y = mx$ . For any line, the  $y$ -intercept is the point of intersection of the line with the  $y$ -axis, and the  $x$ -intercept is the point of intersection of the line with the  $x$ -axis. Thus, the points  $(0, y_1)$  and  $(x_1, 0)$  are the  $y$ - and  $x$ -intercepts, respectively.

Suppose  $\overleftrightarrow{AB}$  intersects the  $x$ -axis at point  $A(a, 0)$  and the  $y$ -axis at point  $B(0, b)$ ; then  $m = \frac{0 - b}{a - 0} = \frac{-b}{a}$ . Substitution of either  $(a, 0)$  or  $(0, b)$  into the formula and rearranging terms gives the equation for  $\overleftrightarrow{AB}$ :  $y - 0 = -\frac{b}{a}(x - a) \rightarrow ay = -bx + ab \rightarrow ay + bx = ab \rightarrow \frac{y}{b} + \frac{x}{a} = 1$ .

Generally, two points are known, and from these,  $m$  is determined. Then, either of the points are substituted into the point-slope form along with the slope to get the equation of the line.

*Example 3:* Find the equation of the line that passes through  $(4, 1)$  and  $(-2, 5)$ . So,

$$m = \frac{1 - 5}{4 - (-2)} = \frac{-4}{6} = -\frac{2}{3}$$

Substituting this value for  $m$  and the point  $(4, 1)$  for  $(x_1, y_1)$  into the point-slope form gives  $y - 1 = -\frac{2}{3}(x - 4)$ .

**Point-Point Form:** Substituting  $m = \frac{y_2 - y_1}{x_2 - x_1}$  into the point-slope form and rearranging terms gives  $y - y_1 = \frac{y_1 - y_2}{x_1 - x_2}(x - x_1)$ , the *point-point form*.

**Slope-Intercept Form:** Another often-used form is  $y = mx + b$ , where  $m$  is the slope and  $b$  is the  $y$ -intercept. (That is, when  $x = 0$ , then  $y = m(0) + b = b$ .) If the previous example is rearranged and solved for  $y$ , then the *slope-intercept form* is arrived at:  $y = -\frac{2}{3}(x - 4) + 1 = -\frac{2}{3}x + \frac{8}{3} + 1 = -\frac{2}{3}x + \frac{11}{3}$ .

**Standard Form of a Line:** In vector representations (see *Complex Numbers* on page 59), lines usually take the standard form,  $Ax + By = C$ , where  $A$ ,  $B$ ,  $C$ . For example,  $7x - 3y = 4$  is a line in standard form, with  $A = 7$ ,  $B = -3$ , and  $C = 4$ .

**Example 4:** What is the standard form equation of a line  $AB$  between points  $A(4, 5)$  and  $B(7, 8)$ ?

**Solution:** Using the point-point form of the line, where  $(4, 5)$  is  $(x_1, y_1)$  and  $(7, 8)$  is  $(x_2, y_2)$ ,

$$y - y_1 = \frac{y_1 - y_2}{x_1 - x_2}(x - x_1)$$

$$y - 5 = \frac{5 - 8}{4 - 7}(x - 4)$$

$$y - 5 = x - 4$$

$$x - y = -1$$

**Example 5:** Find the slope-intercept equation of a line passing through the points  $(3, 2)$  and  $(5, 6)$ . The  $y$ -intercept is the intersection point of the line with the  $y$ -axis.

**Solution:** First, find the slope:

$$m = \frac{\Delta y}{\Delta x} = \frac{6 - 2}{5 - 3} = \frac{4}{2} = 2$$

The slope-intercept form of the line is  $y = 2x + b$ , and the value of the constant  $b$  can be determined by substituting the coordinates of a point on the line into the general form. Using the coordinates of the point  $(3, 2)$  gives  $2 = (2)(3) + b$  and rearranging,  $b = 2 - 6 = -4$ . As a check, using another point on the line,  $(5, 6)$ , yields the same result,  $y = 6 = (2)(5) + b$  and  $b = 6 - 10 = -4$ .

The equation of the line, therefore, is  $y = 2x - 4$ , indicating that line  $y = 2x - 4$  intersects the  $y$ -axis at point  $(0, -4)$ , the  $y$ -intercept.

**Example 6:** Use the point-slope form to find the equation of the line passing through the point  $(3, 2)$  and having a slope of 2.

$$y - 2 = 2(x - 3)$$

$$y = 2x - 6 + 2$$

$$y = 2x - 4$$

The slope of this line is positive and crosses the  $y$ -axis at the  $y$ -intercept, point  $(0, -4)$ .

**Parallel Lines:** The two lines,  $l_1$  and  $l_2$ , are parallel if they have the same slope, that is, if  $m_1 = m_2$ .

Fig. 5. (a) Parallel lines,  $l_1$  and  $l_2$ .

(b) Perpendicular lines,  $l_1$  and  $l_2$ .

**Perpendicular Lines:** The two lines,  $l_1$  and  $l_2$ , are perpendicular if the product of their slopes is  $-1$ , that is, if  $m_1 m_2 = -1$ , since  $m_1 = -1/m_2$ . (The slopes are negative reciprocals of one another.)

**Example 7:** (a) Find the equation of the line that passes through the point (3, 4) and is parallel to line  $2x - 3y = 16$ . (b) Find the equation of the line perpendicular to the given line and through the same point.

**Solution (a):** Line  $2x - 3y = 16$  in slope-intercept form is  $y = \frac{2}{3}x - \frac{16}{3}$ , so the equation of a line passing through (3, 4) is  $y - 4 = m(x - 3)$ .

Parallel lines have equal slope. Thus, from the point-slope form,  $y - 4 = \frac{2}{3}(x - 3)$  is parallel to line  $2x - 3y = -6$  and passes through point (3, 4).

**Solution (b):** As illustrated in part (a), line  $2x - 3y = -6$  has a slope of  $\frac{2}{3}$ . The product of the slopes of perpendicular lines is  $-1$ , thus the slope  $m$  of a line passing through point (3, 4) and perpendicular to  $2x - 3y = -6$  must satisfy the following:

$$m = \frac{-1}{m_1} = \frac{-1}{\frac{2}{3}} = -\frac{3}{2}$$

The equation of a line passing through point (3, 4) and perpendicular to the line  $2x - 3y = 16$  is  $y - 4 = -\frac{3}{2}(x - 3)$ , which rewritten is  $3x + 2y = 17$ .

**Angle Between Two Lines:** For two non-perpendicular lines with slopes  $m_1$  and  $m_2$ , the angle  $\theta$  between the two lines is found by first applying trigonometric equation:

$$\tan \theta = \left| \frac{m_1 - m_2}{1 + m_1 m_2} \right|$$

The discussion of how the angle is determined by this relation is found in **TRIGONOMETRY**, which begins on page 94.

**Example 8:** Find the angle between the lines:  $2x - y = 4$  and  $3x + 4y = 12$ .

**Solution:** Rearranging each to be in the slope-intercept form shows the slopes are 2 and  $-\frac{3}{4}$ , respectively. The angle between two lines is given by

$$\tan \theta = \left| \frac{m_1 - m_2}{1 + m_1 m_2} \right| = \left| \frac{2 - \left(-\frac{3}{4}\right)}{1 + 2\left(-\frac{3}{4}\right)} \right| = \left| \frac{2 + \frac{3}{4}}{1 - \frac{6}{4}} \right| = \left| \frac{\frac{8+3}{4}}{\frac{4-6}{4}} \right| = \left| \frac{11}{-2} \right| = \frac{11}{2}$$

$$\theta = \tan^{-1}\left(\frac{11}{2}\right) = 79.70^\circ, \text{ by trigonometry.}$$

**Distance Between a Point and a Line:** The distance between a point  $(x_1, y_1)$  and a line given in the standard form  $Ax + By + C = 0$  is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

**Example 9:** Find the distance between the point (4, 6) and the line  $2x + 3y - 9 = 0$ .

**Solution:** Using the formula:

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}} = \frac{|2 \times 4 + 3 \times 6 - 9|}{\sqrt{2^2 + 3^2}} = \frac{|8 + 18 - 9|}{\sqrt{4 + 9}} = \frac{17}{\sqrt{13}}$$

**Changing Coordinate Systems.**—For simplicity it may be assumed that the origin in the Cartesian coordinate system coincides with the pole on a polar coordinate system and its  $x$ -axis with the polar horizontal axis. Then, if point  $P$  has polar coordinates of  $(r, \theta)$  and Cartesian coordinates of  $(x, y)$ , by trigonometry  $x = r \cos \theta$  and  $y = r \sin \theta$ .

Furthermore, by the Pythagorean theorem and trigonometry,  $r = \sqrt{x^2 + y^2}$  and  $\theta = \tan^{-1}\left(\frac{y}{x}\right)$ . See **TRIGONOMETRY** on page 94 for a discussion of the related principles of trigonometry.

*Example 1:* Convert the Cartesian coordinate (3, 2) into polar coordinates.

$$r = \sqrt{3^2 + 2^2} = \sqrt{9 + 4} = \sqrt{13} \approx 3.6 \quad \theta = \tan^{-1}\left(\frac{2}{3}\right) = 33.69^\circ$$

Therefore the point is located approximately 3.6 units from the origin at an angle of about  $33.69^\circ$ . Thus, (3.6,  $33.69^\circ$ ) is the polar form of the Cartesian point (3, 2).

Graphically, the polar and Cartesian coordinates are related in the following figure:

*Example 2:* Convert the polar form (5,  $608^\circ$ ) to Cartesian coordinates. First note that this point lies 5 units from the origin at an angle of  $608^\circ$ . As explained on page 105, in **Trigonometric Functions**, this locates the point in Quadrant IV. By trigonometry,  $x = r \cos \theta$  and  $y = r \sin \theta$ . Then,  $x = 5 \cos(608^\circ) = -1.873$  and  $y = 5 \sin(608^\circ) = -4.636$ . Therefore, the Cartesian point equivalent is  $(-1.873, -4.636)$ . This point lies in the fourth quadrant, where both coordinates are negative.

**Spherical Coordinates.**—It is convenient in certain problems, for example, those concerned with spherical surfaces and therefore three-dimensional, to introduce spherical coordinates. In three-dimensional space, as the figure on the right shows, the  $x, y$ -plane is like a floor in a room, and the third dimension is given by the  $z$ -axis, which is where the walls of the room meet. An arbitrary point  $P$  in this space is described by three rectangular coordinates  $(x, y, z)$ , converted to the following *spherical coordinates*: the distance  $r$  between point  $P$  and the origin  $O$ , the angle  $\phi$  that  $OP$  makes with the  $x, y$ -plane, and the angle  $\lambda$  that the projection  $OP'$  (the “shadow” of the segment  $OP$  on the  $x, y$ -plane) makes with the positive  $x$ -axis.

The rectangular coordinates of a point in space can therefore be calculated from the spherical coordinates, and vice versa, by use of the formulas in the following table.

**Relationship Between Spherical and Rectangular Coordinates**

Spherical to Rectangular	Rectangular to Spherical
$x = r \cos \phi \cos \lambda$ $y = r \cos \phi \sin \lambda$ $z = r \sin \phi$	$r = \sqrt{x^2 + y^2 + z^2}$
	$\phi = \tan^{-1} \frac{z}{\sqrt{x^2 + y^2}}$ for $x^2 + y^2 \neq 0$
	$\lambda = \tan^{-1} \left( \frac{y}{x} \right)$ for $x > 0, y > 0$
	$\lambda = \pi + \tan^{-1} \left( \frac{y}{x} \right)$ for $x < 0$
	$\lambda = 2\pi + \tan^{-1} \left( \frac{y}{x} \right)$ for $x > 0, y < 0$

*Example 3:* Find the spherical coordinates of the point  $P(3, -4, -12)$ .

$$r = \sqrt{3^2 + (-4)^2 + (-12)^2} = 13$$

$$\phi = \tan^{-1} \frac{-12}{\sqrt{3^2 + (-4)^2}} = \tan^{-1} \left( -\frac{12}{5} \right) = -67.38^\circ$$

$$\lambda = 360^\circ + \tan^{-1} \left( -\frac{4}{3} \right) = 360^\circ - 53.13^\circ = 306.87^\circ$$

The spherical coordinates of  $P$  are therefore  $r = 13, \phi = -67.38^\circ$ , and  $\lambda = 306.87^\circ$ .

*Cylindrical Coordinates:* For problems in which points lie on the surface of a cylinder it is convenient to use cylindrical coordinates. The cylindrical coordinates  $r, \theta, z$  of  $P$  coincide with the polar coordinates of the point  $P'$  in the  $x, y$ -plane and the rectangular  $z$ -coordinate of  $P$ . Formulas for  $\theta$  hold only if  $x^2 + y^2 \neq 0$ ;  $\theta$  is undetermined if  $x = y = 0$ .

Cylindrical to Rectangular	Rectangular to Cylindrical
$x = r \cos \theta$ $y = r \sin \theta$ $z = z$	$r = \frac{\sqrt{x^2 + y^2}}{1}$
	$\cos \theta = \frac{x}{\sqrt{x^2 + y^2}}$
	$\sin \theta = \frac{y}{\sqrt{x^2 + y^2}}$
	$z = z$

*Example 4:* Given the cylindrical coordinates of a point  $P, r = 3, \theta = -30^\circ, z = 51$ , find the rectangular coordinates. Using the above formulas  $x = 3 \cos(-30^\circ) = 3 \cos(30^\circ) = 2.598$ ;  $y = 3 \sin(-30^\circ) = -3 \sin(30^\circ) = -1.5$ ; and  $z = 51$ . Therefore, the rectangular coordinates of point  $P$  are  $x = 2.598, y = -1.5$ , and  $z = 51$ .

**Circle.**—A circle is the set of points equidistant from a given point in the plane. Another name for this set of points is *locus*, which is a curve formed by all the points satisfying a particular equation. The general form for the equation of a circle is  $x^2 + y^2 + 2gx + 2fy + c = 0$ , where  $-g$  and  $-f$  are the coordinates of the center and the radius is  $r = \sqrt{g^2 + f^2 - c}$ .

The standard form of a circle (center-radius form) is

$$(x - h)^2 + (y - k)^2 = r^2$$

where  $r$  = length of the radius and point  $(h, k)$  is the center.

When the center of circle is at point  $(0, 0)$ , the equation

$$\text{reduces to } x^2 + y^2 = r^2 \quad \text{or} \quad r = \sqrt{x^2 + y^2}$$

*Example 1:* Point  $(4, 6)$  lies on a circle whose center  $(h, k)$  is at point  $(-2, 3)$ . Find the circle's equation.

*Solution:* The radius is the distance from the center point  $(-2, 3)$  to point  $(4, 6)$ , found using the method of **Example 1** on page 43.

$$r = \sqrt{[4 - (-2)]^2 + (6 - 3)^2} = \sqrt{6^2 + 3^2} = \sqrt{45}$$

Using the form  $(x - h)^2 + (y - k)^2 = r^2$   
and substituting  $h = -2, k = 3$ , and  $r^2 = 45$ :

$$\begin{aligned}(x + 2)^2 + (y - 3)^2 &= x^2 + 4x + 4 + y^2 - 6y + 9 = 45 \\ x^2 + y^2 + 4x - 6y - 32 &= 0\end{aligned}$$

**Additional Formulas:** Listed below are additional formulas for determining the geometry of plane circles and arcs. Although trigonometry and circular measure are related, they deal with angles in entirely different ways. In each of these formulas, the entered measure of the angles are in degrees, and the formulas convert them to radian measure (see page 94, in **TRIGONOMETRY**).

$$C = \pi D = 2\pi R$$

$$\text{Radius } R = \sqrt{X^2 + Y^2}$$

$$\text{Diameter } D = \text{diameter of circle} = 2R = \frac{C}{\pi}$$

$$\text{Area } A = \pi R^2$$

$$X = \sqrt{R^2 - Y^2}$$

$$Y = \sqrt{R^2 - X^2}$$

$$\text{Area of complement sector } M$$

$$= R^2 - \frac{\pi R^2}{4} = 0.2146R^2$$

$$I = \text{distance to section } T$$

$$H = \text{height of section } T$$

$$Q = \text{chord length for segment } S$$

$$P = \text{chord length for segment section } T$$

$$T + S = \text{area of segment} = R^2 \sin^{-1}\left(\frac{P}{2R}\right) - \frac{IP}{2}$$

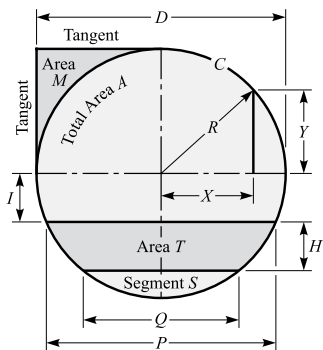

Fig. 6a.

$$\text{Central angle } \phi, \text{ in degrees} = \frac{L}{R} \cdot \frac{\pi}{180}$$

$$\text{Arc length } L = R\phi \cdot \frac{\pi}{180}$$

$$\text{Radius } R = \frac{L}{\phi} \cdot \frac{\pi}{180} = \frac{2K}{L} = \frac{E^2 + 4F^2}{8F}$$

$$\text{Area of sector } K = \phi R^2 \cdot \frac{\pi}{360} = \frac{RL}{2}$$

$$\text{Area of segment } S = \frac{RL}{2} - \frac{E(R-F)}{2}$$

$$\text{Chord length } E = 2\sqrt{F(2R-F)} = D \sin\left(\frac{\phi}{2}\right)$$

$$\text{Depth } F = R - \frac{\sqrt{4R^2 - E^2}}{2} = R \left(1 - \cos\left(\frac{\phi}{2}\right)\right)$$

$$\tan\left(\frac{\phi}{2}\right) = \frac{E/2}{R-F}$$

$$\sin\left(\frac{\phi}{2}\right) = \frac{E}{2R}$$

Fig. 6b.

**Annulus**

$R_1$  = radius of outer circle

$R_2$  = radius of inner circle

Area of annulus  $W = \pi(R_1^2 - R_2^2)$

Area of annulus segment  $U = \frac{\phi}{360} \pi(R_1^2 - R_2^2)$

Fig. 6c.

**Example 2:** Find the area of a sector of a circle having a central angle of  $30^\circ$  and a radius of 7 cm.

**Solution:** Referring to Fig. 6b,  $K = \left(\frac{\phi^\circ}{360}\right) \pi \times R^2 = \left(\frac{30}{360}\right) \pi \times 7^2 = 12.83 \text{ cm}^2$

**Example 3:** Find the chord length  $E$  of a circular segment (Fig. 6b) with a depth of 2 cm at the center that is formed in a circle whose radius 12 cm.

**Solution:** The chord length is

$$\begin{aligned} E &= 2\sqrt{F(2R-F)} = 2\sqrt{2[(2)(12)-2]} = 2\sqrt{44} \\ &= 4\sqrt{11} = 13.27 \text{ cm} \end{aligned}$$

**Example 4:** Find the area  $S$  of the segment in Example 3.

**Solution:** First determine angle  $\phi$ , then find arc length  $L$  of the segment, and then solve for area  $S$ , as follows:

$$\tan\left(\frac{\phi}{2}\right) = \frac{E/2}{R-F} = \frac{13.27/2}{12-2} = 0.6635, \quad \frac{\phi}{2} = \tan^{-1}0.6635 = 33.56^\circ, \quad \phi = 67.13^\circ$$

$$L = R\phi \times \frac{\pi}{180} = 12 \times 67.13^\circ \times \frac{\pi}{180} = 14.06 \text{ cm}$$

$$\text{Area } S = \frac{RL}{2} - \frac{E(R-F)}{2} = \frac{12(14.06)}{2} - \frac{13.27(10)}{2} = 84.36 - 66.35 = 18.01 \text{ cm}^2$$

Another way to find angle  $\phi$  is divide the chord length by twice the radius to obtain

$$\sin\left(\frac{\phi}{2}\right) = \frac{\text{chord length}}{2R} = \frac{E}{2R} = 0.5529, \quad \frac{\phi}{2} = \sin^{-1} 0.5529 = 33.5662^\circ, \quad \phi = 67.13^\circ$$

**Ellipse.**—As a circle is the locus of points equidistant from a single point in the plane, an *ellipse* is the set of points whose location is established by *two* points in the plane. Referring to the figure, these two points are the *foci*,  $F_1$  and  $F_2$ , which lie on the longer of the two diameters of the ellipse. The longer diameter  $a$  is the major axis; the shorter  $b$  is the minor axis. The sum of the distances from the foci to any point  $P$  on the ellipse is constant. That is  $PF_1 + PF_2 = 2a$ .

The latus rectum is the chord through the focus and perpendicular to the major axis.  $V_1$  and  $V_2$  are the vertices.

Like the circle, there is a general form and a standard form of the equation of an ellipse. The general form is:

$$Ax^2 + Cy^2 + Dx + Ey + F = 0 \Big|_{AC > 0} \text{ and } A \neq C$$

The constant  $F$  in this equation is not related to the foci, which are not numbers, but labels for points.

If  $(h, k)$  is the center, the standard equation of an ellipse is  $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$ .

The eccentricity  $e$  of the ellipse is given by  $e = c/a$ , where  $c^2 = a^2 - b^2$ . This is *not* the same  $e$  as the exponential base, which is a constant. Rather, eccentricity varies with

the figure.  $e = \frac{\sqrt{a^2 - b^2}}{a} = \frac{c}{a}$  is a measure of the elongation of the ellipse and is always less than 1. The distance between the two foci is  $2c = 2\sqrt{a^2 - b^2}$ . The aspect

ratio of the ellipse is  $a/b$ . The equation of an ellipse centered at  $(h, k) = (0, 0)$  with foci at  $(\pm c, 0)$  is  $\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1$ , and the ellipse is symmetric about both coordinate axes. Its

$x$ -intercepts are  $(\pm a, 0)$  and  $y$ -intercepts are  $(0, \pm b)$ . The line segment joining  $(0, b)$  and  $(0, -b)$  is called the minor axis. The major vertices of the ellipse are  $(\pm a, 0)$ , and the line segment joining vertices  $V_1$  and  $V_2$  is the major axis of the ellipse.

*Example 1:* Determine the values of  $h, k, a, b, c,$  and  $e$  of the following ellipse:

$$3x^2 + 5y^2 - 12x + 30y + 42 = 0$$

*Solution:* Rearrange the ellipse equation into the standard form as follows, using the method of completing the square (see page 34):

$$\begin{aligned} 3x^2 + 5y^2 - 12x + 30y + 42 &= 3x^2 - 12x + 5y^2 + 30y + 42 = 0 \\ 3(x^2 - 4x + 2^2) + 5(y^2 + 6y + 3^2) &= 15 \\ \frac{3(x-2)^2}{15} + \frac{5(y+3)^2}{15} &= \frac{(x-2)^2}{(\sqrt{5})^2} + \frac{(y+3)^2}{(\sqrt{3})^2} = 1 \end{aligned}$$

Comparing to the form  $\frac{(x-h)^2}{a^2} + \frac{(y-k)^2}{b^2} = 1$  and solving for  $c$  and  $e$  gives:

$$h = 2, \quad k = -3, \quad a = \sqrt{5}, \quad b = \sqrt{3}, \quad c = \sqrt{2}, \quad e = \frac{\sqrt{2}}{\sqrt{5}}$$

*Additional Formulas:* An ellipse can be represented "parametrically" by the equations  $x = a \cos \theta$  and  $y = b \sin \theta$ , where  $x$  and  $y$  are the rectangular coordinates of any point on the ellipse, and the parameter  $\theta$  is the angle at the center measured from the  $x$ -axis counterclockwise. The following figures correspond to the formulas below them for other measurements of the ellipse.

**Length, Point, and Angle Calculations**

$$R_1 = \text{radius of director circle} = \sqrt{A^2 + B^2}, \quad A = \text{major radius} = \sqrt{B^2 + P^2}$$

$$R_2 = \text{radius of equivalent circle} = \sqrt{AB}, \quad B = \text{minor radius} = \sqrt{A^2 - P^2}$$

$$P = \text{center to focus distance} = \sqrt{A^2 - B^2}, \quad \frac{2B^2}{A} = \text{distance, origin to latus rectum}$$

$$J = \text{any point } (X, Y) \text{ on curve where } X = A \sin \theta = A \cos \phi, \text{ and } Y = B \cos \theta = B \sin \phi$$

$$\phi = \text{angle with major axis} = \sin^{-1}\left(\frac{Y}{B}\right) = \cos^{-1}\left(\frac{X}{A}\right), \quad \theta = \text{angle with minor axis} = 90^\circ - \phi$$

$$L = \text{total perimeter (approximate)} = A \left[ 1.2 \left(\frac{B}{A}\right)^2 + 1.1 \left(\frac{B}{A}\right) + 4 \right]$$

$$L = \text{perimeter (sections)} = \left(\frac{\pi}{180}\right) 2\phi \sqrt{AB}$$

**Area Calculations**

$$N = \text{total surface area of ellipse} = \pi AB$$

$$W = \text{area between outer and inner ellipse} = \pi(A_1 B_1 - A_2 B_2)$$

$$M = \text{area of complement section } M = AB - \frac{\pi AB}{4}$$

$$S = \text{area of segment } S = AB \cos^{-1}\left(\frac{X_1}{A}\right) - X_1 Y_1, \text{ where the angle that results from the inverse cosine is in radian measure}$$

$$T+S = \text{combined area of segment } S + \text{area } T = AB \cos^{-1}\left(\frac{X_2}{A}\right) - X_2 Y_2, \text{ where the angle that results from the inverse cosine is in radian measure}$$

$$V = \text{area of segment } V = (R_2)^2 \sin^{-1}\left(\frac{X}{A}\right) - XY, \text{ where the angle that results from the inverse sine is in radian measure}$$

$$K = \text{area of sector } K = AB \cos^{-1}\left(\frac{X}{A}\right), \text{ where the angle that results from the inverse cosine is in radian measure}$$

**Example 2:** Find area of sector  $K$  and complement area  $M$ , given the major radius of ellipse is 10 cm, minor radius of ellipse is 7 cm, dimension  $X = 8.2266$  cm.

**Solution:** Sectional area  $K$ :

$$\text{Area } K = AB \cos^{-1}\left(\frac{X_1}{A}\right) = 10 \times 7 \times \cos^{-1}\left(\frac{8.2266}{10}\right) = 70 \times 0.6047 \text{ rad} = 42.33 \text{ cm}^2$$

**Solution:** Complement area  $M$ :

$$\text{Area } M = AB - \frac{\pi AB}{4} = 10 \times 7 - \frac{\pi \times 10 \times 7}{4} = 15.0221 \text{ cm}^2$$

**Example 3:** Find the area of elliptical segments  $S$ ,  $T + S$ , provided that major radius  $A$  of ellipse is 10 cm, minor radius  $B$  of ellipse is 7 cm, dimension  $X_1 = 8.2266$  cm, dimension  $Y_1 = 4.4717$  cm, and dimension  $X_2 = 6.0041$  cm.

**Solution:** Segment area  $S$  is found:

$$S = AB \cos^{-1}\left(\frac{X_1}{A}\right) - X_1 Y_1 = 10 \times 7 \times \cos^{-1}\left(\frac{8.2266}{10}\right) - 8.2266 \times 4.4717 = 5.5437 \text{ cm}^2$$

*Solution:* Segment area  $T + S$ :

$$\phi = \cos^{-1}\left(\frac{X_2}{A}\right) = 1.51072 \text{ rad}, \quad Y_2 = B \sin \phi = 7 \sin(1.51072 \text{ rad}) = 10.57504$$

$$\begin{aligned} T + S &= AB \cos^{-1}\left(\frac{X_2}{A}\right) - X_2 Y_2 = 10 \times 7 \times 0.9268 - (6.0041 \times 5.5978) \\ &= 64.876 - 33.6097 = 31.266 \text{ cm}^2 \end{aligned}$$

*Example 4:* Find the area of elliptical segment  $V$  if major radius of ellipse is 4 inches, minor radius is 3 inches, dimension  $X = 2.3688$  inches, dimension  $Y = 2.4231$  inches.

*Solution:* Segment area  $V$ :

$$R_2 = \sqrt{AB}, \quad (R_2)^2 = AB = 3 \times 4 = 12$$

$$\begin{aligned} V &= (R_2)^2 \sin^{-1}\left(\frac{X}{A}\right) - XY = 12 \sin^{-1}\left(\frac{2.3688}{4}\right) - (2.3688 \times 2.4231) \\ &= 7.6054 - 5.7398 = 1.8656 \text{ in}^2 \end{aligned}$$

**Four-Arc Oval Approximating an Ellipse\***—The method of constructing an approximate ellipse by circular arcs, described on page 69, fails when the ratio of the major to minor diameter is 4 or greater. Additionally, it is reported that the method always produces a somewhat larger minor axis than intended. The method described below presents an alternative.

An oval that approximates an ellipse, illustrated in Fig. 7, can be constructed from the following equations:

$$r = \frac{B^2}{2A} \left(\frac{A}{B}\right)^{0.38} \quad (1)$$

where  $A$  and  $B$  are dimensions of the major and minor axis, respectively, and  $r$  is the radius of the curve at the long ends.

The radius  $R$  and its location are found from Equations (2) and (3):

$$X = \frac{\frac{A^2}{4} - Ar + Br - \frac{B^2}{4}}{B - 2r} \quad (2) \quad R = \frac{B}{2} + X \quad (3)$$

Fig. 7. Four-Arc Oval Ellipse

To make an oval thinner or fatter than what is given, select a smaller or larger radius  $r$  is chosen than that calculated by Equation (1), and then  $X$  and  $R$  are found using Equations (2) and (3).

\* *Four-Arc Oval* material contributed by Manfred K. Brueckner

**Sphere.**—A sphere is the locus of points equidistant from a given point (the sphere's center) in three-dimensional space. Similar to the circle, the standard form for the equation of a sphere of radius  $R$  and centered at point  $(h, k, l)$  is:

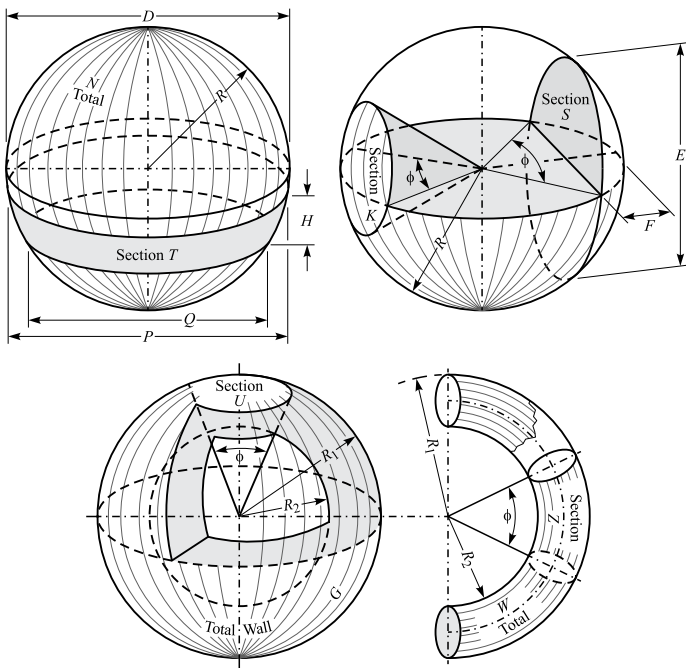

$$(x - h)^2 + (y - k)^2 + (z - l)^2 = R^2$$

The general form for the equation of a sphere can be written as follows, where  $A \neq 0$ :

$$Ax^2 + Ay^2 + Az^2 + Bx + Cy + Dz + E = 0$$

The general and standard forms of the sphere equations are related as follows:

$$h = \frac{-B}{2A} \quad k = \frac{-C}{2A} \quad l = \frac{-D}{2A} \quad R = \sqrt{\frac{B^2 + C^2 + D^2}{4A^2} - \frac{E}{A}}$$

- |                                      |   |
|--------------------------------------|---|
| $R$ = radius of sphere               | $R_1$ = radius of outer sphere                                |
| $D$ = diameter of sphere             | $R_2$ = radius of inner sphere                                |

**Formulas for Spherical Radius**

To Find	Formula	To Find	Formula
Radius of sphere from volume $N_v$	$R_N = \sqrt[3]{\frac{3N_v}{4\pi}}$	Radius of section $T$	$R_T = \sqrt{\left(\frac{P^2 - Q^2 - 4H^2}{8H}\right)^2 + \frac{P^2}{4}}$

**Formulas for Spherical Areas and Volumes**

Section	Area Formula	Volume Formula
Entire sphere	$N_a = 4\pi R^2$	$N_v = \left(\frac{\pi}{6}\right)D^3 = \frac{4\pi}{3}R^3$
Section $G$	$G_a = 4\pi R_1^2 + 4\pi R_2^2$	$G_v = \frac{4\pi}{3}(R_1^3 - R_2^3)$
Section $K$	$K_a = 2\pi R^2 \left(1 - \cos\left(\frac{\phi}{2}\right)\right)$	$K_v = \frac{2\pi R^2 F}{3}$
Section $S$	$S_a = \pi \left(F^2 + \frac{E^2}{4}\right)$	$S_v = \pi F \left(\frac{E^2}{8} + \frac{F^2}{6}\right)$
Section $T$	$T_a = 2\pi RH$	$T_v = H \left(\frac{\pi}{6}\right) \left(H^2 + \frac{3Q^2}{4} + \frac{3P^2}{4}\right)$
Section $U$	$U_a = 2\pi(R_1^2 + R_2^2) \left(1 - \cos\left(\frac{\phi}{2}\right)\right)$	$U_v = 2\pi(R_1^3 - R_2^3) \left(1 - \cos\left(\frac{\phi}{2}\right)\right)$
Section $W$	$W_a = 4\pi^2 R_1 R_2$	$W_v = 2\pi^2 R_1 R_2^2$
Section $Z$	$Z_a = (4\pi^2 R_1 R_2) \frac{\phi}{360}$	$Z_v = (2\pi^2 R_1 R_2^2) \left(\frac{\phi}{360}\right)$

*Example 1:* Find the inside and outside surface area  $G_a$  and volume  $G_v$  of wall  $G$ , provided that  $R_1$  is 12.5 cm and  $R_2$  is 10.0 cm.

*Solution:* Sectional area  $G_a$  and sectional volume  $G_v$ :

$$G_a = 4\pi R_1^2 + 4\pi R_2^2 = 4\pi(12.5)^2 + 4\pi(10)^2 = 3220.13 \text{ cm}^2$$

$$G_v = \frac{4\pi}{3}(R_1^3 - R_2^3) = \frac{4\pi}{3}(12.5^3 - 10^3) = 3992.44 \text{ cm}^3$$

*Example 2:* Find the surface area  $K_a$  and volume  $K_v$  of section  $K$  of a sphere of radius 15.0 cm, if included angle  $\phi = 90^\circ$  and depth  $F = 5.0$  cm.

*Solution:* Sectional area  $K_a$  and sectional volume  $K_v$ :

$$K_a = 2\pi R^2 \left(1 - \cos\left(\frac{\phi}{2}\right)\right) = 2\pi(15^2) \left(1 - \cos\left(\frac{90^\circ}{2}\right)\right) = 414.07 \text{ cm}^2$$

$$K_v = \frac{2\pi R^2 F}{3} = \frac{2\pi(15)^2(5)}{3} = 2356.19 \text{ cm}^3$$

*Example 3:* Find the outside surface area  $S_a$  and sectional volume  $S_v$  of section  $S$  of a sphere if  $E = 20.0$  cm and  $F = 5.0$  cm.

*Solution:* Sectional area  $S_a$  and sectional volume  $S_v$ :

$$S_a = \pi \left( F^2 + \frac{E^2}{4} \right) = \pi \left( 5^2 + \frac{20^2}{4} \right) = 392.70 \text{ cm}^2$$

$$S_v = \pi F \left( \frac{E^2}{8} + \frac{F^2}{6} \right) = \pi \times 5 \left( \frac{20^2}{8} + \frac{5^2}{6} \right) = 850.85 \text{ cm}^3$$

*Example 4:* Find the outside and inside surface area  $U_a$  and volume  $U_v$  of section  $U$  of a sphere if  $R_1 = 5.0$  inches,  $R_2 = 4.0$  inches, and included angle  $\phi = 30^\circ$ .

*Solution:* Sectional area  $U_a$  and sectional volume  $U_v$ :

$$U_a = 2\pi(R_1^2 + R_2^2) \left( 1 - \cos\left(\frac{\phi}{2}\right) \right) = 2\pi(5^2 + 4^2) \left( 1 - \cos\left(\frac{30^\circ}{2}\right) \right) = 8.78 \text{ in}^2$$

$$U_v = 2\pi(R_1^3 - R_2^3) \left( 1 - \cos\left(\frac{\phi}{2}\right) \right) = 2\pi(5^3 - 4^3) \left( 1 - \cos\left(\frac{30^\circ}{2}\right) \right) = 13.06 \text{ in}^3$$

*Example 5:* Find the total surface area  $W_a$  and volume  $W_v$  of ring  $W$ , if  $R_1 = 5.0$  inches and  $R_2 = 4.0$  inches.

*Solution:* Sectional area  $W_a$  and sectional volume  $W_v$ :

$$W_a = 4\pi^2 R_1 R_2 = 4\pi^2 \times 5 \times 4 = 789.57 \text{ in}^2$$

$$W_v = 2\pi^2 R_1 R_2^2 = 2\pi^2 \times 5 \times 4^2 = 1579.14 \text{ in}^3$$

**Parabola.**—A parabola is the set of all points  $P$  in the plane that are equidistant from a focus  $F$  and a line called the directrix. The parts of the parabola are labeled in the figure below.

The general equation of a parabola horizontal axis is given by  $(y - k)^2 = 4p(x - h)$ , where the vertex is located at point  $(h, k)$ , the focus  $F$  at point  $(h + p, k)$ , and the directrix is the line  $x$ -axis at  $x = h - p$ . The latus rectum is the vertical line segment through the focus; its endpoints are on the parabola. Hence, it lies on the line  $x = h + p$ . The length of the latus rectum is four times the absolute value of the  $x$ -coordinate of the focus, hence  $|4(h + p)|$ .

*Example:* Determine the focus, directrix, parabolic axis, vertex, and length of the latus rectum of the parabola

$$4y^2 - 8x - 12y + 1 = 0$$

*Solution:* Rewrite the equation in the general form of a parabolic equation (see *Solving by Completing the Square* on page 34).

$$4y^2 - 8x - 12y + 1 = 0$$

$$4y^2 - 12y = 8x - 1$$

$$y^2 - 3y = 2x - \frac{1}{4}$$

$$y^2 - 3y + \left(\frac{3}{2}\right)^2 = 2x - \frac{1}{4} + \frac{9}{4}$$

$$\left(y - \frac{3}{2}\right)^2 = 2(x + 1)$$

Parabola

Thus,  $k = 3/2$ ,  $h = -1$  and  $p = 1/2$ . Focus  $F$  is located at point  $(h + p, k) = (1/2, 3/2)$ ; the directrix is located at  $x = h - p = -1 - 1/2 = -3/2$ ; the parabolic axis is the horizontal line  $y = 3/2$ ; the vertex  $V(h, k)$  is located at point  $(-1, 3/2)$ ; and the latus rectum lies on the line  $x = h + p = -1/2$ . Its length is  $4|-1/2| = 4(1/2) = 2$ .

**Hyperbola.**—Referring to the figure on the left, below, a hyperbola is the set of all points such that  $|d_1 - d_2|$  is constant. That is, the difference between the distances from any point  $(x, y)$  to the foci, marked  $F_1(-c, 0)$  and  $F_2(c, 0)$  does not change. The distance between the vertices,  $V_1(-a, 0)$  and  $V_2(a, 0)$  (the turning points of the hyperbola) is  $2a$ . Therefore,  $|d_1 - d_2| = 2a$  for any two points on the hyperbola.

The figure on the right shows more detail. The slopes of the asymptotes (lines of approach) relate to the transverse and conjugate axis lengths,  $2a$  and  $2b$ . The center of a hyperbola is the point of intersection of the asymptotes. In the figure, the center is shown as the origin,  $(0, 0)$ . The standard form of the hyperbola, as derived from the foci with center at the origin, is  $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$ . For any center  $(h, k)$ , the equation is  $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$ .

Hyperbola 1

Hyperbola 2

The general form of the hyperbola is given by  $Ax^2 + By^2 + Cx + Dy + E = 0$ , where  $AB < 0$  and  $AB \neq 0$ .

Also, the eccentricity of a hyperbola,  $e = \frac{\sqrt{a^2 + b^2}}{a}$ , is always less than 1.

The distance  $2c$  between the two foci is given by the relation:  $2c = 2\sqrt{a^2 + b^2}$ .

*Example:* Determine the values of  $h, k, a, b, c$ , and  $e$  of the hyperbola general form:

$$9x^2 - 4y^2 - 36x + 8y - 4 = 0$$

*Solution:* Convert the hyperbola equation into the standard form (see *Solving by Completing the Square* on page 34):

$$\begin{aligned}
 9x^2 - 4y^2 - 36x + 8y - 4 &= (9x^2 - 36x) - (4y^2 - 8y) = 4 \\
 9(x^2 - 4x + 4) - 4(y^2 - 2y + 1) &= 36 \\
 \frac{9(x-2)^2}{36} - \frac{4(y-1)^2}{36} &= \frac{(x-2)^2}{2^2} - \frac{(y-1)^2}{3^2} = 1
 \end{aligned}$$

Comparing the results above with the form  $\frac{(x-h)^2}{a^2} - \frac{(y-k)^2}{b^2} = 1$  and calculating eccentricity from  $e = \frac{\sqrt{a^2 + b^2}}{a}$  and distance  $c$  from  $c = \sqrt{a^2 + b^2}$  gives

$$h = 2, \quad k = 1, \quad a = 2, \quad b = 3, \quad c = \sqrt{13}, \quad e = \frac{\sqrt{13}}{2}$$

### Complex Numbers

**Imaginary Number.**—The square root of a negative number cannot be expressed with real numbers, since any negative number multiplied by itself is positive. But technical mathematics often relies on computation involving the square root of  $-1$ . For this, *imaginary number*  $i$  is defined as follows:

$$i = \sqrt{-1}, \text{ so } (\sqrt{-1})^2 = -1$$

Imaginary numbers are not real numbers; they belong to the set of *complex numbers*.

An example of an equation that cannot be solved with real numbers is  $x^2 + 1 = 0$ . Rearranging gives  $x^2 = -1$ , and taking the square root of both sides gives  $x = \pm\sqrt{-1} = \pm i$ .

(Note: The letter  $j$  is also used to represent the imaginary number  $\sqrt{-1}$ .)

**Forms of a Complex Number.**—Complex numbers can be expressed in several forms, all of which are based on the complex coordinate system, as seen in Fig. 1 and Fig. 2.

*Operations on complex numbers:* Complex numbers are added and subtracted much like real numbers, but with real parts added to real parts and imaginary to imaginary:

$$(a + bi) + (c + di) = (a + c) + (bi + di) = (a + c) + (b + d)i$$

$$(a + bi) - (c + di) = (a - c) + (bi - di) = (a - c) + (b - d)i$$

where coefficients  $a$ ,  $b$ ,  $c$ , and  $d$  are real numbers.

$$\text{Example 1: } (3 + 4i) + (2 - i) = (3 + 2) + (4i - i) = 5 + 3i$$

Complex numbers are multiplied as binomials are, by FOIL:

$$(a + bi)(c + di) = ac + adi + bci + bd^2i^2 = ac + (ad + bc)i + bd(-1) = ac + (ad + bc)i - bd$$

$$\text{Example 2: } (1 + 2i)(5 - 7i) = 5 - 7i + 10i - 14i^2 = 5 + 3i - (14)(-1) = 5 + 3i + 14 = 19 + 3i$$

*Standard (rectangular) form of a complex number:* A complex number  $z$  has a real part and an imaginary part. Its standard form is  $z = a + bi$ , where  $a$  is the real part and  $bi$  the imaginary part. Fig. 1 shows how the complex plane is similar to the real plane (see page 42 in *Analytic Geometry*), except here only the horizontal axis,  $x$ , is real, whereas the vertical axis,  $yi$ , is imaginary. Fig. 2 shows examples of complex numbers in rectangular form.

Imaginary axis

Fig. 1. Complex coordinate system

Fig. 2. Examples of standard (rectangular) form,  
 $z = a + bi$

$z = 5 + 3i$  lies in the first quadrant, with  $a$  and  $b$  both positive;  $z = -1 - i$  is in the third quadrant. Complex numbers can be converted from the standard form to any of three *vector forms*: polar, trigonometric, and exponential.

**Polar form of a complex number:** Vectors are objects that have both magnitude ( $r$ ) and direction ( $\theta$ ). Vectors are essential in electrical engineering and other fields for representing many processes such as alternating current and voltage. They are represented graphically by an arrow, as seen in Fig. 3.

Fig. 3. (a) Polar form of a complex number;  
(b) Magnitude  $r = |z|$  relationship to  $a$  and  $b$ ; (c) Angle  $\theta$  to  $a, b$ .

The *polar form* of a complex number is  $z = r\theta$ .  $z$  is a vector in the sense of its magnitude (length)  $r$  and direction angle  $\theta$  from the horizontal (Fig. 3a). By Pythagorean theorem,  $r^2 = a^2 + b^2$ ; thus, magnitude  $r = \sqrt{a^2 + b^2}$ , which is called the *modulus*, is denoted  $|z|$ . From trigonometry,  $\tan \theta = b/a$ ; hence,  $\theta = \tan^{-1}(b/a)$ .

**Trigonometric form of a complex number:** Another form that shows the directional nature of complex numbers is the trigonometric form of  $z$ . From trigonometry,  $\cos \theta = a/r$  and  $\sin \theta = b/r$ ; hence,

$$a = r \cos \theta, \quad b = r \sin \theta, \quad \text{so, } a + bi = r \cos \theta + ir \sin \theta = r(a \cos \theta + i \sin \theta)$$

**Exponential form of a complex number:** Recall that the number  $e$  is the base of the natural logarithm (see page 37). A complex number is represented in exponential form through Euler's formulas, which are used widely in electrical engineering applications:

$$e^{i\theta} = \cos \theta + i \sin \theta, \quad \cos \theta = \frac{e^{i\theta} + e^{-i\theta}}{2}, \quad \sin \theta = \frac{e^{i\theta} - e^{-i\theta}}{2i}$$

Pure Geometry

The labels that identify the parts of a figure (angle  $A$ , radius  $r$ , diameter  $d$ , and so on) are used in the formulas to indicate the *measure* of that feature. By definition, if any two geometric features  $A$  and  $B$  have equal measure, they are said to be *congruent*. So, if the measure of  $A$  equals the measure of  $B$ , then  $A \cong B$ . Polygons are congruent if they have the same shape and size, that is, if one can be superimposed on the other point for point. Triangles are congruent if any of the propositions for triangle congruence hold, as summarized below.

Table 1a. Propositions of Geometry

	<p>A <i>triangle</i> is a three-sided polygon. It is, in fact, the polygon with the least number of sides. The sides of a triangle meet at its <i>vertices</i> (singular <i>vertex</i>). The sum of the measures of all three angles of a triangle is 180 degrees. Hence, if the measures of any two angles are known, the third angle measure can always be found.</p> $A + B + C = 180^\circ$ $A = 180^\circ - (B + C)$ $B = 180^\circ - (A + C)$ $C = 180^\circ - (A + B)$
	<p><b>AAS Proposition:</b> If two angles and the non-included side of one triangle are congruent to the corresponding (similarly located) angles and sides of another triangle, the triangles are congruent.</p> <p>Hence, if <math>a = a_1</math>, <math>A = A_1</math>, and <math>B = B_1</math>, the other corresponding side and angle are equal in measure, and thus the triangles are congruent.</p>
	<p><b>SAS Proposition:</b> If two sides and the included angle (the angle between the sides) of one triangle are congruent (equal in measure) to the corresponding (similarly located) sides and angle of another triangle, then the triangles are congruent.</p> <p>Hence, in the figure, if <math>a = a_1</math>, <math>b = b_1</math>, and <math>A = A_1</math>, then the remaining side and angles also are equal in measure, and thus the triangles are congruent.</p>
	<p><b>SSS Proposition:</b> If all three sides of one triangle are congruent (equal in measure) to all three sides of another triangle, then the triangles are congruent. If the three sides in one triangle are equal in measure to the three sides of another triangle, then the angles in the two triangles are equal in measure.</p> <p>If <math>a = a_1</math>, <math>b = b_1</math>, and <math>c = c_1</math>, then the corresponding angles are also equal in measure, and thus the triangles are congruent.</p>
	<p>If the three sides of a triangle are proportional to corresponding sides of another triangle, then the triangles are <i>similar</i>, and the angles in the one are congruent (equal in measure) to the angles in the other.</p> <p>Hence, if <math>a/d = b/e = c/f</math> then <math>A = D</math>, <math>B = E</math>, <math>C = F</math></p>
	<p><b>Similar triangles</b> are ones whose corresponding angles are congruent. If this is true then the corresponding sides are proportional. If the angles of one triangle are congruent (equal in measure) to the angles of another triangle, then the triangles are similar and their corresponding sides are proportional.</p> <p>Hence, if <math>A = D</math>, <math>B = E</math>, and <math>C = F</math> then <math>a/d = b/e = c/f</math></p>

Table 1b. Propositions of Geometry

	<p>In an <i>isosceles triangle</i>, two sides <math>a, b</math> are congruent, hence the two angles opposite them (the base angles) are congruent. An equilateral (equiangular) triangle is also an isosceles triangle.</p>
	<p>In an <i>equilateral (equiangular) triangle</i>, all three sides (angles) are congruent. Since the sum of angle measures in any triangle is 180 degrees, then each angle in an equilateral (equiangular) triangle measures 60 degrees.</p>
	<p>A line in an equilateral triangle that bisects any of the angles (that is, divides it into two 30-degree angles), also bisects the side opposite the bisected angle and is perpendicular (at right angles) to it.</p> <p>Thus, if line <math>AB</math> bisects angle <math>CAD</math>, it also bisects line <math>CD</math> into two equal parts and is perpendicular to it.</p>
	<p>If a line in an isosceles triangle drawn from the vertex where the two congruent sides meet in such a way that it bisects the third side (or base), then it also bisects the angle at the vertex from which it is drawn.</p>
	<p>In every triangle, the greatest angle is opposite the longest side. And, the longest side is opposite the greatest angle.</p> <p>Thus, if <math>a</math> is longer than <math>b</math>, then the measure of angle <math>A</math> is greater than that of angle <math>B</math>. And, if angle <math>A</math> measure is greater than <math>B</math>, then side <math>a</math> is longer than side <math>b</math>.</p>
	<p>According to the <i>triangle inequality</i>, for any triangle, the sum of the lengths of any two sides must be greater than or equal to the length of the remaining side.</p> <p>Thus, <math>a + b \geq c</math>.</p>
	<p>The <i>Pythagorean theorem</i> states that in a right-angle triangle, the square of the <i>hypotenuse</i>, that is, the side opposite the right angle, is equal to the sum of the squares on the two sides that form the right angle. These sides are the <i>legs</i> of the right triangle.</p> <p>Thus, <math>a^2 + b^2 = c^2</math></p>

**Table 1c. Propositions of Geometry**

	<p>In the figure, angle <math>D</math> is an <i>exterior angle</i>. The measure of an exterior angle is equal to the sum of the measures of the non-adjacent interior angles. Thus,</p> $A + B = D$
	<p>Intersecting lines form congruent <i>vertical angles</i>, that is, the angles opposite one another. In the figure, <math>A</math> and <math>B</math> are vertical angles and therefore congruent, and <math>C</math> and <math>D</math> are vertical angles and therefore congruent. That is,</p> $A \cong B$ $C \cong D$
	<p>Corresponding angles formed when parallel lines are intersected by another line (a <i>transversal</i>) have equal measure (are congruent).</p> <p>Lines <math>l_1</math> and <math>l_2</math> are intersected by <math>s</math> transversal, so all angles <math>A</math> are congruent, and all angles <math>B</math> are congruent.</p>
	<p>A quadrilateral is a four-sided polygon. In any quadrilateral, the sum of the measures of the interior angles is 360 degrees.</p> <p>Thus, <math>A + B + C + D = 360</math> degrees</p>
	<p>A parallelogram is a quadrilateral in which each pair of opposite sides is parallel and thus congruent. Opposite angles are also congruent. Each diagonal divides the parallelogram into congruent triangles, and the diagonals bisect each other. In the figure, diagonal <math>D</math> bisects diagonal <math>d</math> at their midpoints.</p>
	<p>A rectangle is a parallelogram in which all four angles are right angles. In the figure, the rectangle's <i>base</i> is marked <math>b</math>; its <i>height</i> is marked <math>h</math>; the parallelogram's base is marked <math>b_1</math>, and its height is marked <math>h_1</math>. The area of a parallelogram is <math>A = bh</math>. If two parallelograms have a corresponding base and height of equal measure, their areas are equal.</p> <p>Thus, if <math>b = b_1</math> and <math>h</math> and <math>h_1</math>, then area <math>A = \text{area } A_1</math>.</p>
	<p>Triangles having equal base and equal height have equal area.</p> <p>Thus, if <math>b = b_1</math> and <math>h</math> and <math>h_1</math>, then area <math>A = \text{area } A_1</math>.</p>
	<p>If a diameter of a circle is perpendicular (at right angles) to a chord, then it bisects the chord, dividing it into two equal parts. In the figure, the chord has length <math>c</math>, so its parts have length <math>c/2</math>.</p>

**Table 1d. Propositions of Geometry**

	<p>A line tangent to a circle lies perpendicular (at right angles) to a radius drawn to meet it at the point of tangency.</p>
<p style="text-align: center;"><b>Point of Tangency</b></p> 	<p>The figure shows two ways that circles can be tangent. A line drawn through the center of each circle (the diameter) will pass through the point of tangency.</p>
	<p>Two tangents drawn from a single point outside a circle will be equal in length (<math>a</math>), and the angles they make with the chord that connects the points of tangency (<math>A</math>) will be equal in measure. The figure shows this congruency.</p>
	<p>The angle formed by a tangent and a chord drawn from the point of tangency measures one-half the central angle subtended by that chord. That is, <math>B = A/2</math></p>
	<p>The angle formed by a tangent and a chord drawn from the point of tangency has measure equal to the inscribed angle subtended by the chord. That is, <math>B = A</math>.</p>
	<p>All inscribed angles subtended by the same chord in a circle are congruent (equal in measure). In the figure, <math>A</math>, <math>B</math>, and <math>C</math> are subtended by chord <math>cd</math>, and so are equal in measure.</p>
	<p>Referring to the figure, inscribed angle <math>A</math> and central angle <math>B</math> are subtended by the same arc. The measure of inscribed <math>A</math> is half the measure of central angle <math>B</math>. In the figure, <math>A = B/2</math></p>

**Table 1e. Propositions of Geometry**

	<p>A <i>major arc</i> of a circle is one that measures more than half the circumference of the circle. A <i>minor arc</i> measures less than half the circumference of the circle.</p> <p>In the figure, angle <i>A</i> is subtended by a minor arc, so it is an acute angle (it measures less than 90 degrees). Angle <i>B</i> is subtended by a major arc, so it is an obtuse angle (it measures more than 90 degrees).</p>
	<p>An angle subtended by a circle's diameter is a right angle; the arc described by the diameter is a semicircle. Referring to the figure, right angle <i>A</i> is subtended by diameter <i>d</i>.</p> <p style="text-align: center;">Angle <math>C = 90^\circ</math></p>
	<p>In the figure, the product of line segment lengths formed by intersecting chords in a circle are equal. Thus:</p> <p style="text-align: center;"><math>ab = cd</math></p>
	<p>When two lines are drawn from a point outside a circle, one tangent and one through the circle intersecting it at two points, the line segment lengths are such that the square of the tangent segment is equal to the product of the segments formed by the other line. Thus:</p> <p style="text-align: center;"><math>a^2 = bc</math></p>
	<p>Arc lengths of a circle are proportional to the corresponding central angle measures. Thus:</p> <p style="text-align: center;"><math>A:B = a:b</math></p>
	<p>The lengths of circular arcs having the same central angle are proportional to the lengths of the radii. Thus, if <math>A = B</math>, then <math>a/b = r/R</math></p>
	<p>The ratio of the circumferences of two circles is proportional to the ratio of their radii.</p> <p style="text-align: center;"><math>c:C :: r:R</math> so <math>c/C = r/R</math></p> <p>The ratio of the areas of two circles is proportional to the ratio of the squares of their radii.</p> <p style="text-align: center;"><math>a:A :: r^2:R^2</math> so <math>a/A = r^2/R^2</math></p>

The geometric constructions below are produced with a compass, protractor, and straight edge. The compass point marks the "centers" in the constructions that follow. The techniques described also apply for electronic drafting programs. As the section progresses, some constructions rely on previous ones.

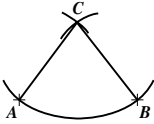

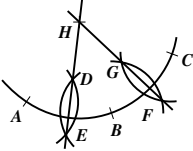

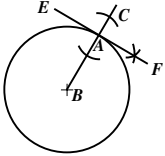

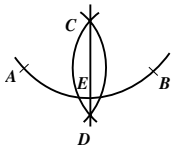

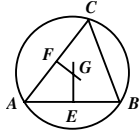

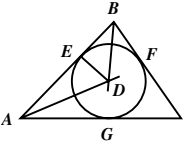

**Table 2a. Geometric Constructions**

	<p>To bisect a line segment (divide it into two equal parts):</p> <p>With the ends <math>A</math> and <math>B</math> as centers and a radius greater than one-half the line segment, use the compass to draw circular arcs. Through intersections <math>C</math> and <math>D</math>, use the straight edge draw line <math>CD</math>. This line bisects <math>AB</math> and is also perpendicular to <math>AB</math>.</p>
	<p>To draw a perpendicular to a line from a point <math>A</math> on that line:</p> <p>With <math>A</math> as the center and with any radius, use the compass to draw circular arcs intersecting the given line at <math>B</math> and <math>C</math>. Then, with <math>B</math> and <math>C</math> as centers and a radius longer than <math>AB</math>, draw circular arcs intersecting at <math>D</math>. With the straight edge, draw line <math>DA</math>. This line is perpendicular to <math>BC</math>.</p>
	<p>To draw a perpendicular line from a point <math>A</math> to <math>C</math> at the end of line <math>AB</math>:</p> <p>Draw line <math>AB</math>, and then with any point <math>D</math> not on <math>AB</math> as center, use the compass to draw a circle intersecting <math>AB</math> at <math>E</math>. Draw a line through <math>E</math> and <math>D</math> intersecting the circle at <math>C</math>; then join <math>AC</math>. This line is the required perpendicular.</p>
	<p>To draw a perpendicular to a line <math>AB</math> from a point <math>C</math> at a distance from it:</p> <p>With <math>C</math> as center, use the compass to draw an arc intersecting the given line at <math>E</math> and <math>F</math>. With <math>E</math> and <math>F</math> as centers, draw circular arcs with a radius longer than one-half the distance between <math>E</math> and <math>F</math>. These arcs intersect at <math>D</math>. Line <math>CD</math>, drawn with the straight edge, is the required perpendicular.</p>
	<p>To divide a line segment <math>AB</math> into a number of equal parts:</p> <p>Assume line segment <math>AB</math> is to be divided into five smaller segments of equal measure. Draw line <math>AC</math> at an acute angle with <math>AB</math>. Mark off on <math>AC</math> five parts of equal measure, any convenient length. With the straight edge, draw the segment <math>B-5</math> and then draw lines parallel to <math>B-5</math> through the other division points on <math>AC</math>. The points where these lines intersect <math>AB</math> are the required division points.</p>

**Table 2b. Geometric Constructions**

	<p>To draw a line parallel to a given line <math>AB</math>, at a given distance from it:</p> <p>Using the compass, with any points <math>C</math> and <math>D</math> on <math>AB</math> as centers, draw with the compass circular arcs with the given distance as radius. Line <math>EF</math>, drawn with the straight edge to be tangent to (that is, touch without intersecting) the circular arcs, is the required parallel line.</p>
	<p>To bisect an angle <math>BAC</math>:</p> <p>With <math>A</math> as a center and any radius, use the compass to draw arc <math>DE</math>. With <math>D</math> and <math>E</math> as centers and a radius greater than one-half <math>DE</math>, use the compass to draw circular arcs intersecting at <math>F</math>. Line <math>AF</math>, drawn with the straight edge, divides the angle into two equal parts.</p>
	<p>To draw an angle upon a line <math>AB</math> equal to a given angle <math>FGH</math>:</p> <p>With point <math>G</math> as a center and with any radius, draw arc <math>KL</math>. With <math>A</math> as a center and with the same radius, draw arc <math>DE</math>. Make arc <math>DE</math> equal in length to <math>KL</math> and draw <math>AC</math> through <math>E</math>. Angle <math>BAC</math> then is equal in length to angle <math>FGH</math>.</p>
	<p>To lay out a 60-degree angle:</p> <p>With <math>A</math> as a center and any radius <math>AB</math>, draw an arc <math>BC</math>. With point <math>B</math> as a center and <math>AB</math> as a radius, draw an arc intersecting at <math>E</math> the arc just drawn. <math>EAB</math> is a 60-degree angle.</p> <p>A 30-degree angle may be obtained either by bisecting a 60-degree angle or by drawing a line <math>EG</math> perpendicular to <math>AB</math>. Angle <math>AEG</math> is then 30 degrees.</p>
	<p>To draw a 45-degree angle:</p> <p>From point <math>A</math> on line <math>AB</math>, set off a distance <math>AC</math>. With a straight edge, draw perpendicular <math>DC</math> and set off a distance <math>CE</math> equal to <math>AC</math>. Draw <math>AE</math>. Angle <math>EAC</math> is a 45-degree angle.</p>
	<p>To draw an equilateral triangle, with the length of the sides equal to <math>AB</math>:</p> <p>Draw <math>AB</math> with straight edge. With <math>A</math> and <math>B</math> as centers and <math>AB</math> as radius, use the compass to draw circular arcs intersecting at <math>C</math>. With the straight edge, draw <math>AC</math> and <math>BC</math>. Then <math>ABC</math> is an equilateral triangle.</p>

**Table 2c. Geometric Constructions**

	<p>To draw a circular arc with a given radius through two given points <math>A</math> and <math>B</math>:</p> <p>With <math>A</math> and <math>B</math> as centers, with the compass draw two circular arcs with the given radius intersecting at <math>C</math>. With <math>C</math> as center and the same radius, draw a circular arc through <math>A</math> and <math>B</math>.</p>
	<p>To locate the center of an arc of a circle:</p> <p>Select three points on the periphery of the circle, as <math>A</math>, <math>B</math>, and <math>C</math>. With each of these points as a center and setting the same radius with the compass, draw arcs intersecting each other. Through the points of intersection, draw lines <math>DE</math> and <math>GF</math>. Point <math>H</math>, where these lines intersect, is the center of the circle.</p>
	<p>To draw a tangent to a circle through a given point on the circumference:</p> <p>Through a chosen point of tangency <math>A</math> on a circle with center <math>B</math>, draw radius <math>BC</math>. At point <math>A</math>, draw a line <math>EF</math> at right angles to <math>BC</math>. This line is the required tangent.</p>
	<p>To divide a circular arc <math>AB</math> into two equal parts:</p> <p>With <math>A</math> and <math>B</math> as centers, and a radius larger than half the distance between <math>A</math> and <math>B</math>, with the compass draw circular arcs intersecting at <math>C</math> and <math>D</math>. Line <math>CD</math> divides arc <math>AB</math> into two equal parts at <math>E</math>.</p>
	<p>To circumscribe a circle about a triangle <math>ABC</math>:</p> <p>Bisect the sides <math>AB</math> and <math>AC</math>, and from the midpoints <math>E</math> and <math>F</math> draw lines at right angles to the sides. These lines intersect at <math>G</math>. With <math>G</math> as a center and <math>GA</math> as a radius, draw circle <math>ABC</math>.</p>
	<p>To inscribe a circle in a triangle <math>ABC</math>:</p> <p>Bisect two of the angles, <math>A</math> and <math>B</math>, by lines intersecting at <math>D</math>. From <math>D</math>, draw a line <math>DE</math> perpendicular to one of the sides, and with <math>DE</math> as a radius, use the compass to draw circle <math>EFG</math>.</p>

**Table 2d. Geometric Constructions**

	<p>To circumscribe a circle about a square and to inscribe a circle in a square <math>ABCD</math>:</p> <p>Draw the square's diagonals <math>AC</math> and <math>BD</math> with the straight edge. The centers of both the circumscribed and inscribed circles are located at the point <math>E</math>, where the two diagonals of the square intersect. The radius of the circumscribed circle is <math>AE</math>, and of the inscribed circle, <math>EF</math>.</p>
	<p>To inscribe a hexagon in a circle with center <math>C</math>:</p> <p>Draw diameter <math>AB</math>. With <math>A</math> and <math>B</math> as centers and with the circle's radius as radius, describe circular arcs intersecting the given circle at <math>D, E, F</math>, and <math>G</math>. Draw chords <math>AD, DE</math>, etc., forming the required hexagon <math>ABCDEFG</math>.</p>
	<p>To circumscribe a hexagon about a circle with center <math>C</math>:</p> <p>Draw the circle's diameter <math>AB</math>, and with <math>A</math> as center and the radius of the circle as radius, cut the circumference of the given circle at <math>D</math>. Draw chord <math>AD</math> and bisect it with radius <math>CE</math>. Through <math>E</math>, draw <math>FG</math> parallel to <math>AD</math> and intersecting diameter <math>AB</math> at <math>F</math>. With <math>C</math> as center and <math>CF</math> as radius, draw a circle. Within this circle, inscribe the hexagon as in the preceding problem. This is the circumscribed hexagon about the first circle.</p>
	<p>To describe an ellipse with the given axes <math>AB</math> and <math>CD</math>:</p> <p>Describe circles with <math>O</math> as center and <math>AB</math> and <math>CD</math> as diameters. From a number of points, <math>E, F, G</math>, etc., on the outer circle, draw radii intersecting the inner circle at <math>e, f</math>, and <math>g</math>. From <math>E, F</math>, and <math>G</math>, draw lines perpendicular to <math>AB</math>, and from <math>e, f</math>, and <math>g</math>, draw line segments parallel to <math>AB</math>. The intersections of these perpendicular and parallel lines are points on the curve of the ellipse.</p>
	<p>To construct an approximate ellipse by circular arcs:</p> <p>Let <math>AC</math> be the major axis and <math>BN</math> the minor. With the compass, draw semicircle <math>ADC</math> with <math>O</math> as center. Divide <math>BD</math> into three equal parts and set off <math>BE</math> equal to one of these parts. With <math>A</math> and <math>C</math> as centers and <math>OE</math> as radius, describe circular arcs <math>KLM</math> and <math>FGH</math>; with <math>G</math> and <math>L</math> as centers, and with the same radius, describe arcs <math>FCH</math> and <math>KAM</math>. Through <math>F</math> and <math>G</math>, draw line <math>FP</math>, and with <math>P</math> as center draw arc <math>FBK</math>. Arc <math>HNM</math> is drawn in the same manner.</p>

**Table 2e. Geometric Constructions**

	<p>To construct a parabola:</p> <p>Divide line segment <math>AB</math> into a number of equal parts and divide <math>BC</math> into the same number of parts. From the division points on <math>AB</math>, draw horizontal lines. From the division points on <math>BC</math>, draw lines to point <math>A</math>. The points of intersection of the lines drawn from points numbered alike are points on the parabola.</p>
	<p>To construct a hyperbola:</p> <p>From focus <math>F</math>, lay off a distance <math>FD</math> to be the transverse axis, or the distance <math>AB</math> between the two branches of the curve. With <math>F</math> as center and any distance <math>FE</math> greater than <math>FB</math> as a radius, describe a circular arc. Then with <math>F_1</math> as center and <math>DE</math> as radius, describe arcs intersecting at <math>C</math> and <math>G</math> the arc just described. <math>C</math> and <math>G</math> are points on the hyperbola. Any number of points can be found in a similar manner; when a sufficient number of points are found, draw a smooth curve through them.</p>
	<p>To construct an involute:</p> <p>Divide the circumference of the base circle <math>ABC</math> into a number of equal parts. Through the division points 1, 2, 3, etc., draw tangents to the circle and make the lengths <math>D-1, E-2, F-3</math>, etc., of these tangents equal to the actual length of the arcs <math>A-1, A-2, A-3</math>, etc. Connect the ends of these tangents with a smooth curve.</p>
	<p>To construct a helix:</p> <p>Divide half the circumference of the cylinder on the surface of which the helix is to be described into a number of equal parts. Divide half the lead of the helix into the same number of equal parts. From the division points on the circle representing the cylinder, draw vertical lines using the straight edge, and from the division points on the lead, draw horizontal lines as shown. The intersections between lines numbered alike are points on the helix. Connect these points with a smooth curve.</p>

## Area and Volume

**The Prismoidal Formula.**—A *right prism* is a three-dimensional figure composed of (two-dimensional) polygons that form the faces of the prism. The end faces are the bases, the other faces are the sides. The prismoidal formula is a general formula by which the volume of any prism, pyramid, or frustum of a pyramid may be found.

$A_1, A_2$  = end areas of the body

$A_m$  = area of faces between the two end surfaces

$h$  = height of body

Then, volume of the body is calculated as  $V = \frac{h}{6}(A_1 + 4A_m + A_2)$ .

**Pappus-Guldinus Rules.**—A *surface of revolution* is generated when a curve is revolved about an external axis. (The curve must lie wholly on one side of the axis of revolution and in the same plane.) The mathematics for finding the curve's length and the length of the path of the centroid involves calculus. Some surface areas and volumes of solids of revolution can then be determined by the rules of the *Pappus-Guldinus theorems*. The area of the resulting surface is equal to the product of the length of the generating curve and the distance traveled by the curve's center of gravity, or *centroid* (see figure below).

The volume of a solid body formed by the revolution of a surface  $FGHJ$  about axis  $KL$  equals the product of the surface area and the length of the path of its center of gravity about axis  $KL$ .

*Example:* By means of the Pappus-Guldinus rules, the area and volume of a cylindrical ring, or torus, may be found. A torus is formed when a circle is rotated about an axis. The center of gravity of the circle is its center. Hence, with the dimensions given in the illustration, the length of the path of the center of gravity of the circle it travels is the circumference  $2\pi r = 2 \times 3.1416 \times 5 = 31.416$  inches. Multiplying this path length by the circumference of the circle, which is  $3.1416 \times 3 = 9.4248$  inches, gives  $31.416 \times 9.4248 = 296.089$  square inches. This is the surface area of the torus.

The volume of the torus equals the area of the circle,  $\frac{\pi d^2}{4} = 0.7854 \times 9 = 7.0686$  square inches, multiplied by the path length of the center of gravity, which is 31.416, as before; hence,

$$\text{Volume} = 7.0686 \times 31.416 = 222.067 \text{ cubic inches}$$

**Approximate Method for Finding the Area of a Surface of Revolution.**—The illustration below is an example of the approximate method based on Guldinus rule for finding the surface area of a symmetrical body. In the illustration, the dimensions in common fractions are the known dimensions; those in decimals are found by actual measurements on a figure drawn to scale.

The surface area is found as follows: First, the entire form is separated into such areas as are cylindrical, conical, or spherical, since their surface areas can be found by exact formulas. In the illustration, the three-dimensional portion marked in the plane by *ABCD* is a cylinder, the area of the surface of which can be easily found. The top area *EF* is simply a circular area and can thus be computed separately. The remainder of the surface generated by rotating line *AF* about the axis *GH* is found by the approximate method. From point *A*, equal distances are set off on line *AF*. In the illustration, each division indicated is  $\frac{1}{8}$  inch long. From the central or middle point of each of these parts a line is drawn at right angles to the axis of rotation *GH*, the length of these lines or diameters (the length of each is given in decimals) is measured, all these lengths are added together and the sum is multiplied by the length of one division set off on line *AF* (in this case,  $\frac{1}{8}$  inch), and this product is multiplied by  $\pi$  to give the approximate area of the surface of revolution.

In setting off divisions  $\frac{1}{8}$  inch long along line *AF*, the last division does not reach all the way to point *F*, but only to a point 0.03 inch below it. The part 0.03 inch high at the top of the cup can be considered as a cylinder of  $\frac{1}{2}$ -inch diameter and 0.03-inch height, the area of the cylindrical surface of which is easily computed. By adding the various surfaces together, the total surface of the cup is found as follows:

Cylinder, $1\frac{5}{8}$ in. diameter, 0.41 in. height	2.093 in <sup>2</sup>
Circle, $\frac{1}{2}$ in. diameter	0.196 in <sup>2</sup>
Cylinder, $\frac{1}{2}$ in. diameter, 0.03 in. height	0.047 in <sup>2</sup>
<u>Irregular surface</u>	<u>3.868 in<sup>2</sup></u>
Total	6.204 in <sup>2</sup>

**Area of Irregular Plane Figure.**—One of the most useful and accurate methods for determining the approximate area of a plane figure or irregular outline is known as *Simpson's rule*. In applying Simpson's rule to find an area, the work is done in four steps:

- 1) The area is divided into an *even* number *N* of parallel strips of equal width *W*; for example, in the accompanying diagram, the area has been divided into 8 strips of equal width.
- 2) The sides of the strips are labeled  $V_0, V_1, V_2, \dots, \text{up to } V_N$ .
- 3) These heights  $V_0, V_1, V_2, \dots, V_N$  are measured.
- 4) The values  $V_0, V_1, \dots$  are substituted in the following formula to find the area *A* of the figure:

$$A = \frac{W}{3} [(V_0 + V_N) + 4(V_1 + V_3 + \dots + V_{N-1}) + 2(V_2 + V_4 + \dots + V_{N-2})]$$

*Example:* The area of the accompanying figure was divided into 8 strips on a full-size drawing and the following data obtained. Calculate the area using Simpson's rule.

- $W = 1 \text{ cm}$
- $V_0 = 0 \text{ cm}$
- $V_1 = 1.91 \text{ cm}$
- $V_2 = 3.18 \text{ cm}$
- $V_3 = 3.81 \text{ cm}$
- $V_4 = 4.13 \text{ cm}$
- $V_5 = 5.27 \text{ cm}$
- $V_6 = 6.35 \text{ cm}$
- $V_7 = 4.45 \text{ cm}$
- $V_8 = 1.27 \text{ cm}$

Substituting the given data in the Simpson's formula,

$$A = \frac{1}{3} [(0 + 1.27) + 4(1.91 + 3.81 + 5.27 + 4.45) + 2(3.18 + 4.13 + 6.35)]$$

$$= \frac{1}{3} [1.27 + 4(15.44) + 2(13.66)] = 30.12 \text{ cm}^2$$

In applying Simpson's rule, it should be noted that the larger the number of strips into which the area is divided the more accurate the results obtained.

**Areas Enclosed by Cycloidal Curves.**—The area between a cycloid and the line upon which the generating circle rolls equals three times the area of the generating circle (see diagram, page 79). The areas between epicycloidal and hypocycloidal curves and the "fixed circle" upon which the generating circle is rolled may be determined by the following formulas, in which  $a$  = radius of the fixed circle upon which the generating circle rolls,  $b$  = radius of the generating circle,  $A$  = the area for the epicycloidal curve, and  $A_1$  = the area for the hypocycloidal curve.

$$A = \frac{\pi b^2(3a + 2b)}{a} \qquad A_1 = \frac{\pi b^2(3a - 2b)}{a}$$

**Contents of Cylindrical Tanks at Different Levels.**—In conjunction with the table *Segments of Circles for Radius = 1* starting on page 84, the following relations can give a close approximation of the liquid contents, at any level, in a cylindrical tank.

A long measuring rule calibrated in length units or a plain stick can be used for measuring contents at a particular level. In turn, the rule or stick can be graduated to serve as a volume gauge for the tank in question. The requirements are that the tank must have a circular cross section; the dimensions of the tank must be known; the gauge rod has to be inserted vertically through the top center of the tank so that it rests precisely in the center at the bottom of the tank; and the calculations must be done using consistent metric or US customary (also called *English*) units. The formulas and parameters are:

$$K = Cr^2L = \text{tank constant (the same for any given tank)} \quad (1)$$

$$V_T = \pi K, \text{ for a tank that is completely full} \quad (2)$$

$$V_s = KA \quad (3)$$

$$V = V_s, \text{ for a tank that is less than half full} \quad (4)$$

$$V = V_T - V_s = V_T - KA, \text{ for a tank that is more than half full} \quad (5)$$

where:  $C$  = liquid volume conversion factor; the exact value depends on the length and liquid volume units used during measurement: 0.00433 US gal/in<sup>3</sup>; 7.48 US gal/ft<sup>3</sup>; 0.00360 UK gal/in<sup>3</sup>; 6.23 UK gal/ft<sup>3</sup>; 0.001 liter/cm<sup>3</sup>; or 1000 liters/m<sup>3</sup>

$V_T$  = total volume of liquid tank can hold

$V_s$  = volume formed by segment of circle having depth  $x$  in the given tank (see diagram)

$V$  = volume of liquid at particular level in tank

$L$  = length of tank;  $r$  = radius of tank ( $= \frac{1}{2}$  diameter)

$A$  = segment area of a corresponding unit circle taken from the table starting on page 84.

$y$  = actual depth of contents in tank as shown on a gauge rod or stick

$x$  = depth of the segment of a circle to be considered in given tank. As can be seen in the diagram, both  $x$  and  $y$  are the actual depth of contents when the tank is less than half full, but  $x$  is the depth of the void ( $d - y$ ) above the contents when the tank is more than half full. In the discussion of the unit circle, page 84,  $r = 1$ , and so the height of a segment of a corresponding unit circle is  $x/r$ .

*Example:* A tank is 20 feet long and 6 feet in diameter. Convert a long stick graduated in inches into a gauge graduated at two points, 1000 and 3000 US gallons.

*Solution:*  $L = 20 \times 12 = 240$  in.       $r = \frac{6}{2} \times 12 = 36$  in.

From **Formula (1)**:  $K = 0.00433 \times 36^2 \times 240 = 1346.80$

From **Formula (2)**:  $V_T = 3.1416 \times 1347 = 4231.7$  US gal.

The 72-inch mark from the bottom on the inch-stick can be graduated for the rounded full volume of 4230 and the halfway point 36 in. for 4230/2 or 2115. It can be seen that the 1000-gal mark would be below the halfway mark. From **Formulas (3) and (4)**:

$A_{1000} = \frac{1000}{1347} = 0.7424$ ; from the table starting on page 84,  $h$  can be interpolated as

0.5724; and  $x = y = 36 \times 0.5724 = 20.61$ . If the desired level of accuracy permits, interpolation can be omitted by choosing  $h$  directly from the table on page 84 for the value of  $A$  nearest that calculated above.

Therefore, the 1000-gal mark is graduated  $20\frac{5}{8}$  in. from bottom of rod.

It can be seen that the 3000 mark would be above the halfway mark. Therefore, the circular segment considered is the cross section of the void space at the top of the tank. From **Formulas (3) and (5)**:

$$A_{3000} = \frac{4230 - 3000}{1347} = 0.9131, \quad h = 0.6648, \quad x = 36 \times 0.6648 = 23.93 \text{ in.}$$

Therefore, the 3000-gal mark is  $72.00 - 23.93 = 48.07$ , or at the  $48\frac{1}{16}$ -in. mark from the bottom.

### Dimensions of Plane Figures

The following pages contain diagrams of plane figures, along with formulas for finding their dimensions. Illustrations are labeled with the variables given in the formulas. Formulas for one dimension are derived from another by rearranging terms or substituting the formula for one dimension with another, where appropriate.

Formulas that include decimals are derived either from the square root of 2 or  $1/2$ . As such, they are approximations of the dimension being solved for. Formulas that include  $\pi$  are approximated as well.

The dimensions generally are as follows, with distinctions shown as needed for each figure:  $A$  = area;  $s$  = side;  $d$  = diagonal or diameter;  $h, H$  = height;  $a, b, c$  = sides or other segments as shown;  $r, R$  = radius;  $l$  = arc length or other.

**Square:**

$$A = s^2 = \frac{1}{2}d^2$$

$$s = 0.7071d = \sqrt{A}$$

$$d = 1.414s = 1.414\sqrt{A}$$

*Example:* Side  $s$  of a square is 15 in. Find the area of the square and the length of its diagonal.

$$A = s^2 = 15^2 = 225 \text{ in}^2$$

$$d = 1.414s = 1.414 \times 15 = 21.21 \text{ in}$$

*Example:* The area of a square is  $625 \text{ cm}^2$ . Find the length of side  $s$  and diagonal  $d$ .

$$s = \sqrt{A} = \sqrt{625} = 25 \text{ cm}$$

$$d = 1.414\sqrt{A} = 1.414 \times 25 = 35.35 \text{ cm}$$

**Rectangle:**

$$A = ab = a\sqrt{d^2 - a^2} = b\sqrt{d^2 - b^2}$$

$$d = \sqrt{a^2 + b^2}$$

$$a = \sqrt{d^2 - b^2} = A/b$$

$$b = \sqrt{d^2 - a^2} = A/a$$

*Example:* Side  $a$  of a rectangle is 12 cm, and the area is  $70.5 \text{ cm}^2$ . Find the length of side  $b$  and diagonal  $d$ .

$$b = A/a = 70.5/12 = 5.875 \text{ cm}$$

$$d = \sqrt{a^2 + b^2} = \sqrt{12^2 + 5.875^2} = \sqrt{178.516} = 13.361 \text{ cm}$$

*Example:* The sides of a rectangle are 30.5 and 11 cm. Find the area.

$$A = ab = 30.5 \times 11 = 335.5 \text{ cm}^2$$

**Parallelogram:**

$$A = ab$$

$$a = A/b$$

$$b = A/a$$

*Note:* The dimension  $a$  is the length of the vertical drawn at a right angle to side  $b$ . Dimension  $a$  is also considered the height of the parallelogram.

*Example:* Base  $b$  of a parallelogram is 16 ft. Height  $a$  is 5.5 ft. Find the area.

$$A = ab = 5.5 \times 16 = 88 \text{ ft}^2$$

*Example:* The area of a parallelogram is  $12 \text{ in}^2$ . The height is 1.5 in. Find the length of the base  $b$ .

$$b = A/a = 12/1.5 = 8 \text{ in.}$$

**Right Triangle (one angle is a 90-degree angle):**

From the Pythagorean theorem,  $a^2 + b^2 = c^2$ , thus  $A = \frac{ab}{2}$

$$c = \sqrt{a^2 + b^2} \quad a = \sqrt{c^2 - b^2} \quad b = \sqrt{c^2 - a^2}$$

*Example:* Side  $a$  is 6 in. and side  $b$  is 8 in. Find side  $c$  and area  $A$ :

$$c = \sqrt{a^2 + b^2} = \sqrt{6^2 + 8^2} = \sqrt{36 + 64} = \sqrt{100} = 10 \text{ in.}$$

$$A = \frac{ab}{2} = \frac{6 \times 8}{2} = \frac{48}{2} = 24 \text{ in}^2$$

*Example:* Side  $c = 10$  and side  $a = 6$ . Find side  $b$ :

$$b \text{ in.} = \sqrt{c^2 - a^2} = \sqrt{10^2 - 6^2} = \sqrt{100 - 36} = \sqrt{64} = 8 \text{ in.}$$

**Acute Triangle (all three angles measure less than 90 degrees):**

$$A = \frac{bh}{2}, \quad h = \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2}, \quad \text{so } A = \frac{b}{2} \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2}$$

$$A = \sqrt{S(S-a)(S-b)(S-c)}, \quad \text{where } S = \frac{a+b+c}{2}$$

*Example:* Side  $b = 7$  inches,  $h = 4$  inches, so  $A = bh/2 = (7 \text{ in.} \times 4 \text{ in.})/2 = 28 \text{ in}^2/2 = 14 \text{ in}^2$

*Example:* Side  $a = 10$  cm,  $b = 9$  cm, and  $c = 8$  cm. Find the area.

$$\begin{aligned} A &= \frac{b}{2} \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2} = \frac{9}{2} \sqrt{10^2 - \left(\frac{10^2 + 9^2 - 8^2}{2 \times 9}\right)^2} = 4.5 \sqrt{100 - \left(\frac{117}{18}\right)^2} \\ &= 4.5 \sqrt{100 - 42.25} = 4.5 \sqrt{57.75} = 4.5 \times 7.60 = 34.20 \text{ cm}^2 \end{aligned}$$

**Obtuse Triangle (one angle measures greater than 90 degrees):**

$$A = \frac{bh}{2}, \quad h = \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2}, \quad \text{so } A = \frac{b}{2} \sqrt{a^2 - \left(\frac{a^2 + b^2 - c^2}{2b}\right)^2}$$

$$A = \sqrt{S(S-a)(S-b)(S-c)}, \quad \text{where } S = \frac{a+b+c}{2}$$

*Example:* If  $b = 5$  cm and  $h = 3$  cm, then  $A = bh/2 = (5 \text{ cm} \times 3 \text{ cm})/2 = 15 \text{ cm}^2/2 = 7.5 \text{ cm}^2$

*Example:* Side  $a = 5$  in., side  $b = 4$  in., and side  $c = 8$  in. Find the area.

$$S = (a + b + c)/2 = (5 + 4 + 8)/2 = 17/2 = 8.5$$

$$A = \sqrt{S(S-a)(S-b)(S-c)} = \sqrt{8.5(8.5-5)(8.5-4)(8.5-8)}$$

$$= \sqrt{8.5 \times 3.5 \times 4.5 \times 0.5} = \sqrt{66.937} = 8.18 \text{ in}^2$$

**Trapezoid:**

$$\text{Area} = A = \frac{(a+b)h}{2}$$

*Note:* In Britain, this figure is called a *trapezium* and the figure below it is known as a *trapezoid*, which is the reverse of the US terms.

*Example:* Side  $a = 23$  meters, side  $b = 32$  meters, and height  $h = 12$  meters. Find the area.

$$A = \frac{(a+b)h}{2} = \frac{(23+32) \times 12}{2} = \frac{55 \times 12}{2} = 330 \text{ m}^2$$

**Trapezium:**

$$\text{Area} = A = \frac{(H+h)a + bh + cH}{2}$$

The area of a trapezium also can be found by dividing it into two triangles, as indicated by the dashed line. Each area is added to give the total area of the trapezium.

*Example:* Let  $a = 10$  in.,  $b = 2$ ,  $c = 3$  in.,  $h = 8$  in., and  $H = 12$  in. Find the area.

$$\begin{aligned} A &= \frac{(H+h)a + bh + cH}{2} = \frac{(12+8) \times 10 + (2 \times 8) + (3 \times 12)}{2} \\ &= \frac{(20 \times 10) + 16 + 36}{2} = \frac{252}{2} = 126 \text{ in}^2 \end{aligned}$$

**Regular Hexagon:**

$$A = 2.598s^2 = 2.598R^2 = 3.464r^2$$

$$R = s = \text{radius of circumscribed circle} = 1.155r$$

$$r = \text{radius of inscribed circle} = 0.866s = 0.866R$$

$$s = R = 1.155r$$

*Example:* The side  $s$  of a regular hexagon is 40 millimeters. Find the area and the radius  $r$  of the inscribed (drawn inside) circle.

$$A = 2.598s^2 = 2.598 \times 40^2 = 2.598 \times 1600 = 4156.8 \text{ mm}^2$$

$$r = 0.866s = 0.866 \times 40 = 34.64 \text{ mm}$$

*Example:* What is the length of the side of a hexagon circumscribed on (drawn around) a circle of 50 millimeters radius? In this case, because the hexagon is circumscribed on the circle, the circle is *inscribed* (drawn within) the hexagon. Hence,  $r = 50$  mm and  $s = 1.155r = 1.155 \times 50 = 57.75$  mm

**Regular Octagon:**

$$A = \text{area} = 4.828s^2 = 2.828R^2 = 3.314r^2$$

$$R = \text{radius of circumscribed circle} = 1.307s = 1.082r$$

$$r = \text{radius of inscribed circle} = 1.207s = 0.924R$$

$$s = 0.765R = 0.828r$$

*Example:* Find the area and the length of the side of an octagon inscribed (drawn inside) in a circle of 12 inches diameter.

Diameter of circumscribed (drawn around) circle = 12 inches; hence,  $R = 6$  in.

$$A = 2.828R^2 = 2.828 \times 6^2 = 2.828 \times 36 = 101.81 \text{ in}^2$$

$$s = 0.765R = 0.765 \times 6 = 4.590 \text{ in.}$$

Regular Polygon:

$A = \text{area}$        $n = \text{number of sides}$

$$\alpha = 360^\circ \div n \quad \beta = 180^\circ - \alpha$$

$$A = \frac{nsr}{2} = \frac{ns}{2} \sqrt{R^2 - \frac{s^2}{4}}$$

$$R = \sqrt{r^2 + \frac{s^2}{4}} \quad r = \sqrt{R^2 - \frac{s^2}{4}} \quad s = 2\sqrt{R^2 - r^2}$$

*Example:* Find the area of a polygon having 12 sides, inscribed in a circle with radius of 8 centimeters. The length of the side  $s$  is 4.141 centimeters.

$$A = \frac{ns}{2} \sqrt{R^2 - \frac{s^2}{4}} = \frac{12 \times 4.141}{2} \sqrt{8^2 - \frac{4.141^2}{4}} = 24.846 \sqrt{59.713}$$

$$= 24.846 \times 7.727 = 191.98 \text{ cm}^2$$

Circle:

$$\text{Area} = A = \pi r^2 = 3.1416 r^2 = 0.7854 d^2$$

$$\text{Circumference} = C = 2\pi r = 6.2832 r = 3.1416 d$$

$$r = C \div 6.2832 = \sqrt{A} \div 3.1416 = 0.564 \sqrt{A}$$

$$d = C \div 3.1416 = \sqrt{A} \div 0.7854 = 1.128 \sqrt{A}$$

$$\text{Length of arc for center angle of } 1^\circ = 0.008727 d$$

$$\text{Length of arc for center angle of } n^\circ = 0.008727 n d$$

*Example:* Find area  $A$  and circumference  $C$  of a circle with a diameter of  $2\frac{3}{4}$  inches.

$$A = 0.7854 d^2 = 0.7854 \times 2.75^2 = 0.7854 \times 2.75 \times 2.75 = 5.9396 \text{ in}^2$$

$$C = 3.1416 d = 3.1416 \times 2.75 = 8.6394 \text{ in}$$

*Example:* The area of a circle is 16.8 in<sup>2</sup>. Find its diameter.

$$d = 1.128 \sqrt{A} = 1.128 \sqrt{16.8} = 1.128 \times 4.099 = 4.624 \text{ in.}$$

Sector of a Circle:

$$\text{Length of arc} = l = \frac{3.1416 r \alpha}{180} = 0.01745 r \alpha = \frac{2A}{r}$$

$$\text{Area} = A = \frac{1}{2} r l = 0.008727 \alpha r^2$$

$$\text{Central angle, in degrees} = \alpha = \frac{57.296 l}{r}, \quad r = \frac{2A}{l} = \frac{57.296 l}{\alpha}$$

*Example:* The radius of a circle is 35 millimeters, and angle  $\alpha$  of a sector of the circle is 60 degrees. Find the area of the sector and the length of arc  $l$ .

$$A = 0.008727 \alpha r^2 = 0.008727 \times 60 \times 35^2 = 641.41 \text{ mm}^2 = 6.41 \text{ cm}^2$$

$$l = 0.01745 r \alpha = 0.01745 \times 35 \times 60 = 36.645 \text{ mm}$$

*Segment of a Circle:*

$$\begin{aligned}
 A &= \text{area} & l &= \text{length of arc} & \alpha &= \text{angle, in degrees} \\
 c &= 2\sqrt{h(2r-h)} & A &= \frac{1}{2}[rl - c(r-h)] \\
 r &= \frac{c^2 + 4h^2}{8h} & l &= 0.01745r\alpha \\
 h &= r - \frac{1}{2}\sqrt{4r^2 - c^2} = r[1 - \cos(\alpha/2)] & \alpha &= \frac{57.296 l}{r}
 \end{aligned}$$

See also *Segments of a Circle* starting on page 83.

*Example:* The radius  $r$  is 60 inches and the height  $h$  is 8 inches. Find the length of the chord  $c$ .

$$c = 2\sqrt{h(2r-h)} = 2\sqrt{8 \times (2 \times 60 - 8)} = 2\sqrt{896} = 2 \times 29.93 = 59.86 \text{ in.}$$

*Example:* If  $c = 16$ , and  $h = 6$  inches, what is the radius of the circle of which the segment is a part?

$$r = \frac{c^2 + 4h^2}{8h} = \frac{16^2 + 4 \times 6^2}{8 \times 6} = \frac{256 + 144}{48} = \frac{400}{48} = 8\frac{1}{3} \text{ in.}$$

*Cycloid:*

$$\begin{aligned}
 \text{Area} &= A = 3\pi r^2 = 9.4248r^2 = 2.3562d^2 \\
 &= 3 \times \text{area of generating circle}
 \end{aligned}$$

$$\text{Length of cycloid} = l = 8r = 4d$$

See also *Areas Enclosed by Cycloidal Curves* on page 73.

*Example:* The diameter of the generating circle of a cycloid is 6 inches. Find the length  $l$  of the cycloidal curve and the area enclosed between the curve and the base line.

$$l = 4d = 4 \times 6 = 24 \text{ in.} \quad A = 2.3562d^2 = 2.3562 \times 6^2 = 84.82 \text{ in.}^2$$

*Circular Ring (Annulus):*

$$\begin{aligned}
 \text{Area} &= A = \pi(R^2 - r^2) = 3.1416(R^2 - r^2) \\
 &= 3.1416(R+r)(R-r) \\
 &= 0.7854(D^2 - d^2) = 0.7854(D+d)(D-d)
 \end{aligned}$$

*Example:* Let the outside diameter  $D = 12$  centimeters and the inside diameter  $d = 8$  centimeters. Find the area of the ring.

$$A = 0.7854(D^2 - d^2) = 0.7854(12^2 - 8^2) = 0.7854(144 - 64) = 0.7854 \times 80 = 62.83 \text{ cm}^2$$

By the alternative formula:

$$A = 0.7854(D+d)(D-d) = 0.7854(12+8)(12-8) = 0.7854 \times 20 \times 4 = 62.83 \text{ cm}^2$$

*Sector of Circular Ring:*

$$\begin{aligned}
 A &= \text{area}, & \alpha &= \text{central angle, in degrees} \\
 A &= \frac{\alpha\pi}{360}(R^2 - r^2) = 0.00873\alpha(R^2 - r^2) \\
 &= \frac{\alpha\pi}{4 \times 360}(D^2 - d^2) = 0.00218\alpha(D^2 - d^2)
 \end{aligned}$$

*Example:* Find the area, if the outside radius  $R = 5$  inches, the inside radius  $r = 2$  inches, and  $\alpha = 72$  degrees.

$$\begin{aligned}
 A &= 0.00873\alpha(R^2 - r^2) = 0.00873 \times 72(5^2 - 2^2) \\
 &= 0.6286(25 - 4) = 0.6286 \times 21 = 13.2 \text{ in.}^2
 \end{aligned}$$

*Spandrel or Fillet:*

The shaded region is the spandrel (fillet).

$$\text{Area} = A = r^2 - \frac{\pi r^2}{4} = 0.215 r^2 = 0.1075 c^2$$

*Example:* Find the area of a spandrel, the radius of which is 0.7 inch.

$$A = 0.215 r^2 = 0.215 \times 0.7^2 = 0.105 \text{ in}^2$$

*Example:* If chord  $c$  were given as 2.2 inches, what would be the area?

$$A = 0.1075 c^2 = 0.1075 \times 2.2^2 = 0.520 \text{ in}^2$$

*Parabola:*

$$\text{Area} = A = \frac{2}{3} xy$$

The area of the shaded portion is equal to two-thirds of a rectangle which has  $x$  for its base and  $y$  for its height.

*Example:* Let  $x$  in the illustration be 15 centimeters, and  $y$  be 9 centimeters. Find the area of the shaded portion of the parabola.

$$A = \frac{2}{3} xy = \frac{2}{3} \times 15 \times 9 = 10 \times 9 = 90 \text{ cm}^2$$

*Parabola:*

$$l = \text{length of arc} = \frac{p}{2} \left[ \sqrt{\frac{2x}{p} \left( 1 + \frac{2x}{p} \right)} + \ln \left( \sqrt{\frac{2x}{p}} + \sqrt{1 + \frac{2x}{p}} \right) \right]$$

When  $x$  is small in proportion to  $y$ , the following is a close approximation:

$$l = y \left[ 1 + \frac{2}{3} \left( \frac{x}{y} \right)^2 - \frac{2}{5} \left( \frac{x}{y} \right)^4 \right] \quad \text{or} \quad l = \sqrt{y^2 + \frac{4}{3} x^2}$$

*Example:* If  $x = 2$  feet and  $y = 24$  feet, what is the approximate length  $l$  of the parabolic curve?

$$\begin{aligned} l &= y \left[ 1 + \frac{2}{3} \left( \frac{x}{y} \right)^2 - \frac{2}{5} \left( \frac{x}{y} \right)^4 \right] = 24 \left[ 1 + \frac{2}{3} \left( \frac{2}{24} \right)^2 - \frac{2}{5} \left( \frac{2}{24} \right)^4 \right] \\ &= 24 \times 1.0046 = 24.04 \text{ ft} \end{aligned}$$

*Segment of Parabola:*

$$\text{Area } BFC = A = \frac{2}{3} \times \text{Area of parallelogram } BCDE$$

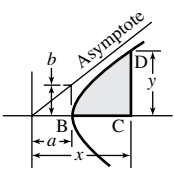

If  $FG$  is the height of the segment, measured at right angles to  $BC$ , then:

$$\text{Area of segment } BFC = \frac{2}{3} (BC)(FG)$$

*Example:* Suppose the length of the chord  $BC = 19.5$  inches, and the distance between lines  $BC$  and  $DE$ , measured at right angles to  $BC$ , is 2.25 inches. Find the area of the segment.

$$\text{Area} = A = \frac{2}{3} (BC)(FG) = \frac{2}{3} \times 19.5 \times 2.25 = 29.25 \text{ in}^2$$

## Hyperbola:

$$\text{Area } BCD = A = \frac{xy}{2} - \frac{ab}{2} \ln \left( \frac{x+y}{a+b} \right)$$

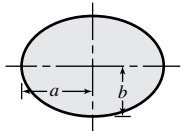

*Example:* The half-axes  $a$  and  $b$  are 3 and 2 inches, respectively. Find the area shown shaded in the illustration for  $x = 8$  inches and  $y = 5$  inches.

Inserting the known values in the formula:

$$\text{Area} = A = \frac{8 \times 5}{2} - \frac{3 \times 2}{2} \times \ln \left( \frac{8+5}{3+2} \right) = 20 - 3 \times \ln(5.167)$$

$$= 20 - 3 \times 1.6423 = 20 - 4.927 = 15.073 \text{ in}^2$$

## Ellipse:

$$\text{Area} = A = \pi ab = 3.1416ab$$

An approximate formula for the perimeter is

$$\text{Perimeter} = P = 3.1416 \sqrt{2(a^2 + b^2)}$$

A closer approximation is  $P = 3.1416 \sqrt{2(a^2 + b^2) - \frac{(a-b)^2}{2.2}}$

*Example:* The larger, or major, axis is 200 millimeters. The smaller, or minor, axis is 150 millimeters. Find the area and the approximate circumference. Here, then,  $a = 100$ , and  $b = 75$ .

$$A = 3.1416ab = 3.1416 \times 100 \times 75 = 23,562 \text{ mm}^2 = 235.62 \text{ cm}^2$$

$$P = 3.1416 \sqrt{2(a^2 + b^2)} = 3.1416 \sqrt{2(100^2 + 75^2)} = 3.1416 \sqrt{2 \times 15,625}$$

$$= 3.1416 \sqrt{31,250} = 3.1416 \times 176.78 = 555.37 \text{ mm} = 55.537 \text{ cm}$$

**Polygons.**—A *polygon* is a many-sided figure in a two-dimensional plane. A polygon is sometimes referred to as an  $n$ -gon, where  $n$  is the number of sides. Triangles are polygons with the least number of sides ( $n = 3$ ), followed by quadrilaterals ( $n = 4$ ), pentagons ( $n = 5$ ), hexagons ( $n = 6$ ), heptagons ( $n = 7$ ), octagons ( $n = 8$ ), and so on.

A *regular polygon* has congruent sides (all sides are of equal measure) and, hence, its interior angles are congruent. In Fig. 4a,  $\beta$  is the measure of each interior angle,  $180 - \beta$  is the exterior angle measure at each vertex.  $\alpha$  is a measure of the central angle. *Irregular polygons* (Fig. 4b) are polygons whose sides are not all congruent.

Both Fig. 4a and Fig. 4b show convex polygons, in which all exterior angles measure less than 180 degrees. A concave polygon has some interior angles that measure greater than 180 degrees (see Fig. 4c). All the formulas in this section concern convex regular polygons.

Fig. 4. Polygons: (a) Convex Regular; (b) Convex Irregular; (c) Concave Irregular.

Fig. 5 shows how a regular polygon is either *inscribed* (drawn inside) or *circumscribed* (drawn around) a circle. A polygon inscribed within a circle, as shown in Fig. 5a, is drawn so that all its vertices touch the circle. Its radius is marked  $r$ . A polygon that circumscribes a circle, as shown in Fig. 5b, is drawn so that the circle touches each of the sides of the polygon. Its radius is marked  $R$ .

Fig. 5. Hexagons: (a) Inscribed (Drawn Inside) a Circle; (b) Circumscribed (Drawn Around) a Circle.

**Formulas and Table for Regular Polygons:** The following formulas and table can be used to calculate area, side length, and radii of inscribed and circumscribed polygons on a circle.

$$A = \frac{nS^2 \cot \alpha}{4} = nR^2 \sin \alpha \cos \alpha = nR^2 \tan \alpha, \quad r = R \cos \alpha = \frac{S \cot \alpha}{2} = \sqrt{\frac{A \cot \alpha}{n}}$$

$$R = \frac{S}{2 \sin \alpha} = \frac{r}{\cos \alpha} = \sqrt{\frac{A}{N \sin \alpha \cos \alpha}}, \quad S = 2R \sin \alpha = 2r \tan \alpha = 2\sqrt{\frac{A \tan \alpha}{N}}$$

**Area, Length of Side, and Inscribed and Circumscribed Radii of Regular Polygons**

**Example 1:** A regular hexagon is inscribed in a circle of 6 in. diameter. Find the area and the radius of an inscribed circle. Here,  $R = 3$  in. and  $n = 6$ . From the table, area  $A = 2.5981R^2 = 2.5981 \times 9 = 23.3829$  in<sup>2</sup>. Radius of inscribed circle,  $r = 0.866R = 0.866 \times 3 = 2.598$  in.

**Example 2:** An octagon is inscribed in a circle of 100 mm diameter. Thus,  $R = 50$  mm and  $n = 8$ . Find the area and radius of an inscribed circle.  $A = 2.8284R^2 = 2.8284 \times 2500 = 7071$  mm<sup>2</sup> = 70.7 cm<sup>2</sup>. Radius of inscribed circle,  $r = 0.9239R = 0.9239 \times 50 = 46.195$  mm.

**Example 3:** Thirty-two bolts are to be equally spaced on the periphery of a 16-in. diameter bolt-circle. Find the chordal distance between the bolts. Chordal distance equals the side length  $S$  of a polygon with  $n = 32$  sides and  $R = 8$ . Hence,  $S = 0.196R = 0.196 \times 8 = 1.568$  in.

**Example 4:** Sixteen bolts are to be equally spaced on the periphery of a bolt-circle, 250 mm diameter. Find the chordal distance between the bolts. Chordal distance equals the side length  $S$  of a polygon with 16 sides.  $R = 125$ . Thus,  $S = 0.3902R = 0.3902 \times 125 = 48.775$  mm.

**Segments of a Circle.**—The table that follows gives the principal formulas for dimensions of circle segments. The dimensions are illustrated in the figures on pages 79 and 84. When two of the dimensions found together in the first column are known, the other dimensions are found by using the formulas in the corresponding row. For example, if radius  $r$  and chord  $c$  are known, solve for angle  $\alpha$  using Equation (13), then use Equations (14) and (15) to solve for  $h$  and  $l$ , respectively. In these formulas, the value of  $\alpha$  is in degrees between 0 and 180°.

### Formulas for Segments of a Circle

Given	Formulas		
$\alpha, r$	$c = 2r \sin\left(\frac{\alpha}{2}\right)$ (1)	$h = r\left(1 - \cos\left(\frac{\alpha}{2}\right)\right)$ (2)	$l = \frac{\pi r \alpha}{180}$ (3)
$\alpha, c$	$r = \frac{c}{2 \sin\left(\frac{\alpha}{2}\right)}$ (4)	$h = -\frac{c}{2} \tan\left(\frac{\alpha}{4}\right)$ (5)	$l = \frac{\pi c \alpha}{360 \sin\left(\frac{\alpha}{2}\right)}$ (6)
$\alpha, h$	$r = \frac{h}{1 - \cos\left(\frac{\alpha}{2}\right)}$ (7)	$c = \frac{2h}{\tan\left(\frac{\alpha}{4}\right)}$ (8)	$l = \frac{\pi h \alpha}{180\left(1 - \cos\left(\frac{\alpha}{2}\right)\right)}$ (9)
$\alpha, l$	$r = \frac{180 l}{\pi \alpha}$ (10)	$c = \frac{360 l \sin\left(\frac{\alpha}{2}\right)}{\pi \alpha}$ (11)	$h = \frac{180 l \left(1 - \cos\left(\frac{\alpha}{2}\right)\right)}{\pi \alpha}$ (12)
$r, c$	$\alpha = \cos^{-1}\left(1 - \frac{c^2}{2r^2}\right)$ (13)	$h = r - \frac{\sqrt{4r^2 - c^2}}{2}$ (14)	$l = \frac{\pi}{90} r \sin^{-1}\left(\frac{c}{2r}\right)$ (15)
$r, h$	$\alpha = 2 \cos^{-1}\left(1 - \frac{h}{r}\right)$ (16)	$c = 2\sqrt{h(2r - h)}$ (17)	$l = \frac{\pi}{90} r \cos^{-1}\left(1 - \frac{h}{r}\right)$ (18)
$r, l$	$\alpha = \frac{180 l}{\pi r}$ (19)	$c = 2r \sin\left(\frac{90 l}{\pi r}\right)$ (20)	$h = r\left(1 - \cos\left(\frac{90 l}{\pi r}\right)\right)$ (21)
$c, h$	$\alpha = 4 \tan^{-1}\left(\frac{2h}{c}\right)$ (22)	$r = \frac{c^2 + 4h^2}{8h}$ (23)	$l = \pi \left(\frac{c^2 + 4h^2}{360h}\right) \tan^{-1}\left(\frac{2h}{c}\right)$ (24)

Given	Formula To Find	Given	Formula To Find
$c, l$	$\frac{360 l}{\pi c} = \frac{\alpha}{\sin\left(\frac{\alpha}{2}\right)}$ (25) Solve Equation (25) for $\alpha$ by iteration <sup>a</sup> , then $r =$ Equation (10) $h =$ Equation (5)	$h, l$	$\frac{180 l}{\pi h} = \frac{\alpha}{1 - \cos\left(\frac{\alpha}{2}\right)}$ (26) Solve Equation (26) for $\alpha$ by iteration <sup>a</sup> , then $r =$ Equation (10) $c =$ Equation (11)

<sup>a</sup> Equations (25) and (26) cannot be easily solved by ordinary means. To solve these equations, test various values of  $\alpha$  until the left side of the equation equals the right side. For example, if given  $c = 4$  and  $l = 5$ , the left side of Equation (25) equals 143.24, and testing various values of  $\alpha$  reveals the right side equals 143.24 when  $\alpha = 129.62^\circ$ .

Angle  $\alpha$  is in degrees,  $0 < \alpha < 180$

Formulas for Circular Segments contributed by Manfred Brueckner.

**Segments of Circles for Radius = 1.**—Formulas for segments of circles are given on pages 79 and 83. When central angle  $\alpha$  and radius  $r$  are known, the following table can be used to find the length of arc  $l$ , height of segment  $h$  ( $x$  in the discussion on page 79), chord length  $c$ , and segment area  $A$ . Column  $A/\pi$  is the ratio of segment area  $A$  to the area of a circle with radius  $r = 1$ , in percent.

When angle  $\alpha$  and radius  $r$  are not known, but segment height  $h$  and chord length  $c$  are known, ratio  $h/c$  can be used to find  $\alpha$ ,  $l$ , and  $A$  by linear interpolation. Radius  $r$  is found by the formula on page 79 or 83. The value of  $l$  is then multiplied by the radius  $r$  and the area  $A$  by  $r^2$ .

Angle  $\alpha$  can be found thus with an accuracy of about 0.001 degree; arc length  $l$  with an error of about 0.02 percent; and area  $A$  with an error ranging from about 0.02 percent for the highest entry value of  $h/c$  to about 1 percent for values of  $h/c$  of about 0.050. For lower values of  $h/c$ , and where greater accuracy is required, area  $A$  should be found by the formula on page 79.

*Example:* A 3-foot diameter cylindrical tank, mounted horizontally, contains fuel. What is the fuel depth, in inches, when the tank is 20% full? *Solution:* Locate 20% in table column  $A/\pi\%$ . The depth equals  $h$  multiplied by the radius:  $hr = 0.50758 \times 1.5 \times 12 = 9.14$  inches

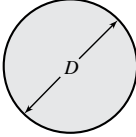

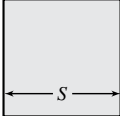

**Segments of Circles for Radius = 1 (US Customary or Metric Units)**

$\alpha$ , Deg.	$l$	$h$	$c$	Area $A$	$A/\pi$ %	$h/c$	$\alpha$ , Deg.	$l$	$h$	$c$	Area $A$	$A/\pi$ %	$h/c$

**Diameters of Circles and Sides of Squares of Equal Area**  
(US Customary or Metric Units)

The table below will be found useful for determining the diameter of a circle of an area equal to that of a square, the side of which is known, or for determining the side of a square which has an area equal to that of a circle, the area or diameter of which is known. For example, if the diameter of a circle is 17½ inches, it is found from the table by reading across from the first column that the side of a square of the same area is 15.51 inches. And both have area 240.53 in<sup>2</sup>.

Dia. of Circle, <i>D</i>	Side of Square, <i>S</i>	Area of Circle or Square	Dia. of Circle, <i>D</i>	Side of Square, <i>S</i>	Area of Circle or Square	Dia. of Circle, <i>D</i>	Side of Square, <i>S</i>	Area of Circle or Square

**Diagonals of Squares and Hexagons.**—The table below gives values of dimensions  $D$  and  $E$  described in the figures and equations that follow.

$$D = \frac{2\sqrt{3}}{3}d = 1.154701d$$

$$E = d\sqrt{2} = 1.414214d$$

A value not given in the table can be obtained from the equations above, or by the simple addition of two or more values taken directly from the table. Further values can be obtained by shifting the decimal point.

*Example 1:* Find  $D$  when  $d = 2 \frac{5}{16}$  inches. From the table, for  $d = 2$ ,  $D = 2.3094$ , and for  $d = \frac{5}{16}$ ,  $D = 0.3608$ . Therefore,  $D = 2.3094 + 0.3608 = 2.6702$  inches.

*Example 2:* Find  $E$  when  $d = 20.25$  millimeters. From the table, for  $d = 20$ ,  $E = 28.2843$ ; for  $d = 0.25$ , that is,  $\frac{1}{4}$ ,  $E = 0.3536$ ; Thus,  $E = 28.2843 + 0.3536 = 28.6379$  millimeters.

## Volumes of Solids

## Cube:

$$\text{Diagonal of cube face} = d = s\sqrt{2}$$

$$\text{Diagonal of cube} = D = \sqrt{\frac{3d^2}{2}} = s\sqrt{3} = 1.732s$$

$$\text{Volume} = V = s^3$$

$$\text{Side } s = \sqrt[3]{V}$$

*Example:* The side of a cube  $s$  measures 9.5 centimeters. Find its volume.

$$\text{Volume} = V = s^3 = 9.5^3 = 9.5 \times 9.5 \times 9.5 = 857.375 \text{ cm}^3$$

*Example:* The volume of cube is 231 cubic centimeters. What is the length of the side?

$$s = \sqrt[3]{V} = \sqrt[3]{231} = 6.136 \text{ cm}$$

## Rectangular Prism:

$$\text{Volume} = V = abc$$

$$a = \frac{V}{bc} \quad b = \frac{V}{ac} \quad c = \frac{V}{ab}$$

*Example:* In a rectangular prism,  $a = 6$  in.,  $b = 5$  in.,  $c = 4$  in. Find the volume.

$$V = abc = 6 \times 5 \times 4 = 120 \text{ in}^3$$

*Example:* What should the height of a box be if it is to contain 25 cubic feet and if it is 4 feet long and  $2\frac{1}{2}$  feet wide? Here,  $a = 4$ ,  $c = 2.5$ , and  $V = 25$ . Then,

$$b = \text{height} = \frac{V}{ac} = \frac{25}{4 \times 2.5} = \frac{25}{10} = 2.5 \text{ ft}$$

## General Right Prism:

$h$  = edge length

$A$  = area of end surface

$V = Ah$

The area  $A$  of the end surface is found by the formulas for areas of plane figures on the preceding pages.

*Example:* A right prism having for its base a regular hexagon with a side  $s$  of 7.5 centimeters is 25 centimeters high. Find the volume.

$$\text{Area of hexagon} = A = 2.598s^2 = 2.598 \times 56.25 = 146.14 \text{ cm}^2$$

$$\text{Volume of prism} = Ah = 25 \times 146.14 = 3653.5 \text{ cm}^3$$

## Right Pyramid:

$$\text{Volume} = V = \left(\frac{1}{3}\right)(\text{Base area} \times h)$$

A square pyramid is pictured. In general, any right pyramid of height  $h$ , whose base is a regular,  $n$ -sided polygon of side length  $s$  has volume:

$$V = \frac{nsrh}{6} = \frac{ns}{6} \sqrt{R^2 - \frac{s^2}{4}}$$

where  $r$  is the radius of the circle inscribed in the base, and  $R$  is the radius of the circle circumscribed on the base.

*Example:* A pyramid having a height of 5 feet has a base formed by a square, the sides of which are 3 feet. Find the volume.

$$\text{Area of base} = 3 \times 3 = 9 \text{ square feet}, \quad h = 5 \text{ feet}$$

$$\text{Volume} = V = \left(\frac{1}{3}\right)(\text{Base area} \times h) = \frac{1}{3} \times 9 \times 5$$

## Frustum of Pyramid:

$$\text{Volume} = V = \frac{h}{3} (A_1 + A_2 + \sqrt{A_1 A_2})$$

*Example:* The pyramid in the previous example is cut off 4.5 feet from the base, and the upper part removed. The sides of the rectangle forming the top surface of the frustum are, then, 1 and 1.5 feet long, respectively. Find the volume of the frustum.

$$\text{Area of top} = A_1 = 1 \times 1.5 = 1.5 \text{ ft}^2 \quad \text{Area of base} = A_2 = 2 \times 3 = 6 \text{ ft}^2$$

$$V = \frac{4 \times 5}{3} (1.5 + 6 + \sqrt{1.5 \times 6}) = 1.5(7.5 + \sqrt{9}) = 1.5 \times 10.5 = 15.75 \text{ ft}^3$$

## Wedge:

$$\text{Volume} = V = \frac{(2a + c)bh}{6}$$

A wedge has five faces, two of them triangles and three trapezoids. *Example:* Let  $a = 4$  inches,  $b = 3$  inches, and  $c = 5$  inches. The height  $h = 4.5$  inches. Find the volume in  $\text{in}^3$  and  $\text{cm}^3$ .

$$V = \frac{(2a + c)bh}{6} = \frac{(2 \times 4 + 5) \times 3 \times 4.5}{6} = \frac{175.5}{6} = 29.25 \text{ in}^3$$

$$V = 29.25 \text{ in}^3 \times 16.387064 \frac{\text{cm}^3}{\text{in}^3} = 479.32162 \text{ cm}^3$$

## Cylinder:

$$\text{Volume} = V = 3.1416r^2h = 0.7854d^2h$$

$$\text{Surface area of open-ended cylinder} = S = 6.2832rh = 3.1416dh$$

$$\text{Total surface area } A \text{ of closed cylinder:}$$

$$A = 6.2832r(r + h)$$

*Example:* Diameter  $d$  of a cylinder is 2.5 inches. Height  $h$  is 20 inches. Find the volume and the area of the open-ended cylindrical surface  $S$ .

$$V = 0.7854d^2h = 0.7854 \times 2.5^2 \times 20 = 0.7854 \times 6.25 \times 20 = 98.17 \text{ in}^3$$

$$S = 3.1416dh = 3.1416 \times 2.5 \times 20 = 157.08 \text{ in}^2$$

## Cylinder Portion:

$$\text{Volume} = V = 1.5708r^2(h_1 + h_2)$$

$$= 0.3927d^2(h_1 + h_2)$$

$$\text{Surface area} = S = 3.1416r(h_1 + h_2)$$

$$= 1.5708d(h_1 + h_2)$$

*Example:* A cylinder 125 millimeters in diameter is cut off at an angle, as shown in the illustration. Dimension  $h_1 = 100$  mm, and  $h_2 = 150$  mm. Find the volume and the surface area  $S$  of the cylinder.

$$V = 0.3927d^2(h_1 + h_2) = 0.3927 \times 125^2 \times (100 + 150)$$

$$= 0.3927 \times 15,625 \times 250 = 1,533,984 \text{ mm}^3 = 1534 \text{ cm}^3$$

$$S = 1.5708d(h_1 + h_2) = 1.5708 \times 125 \times 250$$

$$= 49,087.5 \text{ mm}^2 = 490.9 \text{ cm}^2$$

## Segment of a Cylinder:

In the formulas below, segment area  $A$  and arc length  $l$  refer to the shaded segment of the circle. The formulas of these dimensions, found on page 75, assume the central angle measure is known.

$$\text{Volume} = V = (\% a^3 \pm b \times \text{segment area}) \frac{L}{r \pm b}$$

$$\text{Surface area} = S = (ad \pm b \times \text{arc length area}) \frac{L}{r \pm b}$$

Use + when shaded segment is greater than or equal to one-half the base circle area, use - when it is less than the base circle area.

*Example:* Find the volume of a cylinder segment of a 2-inch high cylinder with a diameter of 5 inches when it is cut so that line  $AC$  passes through the center of the base circle—that is, the base area is a half-circle.

In this case,  $b = 0$ , and  $a = r$ ; that is,  $a = 2.5$  inches. Thus,  $ABC$  is a semicircle, and area  $ABC = 3.1416 \times r^2 \times \frac{1}{2} = 3.1416 \times (2.5)^2 \times \frac{1}{2} = 9.82 \text{ in}^2$ .

$$V = \left( \frac{2}{3} \times 2.5^3 + 0 \times 9.82 \right) \frac{2}{2.5 + 0} = \frac{2}{3} \times 15.625 \times 0.8 = 8.33 \text{ in}^3$$

## Hollow Cylinder:

$$\text{Volume} = V = 3.1416h(R^2 - r^2) = 0.7854h(D^2 - d^2)$$

$$= 3.1416ht(2R - t) = 3.1416ht(D - t)$$

$$= 3.1416ht(2r + t) = 3.1416ht(d + t)$$

$$= 3.1416ht(R + r) = 1.5708ht(D + d)$$

*Example:* A cylindrical shell, 28 cm high, is 36 cm in outside diameter, and 4 cm thick. Find its volume.

$$V = 3.1416ht(D - t) = 3.1416 \times 28 \times 4(36 - 4) = 3.1416 \times 28 \times 4 \times 32 = 11,259.5 \text{ cm}^3$$

## Cone:

$$\text{Volume} = V = \frac{3.1416r^2h}{3} = 1.0472r^2h = 0.2618d^2h$$

$$\text{Conical surface area} = A = 3.1416r\sqrt{r^2 + h^2} = 3.1416rs$$

$$= 1.5708ds$$

$$s = \sqrt{r^2 + h^2} = \sqrt{\frac{d^2}{4} + h^2}$$

*Example:* Find the volume and surface area of a cone, the base of which is a circle of 6 inches diameter and the height of which is 4 inches.

$$V = 0.2618d^2h = 0.2618 \times 6^2 \times 4 = 0.2618 \times 36 \times 4 = 37.7 \text{ in}^3$$

$$A = 3.1416r\sqrt{r^2 + h^2} = 3.1416 \times 3 \times \sqrt{3^2 + 4^2} = 9.4248 \times \sqrt{25} = 47.124 \text{ in}^2$$

## Frustum of Cone:

$V$  = volume       $A$  = area of conical surface

$$V = 1.0472h(R^2 + Rr + r^2) = 0.2618h(D^2 + Dd + d^2)$$

$$A = 3.1416s(R + r) = 1.5708s(D + d)$$

$$a = R - r \quad s = \sqrt{a^2 + h^2} = \sqrt{(R - r)^2 + h^2}$$

*Example:* Find the volume of a frustum of a cone of the following dimensions:  $D = 8$  centimeters;  $d = 4$  centimeters;  $h = 5$  centimeters.

$$V = 0.2618 \times 5(8^2 + 8 \times 4 + 4^2) = 0.2618 \times 5(64 + 32 + 16) = 0.2618 \times 5 \times 112 = 146.61 \text{ cm}^3$$

**Sphere:**

$$\text{Volume} = V = \frac{4\pi r^3}{3} = \frac{\pi d^3}{6} = 4.1888r^3 = 0.5236d^3$$

$$\text{Surface area} = A = 4\pi r^2 = \pi d^2 = 12.5664r^2 = 3.1416d^2$$

$$r = \sqrt[3]{\frac{3V}{4\pi}} = 0.6204\sqrt[3]{V}$$

*Example:* Find the volume and the surface area of a sphere 6.5 centimeters diameter.

$$V = 0.5236d^3 = 0.5236 \times 6.5^3 = 0.5236 \times 6.5 \times 6.5 \times 6.5 = 143.79 \text{ cm}^3$$

$$A = 3.1416d^2 = 3.1416 \times 6.5^2 = 3.1416 \times 6.5 \times 6.5 = 132.73 \text{ cm}^2$$

*Example:* The volume of a sphere is 64 cubic centimeters. Find its radius.

$$r = 0.6204\sqrt[3]{64} = 0.6204 \times 4 = 2.4816 \text{ cm}$$

**Spherical Sector:**

$$V = \frac{2\pi r^2 h}{3} = 2.0944r^2 h$$

= total area of conical and spherical surface

$$A = 3.1416r(2h + \frac{c}{2})$$

$$c = 2\sqrt{h(2r-h)}$$

*Example:* Find the volume of a sector of a sphere with a 6-inch diameter ( $r = 3$  inches) and 1.5-inch height  $h$ . Also find the length of chord  $c$ .

$$V = 2.0944r^2 h = 2.0944 \times 3^2 \times 1.5 = 2.0944 \times 9 \times 1.5 = 28.27 \text{ in}^3$$

$$c = 2\sqrt{h(2r-h)} = 2\sqrt{1.5(2 \times 3 - 1.5)} = 2\sqrt{6.75} = 2 \times 2.598 = 5.196 \text{ in}$$

**Spherical Segment:**

$V =$  volume       $A =$  area of spherical surface

$$V = 3.1416h^2 \left( r - \frac{h}{3} \right) = 3.1416h \left( \frac{c^2}{8} + \frac{h^2}{6} \right)$$

$$A = 2\pi r h = 6.2832r h = 3.1416 \left( \frac{c^2}{4} + h^2 \right)$$

$$c = 2\sqrt{h(2r-h)} \quad r = \frac{c^2 + 4h^2}{8h}$$

*Example:* A segment of a sphere has the following dimensions:  $h = 50$  millimeters;  $c = 125$  millimeters. Find the volume  $V$  and the radius of the sphere of which the segment is a part.

$$V = 3.1416 \times 50 \times \left( \frac{125^2}{8} + \frac{50^2}{6} \right) = 157.08 \times \left( \frac{15,625}{8} + \frac{2,500}{6} \right) = 372,247 \text{ mm}^3 = 372 \text{ cm}^3$$

$$r = \frac{125^2 + 4 \times 50^2}{8 \times 50} = \frac{15,625 + 10,000}{400} = \frac{25,625}{400} = 64 \text{ mm}$$

**Ellipsoid:**

$$V = \frac{4\pi}{3} abc = 4.1888 abc$$

In an ellipsoid of revolution, or spheroid, where  $c = b$ :

$$V = 4.1888 ab^2$$

*Example:* Find the volume of a spheroid in which  $a = 5$  in., and  $b = c = 1.5$  in.

$$V = 4.1888 \times 5 \times 1.5^2 = 47.124 \text{ in}^3$$

**Spherical Zone:**

$$V = 0.5236h\left(\frac{3c_1^2}{4} + \frac{3c_2^2}{4} + h^2\right)$$

$$A = 2\pi rh = 6.2832rh = \text{area of spherical surface}$$

$$r = \sqrt{\frac{c_2^2}{4} + \left(\frac{c_2^2 - c_1^2 - 4h^2}{8h}\right)^2}$$

*Example:* In a spherical zone, let  $c_1 = 3$ ;  $c_2 = 4$ ; and  $h = 1.5$  in. Find the volume.

$$V = 0.5236 \times 1.5 \times \left(\frac{3 \times 3^2}{4} + \frac{3 \times 4^2}{4} + 1.5^2\right) = 0.5236 \times 1.5 \times \left(\frac{27}{4} + \frac{48}{4} + 2.25\right) = 16.493 \text{ in}^3$$

**Spherical Wedge:**

$V =$  volume       $A =$  area of spherical surface

$\alpha =$  center angle in degrees

$$V = \frac{\alpha}{360} \times \frac{4\pi r^3}{3} = 0.0116\alpha r^3$$

$$A = \frac{\alpha}{360} \times 4\pi r^2 = 0.0349\alpha r^2$$

*Example:* Find the area of the spherical surface and the volume of a wedge of a sphere. The diameter of the sphere is 100 mm, and the center angle  $\alpha$  is 45 degrees.

$$V = 0.0116 \times 45 \times 50^3 = 0.0116 \times 45 \times 125,000 = 65,250 \text{ mm}^3 = 65.25 \text{ cm}^3$$

$$A = 0.0349 \times 45 \times 50^2 = 3926.25 \text{ mm}^2 = 39.26 \text{ cm}^2$$

**Hollow Sphere:**

$V =$  volume of material used to make hollow sphere

$$V = \frac{4\pi}{3}(R^3 - r^3) = 4.1888(R^3 - r^3)$$

$$= \frac{\pi}{6}(D^3 - d^3) = 0.5236(D^3 - d^3)$$

*Example:* Find the volume of a hollow sphere, 8 in. in outside diameter, with a thickness of material of 1.5 in.

Here  $R = 4$ ;  $r = 4 - 1.5 = 2.5$ .

$$V = 4.1888(4^3 - 2.5^3) = 4.1888(64 - 15.625) = 4.1888 \times 48.375 = 202.63 \text{ in}^3$$

**Paraboloid:**

$$\text{Volume} = V = \frac{1}{2}\pi r^2 h = 0.3927d^2 h$$

$$\text{Area} = A = \frac{2\pi}{3p} \left[ \sqrt{\left(\frac{d^2}{4} + p^2\right)^3} - p^3 \right]$$

$$\text{where } p = \frac{d^2}{8h}$$

*Example:* Find the volume of a paraboloid in which  $h = 300$  millimeters and  $d = 125$  millimeters.

$$V = 0.3927d^2 h = 0.3927 \times 125^2 \times 300 = 1,840,781 \text{ mm}^3 = 1,840.8 \text{ cm}^3$$

**Paraboloid Segment:**

$$V = \frac{\pi}{2}h(R^2 + r^2) = 1.5708h(R^2 + r^2)$$

$$= \frac{\pi}{8}h(D^2 + d^2) = 0.3927h(D^2 + d^2)$$

*Example:* Find the volume of a segment of a paraboloid in which  $D = 5$  in.,  $d = 3$  in., and  $h = 6$  in.

$$V = 0.3927h(D^2 + d^2) = 0.3927 \times 6 \times (5^2 + 3^2)$$

$$= 0.3927 \times 6 \times 34 = 80.11 \text{ in}^3$$

**Torus:**

$$V = 2\pi^2 Rr^2 = 19.739Rr^2$$

$$= \frac{\pi^2}{4}Dd^2 = 2.4674Dd^2$$

Area of surface =  $A = 4\pi^2 Rr = 39.478Rr$

$$= \pi^2 Dd = 9.8696Dd$$

*Example:* Find the volume and area of surface of a torus in which  $d = 1.5$  in. and  $D = 5$  in.

$$V = 2.4674 \times 5 \times 1.5^2 = 2.4674 \times 5 \times 2.25 = 27.76 \text{ in}^3$$

$$A = 9.8696 \times 5 \times 1.5 = 74.022 \text{ in}^2$$

**Barrel:**

$V =$  approximate volume

If the sides are bent to the arc of a circle:

$$V = \frac{1}{12}\pi h(2D^2 + d^2) = 0.262h(2D^2 + d^2)$$

If the sides are bent to the arc of a parabola:

$$V = 0.209h(2D^2 + Dd + \frac{1}{4}d^2)$$

*Example:* Find the approximate contents of a barrel with sides bent to an arc of a circle, the inside dimensions of which are  $D = 60$  cm,  $d = 50$  cm,  $h = 120$  cm.

$$V = 0.262h(2D^2 + d^2) = 0.262 \times 120 \times (2 \times 60^2 + 50^2)$$

$$= 0.262 \times 120 \times (7200 + 2500) = 0.262 \times 120 \times 9700$$

$$= 304,968 \text{ cm}^3 = 0.305 \text{ m}^3$$

**Ratio of Volumes:**

If  $d =$  base diameter and height of a cone, a paraboloid and a cylinder, and the diameter of a sphere, then the proportions of the volumes of these solids are to each other as follows:

$$\text{Cone:Paraboloid : Sphere:Cylinder} = \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$$

*Example:* Assume, as an example, that a cone, paraboloid, and cylinder each has a diameter of 2 inches, and that the height is 2 inches, and that the diameter of a sphere is 2 inches. Then the volumes, written in formula form, are as follows:

Cone	Paraboloid	Sphere	Cylinder	
$\frac{3.1416 \times 2^2 \times 2}{12}$	$\frac{3.1416 \times (2p)^2 \times 2}{8}$	$\frac{3.1416 \times 2^3}{6}$	$\frac{3.1416 \times 2^2 \times 2}{4}$	$= \frac{1}{3} : \frac{1}{2} : \frac{2}{3} : 1$

### TRIGONOMETRY: SOLUTION OF TRIANGLES

**Terminology.**—A triangle is a polygon with three sides. The sum of the angle measures in any triangle in a plane is 180 degrees. The *triangle inequality* states that the sum of any two side lengths of a triangle is always greater than the length of the third side. It is not possible to construct a triangle that violates the *triangle inequality*.

Triangles are either *right* or *oblique*. A right triangle has a right angle, which measures 90 degrees. Oblique triangles do not contain a right angle.

As with any polygon (see page 60), parts with equal measure are called *congruent*. Thus, a triangle with congruent sides is one whose sides have the same measure. A triangle with two congruent sides is called an *isosceles* triangle; a triangle with all three sides congruent is *equilateral* and hence *equiangular*. Each angle measures  $180 \text{ degrees}/3 = 60 \text{ degrees}$ .

Two positive angles whose measures total 90 degrees are called *complementary* angles. The two acute angles in any right triangle are *complements* of each other. Two positive angles whose sum is 180 degrees are called *supplementary* angles.

An *isosceles* triangle has at least two congruent sides and angles (an equilateral triangle is also *isosceles*). Angles opposite the congruent sides are congruent angles. An *obtuse* triangle has one angle measuring greater than 90 degrees. An *acute* triangle has all three angles measuring less than 90 degrees; hence, an equilateral (equiangular) triangle is also acute.

**Degree and Radian Angle Measure.**—Two modes of measuring angles are *degree* measure and *radian* measure. 1 radian is the measure of a circle's central angle whose arc is the same length as the radius of the circle. For any size circle, 1 radian is approximately 57.3 degrees. Conversion between degree and radian measure is based on the relation  $360^\circ = 2\pi \text{ radians}$ , or  $180^\circ = \pi \text{ radians}$ . ( $\pi$  is the ratio of circumference to diameter,  $C/d$ , and is approximately  $22/7$  or 3.1415926. The actual value of  $\pi$  is an irrational number.) Degree measure is converted to its equivalent radian measure by the formula:

$$\text{Degree measure} \times \pi/180 = \text{Radian measure}$$

For example,  $45^\circ \times \pi/180 = \pi/4$ .

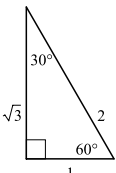

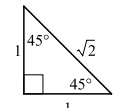

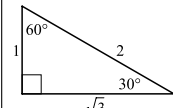

Radian measure is converted to degree by the formula:

$$\text{Radian measure} \times 180/\pi = \text{Degree measure}$$

For example,  $\pi/3 \times 180^\circ = 60^\circ$ . Radian measure is actually unitless, but it is customary to write "rad" to indicate when radian measure is used. Conversions for the essential degree measures of the circle are shown in the chart on page 95.

**Trigonometric Ratios of Essential Angles.**—An acute angle can be any degree measure between  $0^\circ$  and  $90^\circ$ , but the trigonometric values for base angles (designated as  $\theta$  in the table below the diagrams)  $30^\circ$ ,  $45^\circ$ , and  $60^\circ$  are usually memorized. They are derived from right triangles constructed so that the shortest side has length = 1. The other dimensions follow from the geometric construction of the angles (see *Geometric Constructions* starting on page 66) and the Pythagorean theorem. The triangles and trigonometric values of these angle measures, as well as those with base angles  $0^\circ$  and  $90^\circ$  (envisioned by a horizontal and a vertical line segment, respectively) are given in the diagrams and table below. These five are the essential angles.

In the development of the essential angles, the length of the shortest side in each of the triangles is designated as 1, so by construction the other lengths follow. Derivations of the main three functions for the five angle measures is shown. Decimal values of square roots are rounded to three decimal places. In the complete trigonometry tables (Table 2a, Table 2b, and Table 2c), irrational values are carried out to six decimal places, for greater accuracy. For quick estimates, it is useful to memorize the truncated values in the table below.

				
60°-30°-90°	45°-45°-90°	30°-60°-90°	0°-90°-90°	90°-0°-90°
$\sqrt{3}^2 + 1^2 = 2^2$	$1^2 + 1^2 = \sqrt{2}^2$	$1^2 + \sqrt{3}^2 = 2^2$	$1^2 + 0^2 = 1^2$	$0^2 + 1^2 = 1^2$
Base angle = 60°	Base angle = 45°	Base angle = 30°	Base angle = 0°	Base angle = 90°
$\sin 60 = \frac{\sqrt{3}}{2} \approx 0.866$	$\sin 45 = \frac{1}{\sqrt{2}} \approx 0.707$	$\sin 30 = \frac{1}{2} = 0.5$	$\sin 0 = \frac{0}{1} = 0$	$\sin 90 = \frac{1}{1} = 1$
$\cos 60 = \frac{1}{2} = 0.5$	$\cos 45 = \frac{1}{\sqrt{2}} \approx 0.707$	$\cos 30 = \frac{\sqrt{3}}{2} \approx 0.866$	$\cos 0 = \frac{1}{1} = 1$	$\cos 90 = \frac{0}{1} = 0$
$\tan 60 = \frac{\sqrt{3}}{1} \approx 1.732$	$\tan 45 = \frac{1}{1} = 1$	$\tan 30 = \frac{1}{2} = 0.5$	$\tan 0 = \frac{0}{1} = 0$	$\tan 90 = \frac{1}{0}$ UND

Note: Base angles are designated as  $\theta$  in the table below. The values are approximated to three decimal places. If more accuracy is needed, then calculator values carried out further can be used.

Angle $\theta$ , degrees	Angle $\theta$ , radians	$\sin \theta$	$\cos \theta$	$\tan \theta$	csc $\theta$	sec $\theta$	cot $\theta$
0	0	0	1	0	UND	1	UND
30	$\pi/6$	$1/2 = 0.5$	$\sqrt{3}/2 \approx 0.866$	$1/\sqrt{3} \approx 0.577$	2	$2/\sqrt{3} \approx 1.155$	$\sqrt{3}/1 \approx 1.732$
45	$\pi/4$	$1/\sqrt{2} \approx 0.707$	$1/\sqrt{2} \approx 0.707$	1	$\sqrt{2} \approx 1.414$	$\sqrt{2} \approx 1.414$	1
60	$\pi/3$	$\sqrt{3}/2 \approx 0.866$	$1/2 = 0.5$	$\sqrt{3}/1 \approx 1.732$	$2/\sqrt{3} \approx 1.155$	2	$1/\sqrt{3} \approx 0.577$
90	$\pi/2$	1	0	UND	1	UND	0

Note: UND = undefined

### Functions of Angles

**Right Triangle Ratios.**—Trigonometry is the branch of mathematics that addresses the relations of the sides and angles of triangles and the resulting functions of angles. The properties of trigonometry are derived, however, from the relationships of angles and sides in the *right* triangle, as pictured here.

In a right triangle, the 90° angle,  $C$ , is opposite the longest side,  $c$ , the *hypotenuse*. Since the sum of angle measures in any triangle is 180°, the sum of the two acute angles is 90°. The shorter sides,  $a$  and  $b$ , are called the *legs*. They are opposite to angles  $A$  and  $B$ , respectively. By the Pythagorean theorem, the sum of the squares of the legs is equal to the square of the hypotenuse; that is,

$$a^2 + b^2 = c^2$$

Referring to the figure at the bottom of page 95, the ratios of the sides of a right triangle with respect to angle  $A$  are named *sine*  $A$ , *cosine*  $A$ , and *tangent*  $A$  (abbreviated  $\sin A$ ,  $\cos A$ , and  $\tan A$ ). Ratios and reciprocal ratios, named *cosecant*  $A$ , *secant*  $A$ , and *cotangent*  $A$  (abbreviated  $\csc A$ ,  $\sec A$ , and  $\cot A$ ) are defined as:

$$\begin{aligned}\sin A &= \frac{\text{opposite}}{\text{hypotenuse}} = \frac{a}{c} & \csc A &= \frac{\text{hypotenuse}}{\text{opposite}} = \frac{c}{a} = \frac{1}{\sin A} \\ \cos A &= \frac{\text{adjacent}}{\text{hypotenuse}} = \frac{b}{c} & \sec A &= \frac{\text{hypotenuse}}{\text{adjacent}} = \frac{c}{b} = \frac{1}{\cos A} \\ \tan A &= \frac{\text{opposite}}{\text{adjacent}} = \frac{a}{b} & \cot A &= \frac{\text{adjacent}}{\text{opposite}} = \frac{b}{a} = \frac{1}{\tan A}\end{aligned}$$

Similar ratios are defined for angle  $B$ :

$$\begin{aligned}\sin B &= \frac{\text{opposite}}{\text{hypotenuse}} = \frac{b}{c} & \csc B &= \frac{\text{hypotenuse}}{\text{opposite}} = \frac{c}{b} = \frac{1}{\sin B} \\ \cos B &= \frac{\text{adjacent}}{\text{hypotenuse}} = \frac{a}{c} & \sec B &= \frac{\text{hypotenuse}}{\text{adjacent}} = \frac{c}{a} = \frac{1}{\cos B} \\ \tan B &= \frac{\text{opposite}}{\text{adjacent}} = \frac{b}{a} & \cot B &= \frac{\text{adjacent}}{\text{opposite}} = \frac{a}{b} = \frac{1}{\tan B}\end{aligned}$$

Thus, in a given right triangle,  $\sin A = \cos B$ ,  $\cos A = \sin B$ ,  $\tan A = \cot B$ . Similarly,  $\csc A = \sec B$ ,  $\sec A = \csc B$ ,  $\cot A = \tan B$ .

**Law of Sines.**—In any triangle, if  $a$ ,  $b$ , and  $c$  are the sides, and  $A$ ,  $B$ , and  $C$  their opposite angles, respectively, then:

$$\begin{aligned}\frac{a}{\sin A} &= \frac{b}{\sin B} = \frac{c}{\sin C} & \text{so that:} \\ a &= \frac{b \sin A}{\sin B} & \text{or} & \quad a = \frac{c \sin A}{\sin C} \\ b &= \frac{a \sin B}{\sin A} & \text{or} & \quad b = \frac{c \sin B}{\sin C} \\ c &= \frac{a \sin C}{\sin A} & \text{or} & \quad c = \frac{b \sin C}{\sin B}\end{aligned}$$

**Law of Cosines.**—In any triangle, if  $a$ ,  $b$  and  $c$  are the sides and  $A$ ,  $B$ , and  $C$  are the opposite angles, respectively, then:

$$\begin{aligned}a^2 &= b^2 + c^2 - 2bc \cos A \\ b^2 &= a^2 + c^2 - 2ac \cos B \\ c^2 &= a^2 + b^2 - 2ab \cos C\end{aligned}$$

The sine and cosine laws together with the proposition that the sum of the measures of the three angles is 180 degrees are the basis of all formulas relating to the solution of triangles.

Formulas and examples for the solution of right-angle and oblique-angle triangles, arranged in tabular form, are given on the following pages.

**Trigonometric Identities.**—It is possible to express trigonometric ratios in terms of other ratios by way of trigonometric identities. For example,  $\sin(A + B) = \sin A \cos B + \cos A \sin B$ . It may be helpful to use an identity to quickly evaluate a trigonometric function, as shown by the examples given below the trigonometric identities and formulas derived from them.

*Reciprocal Identities:*

$$\tan A = \frac{\sin A}{\cos A} = \frac{1}{\cot A} \qquad \sec A = \frac{1}{\cos A} \qquad \csc A = \frac{1}{\sin A}$$

*Negative-Angle Identities:*

$$\sin(-A) = -\sin A \qquad \cos(-A) = \cos A \qquad \tan(-A) = -\tan A$$

*Cofunction Identities:*

$$\begin{array}{lll} \sin(90 - A) = \cos A & \tan(90 - A) = \cot A & \sec(90 - A) = \csc A \\ \cos(90 - A) = \sin A & \cot(90 - A) = \tan A & \csc(90 - A) = \sec A \end{array}$$

*Pythagorean Identities:*

$$\sin^2 A + \cos^2 A = 1 \qquad 1 + \tan^2 A = \sec^2 A \qquad 1 + \cot^2 A = \csc^2 A$$

*Sum- and Difference-of-Angles Formulas:*

$$\begin{array}{ll} \sin(A + B) = \sin A \cos B + \cos A \sin B & \sin(A - B) = \sin A \cos B - \cos A \sin B \\ \cos(A + B) = \cos A \cos B - \sin A \sin B & \cos(A - B) = \cos A \cos B + \sin A \sin B \\ \tan(A + B) = \frac{\tan A + \tan B}{1 - \tan A \tan B} & \tan(A - B) = \frac{\tan A - \tan B}{1 + \tan A \tan B} \\ \cot(A + B) = \frac{\cot A \cot B - 1}{\cot B + \cot A} & \cot(A - B) = \frac{\cot A \cot B + 1}{\cot B - \cot A} \end{array}$$

*Double-Angle Formulas:*

$$\begin{array}{l} \cos(2A) = \cos^2 A - \sin^2 A = 2 \cos^2 A - 1 = 1 - 2 \sin^2 A \\ \sin(2A) = 2 \sin A \cos A \qquad \tan(2A) = \frac{2 \tan A}{1 - \tan^2 A} = \frac{2}{\cot A - \tan A} \end{array}$$

*Half-Angle Formulas:*

$$\begin{array}{l} \sin(A/2) = \pm \sqrt{(1 - \cos A)/2} \qquad \cos(A/2) = \pm \sqrt{(1 + \cos A)/2} \\ \tan(A/2) = \pm \sqrt{\frac{1 - \cos A}{1 + \cos A}} = \frac{1 - \cos A}{\sin A} = \frac{\sin A}{1 + \cos A} \end{array}$$

*Product-to-Sum Formulas:*

$$\begin{array}{l} \sin A \cos B = \frac{1}{2} [\sin(A + B) + \sin(A - B)] \\ \cos A \cos B = \frac{1}{2} [\cos(A + B) + \cos(A - B)] \\ \sin A \sin B = \frac{1}{2} [\cos(A - B) - \cos(A + B)] \\ \tan A \tan B = \frac{\tan A + \tan B}{\cot A + \cot B} \end{array}$$

*Sum and Difference of Functions Formulas:*

$$\begin{array}{ll} \sin A + \sin B = 2 \sin\left(\frac{A+B}{2}\right) \cos\left(\frac{A-B}{2}\right) & \tan A + \tan B = \frac{\sin(A+B)}{\cos A \cos B} \\ \sin A - \sin B = 2 \sin\left(\frac{A-B}{2}\right) \cos\left(\frac{A+B}{2}\right) & \tan A - \tan B = \frac{\sin(A-B)}{\cos A \cos B} \\ \cos A + \cos B = 2 \cos\left(\frac{A+B}{2}\right) \cos\left(\frac{A-B}{2}\right) & \cot A + \cot B = \frac{\sin(B+A)}{\sin A \sin B} \\ \cos A - \cos B = 2 \sin\left(\frac{A+B}{2}\right) \sin\left(\frac{A-B}{2}\right) & \cot A - \cot B = \frac{\sin(B-A)}{\sin A \sin B} \end{array}$$

### Solution of Right Triangles

Right triangles (one angle measures  $90^\circ$ ) are the easiest to “solve” (that is, to find the missing sides or angles), thanks to the Pythagorean theorem and right triangle ratios.

	<p>The figure to the left shows right triangle <math>ABC</math>. Sides opposite corresponding angles are labeled <math>a, b, c</math>. The formulas in the table are for finding an unknown side or angle from given information as shown. There are several ways to solve for the missing dimension through one of the three basic trigonometric functions.</p> <p>Right angle <math>C</math> is always known (<math>90^\circ</math>), thus, <math>A = 90^\circ - B</math> and <math>B = 90^\circ - A</math>.</p>		
Sides and Angle Known	Formulas for Sides, Angles to be Found		
Sides $a$ and $b$	$c = \sqrt{a^2 + b^2}$	$A = \tan^{-1}(a/b)$	$B = 90^\circ - A$
Side $a$ , hypotenuse $c$	$b = \sqrt{c^2 - a^2}$	$A = \sin^{-1}(a/c)$ or $A = \cos^{-1}(b/c)$	$B = 90^\circ - A$
Side $b$ , hypotenuse $c$	$a = \sqrt{c^2 - b^2}$	$B = \sin^{-1}(b/c)$ or $B = \cos^{-1}(a/c)$	$A = 90^\circ - B$
Hypotenuse $c$ , angle $B$	$b = c \sin B$ or $a = c \cos B$	$a = c \cos B$ or $b = c \sin B$	$A = 90^\circ - B$
Hypotenuse $c$ , angle $A$	$b = c \cos A$ or $a = c \sin A$	$a = c \sin A$ or $b = c \cos A$	$B = 90^\circ - A$
Side $b$ , angle $B$	$c = \frac{b}{\sin B}$ or $c = \frac{a}{\cos B}$	$a = \frac{b}{\tan B}$	$A = 90^\circ - B$
Side $b$ , angle $A$	$c = \frac{b}{\cos A}$ or $c = \frac{a}{\sin A}$	$a = b \tan A$	$B = 90^\circ - A$
Side $a$ , angle $B$	$c = \frac{a}{\cos B}$	$b = a \tan B$	$A = 90^\circ - B$
Side $a$ , angle $A$	$c = \frac{a}{\sin A}$	$b = \frac{a}{\tan A}$	$B = 90^\circ - A$

The solutions of triangles—both right and oblique—rely not only on the Pythagorean theorem and the laws of cosines and of sines, but also on correct use of the trigonometry

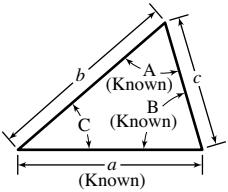

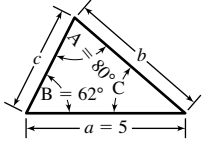

tables, either when given an angle and seeking a trigonometric ratio, or "in reverse," when given a ratio (side lengths) and seeking an angle. A full explanation of trigonometric functions and the use of their tables begins on page 105.

**Solution and Examples of Right Triangles (US Customary or Metric Units)**

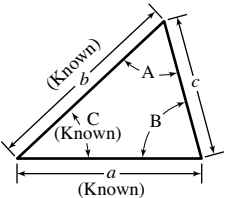

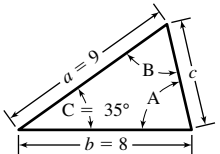

Examples below show angle measure further divided into units of minutes (') and seconds (").  $1^\circ = 60'$ ;  $1' = 60''$ , rather than decimal parts.

 <p>Hypotenuse and One Acute Angle Known</p>	$c = 22 \text{ inches}; B = 41^\circ 36'$ $a = c \cos B = 22 \times \cos 41^\circ 36' = 22 \times 0.74780 = 16.4516 \text{ in.}$ $b = c \sin B = 22 \times \sin 41^\circ 36' = 22 \times 0.66393 = 14.6065 \text{ in.}$ $A = 90^\circ - B = 90^\circ - 41^\circ 36' = 48^\circ 24'$
 <p>Hypotenuse and One Side Known</p>	$c = 25 \text{ centimeters}; a = 20 \text{ centimeters}$ $b = \sqrt{c^2 - a^2} = \sqrt{25^2 - 20^2} = \sqrt{625 - 400} = \sqrt{225} = 15 \text{ cm}$ $\sin A = \frac{a}{c} = \frac{20}{25} = 0.8$ Hence, $A = \sin^{-1}(0.8) = 53^\circ 8'$ $B = 90^\circ - A = 90^\circ - 53^\circ 8' = 36^\circ 52'$
 <p>Two Sides Known</p>	$a = 36 \text{ mm}; b = 15 \text{ mm}$ $c = \sqrt{a^2 + b^2} = \sqrt{36^2 + 15^2} = \sqrt{1296 + 225} = \sqrt{1521} = 39 \text{ mm}$ $\tan A = \frac{a}{b} = \frac{36}{15} = 2.4$ Hence, $A = \tan^{-1}(2.4) = 67^\circ 23'$ $B = 90^\circ - A = 90^\circ - 67^\circ 23' = 22^\circ 37'$
 <p>One Side and One Angle Known</p>	$a = 12 \text{ meters}; A = 65^\circ$ $c = \frac{a}{\sin A} = \frac{12}{\sin 65^\circ} = \frac{12}{0.90631} = 13.2405 \text{ m}$ $b = \frac{a}{\tan A} = 12 \times \cot 65^\circ = 12 \times 0.46631 = 5.5957 \text{ m}$ $B = 90^\circ - A = 90^\circ - 65^\circ = 25^\circ$

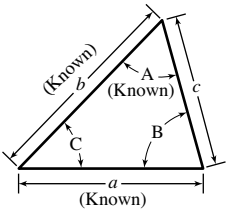

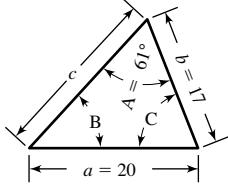

**Solution and Examples of Oblique Triangles (US Customary or Metric Units)**  
*One Side and Two Excluded (Not Between) Angles Known (Law of Sines):*

 <p>One Side and Two Excluded Angles Known</p>	<p>If side <math>a</math>, angle <math>A</math> opposite it, and angle <math>B</math>, are known:</p> $C = 180^\circ - (A + B)$ $b = \frac{a \sin B}{\sin A} \quad c = \frac{a \sin C}{\sin A}$ $\text{Area} = \frac{ab \sin C}{2}$ <p>If angles <math>B</math> and <math>C</math> are known, but not <math>A</math>, then</p> $A = 180^\circ - (B + C).$
 <p>Side and Angles Known</p>	<p><i>Example:</i> <math>a = 5 \text{ cm}; A = 80^\circ; B = 62^\circ</math></p> $C = 180^\circ - (80^\circ + 62^\circ) = 180^\circ - 142^\circ = 38^\circ$ $b = \frac{a \sin B}{\sin A} = \frac{5 \times \sin 62^\circ}{\sin 80^\circ} = \frac{5 \times 0.88295}{0.98481}$ $= 4.483 \text{ cm}$ $c = \frac{a \sin C}{\sin A} = \frac{5 \times \sin 38^\circ}{\sin 80^\circ} = \frac{5 \times 0.61566}{0.98481}$ $= 3.126 \text{ cm}$

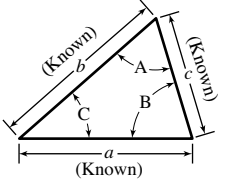

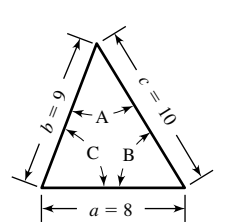

*Two Sides and Included Angle Known:*

 <p>Two Sides and One Included Angle Known</p>	<p>If sides <math>a</math> and <math>b</math>, and angle <math>C</math> between them are known:</p> $\tan A = \frac{a \sin C}{b - (a \cos C)}, \text{ so } A = \tan^{-1} \frac{a \sin C}{b - (a \cos C)}$ $B = 180^\circ - (A + C) \quad c = \frac{a \sin C}{\sin A}$ <p>Side <math>c</math> may also be found directly as below:</p> $c = \sqrt{a^2 + b^2 - (2ab \cos C)}$ $\text{Area} = \frac{ab \sin C}{2}$
 <p>Sides and Angle Known</p>	<p><i>Example:</i> <math>a = 9 \text{ inches}; b = 8 \text{ inches}; C = 35^\circ</math></p> $\tan A = \frac{a \sin C}{b - (a \cos C)} = \frac{9 \times \sin 35^\circ}{8 - (9 \times \cos 35^\circ)}$ $= \frac{9 \times 0.57358}{8 - (9 \times 0.81915)} = \frac{5.16222}{0.62765} = 8.22468$ <p>Hence, <math>A = \tan^{-1}(8.22468) = 83^\circ 4'</math></p> $B = 180^\circ - (A + C) = 180^\circ - 118^\circ 4' = 61^\circ 56'$ $c = \frac{a \sin C}{\sin A} = \frac{9 \times 0.57358}{0.99269} = 5.2 \text{ inches}$

Two Sides and the Angle Opposite One of the Sides Known:

 <p>Two Sides and Angle Opposite One Side Known</p>	<p>If angle A, opposite side a, and other side b are known:</p> $\sin B = \frac{b \sin A}{a} \quad C = 180^\circ - (A + B)$ $c = \frac{a \sin C}{\sin A} \quad \text{Area} = \frac{ab \sin C}{2}$ <p>If <math>B &gt; A</math> but <math>&lt; 90^\circ</math>, a second solution, <math>B_2, C_2, c_2</math>, exists:</p> $B_2 = 180^\circ - B, \quad C_2 = 180^\circ - (A + B_2)$ $c_2 = (a \sin C_2) / \sin A, \quad \text{area} = (ab \sin C_2) / 2$ <p>If <math>a \geq b \sin A</math>, then only the first solution exists. If <math>a &lt; b \sin A</math>, then no solution exists.</p>
 <p>Sides and Angle Known</p>	<p>Example: <math>a = 20</math> cm; <math>b = 17</math> cm; <math>A = 61^\circ</math></p> $\sin B = \frac{b \sin A}{a} = \frac{17 \times \sin 61^\circ}{20}$ $= \frac{17 \times 0.87462}{20} = 0.74343$ <p>Hence, <math>B = \sin^{-1}(0.74343) = 48^\circ 1'</math></p> $C = 180^\circ - (A + B) = 180^\circ - 109^\circ 1' = 70^\circ 59'$ $c = \frac{a \sin C}{\sin A} = \frac{20 \times \sin 70^\circ 59'}{\sin 61^\circ} = \frac{20 \times 0.94542}{0.87462}$ $= 21.62 \text{ cm}$

All Three Sides Known:

 <p>All Three Sides Known</p>	<p>If all three sides a, b, and c are known, then any angle can be found:</p> $\cos A = \frac{b^2 + c^2 - a^2}{2bc} \quad \sin B = \frac{b \sin A}{a}$ $C = 180^\circ - (A + B) \quad \text{Area} = \frac{ab \sin C}{2}$
 <p>Sides Known</p>	<p>Example: <math>a = 8</math> in.; <math>b = 9</math> in.; <math>c = 10</math> in.</p> $\cos A = \frac{b^2 + c^2 - a^2}{2bc} = \frac{9^2 + 10^2 - 8^2}{2 \times 9 \times 10}$ $= \frac{81 + 100 - 64}{180} = \frac{117}{180} = 0.65000$ <p>Hence, <math>A = \cos^{-1}(0.65000) = 49^\circ 27'</math></p> $\sin B = \frac{b \sin A}{a} = \frac{9 \times 0.75984}{8} = 0.85482$ <p>Hence, <math>B = \sin^{-1}(0.85482) = 58^\circ 44'</math></p> $C = 180^\circ - (A + B) = 180^\circ - 108^\circ 11' = 71^\circ 49'$

**Rapid Solution of Right and Oblique Triangles**

		$E = 90^\circ - D$	
	$D = 90^\circ - E$		
	$D = 180^\circ - (E + F)$		
$F = 180^\circ - (D + E)$			$E = 180^\circ - (D + F)$
			$F = 180^\circ - (D + E)$

**Conversion Tables of Angular Measure.**—The accompanying tables of degrees, minutes, and seconds into radians; radians into degrees, minutes, and seconds; radians into degrees and decimals of a degree; and minutes and seconds into decimals of a degree and vice versa facilitate the conversion of measurements.

*Example 1:* The “Degrees, Minutes, and Seconds into Radians” table is used to find the number of radians in 324 degrees, 25 minutes, 13 seconds as follows:

300 degrees	=	5.235988 radians
20 degrees	=	0.349066 radian
4 degrees	=	0.069813 radian
25 minutes	=	0.007272 radian
13 seconds	=	0.000063 radian
324°25'13"	=	5.662202 radians

*Example 2:* The “Radians into Degrees and Decimals of a Degree,” and “Radians into Degrees, Minutes and Seconds” tables are used to find the number of decimal degrees or degrees, minutes and seconds in 0.734 radian as follows:

0.7 radian = 40.1070 degrees	0.7 radian = 40°6'25"
0.03 radian = 1.7189 degrees	0.03 radian = 1°43'8"
0.004 radian = 0.2292 degree	0.004 radian = 0°13'45"
0.734 radian = 42.0551 degrees	0.734 radian = 41°62'78" or 42°3'18"

19	0.3167	39	0.6500	59	0.9833	19	0.0053	39	0.0108	59	0.0164
20	0.3333	40	0.6667	60	1.0000	20	0.0056	40	0.0111	60	0.0167

*Example 3:* Convert 11°37' to decimals of a degree. From the "Min. into Dec. Deg." table, 11' = 0.1833 degree. From the "Sec. into Dec. Deg." table, 37" = 0.0103 degree. Adding, 11°37' = 0.1833 + 0.0103 = 0.1936 degree.

*Example 4:* Convert 0.1234 degree to minutes and seconds. From the "Min. into Dec. Deg." table, 0.1167 degree = 7'. Subtracting 0.1167 from 0.1234 gives 0.0067. From the "Sec. into Dec. Deg." table, 0.0067 = 24" so that 0.1234 = 7°24'.

**Trigonometric Functions.**—Like algebraic functions, trigonometric functions define a relationship between input values (angle measure, expressed in radians) and output values (the trigonometric ratios associated with the angles). Recalling function notation,  $y = f(x)$  (see *ALGEBRA* on page 24), the main trigonometric functions are:  $f(x) = \sin x$ ,  $f(x) = \cos x$ , and  $f(x) = \tan x$ . The trigonometric graphs are derived from the points on the unit circle (circle of radius = 1) “translated” onto the  $(x, y)$ -coordinate system. Because the radius is 1,  $\cos \theta = x/1 = x$ , and  $\sin \theta = y/1 = y$ . Thus, the rectangular coordinate ordered pair  $(x, y)$  on the unit circle corresponds to the trigonometric coordinates  $(\cos \theta, \sin \theta)$ .

Possible confusion arises from the different roles of  $x$  and  $y$  in the two graphs. On the unit circle (Fig. 1),  $x$  and  $y$  are the coordinates of the points that correspond to the adjacent (cosine) and opposite (sine) sides of the right triangle with radius 1. But on the function graphs (Fig. 2a),  $x$  is the *angle measure*, the same as  $\theta$ , and  $y$  is the *value* of the function being plotted. So, “ $\sin x$ ” is the same as “ $\sin \theta$ .” Angle measure is marked in radians (*not degrees*). The graphs of  $y = \sin x$  and  $y = \cos x$  are seen in the figure on the same set of axes (Fig. 2a).  $y = \tan x$  is graphed on its own set of axes (Fig. 2b).

The *domain* of a trigonometric function is the set of angle measures for which the function is defined. The domain of both  $y = \sin x$  and  $y = \cos x$  is the set of all real numbers, since it makes sense to substitute any angle—positive or negative—into these functions. The answer is always a real number. Negative angles indicate an angle measured clockwise from the horizontal, whereas a positive angle (the usual situation) is measured counterclockwise. The domain of  $y = \tan x$ , however, does not include the odd multiples of  $\pi/2$ , since  $\tan x = \sin x/\cos x$ , and so, when  $\cos x = 0$ ,  $\tan x$  is undefined. This happens at  $\pm\pi/2$ ,  $\pm 3\pi/2$ ,  $\pm 5\pi/2$ , . . . . As Fig. 2b shows, the tangent function approaches the dotted lines increasingly closer, never meeting them.

Fig. 1. The Unit Circle, which Gives the Sine and Cosine Relationship for All Angle Measures.

Fig. 2. (a) Graph of  $y = \sin x$  and  $y = \cos x$ ; (b) Graph of  $y = \tan x$ .

Note: For any real number  $x$ ,  $\sin x$  (for example) is defined to be  $\sin(x \text{ radians})$ . Equivalent degree measures are shown here for reference.

The signs of the three main trigonometric functions (positive or negative) are shown in the diagram at the top of page 106. The names of the positive-signed functions of angles that lie in a particular quadrant are shown. All the functions are positive in the first, only  $\sin x$  in the second, only  $\tan x$  in the third, and only  $\cos x$  is positive in the fourth. The mnemonic device “ASTC” for “All Students Take Calculus” is a simple way to remember the signs.  $\csc x$ ,  $\sec x$ , and  $\cot x$  have the same signs as their respective reciprocal functions.

Sin	All
Tan	Cos

Fig. 3. Signs of the Three Main Trigonometric Functions

Fig. 3 shows the values of angles and ratios on the unit circle in great detail, as well as the signs of the functions in each of the four quadrants. Radian and degree measure are also marked off.

The figure also shows the sign (+ or -) and the values of trigonometric functions for angles in each of the four quadrants, 0 to 90, 90 to 180, 180 to 270, and 270 to 360 degrees. A  $\pi$  radian is approximately 3.14, and  $2\pi$  is approximately 6.3 radian measure, as the completed circle indicates. The corresponding degree measures are marked as well, as are the pure radian equivalents. The chart indicates, for example, that all the functions are positive for angles between 0 and 90 degrees. This is because  $x$  and  $y$  are both positive in the first quadrant, and all the trigonometric ratios are therefore also positive. In the same way, the cotangent of an angle between 180 and 270 degrees is positive and has a value between infinity and 0; in other words, the cotangent for 180 degrees is infinitely large and then the cotangent gradually decreases for increasing angles, so that the cotangent for 270 degrees equals 0. The cosine, tangent, and cotangent for angles between 90 and 180 degrees are negative, although they have the same absolute values as their respective angles from 0 to 90 degrees. Negative trigonometric values are preceded by a minus sign; thus,  $\tan 123^\circ 20' = -1.5204$ .

**Inverse Trigonometric Functions:** If the value of the sides of a triangle are known but an angle is unknown, the trigonometric function inverse is used to work backwards to find the angle measure. Inverse trigonometric functions are known by either the prefix "arc" before the name, or by the superscript  $-1$  after the name. The notation is not to be confused with the meaning of a negative exponent.

Trigonometric functions and their inverses are shown below. The roles of  $x$  and  $y$  are reversed in the inverse functions:  $x$  is the ratio given and  $y$  is the angle measure that is sought:

Function	Inverse Function
$y = \sin x$	$y = \arcsin x$ , or $y = \sin^{-1} x$
$y = \cos x$	$y = \arccos x$ , or $y = \cos^{-1} x$
$y = \tan x$	$y = \arctan x$ , or $y = \tan^{-1} x$

The value of the angle that corresponds to the ratio is intended. Any angle can be found using the inverse trig function and relying on trig tables or a calculator. The examples give a few of the essential, familiar ratios for which the angles are readily known.

**Examples:** Given  $\sin x = 1$ ,  $\arcsin(1)$ , or  $\sin^{-1}(1) = 90^\circ$ , or  $\pi/2$ .  
 Given  $\cos x = 0.866$ ,  $\arccos(0.866)$ , or  $\cos^{-1}(0.866) = 60^\circ$ , or  $\pi/3$ .  
 Given  $\tan x = 1$ ,  $\arctan(1)$ , or  $\tan^{-1}(1) = 45^\circ$ , or  $\pi/4$ .

**Trigonometry Tables.**—Table 2a, Table 2b, and Table 2c, starting on page 108, contain the values of the sine, cosine, tangent, and cotangent functions of angles from 0 to 90 degrees. Commonly referred to as "trig tables," these values also are accessible on standard scientific calculators. Function values for all other angles can be obtained from the trig tables by applying the rules for signs of trigonometric functions and the useful relationships among angles given in the following. Secant and cosecant functions can be found from  $\sec A = 1/\cos A$  and  $\csc A = 1/\sin A$ .

The trig tables are divided by a double line. The body of each half table consists of four labeled columns of data between the columns that contain the angles. The angles left of the data increase moving down the table, and angles right of the data increase moving up the table. Column labels above the data identify the trig functions for angles listed in the left column of each half table. Column labels below the data are for angles listed in the right column of each half table. To find the value of a function for a particular angle, first the angle is located in the table, then the appropriate function label across the top or bottom row of the table is located. At the intersection of the angle row and label column is the function value. Angles on opposite sides of each table are complementary angles (i.e.,

their sum is  $90^\circ$ ) and are related (see *Cofunction Identities*, page 97). For example,  $\sin 10^\circ = \cos 80^\circ$  and  $\cos 10^\circ = \sin 80^\circ$ . Expanded trig tables are also available in the *ADDITIONAL* material in the *Machinery's Handbook 31 Digital Edition*.

Angle measures greater than 90 degrees are converted to their *reference angle* (that is, its angle equivalent) before a trigonometric value can be found. If the angle  $\theta$  is between 90 and 180, its reference angle is  $180 - \theta$ ; if  $\theta$  is between 180 and 270, then  $\theta - 180$  is its reference angle; and if it is between 270 and 360 degrees,  $360 - \theta$  is its acute angle equivalent. To determine trigonometric values of functions of angles greater than  $90^\circ$ , subtract 90, 180, 270, or 360 from the angle to get the reference angle less than  $90^\circ$  and use *Table 1, Useful Relationships Among Angles*, to find the equivalent first-quadrant function and angle to look up in the trig tables.

Fig. 4. Signs of Trigonometric Functions, Fractions of  $\pi$ , and Degree-Radian Conversion

Table 1. Useful Relationships Among Angles

Angle Function	$\theta$	$-\theta$	$90^\circ \pm \theta$	$180^\circ \pm \theta$	$270^\circ \pm \theta$	$360^\circ \pm \theta$
sine	$\sin \theta$	$-\sin \theta$	$+\cos \theta$	$\mp \sin \theta$	$-\cos \theta$	$\pm \sin \theta$
cosine	$\cos \theta$	$+\cos \theta$	$\mp \sin \theta$	$-\cos \theta$	$\pm \sin \theta$	$+\cos \theta$
tangent	$\tan \theta$	$-\tan \theta$	$\mp \cot \theta$	$\pm \tan \theta$	$\mp \cot \theta$	$\pm \tan \theta$
cotangent	$\cot \theta$	$-\cot \theta$	$\mp \tan \theta$	$\pm \cot \theta$	$\mp \tan \theta$	$\pm \cot \theta$
secant	$\sec \theta$	$+\sec \theta$	$\mp \csc \theta$	$-\sec \theta$	$\pm \csc \theta$	$+\sec \theta$
cosecant	$\csc \theta$	$-\csc \theta$	$+\sec \theta$	$\mp \csc \theta$	$-\sec \theta$	$\pm \csc \theta$

Examples:  $\cos (270^\circ - \theta) = -\sin \theta$ ;  $\tan (90^\circ + \theta) = -\cot \theta$ .

Example: Find the cosine of  $336^\circ 40'$ . Fig. 4 shows that the cosine of every angle in Quadrant IV ( $270^\circ$  to  $360^\circ$ ) is positive. To find the angle and trig function to use when entering the trig table, subtract 270 from 336 to get  $\cos 336^\circ 40' = \cos (270^\circ + 66^\circ 40')$  and then find the intersection of the "cos row" and the  $270 \pm \theta$  column in Table 1. Because  $\cos (270 \pm \theta)$  in the fourth quadrant is equal to  $\pm \sin \theta$  in the first quadrant, find  $\sin 66^\circ 40'$  in the trig table. Therefore,  $\cos 336^\circ 40' = \sin 66^\circ 40' = 0.918216$ .

Table 2a. Trigonometric Values of Angles from 0° to 15° and 75° to 90°

	cos	sin	cot	tan	Angle		cos	sin	cot	tan	Angle

For angles 30° to 45° 0' (angles found in a column to the left of the data), use the column labels at the top of the table; for angles 45° to 60° 0' (angles found in a column to the right of the data), use the column labels at the bottom of the table.

**Using a Calculator to Find Trigonometric Function Values.**—Scientific calculators are quicker and more accurate than tables for finding trigonometric ratios or angles than relying on trigonometric tables. Inputting an angle, in either degree (**DEG**) or radian (**RAD**) measure, and pressing **SIN**, **COS**, or **TAN** key will produce the ratio value to a many decimal places, which can be rounded to the desired accuracy. Though reciprocal function keys are not usually included on the calculator, using the main three functions and the **1/x** key will produce these ratios as well, since  $\csc x = 1/\sin x$ ,  $\sec x = 1/\cos x$ , and  $\cot x = 1/\tan x$ .

If the triangle's side dimensions are known and the angle measure is sought, then ratio is entered using the keys labeled **sin<sup>-1</sup>**, **cos<sup>-1</sup>**, and **tan<sup>-1</sup>**. If these keys are not present, then **INV** is used with **SIN**, **COS**, or **TAN**. Again, the correct units, whether degree or radian measure, can be chosen.

An advantage of using a calculator instead of a trigonometry table to find function values is that both positive and negative degree measures can be entered into a calculator; also, angles greater than 90 degrees do not need to be converted to their acute angle equivalent. Interpolation for angles whose measures fall between the values available in the tables is also not necessary.

*Example:* Use a calculator to find all six of the trigonometry function values, to four decimal places, of 172°.

*Solution:* The degree measure can be entered as is, without having to first inspect its quadrant and reference (acute) angle. Enter 172 in DEG mode, then, for the three main values, choose **SIN**, **COS**, **TAN**, each time rounding answer to four decimal places.

$$\begin{array}{ll} \sin(172^\circ) = 0.1392 & \csc(172^\circ) = 1/\sin(172^\circ) = 7.1853 \\ \cos(172^\circ) = -0.9903 & \sec(172^\circ) = 1/\cos(172^\circ) = -1.0098 \\ \tan(172^\circ) = -0.1405 & \cot(172^\circ) = 1/\tan(172^\circ) = -7.1153 \end{array}$$

If a scientific calculator or computer is not available, tables are the easiest way to find trig values. However, trigonometric function values can be calculated very accurately without a scientific calculator by using the infinite series formulas (see **CALCULUS**):

$$\begin{array}{l} \sin A = A - \frac{A^3}{3!} + \frac{A^5}{5!} - \frac{A^7}{7!} \pm \dots \quad \cos A = 1 - \frac{A^2}{2!} + \frac{A^4}{4!} - \frac{A^6}{6!} \pm \dots \\ \sin^{-1} A = A + \frac{1}{2} \times \frac{A^3}{3} + \frac{1}{2} \times \frac{3}{4} \times \frac{A^5}{5} + \dots \quad \tan^{-1} A = A - \frac{A^3}{3} + \frac{A^5}{5} - \frac{A^7}{7} \pm \dots \end{array}$$

where angle *A* is expressed in radians (multiplying degrees by  $\pi/180 = 0.0174533$  gives radian measure). Generally, calculating just three or four terms of the expression is sufficient for accuracy. In these formulas, a number followed by the symbol **!** is called a **factorial** (see **Factorial Notation** on page 13). Except for 0!, which equals 1,  $n! = n(n-1)(n-2) \dots$  down to 1. For example,  $4! = 4 \times 3 \times 2 \times 1 = 24$ . As an example,  $\sin 42^\circ = \sin(42 \times 0.0174533) = \sin(0.733) = 0.733 - (0.733)^3/3! + (0.733)^5/5! - \dots \approx 0.66912$ , which is close to the calculator answer of higher accuracy, 0.669130606.

**Versed Sine and Versed Cosine.**—These functions are sometimes used in formulas for segments of a circle and may be obtained using the relationships:

$$\text{versed } \sin \theta = 1 - \cos \theta; \quad \text{versed } \cos \theta = 1 - \sin \theta.$$

**Sevolute Functions.**—Sevolute functions are used in calculating the form diameter of involute splines. They are computed by subtracting the involute function of an angle from the secant of the angle ( $1/\cos \theta = \sec \theta$ ). For example,  $\text{sevolute of } 20^\circ = \secant \text{ of } 20^\circ - \text{involute function of } 20^\circ = 1.064178 - 0.014904 = 1.049274$ .

**Involute Functions.**—Involute functions are used in certain formulas relating to the design and measurement of gear teeth as well as measurement of threads over wires. (See, for example, pages 2130 through 2133, 2286, and 2350).

The value of an involute function is calculated from the following formulas:

$$\begin{array}{ll} \text{Involute of } \theta = (\tan \theta) - \theta & \text{for } \theta \text{ in radians, and} \\ \text{Involute of } \theta = (\tan \theta) - \pi \times \theta/180 & \text{for } \theta \text{ in degrees.} \end{array}$$

*Example:* For an angle of 14 degrees and 10 minutes (14° 10'), the involute function is found as follows: 10 minutes = 10/60 = 0.166666°, 14 + 0.166666 = 14.166666°, so that the involute of 14.166666° = (tan 14.166666) -  $\pi \times 14.166666/180 = 0.252420 - 0.247255 = 0.005165$ .

The same result would be obtained by using the conversion tables beginning on page 112 to convert 14° 10' to radians and then applying the first involute formula for radian measure given above.

## Involute Function Values for Angles from 14 to 23 Degrees

## Spherical Trigonometry

Spherical trigonometry deals with the measurement of angles of polygons—triangles in particular—that lie on the surface of spheres. The sides of a spherical triangle conform to the surface of the sphere, and, unlike a plane triangle, the sum of angle measures of a spherical triangle ranges from  $180^\circ$  to  $540^\circ$ .

**Right-Angle Spherical Trigonometry.**—The solid black lines  $A$ ,  $B$ , and  $C$  of Fig. 1 represent the sides of a *right* spherical triangle. The dashed lines  $J$  and  $K$  are radii of the sphere extending from the center of the sphere to the triangle's vertices. The several plane triangles, indicated by the various broken lines, are formed from the radii and vertices of the spherical triangle.  $J$  and  $K$  are radii and thus have the same value.

Fig. 1. Right Spherical Triangle

## Formulas for Right Spherical Triangles

Formulas for Lengths				
$A = K \times \frac{\pi}{180} \times F^\circ$	$B = J \times \frac{\pi}{180} \times G^\circ$	$C = J \times \frac{\pi}{180} \times H^\circ$	$J = \frac{180}{\pi} \times \frac{B}{G^\circ}$	$K = \frac{180}{\pi} \times \frac{A}{F^\circ}$

Formulas for Angles		
$F^\circ = \frac{180}{\pi} \times \frac{A}{K}$	$G^\circ = \frac{180}{\pi} \times \frac{B}{J}$	$H^\circ = \frac{180}{\pi} \times \frac{C}{J}$

Angle	Angular Relationships		
$D$	$\sin D = \sin F \times \csc H$	$\cos D = \tan G \times \cot H$	$\tan D = \tan F \times \csc G$
$E$		$\cos E = \cos G \times \sin D$	$\tan E = \tan G \times \csc F$
$F$	$\sin F = \tan G \times \cot E$	$\cos F = \sec G \times \cos H$	$\tan F = \tan D \times \sin G$
$G$		$\cos G = \cos H \times \sec F$	$\tan G = \sin F \times \tan E$
$H$	$\cos H = \cos G \times \cos F$	$\cos H = \cot D \times \cot E$	

Area Formula
$\text{Area} = K^2 \times \frac{\pi}{180} (D^\circ + E^\circ + 90^\circ - 180^\circ) = K^2 \times \frac{\pi}{180} (D^\circ + E^\circ - 90^\circ)$

The side and angle labels in examples that follow refer to those of the right spherical triangle in Fig. 1.

*Example 1:* Find the length of arc  $A$  of a right spherical triangle on the surface of a sphere where radius  $K = 30.00$  inches and angle  $F = 10^\circ$ .

$$\text{Solution: } A = K \times \frac{\pi}{180} \times F = 30 \times \frac{\pi}{180} \times 10 = 5.2359 \text{ in.}$$

*Example 2:* Find length of arc  $B$  on a sphere of radius  $J = 11.20$  inches if angle  $G = 10^\circ$ .

$$\text{Solution: } B = J \times \frac{\pi}{180} \times G = 11.20 \times \frac{\pi}{180} \times 10 = 1.9547 \text{ in.}$$

*Example 3:* A right spherical triangle is to be constructed on the surface of a sphere 22.400 inches in diameter. Side  $A$  is 7.125 inches and angle  $E$  is  $57^\circ 59' 19''$ . Determine the lengths of sides  $B$  and  $C$ , and the measure of angle  $D$ , and the area of the triangle.

*Solution:* The radius of the sphere,  $J = K = 11.200$ , and the length of side  $A$  is used to find the value of angle  $F$ . Angle  $E$  is converted to decimal degree format for simplicity; then angles  $E$  and  $F$  are used to solve the equation for angle  $\tan G$ . Side  $B$  and angle  $D$  can then be found. Angle  $H$  can be calculated using either of the two equations given for  $\cos H$ , and finally the length of side  $C$  can be found. Notice that the sum of angles  $D + E + 90^\circ$  is not equal to  $180^\circ$ , but  $194.98^\circ$ . Calculation details are as follows:

$$F^\circ = \frac{180}{\pi} \times \frac{A}{K} = \frac{180}{\pi} \times \frac{7.125}{11.200} = 36.449324^\circ$$

$$E = 57^\circ 59' 19'' = 57 + \frac{59}{60} + \frac{19}{3600} = 57.988611^\circ$$

$$\tan G = \sin F \times \tan E = \sin(36.449324^\circ) \times \tan(57.988611^\circ) = 0.950357$$

$$G = \tan^{-1}(0.950357) = 43.541944^\circ$$

$$B = J \times \frac{\pi}{180} \times G^\circ = 11.200 \times \frac{\pi}{180} \times 43.541944 = 8.511443$$

$$\tan D = \tan F \times \csc G = \tan(36.449324^\circ) \times \csc(43.541944^\circ) = 1.0721569$$

$$D = \frac{180}{\pi} \times \tan^{-1}(1.0721569) = 46.994354^\circ$$

$$\cos H = \cos G \times \cos F = \cos(43.541944^\circ) \times \cos(36.449324^\circ) = 0.58307306$$

$$H = \frac{180}{\pi} \times \cos^{-1}(0.58307306) = 54.333023^\circ$$

$$C = J \times \frac{\pi}{180} \times H^\circ = 11.200 \times \frac{\pi}{180} \times 54.333023^\circ = 10.62085$$

$$\text{Angles}(D + E + 90^\circ) = 46.994354^\circ + 57.988611^\circ + 90^\circ = 194.98297^\circ$$

$$\text{Area} = 11.200^2 \times (194.98297 - 180) = 50.142591 \text{ in}^2$$

*Example 4:* A right spherical triangle on a 20-mm diameter sphere has two  $90^\circ$  angles, and the distance  $B$  between the  $90^\circ$  angles is  $\frac{1}{3}$  the circumference of the sphere. Find angle  $E$ , the area of the triangle, and check using the conventional formula for area of a sphere.

*Solution:* By inspection, angle  $G$  is  $360^\circ/3 = 120^\circ$ . Because angles  $D$  and  $G$  are known, angle  $E$  can be calculated using  $\cos E = \cos G \times \sin D$ . Therefore,

$$\cos E = \cos G \times \sin D = \cos(120^\circ) \times \sin(90^\circ) = -0.5$$

$$E = \cos^{-1}(-0.5) = 120^\circ$$

$$\text{Area} = 10^2 \times \frac{\pi}{180} (120^\circ + 90^\circ + 90^\circ - 180^\circ) = 100 \times 2.0943951 = 209.4 \text{ mm}^2$$

$$\text{Check: Total area of 20-mm diameter sphere}/6 = \frac{4\pi R^2}{6} = \frac{4\pi(100)}{6} = 209.4 \text{ mm}^2$$

**Oblique Spherical Trigonometry.**—The heavy solid lines  $B$ ,  $C$ , and  $S$  of Fig. 2 represent the sides of an *oblique* spherical triangle. The dashed lines  $J$  and  $L$  are radii of the sphere extending from the center of the sphere to the vertices of the triangle. The several plane triangles, indicated by the various broken lines, are formed from the radii and vertices of the spherical triangle.  $J$  and  $L$  are radii and thus have the same value.

Fig. 2. Oblique Spherical Triangle

**Formulas for Oblique Spherical Triangles**

Formulas for Lengths				
$B = J \times \frac{\pi}{180} \times G^\circ$	$C = J \times \frac{\pi}{180} \times H^\circ$	$S = L \times \frac{\pi}{180} \times R^\circ$	$J = \frac{180}{\pi} \times \frac{B}{G^\circ}$	$L = \frac{180}{\pi} \times \frac{S}{R^\circ}$
Formulas for Angles				
$G^\circ = \frac{180}{\pi} \times \frac{B}{J}$	$H^\circ = \frac{180}{\pi} \times \frac{C}{J}$	$R^\circ = \frac{180}{\pi} \times \frac{S}{L}$		
Angular Relationships				
Angle	Relationships	Angle	Relationships	
$D$	$\sin D = \sin R \times \sin E \times \csc G$	$E$	$\sin E = \sin D \times \sin G \times \csc R$	
$G$	$\sin G = \sin R \times \sin E \times \csc D$	$E_1$	$\cot E_1 = \tan D \times \cos H$	
$N$	$\cos N = \cos D \times \csc E_1 \times \sin E_2$	$E_2$	$\cot E_2 = \tan N \times \cos R$	
$N$	$\cot\left(\frac{N}{2}\right) = \frac{\sin\left(\frac{R+G}{2}\right)}{\sin\left(\frac{R-G}{2}\right)} \times \tan\left(\frac{D-E}{2}\right)$	$H$	$\tan\left(\frac{H}{2}\right) = \frac{\sin\left(\frac{D+E}{2}\right)}{\sin\left(\frac{D-E}{2}\right)} \times \tan\left(\frac{R-G}{2}\right)$	
$R$	$\sin R = \sin D \times \sin G \times \csc E$			
Area Formula				
$\text{Area} = L^2 \times \frac{\pi}{180} (D + E + N - 180^\circ)$				

The side and angle labels in the examples that follow refer to those of the oblique spherical triangle in Fig. 2.

*Example:* An oblique spherical triangle is to be constructed on the surface of a sphere of unknown size. The length of side  $S$  will be 5.470 inches; the spherical angle of arc  $S$  must be  $51^\circ 17' 31''$  (angle  $R$  in Fig. 2). Angle  $D$  must be  $59^\circ 55' 10''$ , and angle  $E$  must be  $85^\circ 36' 32''$ . Find the size of the sphere, lengths of sides  $B$  and  $C$ , and the value of angle  $N$ .

*Solution:* Convert known angles to decimal degree format to simplify calculations:

$$R = 51^\circ + \frac{17}{60} + \frac{31}{3600} = 51.291944^\circ$$

$$D = 59^\circ + \frac{55}{60} + \frac{10}{3600} = 59.919444^\circ$$

$$E = 85^\circ + \frac{36}{60} + \frac{32}{3600} = 85.608889^\circ$$

Find the radius of the sphere:

$$L = \frac{180}{\pi} \times \frac{S}{R^\circ} = \frac{180}{\pi} \times \frac{5.470}{51.291944^\circ} = 6.11 \text{ inches}$$

Find the values of angles of  $G$  and  $H$  in order to get lengths of sides  $B$  and  $C$ . Then solve for the value of angle  $N$ , and finally the area. Remember that both  $J$  and  $L$  are radii, thus  $J=L$ .

$$\begin{aligned} \sin G &= \sin R \times \sin E \times \csc D = 0.780342 \times 0.997065 \times 1.15564 \\ &= 0.899148 \end{aligned}$$

$$G = \sin^{-1}(0.899148) = 64.046301^\circ$$

$$B = J \times \frac{\pi}{180} \times G^\circ = 6.11 \times \frac{\pi}{180} \times 64.046301^\circ = 6.829873 \text{ inches}$$

$$\tan\left(\frac{H}{2}\right) = \frac{\sin\left(\frac{D+E}{2}\right)}{\sin\left(\frac{D-E}{2}\right)} \times \tan\left(\frac{R-G}{2}\right) = \frac{\sin(72.76417)}{\sin(-12.844723)} \times \tan(-6.377185)$$

$$= \frac{0.955093}{-0.222310} (-0.111765) = 0.480167$$

$$\frac{H}{2} = \tan^{-1}(0.480167) = 25.648772^\circ, \quad H = 51.297543^\circ$$

$$C = J \times \frac{\pi}{180} \times H^\circ = 6.11 \times \frac{\pi}{180} \times 51.297543^\circ = 5.470350 \text{ inches}$$

$$\cot\left(\frac{N}{2}\right) = \frac{\sin\left(\frac{R+G}{2}\right)}{\sin\left(\frac{R-G}{2}\right)} \times \tan\left(\frac{D-E}{2}\right) = \frac{\sin(57.669123)}{\sin(-6.377185)} \times \tan(-12.844723)$$

$$= \frac{0.844974}{-0.111073} (-0.228015) = 1.7345957$$

$$\frac{N}{2} = \cot^{-1}(1.7345957) = 29.963587^\circ, \quad N = 59.927175^\circ$$

$$\text{Area} = L^2 \times \frac{\pi}{180} (D + E + N - 180^\circ) = 16.585 \text{ in}^2$$

The triangle is an isosceles spherical triangle with legs  $B$  and  $C$  each being 5.470 inches.

If angle  $E_1$  or  $E_2$  is known, then any problem involving oblique spherical triangles can be solved as two right spherical triangles; in that case, the equations for right spherical triangles are used.

## Compound Angles

Referring to the *Formulas for Compound Angles* on page 121, in Fig. 1 is shown what might be considered as a thread-cutting tool without front clearance.  $A$  is a known angle in plane  $y-y$  of the top surface.  $C$  is the corresponding angle in plane  $x-x$  that is at some given angle  $B$  with plane  $y-y$ . Thus, angles  $A$  and  $B$  are components of the compound angle  $C$ .

*Example Referring to Fig. 1:* Angle  $2A$  in plane  $y-y$  is known, as is angle  $B$  between planes  $x-x$  and  $y-y$ . It is required to find compound angle  $2C$  in plane  $x-x$ .

*Solution:* Let  $2A = 60$  and  $B = 15$ ; then

$$\tan C = \tan A \times \cos B = \tan 30^\circ \times \cos 15^\circ$$

$$\tan C = 0.57735 \times 0.96592 = 0.55767$$

$$C = 29^\circ 8.8' \quad 2C = 58^\circ 17.6'$$

Fig. 2 shows a thread-cutting tool with front clearance angle  $B$ . Angle  $A$  is one-half the angle between the cutting edges in plane  $y-y$  of the top surface, and compound angle  $C$  is one-half the angle between the cutting edges in a plane  $x-x$  at right angles to the inclined front edge of the tool. The angle between planes  $y-y$  and  $x-x$  is, therefore, equal to clearance angle  $B$ .

*Example Referring to Fig. 2:* Find the angle  $2C$  between the front faces of a thread-cutting tool having a known clearance angle  $B$  that will permit the grinding of these faces so their top edges form the desired angle  $2A$  for cutting the thread.

*Solution:* Let  $2A = 60$  and  $B = 15$ ; then

$$\tan C = \frac{\tan A}{\cos B} = \frac{\tan 30^\circ}{\cos 15^\circ} = \frac{0.57735}{0.96592}$$

$$\tan C = 0.59772$$

$$C = 30^\circ 52' \quad 2C = 61^\circ 44'$$

In Fig. 3 is shown a form-cutting tool in which the angle  $A$  is one-half the angle between the cutting edges in plane  $y-y$  of the top surface;  $B$  is the front clearance angle; and  $C$  is one-half the angle between the cutting edges in plane  $x-x$  at right angles to the front edges of the tool. The formula for finding angle  $C$  when angles  $A$  and  $B$  are known is the same as that for Fig. 2.

*Example Referring to Fig. 3:* Find the angle  $2C$  between the front faces of a form-cutting tool having a known clearance angle  $B$  that will permit the grinding of these faces so their top edges form the desired angle  $2A$  for form cutting.

*Solution:* Let  $2A = 46$  and  $B = 12$ ; then

$$\tan C = \frac{\tan A}{\cos B} = \frac{\tan 23^\circ}{\cos 12^\circ} = \frac{0.42447}{0.97815}$$

$$\tan C = 0.43395$$

$$C = 23^\circ 27.5' \quad 2C = 46^\circ 55'$$

In Fig. 4 is shown a wedge-shaped block, the top surface of which is inclined at compound angle  $C$  with the base in a plane at right angles with the base and at angle  $R$  with the front edge. Angle  $A$ , in the vertical plane of the front of the plate, and angle  $B$ , in the vertical plane of one side that is at right angles to the front, are components of angle  $C$ .

**Formulas for Compound Angles**

<p>Fig. 1.      Fig. 2.      Fig. 3.</p>	<p>For given angles <math>A</math> and <math>B</math>, find the resultant angle <math>C</math> in plane <math>x-x</math>. <p>Fig. 4.</p>	<p><b>Fig. 4.</b> In machining a plate to angles <math>A</math> and <math>B</math>, the plate is held at angle <math>C</math> in plane <math>x-x</math>. Angle of rotation <math>R</math> in plane parallel to base (or complement of <math>R</math>) is for locating plate so that plane <math>x-x</math> is perpendicular to axis of pivot on angle-plate or work-holding vise.</p> $\tan R = \frac{\tan B}{\tan A}, \quad \tan C = \frac{\tan A}{\cos R}$
<p>Fig. 5.</p>	<p><b>Fig. 5.</b> Angle <math>R</math> in horizontal plane parallel to base is angle from plane <math>x-x</math> to side having angle <math>A</math>.</p> $\tan R = \frac{\tan A}{\tan B}$ $\tan C = \tan A \times \cos R = \tan B \times \sin R$ <p>Compound angle <math>C</math> is angle in plane <math>x-x</math> from base to corner formed by intersection of planes inclined to angles <math>A</math> and <math>B</math>. This formula for <math>C</math> may be used to find cotangent of complement of <math>C_1</math>, Fig. 6.</p>
<p>Fig. 6.</p>	<p><b>Fig. 6.</b> Angles <math>A_1</math> and <math>B_1</math> are measured in vertical planes of front and side elevations. Plane <math>x-x</math> is located by angle <math>R</math> from center-line or from plane of angle <math>B_1</math>.</p> $\tan R = \frac{\tan A_1}{\tan B_1}$ $\tan C_1 = \frac{\tan A_1}{\sin R} = \frac{\tan B_1}{\cos R}$ <p>The resultant angle <math>C_1</math> would be required in drilling hole for pin.</p>

*Example Referring to Fig. 4:* Find the compound angle  $C$  of a wedge-shaped block having known component angles  $A$  and  $B$  in sides at right angles to each other.

$C$  = compound angle in plane  $x-x$ , which is the resultant of angles  $A$  and  $B$

*Solution:* Let  $A = 47^{\circ}14'$  and  $B = 38^{\circ}10'$ ; then

$$\tan R = \frac{\tan B}{\tan A} = \frac{\tan 38^{\circ}10'}{\tan 47^{\circ}14'} = \frac{0.78598}{1.0812} = 0.72695 \quad R = 36^{\circ}0.9'$$

$$\tan C = \frac{\tan A}{\cos R} = \frac{\tan 47^{\circ}14'}{\cos 36^{\circ}0.9'} = \frac{1.0812}{0.80887} = 1.3367 \quad C = 53^{\circ}12'$$

In Fig. 5 is shown a four-sided block, two sides of which are at right angles to each other and to the base of the block. The other two sides are inclined at an oblique angle with the base. Angle  $C$  is a compound angle formed by the intersection of these two inclined sides and the intersection of a vertical plane passing through  $x-x$ , and the base of the block. The components of angle  $C$  are angles  $A$  and  $B$ , and angle  $R$  is the angle in the base plane of the block between the plane of angle  $C$  and the plane of angle  $A$ .

*Example Referring to Fig. 5:* Find the angles  $C$  and  $R$  in the block shown in Fig. 5 when angles  $A$  and  $B$  are known.

*Solution:* Let angle  $A = 27^{\circ}$  and  $B = 36^{\circ}$ ; then

$$\cot C = \sqrt{\cot^2 A + \cot^2 B} = \sqrt{1.9626^2 + 1.3764^2} = \sqrt{5.74627572} = 2.3971$$

$$C = 22^{\circ}38.6'$$

$$\tan R = \frac{\cot B}{\cot A} = \frac{\cot 36^{\circ}}{\cot 27^{\circ}} = \frac{1.3764}{1.9626} = 0.70131 \quad R = 35^{\circ}2.5'$$

*Example Referring to Fig. 6:* A rod or pipe is inserted into a rectangular block at an angle. Angle  $C_1$  is the compound angle of inclination (measured from the vertical) in a plane passing through the center line of the rod or pipe and at right angles to the top surface of the block. Angles  $A_1$  and  $B_1$  are the angles of inclination of the rod or pipe when viewed respectively in the front and side planes of the block. Angle  $R$  is the angle between the plane of angle  $C_1$  and the plane of angle  $B_1$ . Find angles  $C_1$  and  $R$  when a rod or pipe is inclined at known angles  $A_1$  and  $B_1$ .

*Solution:* Let  $A_1 = 39^{\circ}$  and  $B_1 = 34^{\circ}$ ; then

$$\tan C_1 = \sqrt{\tan^2 A_1 + \tan^2 B_1} = \sqrt{0.80978^2 + 0.67451^2} = 1.0539$$

$$C_1 = 46^{\circ}30.2'$$

$$\tan R = \frac{\tan A_1}{\tan B_1} = \frac{0.80978}{0.67451} = 1.2005 \quad R = 50^{\circ}12.4'$$

**Interpolation.**—In mathematics, interpolation is the process of finding a value in a table or in a mathematical expression which falls between two given tabulated or known values. In engineering handbooks, the values of trigonometric functions are usually given only in degrees and minutes; hence, if the angle is given in degrees, minutes and seconds, the value of the function is determined from the nearest given values by interpolation.

*Interpolation to Find Functions of an Angle:* Assume that the sine of  $14^{\circ}22'26''$  is to be determined. It is evident that this value lies between the  $\sin 14^{\circ}22'$  and the  $\sin 14^{\circ}23'$ .  $\sin 14^{\circ}23' = 0.24841$  and  $\sin 14^{\circ}22' = 0.24813$ . The difference is  $0.24841 - 0.24813 = 0.00028$ . Consider this difference as a whole number (28) and multiply it by a fraction having as its numerator the number of seconds (26) in the given angle, and as its denominator 60 (number of seconds in one minute). Thus  $\frac{26}{60} \times 28 = 12$  (nearly); hence, by adding 0.00012 to  $\sin 14^{\circ}22'$  we find that  $\sin 14^{\circ}22'26'' \approx 0.24813 + 0.00012 = 0.24825$ . The correction value (represented in this example by 0.00012) is *added* to the function of the *smaller* angle nearest the given angle in dealing with *sines* or *tangents*, but this correction value is *subtracted* in dealing with *cosines* or *cotangents*.

## MATRICES

Multiple variables are often present in technology and engineering scenarios; some examples include electrical circuitry, in which there is a long series of resistors, and cost analysis (labor, materials, capital) in industrial economics.

A system of linear equations can be solved by several methods, such as substitution and elimination (see pages 32 to 33, *Solving a System of Linear Equations* in *ALGEBRA*). Another way to solve a system, useful especially when more than two variables are involved, is to set up a *matrix* of the equations' coefficients.

A matrix consists of real numbers arranged in horizontal rows and vertical columns to form a rectangular array. An array of  $m$  rows and  $n$  columns is an  $m \times n$  matrix (read as " $m$  by  $n$ ") and is written as

$$\begin{pmatrix} a_{11} & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & & & \cdot \\ \cdot & \cdot & & & \cdot \\ \cdot & & & & \cdot \\ 0 & \cdot & \cdot & \cdot & a_{mn} \end{pmatrix}$$

The  $a_{ij}$  terms are called the entries or elements of the matrix. The subscript  $i$  identifies the row position of an entry, and the subscript  $j$  identifies its column position in the matrix. For example, in the matrix below,  $a_{11} = 3$ ,  $a_{12} = 4$ ,  $a_{21} = -1$ , and  $a_{22} = 2$ :

$$\begin{bmatrix} 3 & 4 \\ -1 & 2 \end{bmatrix}$$

Special matrices used in matrix operations include:

$$\begin{pmatrix} a_{11} \\ \cdot \\ \cdot \\ \cdot \\ a_{m1} \end{pmatrix}$$

Column Matrix  
( $m \times 1$ )

$$(a_{11} \ \dots \ a_{1n})$$

Row Matrix  
( $1 \times n$ )

$$\begin{pmatrix} a_{11} & \cdot & \cdot & \cdot & a_{1n} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ a_{n1} & \cdot & \cdot & \cdot & a_{nn} \end{pmatrix}$$

Square Matrix  
( $n \times n$ )

$$\begin{pmatrix} 0 & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & \cdot & 0 \end{pmatrix}$$

Zero, or Null,  
Matrix ( $n \times n$ )

The two types of special square matrices include:

$$\begin{pmatrix} a_{11} & \cdot & \cdot & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ 0 & \cdot & \cdot & \cdot & a_{nn} \end{pmatrix}$$

Diagonal Matrix ( $n \times n$ )  
All entries are 0, except  
possibly those on the diagonal.

$$\begin{pmatrix} 1 & \cdot & \cdot & \cdot & a_{1n} \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot & \cdot \\ a_{n1} & \cdot & \cdot & \cdot & 1 \end{pmatrix}$$

Identity Matrix ( $n \times n$ )  
All diagonal entries are 1,  
all others are 0.

### Matrix Operations

**Matrix Addition and Subtraction.**—The sum or difference of matrices is determined simply by adding or subtracting the corresponding elements of each matrix.

So, matrix  $C$  is the result of adding or subtracting matrices  $A$  and  $B$ ; the entries are combined as follows:

$$a_{ij} + b_{ij} = c_{ij} \quad \text{or} \quad a_{ij} - b_{ij} = c_{ij}$$

Matrices must be the same size,  $m \times n$ , to be combined this way. That is,  $A_{mn} + B_{mn} = C_{mn}$ ;  $A_{mn} - B_{mn} = C_{mn}$ .

An efficient way to indicate both + and - is with the symbol  $\pm$ . Thus, in the matrix display below,  $a_{ij} \pm b_{ij}$  covers both matrix operations.

*Example 1:*

$$\begin{bmatrix} 4 & 6 & -5 \\ 5 & -7 & 8 \\ -8 & 6 & -7 \end{bmatrix} + \begin{bmatrix} 8 & -2 & 6 \\ -6 & 9 & 5 \\ 9 & -2 & 2 \end{bmatrix} = \begin{bmatrix} (4+8) & (6-2) & (-5+6) \\ (5-6) & (-7+9) & (8+5) \\ (-8+9) & (6-2) & (-7+2) \end{bmatrix} = \begin{bmatrix} 12 & 4 & 1 \\ -1 & 2 & 13 \\ 1 & 4 & -5 \end{bmatrix}$$

**Matrix Multiplication.**—Two matrices can be multiplied *only* if the number of columns in the first matrix equals the number of rows of the second matrix. For example, a  $1 \times 3$  matrix can multiplied by a  $3 \times 2$  matrix, but not the other way around. Or a  $2 \times 4$  by a  $4 \times 3$ , in that order. In general, an  $m \times n$  and an  $n \times p$  can be multiplied; the product matrix is an  $m \times p$  matrix. Matrix multiplication is not commutative, that is,  $A \times B$  is not necessarily equal to  $B \times A$ .

The steps in matrix multiplication are shown in the instructive example below for a general  $3 \times 2$  matrix multiplied by a  $2 \times 1$  matrix. The result is a  $3 \times 1$  matrix.

$$\begin{bmatrix} 1 & 4 \\ -3 & 1 \\ 2 & -1 \end{bmatrix} \times \begin{bmatrix} 0 \\ -2 \end{bmatrix} = \begin{bmatrix} 1 \cdot 0 + 4 \cdot -2 \\ -3 \cdot 0 + 1 \cdot -2 \\ 2 \cdot 0 + -1 \cdot -2 \end{bmatrix} = \begin{bmatrix} -8 \\ -2 \\ 2 \end{bmatrix}$$

In general, *each entry*  $(AB)_{ij}$  in the product matrix (where  $i$  is the row number and  $j$  is the column number) is equal to  $a_{i1}b_{1j} + a_{i2}b_{2j} + \dots + a_{in}b_{nj}$ . For example:

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ a_{31} & a_{32} \end{bmatrix} \times \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} a_{11}b_{11} + a_{12}b_{21} & a_{11}b_{12} + a_{12}b_{22} \\ a_{21}b_{11} + a_{22}b_{21} & a_{21}b_{12} + a_{22}b_{22} \\ a_{31}b_{11} + a_{32}b_{21} & a_{31}b_{12} + a_{32}b_{22} \end{bmatrix}$$

$\begin{matrix} 3 \times 2 \\ \text{matrix} \end{matrix}$ 
                    
  $\begin{matrix} 2 \times 2 \\ \text{matrix} \end{matrix}$ 
                    
  $\begin{matrix} 3 \times 2 \\ \text{matrix} \end{matrix}$

*Example 2:*

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix} \times \begin{bmatrix} 7 & 8 & 9 \\ 4 & 5 & 7 \end{bmatrix} = \begin{bmatrix} (1 \cdot 7 + 2 \cdot 1 + 3 \cdot 4) & (1 \cdot 8 + 2 \cdot 2 + 3 \cdot 5) & (1 \cdot 9 + 2 \cdot 3 + 3 \cdot 7) \\ (4 \cdot 7 + 5 \cdot 1 + 6 \cdot 4) & (4 \cdot 8 + 5 \cdot 2 + 6 \cdot 5) & (4 \cdot 9 + 5 \cdot 3 + 6 \cdot 7) \\ (3 \cdot 7 + 2 \cdot 1 + 1 \cdot 4) & (3 \cdot 8 + 2 \cdot 2 + 1 \cdot 5) & (3 \cdot 9 + 2 \cdot 3 + 1 \cdot 7) \end{bmatrix}$$

$$= \begin{bmatrix} (7+2+12) & (8+4+15) & (9+6+21) \\ (28+5+24) & (32+10+30) & (36+15+42) \\ (21+2+4) & (24+4+5) & (27+6+7) \end{bmatrix} = \begin{bmatrix} 21 & 27 & 36 \\ 57 & 72 & 93 \\ 27 & 33 & 40 \end{bmatrix}$$

**Transpose of a Matrix.**—If the rows of a matrix  $A_{mn}$  are interchanged with its columns, the new matrix is called the *transpose of matrix A*, or  $A^T$ . The first row of the matrix becomes the first column in the transposed matrix, the second row of the matrix becomes the second column, and the third row of the matrix becomes the third column.

Example 3:

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 7 & 8 & 9 \end{bmatrix} \quad A^T = \begin{bmatrix} 1 & 4 & 7 \\ 2 & 5 & 8 \\ 3 & 6 & 9 \end{bmatrix}$$

**Determinant of a Square Matrix.**—Every square matrix  $A$  is associated with a real number, its determinant, which may be written  $\det A$  or  $|A|$ .

$$\text{For } A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}, \det A = |A| = ad - bc.$$

$$\text{Example 4: } A = \begin{bmatrix} 2 & -1 \\ 1 & -3 \end{bmatrix} \quad \det A = \begin{vmatrix} 2 & -1 \\ 1 & -3 \end{vmatrix} = (2)(-3) - (1)(-1) = -5$$

The process for taking the determinant of a  $3 \times 3$  matrix is shown next. It entails multiplying the first entry of each column by the determinant of the remaining  $2 \times 2$  matrix and alternately adding or subtracting the product.

$$B = \begin{bmatrix} a & b & c \\ d & e & f \\ g & h & i \end{bmatrix}, \quad \det B = \begin{vmatrix} a & b & c \\ d & e & f \\ g & h & i \end{vmatrix} = a \begin{vmatrix} e & f \\ h & i \end{vmatrix} - b \begin{vmatrix} d & f \\ g & i \end{vmatrix} + c \begin{vmatrix} d & e \\ g & h \end{vmatrix}$$

Example 5: Find the determinant of the following matrix.

$$A = \begin{bmatrix} 5 & 6 & 7 \\ 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$

$$\begin{aligned} \text{Solution: } \det A &= 5(12 - 15) - 6(6 - 12) + 7(5 - 8) \\ &= 5(-3) - 6(-6) + 7(-3) = -15 + 36 - 21 = 0 \end{aligned}$$

**Minors and Cofactors.**—The *minor*  $M_{ij}$  of a matrix  $A$  is the determinant of a submatrix resulting from the elimination of row  $i$  and column  $j$ . If  $A$  is a square matrix, the minor  $M_{ij}$  of the entry  $a_{ij}$  is the determinant of the matrix obtained by deleting the  $i$ th row and  $j$ th column of  $A$ .

The *cofactor*  $C_{ij}$  of the entry  $a_{ij}$  is given by  $C_{ij} = (-1)^{(i+j)}M_{ij}$ . Thus, the sign of cofactor  $a_{ij}$  alternates across the row it lies in. The matrix formed by its cofactors is called the *cofactor matrix*.

$$\text{Example 6: Find the minors and cofactors of } A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix}$$

**Solution:** To determine the minor  $M_{11}$ , delete the first row and first column of  $A$  and find the determinant of the resulting matrix.

$$M_{11} = \begin{vmatrix} 5 & 6 \\ 2 & 1 \end{vmatrix} = (5 \times 1) - (6 \times 2) = 5 - 12 = -7$$

Similarly to find  $M_{12}$ , delete the first row and second column of  $A$  and find the determinant of the resulting matrix.

$$M_{12} = \begin{vmatrix} 4 & 6 \\ 3 & 1 \end{vmatrix} = (4 \times 1) - (6 \times 3) = 4 - 18 = -14$$

Continuing this way, we obtain the following minors:

$$\begin{array}{lll} M_{11} = -7 & M_{12} = -14 & M_{13} = -7 \\ M_{21} = -4 & M_{22} = -8 & M_{23} = -4 \\ M_{31} = -3 & M_{32} = -6 & M_{33} = -3 \end{array}$$

To find the cofactor, calculate  $C_{ij} = (-1)^{(i+j)} \times M_{ij}$ , thus  $C_{11} = (-1)^{(1+1)} \times M_{11} = 1 \times (-7) = -7$ .

Similarly  $C_{12} = (-1)^{(1+2)} \times M_{12} = (-1)(-14) = 14$ , and continuing this way we obtain the following cofactors

$$\begin{array}{lll} C_{11} = -7 & C_{12} = 14 & C_{13} = -7 \\ C_{21} = 4 & C_{22} = -8 & C_{23} = 4 \\ C_{31} = -3 & C_{32} = 6 & C_{33} = -3 \end{array}$$

Thus, the cofactor matrix is  $\begin{pmatrix} -7 & 14 & -7 \\ 4 & -8 & 4 \\ -3 & 6 & -3 \end{pmatrix}$

**Adjoint of a Matrix.**—The transpose of cofactor matrix is called the *adjoint* matrix. To obtain the adjoint matrix, the cofactor matrix is determined and then transposed.

*Example 7:* Find the adjoint matrix of  $A$ :

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix}$$

*Solution:* The cofactor matrix from the above example is shown below at the left, and the adjoint matrix is shown on the right.

$$\text{cofactor}(A) = \begin{bmatrix} -7 & 14 & -7 \\ 4 & -8 & 4 \\ -3 & 6 & -3 \end{bmatrix} \quad \text{adj}(A) = \begin{bmatrix} -7 & 14 & -7 \\ 4 & -8 & 4 \\ -3 & 6 & -3 \end{bmatrix}^T = \begin{bmatrix} -7 & 4 & -3 \\ 14 & -8 & 6 \\ -7 & 4 & -3 \end{bmatrix}$$

**Singularity and Rank of a Matrix.**—A *singular* matrix is one whose determinant is zero. The *rank* of a matrix is the maximum number of linearly independent row or column vectors it contains. In *ALGEBRA, Solving a System of Linear Equations*, it is explained that a system with a unique solution is a linearly independent system. Such systems are vital to depicting many real-life processes. Dependent systems are those with infinite solutions (the lines are collinear), and their determinant is zero. Linearly independent vectors have a non-zero determinant.

**Inverse of a Matrix.**—A square non-singular matrix  $A$  has an inverse  $A^{-1}$  such that the product of matrix  $A$  and inverse matrix  $A^{-1}$  is the identity matrix  $I$ . The operation is commutative as well. Thus,  $AA^{-1} = A^{-1}A = I$ . The inverse is the ratio of adjoint of the matrix and the determinant of that matrix.

$$A^{-1} = \frac{\text{adj}(A)}{|A|}$$

*Example 8:* What is the inverse of the following matrix?

$$A = \begin{bmatrix} 2 & 3 & 5 \\ 4 & 1 & 6 \\ 1 & 4 & 0 \end{bmatrix}$$

*Solution:* The basic formula of an inverse of a matrix is

$$A^{-1} = \frac{\text{adj}(A)}{|A|}$$

The determinant of  $A$  is

$$\begin{aligned} |A| &= 2(1 \times 0 - 4 \times 6) - 3(4 \times 0 - 1 \times 6) + 5(4 \times 4 - 1 \times 1) \\ &= 2(0 - 24) - 3(0 - 6) + 5(16 - 1) \\ &= -48 + 18 + 75 = 45 \end{aligned}$$

The cofactors are

$$\begin{aligned} a_{11} &= (-1)^{1+1} \begin{vmatrix} 1 & 6 \\ 4 & 0 \end{vmatrix} = -24 & a_{12} &= (-1)^{1+2} \begin{vmatrix} 4 & 6 \\ 1 & 0 \end{vmatrix} = 6 & a_{13} &= (-1)^{1+3} \begin{vmatrix} 4 & 1 \\ 1 & 4 \end{vmatrix} = 15 \\ a_{21} &= (-1)^{2+1} \begin{vmatrix} 3 & 5 \\ 4 & 0 \end{vmatrix} = 20 & a_{22} &= (-1)^{2+2} \begin{vmatrix} 2 & 5 \\ 1 & 0 \end{vmatrix} = -5 & a_{23} &= (-1)^{2+3} \begin{vmatrix} 2 & 3 \\ 1 & 4 \end{vmatrix} = -5 \\ a_{31} &= (-1)^{3+1} \begin{vmatrix} 3 & 5 \\ 1 & 6 \end{vmatrix} = 13 & a_{32} &= (-1)^{3+2} \begin{vmatrix} 2 & 5 \\ 4 & 6 \end{vmatrix} = 8 & a_{33} &= (-1)^{3+3} \begin{vmatrix} 2 & 3 \\ 4 & 1 \end{vmatrix} = -10 \end{aligned}$$

The matrix of cofactors is  $\begin{bmatrix} -24 & 6 & 15 \\ 20 & -5 & -5 \\ 13 & 8 & -10 \end{bmatrix}$  and the adjoint matrix is  $\begin{bmatrix} -24 & 20 & 13 \\ 6 & -5 & 8 \\ 15 & -5 & -10 \end{bmatrix}$

Then the inverse of matrix  $A$  is

$$A^{-1} = \frac{\text{adj}(A)}{|A|} = \frac{1}{45} \begin{bmatrix} -24 & 20 & 13 \\ 6 & -5 & 8 \\ 15 & -5 & -10 \end{bmatrix}$$

Multiplying  $A^{-1}$  by  $A$  results in the identity matrix:

$$\frac{1}{45} \begin{pmatrix} -24 & 20 & 13 \\ 6 & -5 & 8 \\ 15 & -5 & -10 \end{pmatrix} \begin{pmatrix} 2 & 3 & 5 \\ 4 & 1 & 6 \\ 1 & 4 & 0 \end{pmatrix} = \frac{1}{45} \begin{pmatrix} 45 & 0 & 0 \\ 0 & 45 & 0 \\ 0 & 0 & 45 \end{pmatrix} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}$$

**Solving a System of Equations.**— Matrices can be used to solve systems of simultaneous equations with a large number of unknowns. Geometrically, the solution of a system is the point in the plane or in space where the lines intersect. Variables may represent the unknowns in industrial and other engineering applications: a series of resistances in a circuit, for example, or, perhaps, factors in a manufacturing process, such as labor costs, materials, and equipment. Generally, this method is less cumbersome than using substitution methods (see *Solving a System of Linear Equations* in *ALGEBRA*). The coefficients of the equations are placed in matrix form. The matrix is then transformed by row and column operations into the identity matrix to yield a solution. The process, as described in the example, is called *matrix reduction to row echelon form*. It is done using any or all of three valid vector operations: 1) multiplying each entry in a row by a constant; 2) adding or subtracting two rows; 3) changing the order of rows.

*Example 9:* Solve the system of linear equations in three dimensions using matrix operations.

$$\begin{aligned} -4x_1 + 8x_2 + 12x_3 &= 16 \\ 3x_1 - x_2 + 2x_3 &= 5 \\ x_1 + 7x_2 + 6x_3 &= 10 \end{aligned}$$

*Solution:* First, the equation coefficients and constants are placed into what is called an *augmented matrix*. The object is to transform the matrix of the original coefficients into the following form, thereby obtaining a solution  $(x_1, x_2, x_3)$  to the system of equations.

$$\left[ \begin{array}{ccc|c} -4 & 8 & 12 & 16 \\ 3 & -1 & 2 & 5 \\ 1 & 7 & 6 & 10 \end{array} \right] \Leftrightarrow \left[ \begin{array}{ccc|c} 1 & 0 & 0 & x_1 \\ 0 & 1 & 0 & x_2 \\ 0 & 0 & 1 & x_3 \end{array} \right]$$

The coefficient matrix is transformed so that element  $c_{11}$  is 1 and all other elements in the first column are 0, as follows: a) divide row 1 ( $R_1$ ) by  $-4$ ; b) multiply new  $R_1$  by  $-3$ , then add to  $R_2$ ; and c) multiply  $R_1$  by  $-1$ , then add to  $R_3$ .

$$\left[ \begin{array}{ccc|c} -4 & 8 & 12 & 16 \\ -4 & -4 & -4 & -4 \\ 3 & -1 & 2 & 5 \\ 1 & 7 & 6 & 10 \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & -2 & -3 & -4 \\ (3-3) & (-1+6) & (2+9) & (5+12) \\ (1-1) & (7+2) & (6+3) & (10+4) \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & -2 & -3 & -4 \\ 0 & 5 & 11 & 17 \\ 0 & 9 & 9 & 14 \end{array} \right]$$

The resulting matrix is transformed so that element  $c_{22}$  is 1 and all other elements in the second column are 0, as follows: a) divide  $R_3$  by 9; b) multiply new  $R_3$  by  $-5$ , then add to  $R_2$ ; c) multiply  $R_3$  by 2, then add to  $R_1$ ; and d) swap  $R_2$  and  $R_3$ .

$$\left[ \begin{array}{ccc|c} 1 & -2 & -3 & -4 \\ 0 & 5 & 11 & 17 \\ 0 & \frac{9}{9} & \frac{9}{9} & \frac{14}{9} \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & (-2+2) & (-3+2) & (-4+\frac{28}{9}) \\ 0 & (5-5) & (11-5) & (17-\frac{70}{9}) \\ 0 & 1 & 1 & \frac{14}{9} \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & 0 & -1 & \frac{8}{9} \\ 0 & 0 & 6 & \frac{83}{9} \\ 0 & 1 & 1 & \frac{14}{9} \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & 0 & -1 & \frac{8}{9} \\ 0 & 1 & 1 & \frac{14}{9} \\ 0 & 0 & 6 & \frac{83}{9} \end{array} \right]$$

The resulting matrix is finally reduced so that element  $c_{33}$  is 1 and all other elements in the third column are 0, as follows: a) divide  $R_3$  by 6; b) multiply new  $R_3$  by  $-1$ , then add to  $R_2$ ; and c) add  $R_3$  to  $R_1$ .

$$\left[ \begin{array}{ccc|c} 1 & 0 & -1 & \frac{8}{9} \\ 0 & 1 & 1 & \frac{14}{9} \\ 0 & 0 & \frac{6}{6} & \frac{83}{9(6)} \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & 0 & (-1+1) & (-\frac{8}{9}+\frac{83}{54}) \\ 0 & 1 & (1-1) & (\frac{14}{9}-\frac{83}{54}) \\ 0 & 0 & 1 & \frac{83}{54} \end{array} \right] \Rightarrow \left[ \begin{array}{ccc|c} 1 & 0 & 0 & \frac{35}{54} \\ 0 & 1 & 0 & \frac{1}{54} \\ 0 & 0 & 1 & \frac{83}{54} \end{array} \right]$$

When the identity matrix has been formed, the last column contains the values of  $x_1, x_2,$  and  $x_3$  that satisfy the original equations.

$$x_1 = \frac{35}{54} \quad x_2 = \frac{1}{54} \quad x_3 = \frac{83}{54}$$

Checking that the solutions satisfy the original system:

$$-4\left(\frac{35}{54}\right) + 8\left(\frac{1}{54}\right) + 12\left(\frac{83}{54}\right) = \frac{864}{54} = 16$$

$$3\left(\frac{35}{54}\right) - 1\left(\frac{1}{54}\right) + 2\left(\frac{83}{54}\right) = \frac{270}{54} = 5$$

$$1\left(\frac{35}{54}\right) + 7\left(\frac{1}{54}\right) + 6\left(\frac{83}{54}\right) = \frac{540}{54} = 10$$

**Example 10:** Use matrix operations to find the amperages of the currents ( $I_1, I_2, I_3$ ) in the following electrical network.

By Kirchoff's first law, concerning the sum

$$\text{of currents: } I_1 + I_2 = I_3$$

$$\text{that is, } I_1 + I_2 - I_3 = 0$$

By Kirchoff's second law, concerning the sum of voltages, and Ohm's law, that voltage is the product of current and resistance:

$$2I_1 + 5I_3 - 40 = 0$$

$$10I_2 + 5I_3 - 30 = 0$$

By combining the three equations, a linear system of independent equations is formed. A system is linearly independent if no one equation is a constant multiple of any other. That is, the equations represent distinct lines, but they are not parallel (hence, they have a solution, that is, a point of intersection). Solve the system for the currents  $I_1, I_2$ , and  $I_3$ :

$$I_1 + I_2 - I_3 = 0$$

$$2I_1 + 5I_3 = 40$$

$$10I_2 + 5I_3 = 30$$

**Solution:** If  $A$  is the matrix of coefficients of the currents,  $B$  is the matrix of the currents themselves (the variables), and  $C$  is the matrix of constants from the right side of the equations (the voltages), then the problem can be written in the following form:  $AB = C$ , or equivalently,  $B = A^{-1}C$ , where  $A^{-1}$  is the inverse of matrix  $A$ .

Thus,

$$A = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & 5 \end{bmatrix} \quad B = \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} \quad C = \begin{bmatrix} 0 \\ 40 \\ 30 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & 5 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 40 \\ 30 \end{bmatrix}$$

Using the method of **Example 8**, the inverse of matrix  $A$  is

$$A^{-1} = \begin{bmatrix} 1 & 1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & 5 \end{bmatrix}^{-1} = -\frac{1}{80} \begin{bmatrix} 50 & 15 & -5 \\ 10 & -5 & 7 \\ -20 & 10 & 2 \end{bmatrix} = \begin{bmatrix} \frac{5}{8} & \frac{3}{16} & -\frac{1}{16} \\ \frac{1}{8} & -\frac{1}{16} & \frac{7}{80} \\ -\frac{1}{4} & \frac{1}{8} & \frac{1}{40} \end{bmatrix}$$

and finally, matrix  $B$  can be found by matrix multiplication:

$$B = A^{-1}C = \begin{bmatrix} \frac{5}{8} & \frac{3}{16} & -\frac{1}{16} \\ \frac{1}{8} & -\frac{1}{16} & \frac{7}{80} \\ -\frac{1}{4} & \frac{1}{8} & \frac{1}{40} \end{bmatrix} \begin{bmatrix} 0 \\ 40 \\ 30 \end{bmatrix} = \begin{bmatrix} 5.625 \\ 0.125 \\ 5.75 \end{bmatrix}$$

Thus,  $I_1 = 5.625$  amps,  $I_2 = 0.125$  amp, and  $I_3 = 5.75$  amps.

## CALCULUS

Problems in engineering and other sciences are often modeled by functions other than simple first- and second-degree polynomials. The features of higher order polynomials, as well as trigonometric and other non-algebraic functions, are found using techniques of calculus. The essential operations of calculus are *differentiation* and *antidifferentiation* (or *integration*). Brief explanations of these processes, as well as detailed formulas, are given here.

## Derivatives

Between any two points of a linear function  $y = mx + b$ , the change in  $y$  with respect to  $x$  is the constant  $m$ . Most functions of interest, however, are nonlinear. For example, the velocity of a projectile is not modeled by a line, since objects are subject to gravity, among other outside forces, and therefore accelerate as they fall. The *instantaneous rate of change* of a function  $y = f(x)$  at a single point of a curve is a critical feature for any model. This quantity is called the *derivative of  $f$  with respect to  $x$*  (or other independent variable).

A derivative is notated in one of three ways:  $y'$ ,  $f'(x)$ , or  $dy/dx$ . As an example, the instantaneous rate of change of *displacement  $s$*  of an object at any instant in time  $t$  is its derivative function, *velocity*; that is,  $s'(t)$  or  $ds/dt = v(t)$ .

Graphically, the derivative function gives the *slope* of the line tangent to a point of the graph of  $f$ . That is,  $y' = m_{\text{tan}}$ . Any constant function  $y = c$  has a slope of zero, since its graph is a horizontal line. Hence,  $y' = 0$  at every point of a line. Fig. 1a shows a portion of a nonlinear function. The tangent line drawn to the point of the curve at  $x$  has a slope equal to the derivative  $f'(x)$ .

Any group of curves that represent a *family* of functions, such as the parabolas  $f_1, f_2$ , and  $f_3$  in Fig. 1b, have the same derivative function, since the slope of the tangent lines at any given value of  $x$  is the same for each curve. The slope of the tangent line drawn to each of the curves at  $x = 0$  is  $f'(0) = 2(0) + 2 = 2$ .

Fig. 1. (a)  $f'(x)$  gives the slope of the tangent line to a curve  $f(x)$  for any  $x$  in the domain; (b) A family of parabola functions, all with the same derivative function,  $f'(x) = 2x + 2$ .

Any continuous, smooth function is *differentiable* (that is, it has a derivative) at each point on its domain. (Roughly speaking, a “continuous” function has no breaks, and a “smooth” function has no sharp corners.) Polynomial, trigonometric, exponential, and logarithmic functions are differentiable everywhere on their domains. To “differentiate” a function means to find (or “take”) its derivative.

**Derivative Formulas.**—The formulas used most often in derivative applications are:

*Constant:* If  $y = c$ , then  $y' = 0$ .

*Coefficient:* If  $y = cx$ , then  $y' = c$ .

*Power:* If  $y = x^n$ , then  $y' = nx^{n-1}$ , for any  $n$  in the set of real numbers.

Note: The power rules when  $n = -1$  and when  $n = \frac{1}{2}$  are often stated as their own rules:

$$y' = x^{-1}, \quad y' = -x^{-2} = \frac{-1}{x^2} \quad \text{and} \quad y = \sqrt{x} = x^{\frac{1}{2}}, \quad y' = \frac{1}{2}x^{-\frac{1}{2}} = \frac{1}{2x^{\frac{1}{2}}} = \frac{1}{2\sqrt{x}}$$

**Logarithmic:**

For any base  $a$ , if  $y = \log_a x$ , then  $y' = \frac{1}{x \ln a}$ ; for natural base  $e$ ,  $y = \ln x$ , then  $y' = \frac{1}{x}$ .

**Exponential:** If  $y = a^x$ , then  $y' = a^x \ln a$ . If  $y = e^x$ , then  $y' = e^x$ .

**Trigonometric:**

If  $y = \sin x$ , then  $y' = \cos x$ . If  $y = \cos x$ , then  $y' = -\sin x$ . If  $y = \tan x$ , then  $y' = \sec^2 x$ .

For a complete list of the differentiation formulas, see *Table of Derivatives and Integrals*.

**Derivative Rules.**—Just like other functions, derivatives have certain properties:

	Rule	Example
Sum or difference	$(f \pm g)'(x) = f'(x) \pm g'(x)$	$y = x^5 + \frac{1}{x} - 9, \quad y' = 5x^4 - \frac{1}{x^2}$
Product	$(fg)'(x) = f'(x)g(x) + g'(x)f(x)$	$y = 2x \ln x, \quad y' = 2 \ln x + (2x)\left(\frac{1}{x}\right) = 2 \ln x + 2$
Quotient	$\left(\frac{f(x)}{g(x)}\right)' = \frac{f'(x)g(x) - g'(x)f(x)}{[g(x)]^2}$	$y = \frac{4x-9}{x^2}, \quad y' = \frac{4x^2 - (4x-9)(2x)}{(x^2)^2} = \frac{4x^2 - 8x^2 + 18x}{x^4}$
Chain rule	$[f(u(x))]' = f'(u(x))u'(x)$	$y = \sqrt{x^2 + 5x - 1} = (x^2 + 5x - 1)^{1/2}$ $y' = \frac{1}{2}(x^2 + 5x - 1)^{-1/2} (2x + 5) = \frac{2x + 5}{2(x^2 + 5x - 1)^{1/2}}$

### Integrals (Antiderivatives)

The other fundamental calculus operation, *antidifferentiation*, also called *integration*, is the reverse process of differentiation. Whereas derivatives are rate-of-change functions, antiderivatives are *accumulation* functions.

We define  $F$  to be an *antiderivative* of  $f$  if  $F'(x) = f(x)$ . Each function in a *family of antiderivatives*  $F(x) + C$ , where  $C$  is a constant, has the same derivative  $f$ , since  $(F + C)' = F' + C' = F' + 0 = F'$ . For this reason, an antiderivative function  $F(x)$  also is called an *indefinite integral*. The operation of antidifferentiation is indicated by the notation  $F(x) = \int f(x) dx$ .

A *definite integral* indicates the *area* under  $f$  on a closed interval  $[a, b]$  of its domain (Fig. 2). It is denoted by  $F(b) - F(a) = \int_a^b f(x) dx$ , where  $a$  and  $b$  are the *bounds of integration*, and  $F(a)$  and  $F(b)$  are the antiderivative values of  $f$  at these bounds.

Just as velocity is the derivative of displacement, so displacement is the antiderivative of velocity. On a time interval  $[t_1, t_2]$ , displacement is found by  $s(t_2) - s(t_1) = \int_{t_1}^{t_2} v(t) dt$ .

Fig. 2. The definite integral on  $[a, b]$  is the area under the curve from  $x = a$  to  $x = b$ .

**Integral Rules.**—Integration rules are somewhat similar to differentiation rules, since they undo what the derivative does. The analogous processes for the chain, product, and quotient rules of derivatives are covered by either *u*-substitution or integration by parts for integrals. *Table of Derivatives and Integrals* contains integration formulas.

**Newton's Method for Solving Equations.**—Algebraic (polynomial, rational, and root) and transcendental (trigonometric, exponential and logarithmic) equations often can be quickly solved directly, using the processes described in *ALGEBRA* and *TRIGONOMETRY* (for example,  $\cos x = 1$  or  $\log x = 4$ ). But, long before there were calculators that could solve less straightforward equations to a high degree of accuracy, *approximation methods* were developed. One such method is *Newton's* (or the *Newton-Raphson*) method, which produces excellent approximations of the solution of more difficult equations, with the help of differentiation. Some equations that can be solved by Newton's method are:

$$x^2 = 101 \quad x^3 - 2x^2 = 5 \quad \cos x = x$$

Rewriting any of these equations as a function  $f(x) = 0$  converts the problem into one of finding the roots of  $f(x)$ —that is, those values where the function crosses the *x*-axis. For example,  $x^2 = 101$  is rewritten as  $f(x) = x^2 - 101 = 0$ . This function has two real roots (see *ALGEBRA*). A good first estimate of the positive root is 10. Rewriting the other two equations,  $x^3 - 2x^2 = 5$  and  $\cos x = x$  in the  $f(x) = 0$  form does not give as obvious an estimate of the root(s), but by inspection (trial and error) or a rough graph, an estimate can be made. In each case, this first estimate is called  $r_1$ . From these, successive estimates  $r_2, r_3, \dots$  are made, each progressively closer to the exact value of the root.

After estimating  $r_1$ , the first derivative of the function,  $f'(x)$ , is found. This is the equation for the function's instantaneous rate of change at any value of *x*.  $f'(x)$  is the equation that gives the slope of the line tangent to the function's curve at a given *x*.

In the above examples,  $f'(x)$  is, respectively,  $2x$ ,  $3x^2 - 4x$ , and  $-\sin x + 1$ . These were found by the methods described in *Table of Derivatives and Integrals* on page 133.

Starting with the first estimate, the steps of Newton's method are as follows:

$r_1$  is the first estimate of the value of the root of  $f(x) = 0$ .

Find  $f(r_1)$ , the value of  $f(x)$  at  $x = r_1$ .

Find  $f'(x)$ , the first derivative of  $f(x)$ .

Find  $f'(r_1)$ , the value of  $f'(x)$  at  $x = r_1$ .

Get the second approximation of the root of  $f(x) = 0$ ,  $r_2$ , by calculating

$$r_2 = r_1 - f(r_1)/f'(r_1)$$

and, further approximations,

$$r_n = r_{n-1} - f(r_{n-1})/f'(r_{n-1})$$

*Example:* Find the square root of 101 using the Newton-Raphson method.

*Solution:* The problem is restated as the algebraic equation  $x^2 = 101$ , rewritten as  $x^2 - 101 = 0$ , and solved for the positive root.  $r_1 = 10$  is a good first estimate. Then, apply the steps of the algorithm:

$$f(r_1) = f(10) = 10^2 - 101 = -1$$

Step 2. The first derivative,  $f'(x)$ , of  $x^2 - 101$  is  $2x$ , as stated previously, so that

$$f'(10) = 2(10) = 20. \text{ Then,}$$

$$r_2 = r_1 - f(r_1)/f'(r_1) = 10 - (-1)/20 = 10 + 0.05 = 10.05$$

Check:  $10.05^2 = 101.0025$ ; a calculator determination of  $\sqrt{101}$  gives 10.0498756; the error using Newton's method is 0.0001244.

Step 3. The next, better approximation is

$$r_3 = r_2 - f(r_2)/f'(r_2) = 10.05 - f(10.05)/f'(10.05)$$

$$= 10.05 - (10.05^2 - 101)/2(10.05) = 10.049875$$

$$\text{Check: } 10.049875^2 = 100.9999875; \text{ error} = 0.0000125$$

Closer approximations result from subsequent applications of the algorithm.

**Formulas for Differential and Integral Calculus.**—The following are formulas for obtaining the derivatives and integrals of basic mathematical functions. In these formulas, the letters  $a$ ,  $b$ , and  $c$  denote constants; the letter  $x$  denotes a variable; and the letters  $u$  and  $v$  denote functions of the variable  $x$ . The expression  $d/dx$  means the derivative with respect to  $x$ , and as such applies to whatever expression in parentheses follows it. Thus,  $d(cx)/dx$  means the derivative with respect to the variable  $x$  of the product  $cx$  where  $c$  is a constant.

**Table of Derivatives and Integrals**

Derivatives	Integrals
$\frac{d}{dx}(c) = 0$	$\int c dx = cx + \text{constant}$
$\frac{d}{dx}(x) = 1$	$\int 1 dx = x + C$
$\frac{d}{dx}(x^n) = nx^{n-1}$ , for all real numbers $n$	$\int x^n dx = \frac{x^{n+1}}{n+1} + C$ , for all real numbers $n \neq -1$
$\frac{d}{dx}\left(\frac{1}{x}\right) = -\frac{1}{x^2} + C$	$\int \frac{dx}{ax+b} = \frac{1}{a} \ln ax+b  + C$
$\frac{d}{dx}(\log_a x) = \frac{1}{x \ln a}$	$\int \frac{1}{x} dx = \ln x  + C$
$\frac{d}{dx}(e^x) = e^x$	$\int e^x dx = e^x + C$
$\frac{d}{dx}(e^{ax}) = ae^{ax}$	$e^{ax} dx = \frac{e^{ax}}{a} + C$
$\frac{d}{dx}(a^x) = a^x \ln a$	$\int a^x dx = \frac{a^x}{\ln a} + C$
$\frac{d}{dx}(\sqrt{x}) = \frac{1}{2\sqrt{x}}$	$\int \frac{dx}{\sqrt{x}} = 2\sqrt{x} + C$
$\frac{d}{dx}(\ln x) = \frac{1}{x}$	$\int \ln x dx = x \ln x - x + C$
$\frac{d}{dx}(\sin x) = \cos x$	$\int \cos x dx = \sin x + C$

**Table of Derivatives and Integrals (Continued)**

Derivatives	Integrals
$\frac{d}{dx}(\cos x) = -\sin x$	$\int \sin x dx = -\cos x + C$
$\frac{d}{dx}(\tan x) = \sec^2 x$	$\int \tan x dx = -\ln  \cos x  + C$
$\frac{d}{dx}(\cot x) = -\csc^2 x$	$\int \cot x dx = \ln  \sin x  + C$
$\frac{d}{dx}(\sec x) = \sec x \tan x$	$\int \sin^2 x dx = -\frac{1}{4} \sin(2x) + \frac{1}{2} x + C$
$\frac{d}{dx}(\csc x) = -\csc x \cot x$	$\int \cos^2 x dx = \frac{1}{4} \sin(2x) + \frac{1}{2} x + C$
$\frac{d}{dx}(\sin^{-1} x) = \frac{1}{\sqrt{1-x^2}} \quad x \neq 1, -1$	$\int \frac{dx}{\sqrt{b^2-x^2}} = \sin^{-1}\left(\frac{x}{b}\right) + C$
$\frac{d}{dx}(\cos^{-1} x) = \frac{-1}{\sqrt{1-x^2}} \quad x \neq 1, -1$	$\int \frac{dx}{\sqrt{x^2-b^2}} = \ln\left(\frac{x}{b} + \frac{\sqrt{x^2-b^2}}{b}\right) + C$
$\frac{d}{dx}(\tan^{-1} x) = \frac{1}{1+x^2}$	$\int \frac{dx}{b^2+x^2} = \frac{1}{b} \tan^{-1}\left(\frac{x}{b}\right) + C$
$\frac{d}{dx}(\cot^{-1} x) = \frac{-1}{1+x^2}$	$\int \frac{dx}{b^2-x^2} = \frac{1}{b} \tan^{-1}\left(\frac{x}{b}\right) = \frac{-1}{2b} \log \left  \frac{x-b}{x+b} \right  + C$
$\frac{d}{dx}(\sec^{-1} x) = \frac{1}{x\sqrt{x^2-1}} \quad x \neq 1, -1$	$\int \frac{dx}{x^2-b^2} = -\frac{1}{b} \cos^{-1}\left(\frac{x}{b}\right) = \frac{1}{2b} \log \left  \frac{ x-b }{ x+b } \right  + C$
$\frac{d}{dx}(\csc^{-1} x) = \frac{-1}{x\sqrt{x^2-1}} \quad x \neq 1, -1$	$\int \frac{dx}{ax^2+bx+c} = \frac{2}{\sqrt{4ac-b^2}} \tan^{-1} \left[ \frac{2ax+b}{\sqrt{4ac-b^2}} \right] + C$
$\frac{d}{dx}(\ln(\sin x)) = \cot x$	$\int e^{ax} \sin(bx) dx = \frac{a \sin(bx) - b \cos(bx)}{a^2 + b^2} e^{ax} + C$
$\frac{d}{dx}(\ln(\cos x)) = -\tan x$	$\int e^{ax} \cos(bx) dx = \frac{a \cos(bx) + b \sin(bx)}{a^2 + b^2} e^{ax} + C$
$\frac{d}{dx}(\ln(\tan x)) = \frac{2}{\sin(2x)}$	$\int \frac{1}{\sin x} dx = \ln  \csc x - \cot x  + C$
$\frac{d}{dx}(\ln(\cot x)) = \frac{-2}{\sin(2x)}$	$\int \frac{1}{\cos x} dx = \ln  \sec x + \tan x  + C$
$\frac{d}{dx}(\ln(ax+b)) = \frac{a}{ax+b}$	$\int \frac{1}{1+\cos x} dx = \csc x - \cot x + C$

## Series Representation of a Function

Some hand calculations, as well as computer programs of certain types of mathematical problems, may be facilitated by the use of an appropriate series. For example, in some gear problems, the angle corresponding to a given or calculated involute function (see **TRIGONOMETRY**) is found by using a series together with an iterative procedure such as the Newton-Raphson method described in the previous section. The following are those series most commonly used for such purposes. In the series for trigonometric functions, the angles  $x$  are in radians (1 radian =  $180/\pi$  degrees, or about 57.3 degrees). The expression  $\exp(-x^2)$  means that the base  $e$  of the natural logarithm system is raised to the  $-x^2$  power, where  $e = 2.7182818$ .

A sum of terms in a sequence of terms is called a *series*. In its simplest notation, the infinite sum of the sequence  $a_0, a_1, a_2, \dots$  is the series  $\sum_{n=0}^{\infty} a_n = a_0 + a_1 + a_2 + \dots$ . For example, for the sequence of  $x, x^2, x^3, \dots$ , the series is given as  $\sum_{n=1}^{\infty} x^n = x^1 + x^2 + \dots = x^1 + x^2 + \dots$ .

In calculus, it is helpful to represent certain functions by a special series called the Taylor series. In a manner similar to the Newton-Raphson method, the terms of a Taylor series include the derivatives of the function being approximated. In the table below, common functions and their corresponding infinite series are shown. For any  $x$  in the domain (shown to the right of each series), the value of the function can be found.

<b>Common Series</b>	
$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots$	for all real $x$
$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots$	for all real $x$
$\tan x = x + \frac{x^3}{3} + \frac{2x^5}{15} - \frac{17x^7}{315} + \dots$	for $ x  < \frac{\pi}{2}$
$\sin^{-1} x = x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{15x^7}{336} + \dots$	for $ x  \leq 1$
$\cos^{-1} x = \frac{\pi}{2} - (x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{15x^7}{336} + \dots) = \frac{\pi}{2} - \sin^{-1} x$	for $ x  \leq 1$
$\tan^{-1} x = x - \frac{x^3}{3} + \frac{x^5}{5} - \frac{x^7}{7} + \dots$	for $ x  \leq 1$
$\frac{\pi}{4} = 1 - \frac{1}{3} + \frac{1}{5} - \frac{1}{7} + \dots$	
$e = 1 + \frac{1}{1!} + \frac{1}{2!} + \frac{1}{3!} + \dots$	
$e^x = 1 + \frac{x}{1!} + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots$	for all real $x$
$a^x = 1 + \frac{x \ln a}{1!} + \frac{(x \ln a)^2}{2!} + \frac{(x \ln a)^3}{3!} + \dots$	for all real $x$
$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \dots$	for $-1 < x \leq 1$
$\frac{1}{1+x} = 1 - x + x^2 - x^3 + x^4 - \dots$	for $ x  \leq 1$
$\frac{1}{1-x} = 1 + x + x^2 + x^3 + x^4 + \dots$	for $ x  \leq 1$
$\frac{1}{(1+x)^2} = 1 - 2x + 3x^2 - 4x^3 + 5x^4 - \dots$	for $ x  \leq 1$
$\frac{1}{(1-x)^2} = 1 + 2x + 3x^2 + 4x^3 + 5x^4 + \dots$	for $ x  \leq 1$
$\frac{1}{\sqrt{1+x}} = 1 - \frac{x}{2} + \frac{1 \cdot 3x^2}{2 \cdot 4} - \frac{1 \cdot 3 \cdot 5x^3}{2 \cdot 4 \cdot 6} - \dots$	for $ x  \leq 1$
$(a+x)^n = a^n + \frac{na^{(n-1)}x}{1!} + \frac{(n-1)na^{n-2}x^2}{2!} + \frac{(n-2)(n-1)a^{n-3}x^3}{3!} + \dots$	for all real $x$

## STATISTICAL ANALYSIS OF MANUFACTURING DATA

### Statistics Theory in Brief

High-volume manufacturing production, unlike prototype design work, typically involves repeating machining operations and processes hundreds, thousands, or even millions of times during a given product or product family's production run. Understanding the failure mechanisms in a product's tooling and improving the efficiency of these operations by adjusting manufacturing parameters brings many essential benefits to the manufacturing process. Seeing where failure and inefficiency occur can save on tool wear of indexable inserts, milling cutters, reamers, twist drills, etc.; improve speed, feeds, and power consumption profiles; reduce machine tool accuracy drift; and reduce lubrication and other maintenance-related failures. Improving these and other related process, even by a tiny amount, can result in huge cost savings in large production run environments.

To begin this process, measurements and other production process values must be collected so that patterns can be found. This is the collection of *raw* (or *source*) *data*. The information is put into tables (tabular form), to be processed (usually) by a computer program that analyzes and interprets it by rigorous *statistical analysis*. Without statistics theory, it would be impossible to know whether or not the testing was comprehensive enough to offer valid experimental conclusions that can then be used to make manufacturing process changes.

**Probability.**—In commercial enterprises, predictions about a particular outcome or event are made regularly to determine best practices and to minimize risk. Predictions are formed by observing events and collecting data, which is then interpreted using statistical analysis, based on concepts of *probability theory*. Probability is the likelihood of an event happening randomly among all possible events. Simple experiments, such as observing the number of times heads or tails turn up in a coin toss, and complex ones, like locating the position of an electron in an atom, are studied using probability. Data analysis enables development of a detailed statistical picture of the event being studied, and probability quantifies how likely the particular event is.

In industry, statistical analysis is used to investigate data to evaluate the success and/or efficiency of a manufacturing process. Statistical methods are described in this section using these terms:

*Experiment:* A well-defined action that is repeatable.

*Data:* Information collected during an experiment.

*Trial:* A particular performance of an experiment.

*Set:* A collection of events (or elements), such as may occur in an experiment.

*Sample space:* The set of all possible outcomes.

*Event:* Any subset of the sample space; one outcome or a collection of outcomes.

*Probability of an event:* Ratio of number of outcomes of a particular event to total number of outcomes possible in the sample space of events.

The probability of an event can be expressed as a *decimal* between 0 and 1, as a *fraction*, or as a *percent* between 0 and 100. The sum of all probabilities for outcomes of a particular experiment is 1; that is, it is 100% likely that one of the outcomes will occur.

In the coin toss example, each toss is a trial, and there are two possible outcomes: heads or tails (as long as the coin is fair, that is, both sides have an equal chance of turning up). So the probability of tossing a head is  $\frac{1}{2}$  or 0.5 (50%). As another example with two outcomes, consider a water treatment plant with 34 female workers (set A) and 36 male workers (set B); the universal set is  $34 + 36 = 70$  workers. The probability that a female worker is chosen at random from the universal set is  $\frac{34}{70}$ , or approximately 0.486 (48.6%).

In manufacturing parts, the probability of a defective part occurring in a production run would be the number of parts found to be defective (the "event") in relation to the total number of parts in the run (the "trials"); defective parts ought to be far fewer than acceptable ones. So, to say there is a 3% probability of a defect means that for every 100 parts that are produced, on average, 3 will be defective and the other 97 will be acceptable. In other words, the predicted defect rate is 3% and the yield of acceptable parts is 97%.

Such simple examples are not that useful in explaining *manufacturing statistics*, where any event can have many values—for instance, in the hardness of an alloy or duration of tool life. However, more complex statistical analysis starts with the same concepts: whether a company is inspecting for defects or for a range of values of physical characteristics, the analysis involves how data from an experiment is regarded and how it can be used to determine the probability of various outcomes.

Statistical analysis depends on the type of statistical distributions that apply to various properties of the data being examined.

Some common statistical distributions are: 1) normal; 2) log-normal; 3) exponential; 4) binomial; 5) Weibull; and 6) Poisson. Normal distribution is described here.

**Normal Distribution Analysis.**—The *normal* distribution is the most widely used statistical distribution for modeling mechanical, physical, electrical, and chemical properties that scatter randomly about a well-defined mean value without either positive or negative bias. This curve is frequently called a bell curve. In the following discussion, the characteristics of the normal distribution curve are assumed.

Statistical analysis of raw data is a crucially important scientific and engineering tool that summarizes the characteristics of samples (number of observations, trials, data points, etc.). If a sample of data is randomly selected from the population, its statistical characteristics converge towards the statistical characteristics of the population as the sample size increases. Because economic constraints, such as testing time and cost, prevent a large number of repeat tests, it is important to understand how a sample of data represents an approximation of the real population of data. The following parameters must be calculated to evaluate the sample of data with respect to the population of data:

$\bar{X}$  = sample mean     $S$  = sample standard deviation     $V$  = coefficient of variation

$A_x$  = absolute error of the sample mean

$R_x$  = relative error of the sample mean

$t$  = critical value of  $t$ -distribution (or Student's  $t$ -distribution)

$\mu$  = population mean     $\sigma$  = population standard deviation

$\bar{X} \pm t A_x$  = confidence interval for the population mean

**Sample Mean ( $\bar{X}$ ):** There are several types of *average* measures, the most common being the *arithmetic mean*, or *sample mean*. It is the value about which all data are “centered.” The sample mean  $\bar{X}$  is calculated as:

$$\bar{X} = \frac{1}{n} \sum_{i=1}^n x_i \quad (1)$$

where  $x_i$  = individual data point values, and  $n$  = number of data points. According to the *central limit theorem*, when a large number of samples is taken independently from a population, the sample means follow a normal distribution, regardless of how data in each sample are distributed.

**Sample Standard Deviation ( $S$ ):** A measure of the dispersion of data about its standard mean  $\bar{X}$ . The sample standard deviation is calculated by the formula:

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n - 1}} \quad (2)$$

where  $n - 1$  = the number of *degrees of freedom* (*d.f.*)

**Degrees of Freedom (*d.f.*):** The number of observations made in excess of the minimum needed to estimate a statistical parameter or quantity. For example, only one measurement is required to identify the width of an indexable insert's flank wear that occurs while machining a workpiece. If the measurements are repeated seven times, then the sample variance of flank wear measurement has six degrees of freedom.

**Coefficient of Variation ( $V$ ):** Used to evaluate or control the variability in data points. The coefficient of variation is calculated by dividing the sample standard deviation  $S$  by the sample mean  $\bar{X}$  and expressing the result as a percent:

$$V = \frac{S}{\bar{X}} 100\% \quad (3)$$

**Absolute Error of the Sample Mean ( $A_x$ ):** Calculated by dividing the sample standard deviation by the square root of the number of data points. The result is expressed in the same unit of measure as the sample standard deviation and the sample mean:

$$A_x = \frac{S}{\sqrt{n}} \quad (4)$$

**Relative Error of the Sample Mean ( $R_x$ ):** Calculated by dividing the absolute error of the sample mean by the sample mean and expressing the result as a percent:

$$R_x = \frac{A_x}{\bar{X}} (100) \quad (5)$$

**Critical Value of "t-Distribution" ("Student's t-distribution"):** The *t*-distribution was discovered in 1908, by W. S. Gosset, who wrote under the name "Student" (the brewery he worked for did not allow him to publish under his own name). The critical value of *t* depends on the number of degrees of freedom and the probability of error. If a 95% two-sided confidence is used for statistical analysis, then the probability of error is 5%, or 2.5% per side. A 5% probability of error provides practical accuracy, which is commonly acceptable in various engineering calculations. The *t*-distribution is broader than the normal distribution for small sample sizes, but approaches the shape of a normal distribution as sample size increases, with the difference negligible even for moderately large sample sizes ( $n > 30$ ).

For a 5% probability of error, the critical value of *t*-distribution can be determined from Table 1, page 140, at the intersection of the column under the heading  $t_{0,025}$  and the row corresponding to the number of degrees of freedom shown in the column heading *d.f.*

**Population Mean ( $\mu$ ):** The normal distribution has two parameters: the population mean  $\mu$  and the population standard deviation  $S$ . The sample mean  $\bar{X}$  is an estimate of the population mean ( $\bar{X} \approx \mu$ ), and the sample standard deviation is an estimate of the population standard deviation ( $\sigma \approx S$ ). A graph of the normal distribution is symmetric about its mean  $\mu$ . Virtually all of the area (99.74%) under the graph is contained within the interval:

$$(\mu - 3\sigma, \mu + 3\sigma)$$

The population mean lies at the center of the normal distribution curve. Thus, almost all of the probability associated with a normal distribution falls within  $\pm$  three standard deviations of the population mean  $\mu$ . Also, 95.44% of the area falls within  $\pm$  two standard deviations of  $\mu$ , and 68.26% within  $\pm$  one standard deviation.

**Confidence Interval for the Population Mean:** The interval of the normal curve associated with the probability of a parameter occurring is the *confidence interval*. The probability itself is the *confidence level*. The ends of this interval are the *confidence limits*. Larger samples tend to give better estimates of a population parameter. A higher confidence level tends to produce a wider confidence interval. Confidence levels of 90%, 95%, and 99% are commonly used. For example, a 95% confidence level implies that the true population parameter (say, a measurement being looked at) has a 95% probability of falling within the presented interval.

Equations (1) through (5) describe a sample mean that is only an estimate of the true (population) mean. Therefore, it is important to define a confidence interval that determines a range within which the population mean lies. Such an interval depends on

the sample mean,  $\bar{X}$ , absolute error of the sample mean,  $A_x$ , and  $t$ -distribution (Student's) value. A confidence interval for the population mean satisfies the inequality:

$$\bar{X} - A_x t \leq \mu \leq \bar{X} + A_x t \quad (6)$$

### Applying Statistics

**Minimum Number of Test or Data Points.**—The minimum number of data points needed to represent a sample size can be determined through the formulas for the coefficient of variation  $V$ , Equation (3), the absolute error of the sample mean  $A_x$ , Equation (4), and the relative error of the sample mean  $R_x$ , Equation (5).

According to Equation (4), the absolute error of the sample mean is:

$$A_x = \frac{S}{\sqrt{n}}$$

The other expression for the absolute error of the sample mean from Equation (5) is:

$$A_x = \bar{X} R_x \quad (7)$$

Because the values to the left of the equal sign in Equations (4) and (7) are equal, the values on the right are also equal and, therefore:

$$\frac{S}{\sqrt{n}} = \bar{X} R_x \quad (8)$$

Solving for  $\sqrt{n}$  in Equation (8) produces:

$$\sqrt{n} = \frac{S}{\bar{X} R_x} \quad (9)$$

Because  $S/\bar{X}$  is the coefficient of variation  $V$ , see Equation (3), then:

$$\sqrt{n} = \frac{V}{R_x} \quad \text{and} \quad n = \frac{V^2}{(R_x)^2} \quad (10)$$

The coefficient of variation of the sample mean must be known or selected according to previously collected data of a similar kind, or, if necessary, preliminary tests should be conducted to estimate its value. Based on numerous studies of cutting tool performance and publications on mechanical properties of cutting tool materials, values of the coefficient of variation within 25 to 45% are considered typical. A relative error of the sample mean between 6 and 12% is also considered typical. The coefficient of variation and the relative error are used to estimate how many tests are required. For example, if  $V = 30\%$  and  $R_x = 8\%$ , then the number of tests required is  $n = 30^2/8^2 = 14$ .

**Comparing Products with Respect to Average Performance.**—Lab and field tests are usually conducted to compare the average performance of two or more products. The term “average performance” is a quantitative value, which can be any mechanical, physical, or chemical characteristic of a product. For example, the average tool life of drills and indexable cutting inserts or the average hardness of cemented carbide grades, etc. (*Tool life* usually refers to the usable life of the tool based on wear, a judgment that is made by the manufacturer for a specific product based on various factors.) The products may differ in manufacturing procedure (CVD or PVD coatings), in chemical composition (alloying elements and their amount), and in other parameters. Data collected during experiments must be statistically treated to determine whether products have the same performance characteristics or not.

Statistical treatment of data obtained from experiments with two products includes the following steps:

- a) Calculation of the sample means  $\bar{X}_1$  and  $\bar{X}_2$  using Equation (1)
- b) Calculation of the sample standard deviations  $S_1$  and  $S_2$  using Equation (2)
- c) Calculation of a weighted, or pooled standard deviation using the following formula:

$$S_p = \sqrt{\frac{(n_1 - 1)S_1^2 + (n_2 - 1)S_2^2}{(n_1 - 1) + (n_2 - 1)}} \tag{11}$$

where  $n_1$  and  $n_2$  represent the number of data points for products 1 and 2 respectively.

d) Selection of a confidence level. A 95% two-sided confidence level is recommended. At this confidence level, the probability of error is  $\pm 2.5\%$  per side. The values of  $t$ -distribution versus *degrees of freedom* ( $d.f.$ ) are provided in Table 1, and for a 95% confidence level are located in the column under the heading “ $t_{0.025}$ ” with respect to given degrees of freedom ( $d.f. = n_1 + n_2 - 2$ ).

- e) Calculation of *decision criterion* ( $d.c.$ ) using the following formula:

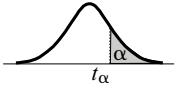

$$d.c. = t_{0.025} \times S_p \sqrt{\frac{n_1 + n_2}{n_1 n_2}} \tag{12}$$

f) Comparison of the value of the decision criterion with the difference of the sample means:  $\bar{X}_1 - \bar{X}_2$  if  $\bar{X}_1 > \bar{X}_2$ , or  $\bar{X}_2 - \bar{X}_1$  if  $\bar{X}_2 > \bar{X}_1$ .

A product's average performance is statistically significant if the difference in the two sample means is greater than the decision criterion  $d.c.$

$$\bar{X}_1 - \bar{X}_2 > d.c. \quad \text{or} \quad \bar{X}_2 - \bar{X}_1 > d.c.$$

Example 1:

### Tool Life Tests of CNMG-432 Indexable Inserts Made of Two Different Carbide Grades (A and B)

Carbide Grade A				Carbide Grades		
Test Number $n_i$	Data, $x_i$ minutes	Treatment of Data		A	B	
		$x_i - \bar{X}$	$(x_i - \bar{X})^2$			
1	15.0	-2.1	4.41	7	7	
2	19.0	1.9	3.61	6	6	
3	16.9	-0.2	0.04	17.1	14.8	
4	16.6	-0.5	0.25	1.6	2.1	
5	16.6	-0.5	0.25	9.4%	14.2%	
6	16.1	-1.0	1.00	0.6	0.8	
7	19.4	2.3	5.29	3.5%	5.4%	
$n = 7$		$\bar{X} = 17.1$		$t$ -value at 95% confidence level at given degrees of freedom, d.f. = 6, Table 1	2.447	2.447
$\Sigma x_i = 119.6$		$\Sigma(x_i - \bar{X})^2 = 14.85$		Population mean is greater than:	15.6	12.8
				Population mean is less than:	18.6	16.8

Carbide Grade B				Comparison of Grades A and B	
Test Number $n_i$	Data, $x_i$ minutes	Treatment of Data			
		$x_i - \bar{X}$	$(x_i - \bar{X})^2$		
1	14.6	-0.2	0.04	Pooled standard deviation, Equation (11)	1.9
2	13.5	-1.3	1.69	$t$ -value at 95% confidence level at given degrees of freedom, d.f. = 6 + 6 = 12, Table 1	2.179
3	15.6	0.8	0.64	Decision criterion, Equation (12)	2.2
4	12.4	-2.4	5.76	Difference between the two sample means	2.3
5	14.6	-0.2	0.04	<b>Conclusion:</b>	
6	13.8	-1.0	1.00	Sample means of the tool life of carbide grades A and B are statistically <i>significant</i> at the 95% confidence level, since the difference of the sample means (17.1 - 14.8 = 2.3 min) is <b>greater</b> than the <i>decision criterion</i> (2.2 min).	
7	19.1	4.3	18.49	Note: $n_i = i$ th test or data point, $x_i = i$ th value of the data point	
$n = 7$		$\bar{X} = 14.8$			
$\Sigma x_i = 103.6$		$\Sigma(x_i - \bar{X})^2 = 27.66$			

Example 2:

### Tensile Strength of Carbon Steel Specimens Versus Heat Treatment

Carbon Steel Sample A				Samples		
Test Number $n_i$	Data, $x_i$ MPa	Treatment of Data		A	B	
		$x_i - \bar{X}$	$(x_i - \bar{X})^2$			
1	522.0	6.9	47.61	5	5	
2	511.0	-4.1	16.81	4	4	
3	488.9	-26.2	686.44	515.1	504.7	
4	553.7	38.6	1490.00	24.8	11.1	
5	499.9	-15.1	228.01	4.8%	2.2%	
$n = 5$		$\bar{X} = 515.1$		11.1	5.0	
$\Sigma x_i = 2575.5$		$\Sigma(x_i - \bar{X})^2 = 2468.9$		2.2%	1.0%	
				$t$ -value at 95% confidence level at given degrees of freedom, d.f. = 4, Table 1	2.776	2.776
				Population mean is greater than:	484.3	490.8
				Population mean is less than:	545.9	518.6

Carbon Steel Sample B				Comparison of Samples A and B	
Test Number $n_i$	Data, $x_i$ MPa	Treatment of Data			
		$x_i - \bar{X}$	$(x_i - \bar{X})^2$		
1	517.1	12.4	153.76	Pooled standard deviation, Equation (11)	19.2
2	490.2	-14.5	210.25	$t$ -value at 95% confidence level at given degrees of freedom, d.f. = 4 + 4 = 8, Table 1	2.306
3	499.1	-5.6	31.36	Decision criterion, Equation (12)	28.0
4	514.4	9.7	94.09	Difference between the two sample means	10.4
5	502.6	-2.1	4.41	<b>Conclusion:</b>	
$n = 5$		$\bar{X} = 504.7$		Sample means of the tensile strength of samples A and B are statistically <i>insignificant</i> at the 95% confidence level, since the difference of the sample means (515.1 - 504.7 = 10.4 MPa) is <b>less</b> than the <i>decision criterion</i> (28.0 MPa).	
$\Sigma x_i = 2523.4$		$\Sigma(x_i - \bar{X})^2 = 493.87$			

Note:  $n_i = i$ th test or data point,  $x_i = i$ th value of the data point

Example 3:

### Tool Life Tests of 6.0-mm Diameter Drills with Different Web Thickness

Drills with 2.0 mm Web, Group A				Drill Groups	
Test Number $n_i$	Data, $x_i$ minutes	Treatment of Data		A	B
		$x_i - \bar{X}$	$(x_i - \bar{X})^2$

				15	24.60	9.59	91.9681
				16	30.40	15.39	236.8521
				$n = 16$		$\bar{X} = 15.01$	
				$x_i = 240.20$		$(x_i - \bar{X})^2 = 800.2008$	

#### Conclusion:

Sample means of the tool life of the drills in Group A and B are statistically *significant* at the 95% confidence level, since the difference of the sample means (26.74 - 15.01 = 11.73 min) is **greater** than the decision criterion (5.35 min Difference). Note:  $n_i = i$ th test or data point,  $x_i = i$ th value of the data point

**Regarding Machinability and Hardness:** In cutting steels, the allowable cutting speed for a given tool life between grindings is, as a general rule, inversely proportional to the hardness of a given steel. To illustrate, tests in turning an alloy steel with a high-speed steel tool showed a cutting speed of 70 feet per minute (21.3 meters per minute) when the hardness of the steel was 180 BHN (Brinell Hardness Number); the cutting speed had to be reduced to about 35 feet per minute (10.7 meters per minute) when the hardness was increased to 360 BHN, the life between tool grindings for these tests being 20 minutes in each case. The machinability of other steels of the same hardness might vary. For example, the tests just referred to showed more or less variation in the cutting speeds for steels of the same hardness, but having different compositions or properties. Thus, while there is a constant relationship between the hardness of a steel and its tensile strength, there is not the same constant relationship between steel hardness and machinability as applied to different steels.

## ENGINEERING ECONOMICS

Engineers, managers, purchasing agents, and others are often required to plan and evaluate project alternatives and make economic decisions that may greatly affect the success or failure of a project. In industry, equipment has to be justified before it can be put into use; multiple projects demand money. The topic of this section is how decisions are made on which projects to prefer over others, based on financial considerations.

The goals of a project, such as reducing manufacturing cost or increasing production, selection of machine tool alternatives, or reduction of tooling, labor and other costs, determine which of the available alternatives may bring the most attractive economic return.

Various cost analysis techniques that may be used to obtain the desired outcome are discussed in the material that follows.

## Interest

*Interest* is money paid out or earned for the use of money that has been borrowed or lent (the *principal*). *Simple interest* is interest paid only on the principal; *compound interest* is interest paid on the principal and any previous interest earned. Principal multiplied by annual interest rate, expressed as a decimal, gives *accrued interest*. *Annual percentage rate* (APR) is percent of principal charged or earned in a year, also referred to as *nominal interest rate per year*. An APR is stated when no intermediate compounding occurs within a year. *Effective rate per year* is calculated by considering multiple compoundings occurring in periods throughout a year, using the nominal interest rate. Thus, effective rate is higher than nominal rate, and the more compounding periods per year, the higher the interest paid over the duration of the loan. Most commercial financial dealings these days involve compound interest.

For example, a nominal interest rate of 10% would be  $10/100 = 0.1$  as a decimal. Adding the principal to the interest that results from this calculation gives the total value of the account after a year. This is the basis of the formulas for both simple and compound interest.

An example illustrates the difference between simple and compound calculations: A person borrows \$10,000 from a bank for 2 years at an annual rate of 10%. At the end of the first year, the net amount owed, using both the simple interest and the compound interest calculation, is  $\$10,000 + (\$10,000 \times 0.1) = \$11,000$ . Hence, the interest paid for the first year is \$1,000, for both ways of calculating. In the second year, if simple interest is applied, the interest owed is still calculated on just the amount borrowed, \$10,000. So, at the end of the second year, the interest paid will be the principal of \$10,000 plus \$2,000 in interest, or a total of \$12,000. But, if compound interest is applied, for the second year, the borrower pays an interest of  $\$11,000 \times 0.1 = \$1,100$ . Hence, the total paid to pay the bank is \$10,000, plus this first-year interest of \$1,000, plus the second-year accrued interest of \$1,100, for a total of \$12,100.

**Variables.**—The symbols used in the formulas to calculate various types of interest are:

$P$  = principal amount of money lent, invested, or borrowed; sometimes also present value ( $PV$ )

$I$  = nominal annual interest rate stated as a percentage, e.g., 10 percent per annum

$EIR$  = effective annual interest rate when interest is compounded more often than once a year

$i$  = nominal annual interest rate percent expressed as a decimal, e.g., if  $I = 12$  percent, then  $i = 12/100 = 0.12$

$n$  = number of annual interest periods (that is, number of years)

$m$  = number of interest compounding periods in one year

$F$  = future sum of money at the end of  $n$  interest periods from the present date that is equivalent to  $P$  with added interest  $i$

$A$  = the payment at the end of each period in a uniform series of payments continuing for  $n$  periods, the entire series equivalent to  $P$  at interest rate  $i$

**Simple Interest.**—Over  $n$  years, the simple interest formulas are:

Value of interest ( $I$ ):  $I = Pni$

Future account value ( $F$ ):  $F = P + I = P + Pni = P(1 + ni)$

*Example:* \$250 is lent for three years at 6 percent simple interest.  $P = 250$ ,  $i = 6/100 = 0.06$ ,  $n = 3$ . Then:

$$F = 250 + (250 \times 3 \times 0.06) = 250[1 + (0.06 \times 3)] = 250[1.18] = \$295$$

**Compound Interest.**—If compound interest is calculated multiple times in a year, say  $m$  times a year, then the future value  $F$  of principal  $P$  over  $n$  years at annual rate  $i$  is found by the formula:

$$F = P \left( 1 + \frac{i}{m} \right)^{mn}$$

*Example:* Suppose \$10,000 is borrowed from a bank as discussed above for 2 years at 10% APR or nominal interest rate; there are three ways the bank can calculate interest:

Simple interest over 2 years: The borrower will pay  $F = P + Pni = 10,000 + (10,000 \times 2 \times 0.1) = 10,000 + 2,000 = \$12,000$ .

Compound interest over 2 years with a nominal interest rate of 10% compounded only at the end of the year:  $F = P[1 + (i/m)]^{mn} = 10,000[1 + (0.10/1)]^{1 \times 2} = 10,000 \times 1.1^2 = 10,000 \times 1.21 = \$12,100$ . This is the same the calculation at the beginning of the discussion.

Compound interest over 2 years with a nominal interest rate of 10% compounded four times a year, or  $m = 4$ :  $F = P[1 + (i/m)]^{mn} = 10,000[1 + (0.10/4)]^{4 \times 2} = 10,000 \times 1.2184 = \$12,184$ . Hence, the interest compounded multiple times ( $m = 4$ ) in a year gives more interest than if compounded only once a year. The effect of the four compounds is that the interest is higher by \$84.

Clearly, compounding yields more interest than simple interest. This example shows the effect of once a year compounding over a number of years, compared to a single calculation at the end of the same number years.

**Determining Principal, Rate, or Time.**—What principal should be invested to reach a known or desired future value, based on a given interest rate and time? At what annual rate should an investment be made when the other parameters are known? How much time will a principal take to reach a future value given an annual rate of interest? Solutions to these questions are found by transposing the main formula to isolate the unknown in question.

*Note:* In the formulas below, the units for time are years. If time is given in months or any other unit, it must be converted to years before substituting it into the formula.

*Principal Value of an Investment or Loan ( $P$ ):* These days all commercial banks use compound interest only, so only the formulas and steps for calculating compound interest are shown:

Simple interest:

$$F = P(1 + ni), \text{ so } P = \frac{F}{1 + ni} = F(1 + ni)^{-1}$$

Compound interest,  $m = 1$ :

$$F = P(1 + i)^n, \text{ so } P = \frac{F}{(1 + i)^n}, \text{ or } P = F(1 + i)^{-n}$$

Compound interest,  $m > 1$ :

$$F = P \left( 1 + \frac{i}{m} \right)^{mn}, \text{ so } P = \frac{F}{\left( 1 + \frac{i}{m} \right)^{mn}} \text{ or } P = F \left( 1 + \frac{i}{m} \right)^{-mn}$$

*Example:* Determine the initial deposit (principal) required for an account to reach \$8,000 ( $F$ ), in 10 years ( $n$ ), at an annual interest rate of 4% ( $i = 0.04$ ), compounded monthly ( $m = 12$ ).

*Solution:* Substituting known values into the formula:

$$P = F \left( 1 + \frac{r}{n} \right)^{-nt} = 8000 \left( 1 + \frac{0.04}{12} \right)^{-12 \times 10} = 8000(1.003333)^{-120} = \$5,366$$

*Example:* Determine the principal needed for an account to have a future value of \$25,000 ( $F$ ) in 10 years ( $n$ ), given that interest is compounded *quarterly* (four times a year; so  $m = 4$ ) at an annual rate of 2.5% ( $i = 0.025$ ).

*Solution:*  $P$  is sought, so the formula is:

$$P = F \left(1 + \frac{i}{m}\right)^{-nm} \quad ; \quad P = 25000 \left(1 + \frac{0.025}{4}\right)^{-4 \times 10} = 25000(0.7794) = \$19,485.17$$

To find  $i$  when the other parameters of the loan or investment are known, use the formulas:

$$\text{At compound interest: } i = m \sqrt[m]{\frac{F}{P}} - 1$$

*Solving for Time (n):* Solving the future value formulas for  $n$  requires logarithms. The process for compound interest is shown (for properties of logarithms, see page 36):

$$\begin{aligned} F &= P \left(1 + \frac{i}{m}\right)^{nm} \rightarrow \frac{F}{P} = \left(1 + \frac{i}{m}\right)^{nm} \rightarrow \log\left(\frac{F}{P}\right) = \log\left(1 + \frac{i}{m}\right)^{nm} \\ &\rightarrow \log\left(\frac{F}{P}\right) = mn \log\left(1 + \frac{i}{m}\right) \rightarrow n = \frac{\log\left(\frac{F}{P}\right)}{n \log\left(1 + \frac{i}{m}\right)} \end{aligned}$$

*NOTE:* From logarithm properties,  $\log(a/b) = \log a - \log b$ .

*Time to Increase Investment (n):* A related approach is taken when calculating time to reach a specific total value:

$$\text{Compound interest: } n = \frac{\log\left(\frac{F}{P}\right)}{n \log\left(1 + \frac{i}{m}\right)}$$

*Example:* Determine the time required to double \$500, when interest is compounded monthly at a rate of 5%.

*Solution:* Here,  $i = 0.05$ ,  $m = 12$ ,  $P = \$500$ , and  $F = 2P = \$1000$ .

$$n = \frac{\log\left(\frac{1000}{500}\right)}{12 \log\left(1 + \frac{0.05}{12}\right)} = \frac{\log 2}{12 \log(1.0042)} = 13.9 \text{ years}$$

*Doubling Time for an Investment:* The time needed to double an investment is the same for any principal, since the variables  $F$  and  $P$  drop out.

$$\text{Compound interest: } n_{\text{double}} = \frac{\log 2}{n \log\left(1 + \frac{i}{m}\right)}$$

**Nominal versus Effective Interest Rates.**—Deposits in savings banks, automobile loans, interest on bonds, and many other transactions of this type involve computation of interest due and payable more often than once a year. For such instances, there is a difference between the *nominal* annual interest rate (the stated rate) for the cost of borrowed money and the *effective annual interest rate* (the amount that is actually accrued).

The formula for calculating the effective interest rate (EIR) is:

$$EIR = (1 + i/m)^m - 1$$

The nominal interest rate is also called the “APR,” or the annual percentage rate. APR is quoted without compounding frequency per year. If compounding is done only at the end of the year, the APR is the same as the effective rate. If compounding happens more than once in a year, then the effective rate will be greater than the APR. In this case, it is essential the frequency of compounding be stated when APR is quoted. For example, simply saying APR is 10% is not sufficient. Rather, it must be stated that the APR is 10% compounded yearly, for example, or that it is compounded monthly.

*Example:* For a nominal per annum rate of 12%, with monthly compounding, the effective per annum rate is:

$$EIR = (1 + 0.12/12)^{12} - 1 = 0.1268 = 12.7\% \text{ effective annual interest rate}$$

*Example:* Same as before but with quarterly compounding:

$$EIR = (1 + 0.12/4)^4 - 1 = 0.1255 = 12.6\% \text{ effective annual interest rate}$$

### Cash Flow and Equivalence

*Cash flow* refers to the sum of money received or disbursed, as shown in a project's financial report. Due to the time value of money, the timing of cash flows over a project's lifespan plays a vital role in project success. Engineering economics problems involve four patterns of cash flow, both separately and in combination. Two cash flow patterns are *equivalent* if they have the same value at a particular time.

**Present Value and Discount.**—The *present value* or present worth  $P$  of a given future or final sum  $F$  is the amount  $P$  that, when placed at interest  $i$  for a given time  $n$ , will produce the given amount  $F$ .

$$\text{Simple interest: } P = \frac{F}{1 + ni} = F(1 + ni)^{-1} \quad \text{Compound interest: } P = \frac{F}{(1 + i)^n} = F(1 + i)^{-n}$$

The *true discount*  $D$  is the difference between  $F$  and  $P$ :

$$D = F - P.$$

*Example:* Find the present value and discount of \$500 due in six months at 6% simple interest. Here,  $F = 500$ ;  $n = 6/12 = 0.5$  year;  $i = 0.06$ . Then,  $P = 500/(1 + 0.5 \times 0.06) = \$485.44$ . The discount is  $D = 500 - 485.44 = \$14.56$ .

*Example:* Find the sum that, placed at 5% compound interest, will in three years produce \$5,000. Here,  $F = 5000$ ,  $i = 0.05$ ,  $n = 3$ . Then,

$$P = \frac{5000}{(1 + 0.05)^3} = \$4,319.19$$

**Annuities.**—An *annuity* is a fixed sum paid at regular (uniform) intervals. In the formulas that follow, yearly payments are assumed. When a situation entails a monthly payment, such as rent, the interest rate and duration are modified as needed. It is customary to calculate annuities on the basis of compound interest. If an annuity  $A$  is to be paid out for  $n$  consecutive years, the interest rate being  $i$ , then the present value  $P$  of the annuity is

$$P = A \frac{(1 + i)^n - 1}{i(1 + i)^n}$$

If at the *beginning* of each year a sum  $A$  is set aside at an interest rate  $i$ , the total value  $F$  of the sum set aside, with interest, at the end of  $n$  years, will be

$$F = A \frac{(1 + i)[(1 + i)^n - 1]}{i}$$

If at the *end* of each year a sum  $A$  is set aside at an interest rate  $i$ , then the total value  $F$  of the principal, with interest, at the end of  $n$  years will be

$$F = A \frac{(1 + i)^n - 1}{i}$$

If a principal  $P$  is increased or decreased by a sum  $A$  at the end of each year, then the value of the principal after  $n$  years will be

$$F = P(1 + i)^n \pm A \frac{(1 + i)^n - 1}{i}$$

If the sum  $A$  by which the principal  $P$  is decreased each year is greater than the total yearly interest on the principal, then the principal, with the accumulated interest, will be entirely used up in  $n$  years:

$$n = \frac{\log\left(\frac{A}{A-iP}\right)}{\log(i+1)}$$

*Example:* If an annuity of \$200 is to be paid for 10 years, what is the present amount of money that needs to be deposited if the interest is 5%? Here,  $A = 200$ ,  $i = 0.05$ ,  $n = 10$ :

$$P = 200 \frac{(1 + 0.05)^{10} - 1}{0.05(1 + 0.05)^{10}} = \$1,544.35$$

The annuity a principal  $P$  drawing interest at the rate  $i$  will give for a period of  $n$  years is

$$A = P \frac{i(1+i)^n}{(1+i)^n - 1}$$

*Example:* A sum of \$10,000 is placed at 4%. What is the amount of the annuity payable for 20 years out of this sum: Here,  $P = 10000$ ,  $i = 0.04$ ,  $n = 20$ :

$$A = 10000 \frac{0.04(1 + 0.04)^{20}}{(1 + 0.04)^{20} - 1} = \$735.82$$

**Sinking Funds.**—Amortization is the extinction of debt, usually by means of a *sinking fund*. The sinking fund is created by a fixed investment  $A$  placed each year at compound interest for a term of years  $n$ , and is therefore an annuity of sufficient size to produce at the end of the term of years the amount  $F$  necessary for the repayment of the principal of the debt, or to provide a definite sum for other purposes. Then,

$$F = A \frac{(1+i)^n - 1}{i} \quad \text{and} \quad A = F \frac{i}{(1+i)^n - 1}$$

*Example:* If \$2,000 is invested annually for 10 years at 4% compound interest, as a sinking fund, what would be the total amount of the fund at the expiration of the term? Here,  $A = 2000$ ,  $n = 10$ ,  $i = 0.04$ :

$$F = 2000 \frac{(1 + 0.04)^{10} - 1}{0.04} = \$24,012.21$$

**Cash Flow Diagrams.**—The following conventions are used to standardize cash flow diagrams. The horizontal (time) axis (as seen in several patterns in Table 1 and Table 2) is marked off in equal increments, representing periods, up to the duration of the project. Receipts are represented by arrows directed upwards and disbursements are represented by arrows directed downwards. Arrow length is proportional to magnitude of cash flow. In the following,  $A$  = uniform annuity,  $i$  = interest rate, and  $n$  = number of payments or periods.

**Table 1. Cash Flow Patterns**

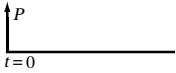

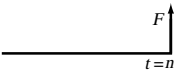

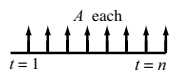

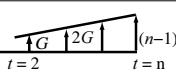

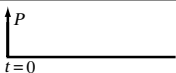

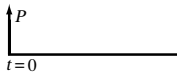

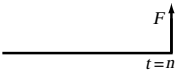

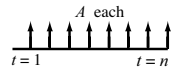

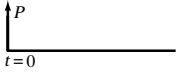

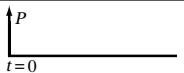

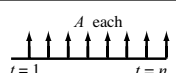

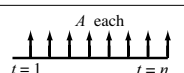

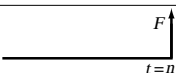

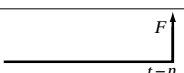

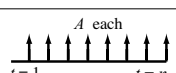

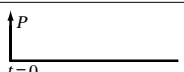

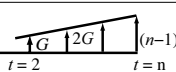

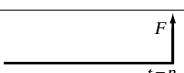

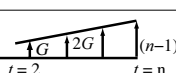

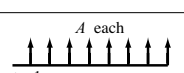

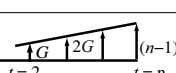

$P$ -pattern $P$ = present value	A single amount $P$ occurring at the beginning of $n$ years. $P$ represents <i>Present</i> amount.	
$F$ -pattern $F$ = future value	A single amount $F$ occurring at the end of $n$ years. $F$ represents <i>Future</i> amount.	
$A$ -pattern $A$ = annual value	Equal amounts $A$ occurring at the end of each of $n$ years. $A$ represents <i>Annual</i> amount.	
$G$ -pattern $G$ = uniform gradient of expense	$G$ is increasing by an equal amount for each time increment (e.g., month) over the period of life $n$ . $G$ represents <i>Gradient</i> amount.	

Table 2. Standard Cash Flow Factors

Symbol	To Find	Formula	Symbol
	$F$ given $P$	$F = P(1+i)^n$	
	$P$ given $F$	$P = \frac{F}{(1+i)^n}$	
	$A$ given $P$	$A = P \frac{i(1+i)^n}{(1+i)^n - 1}$	
	$P$ given $A$	$P = A \frac{(1+i)^n - 1}{i(1+i)^n}$	
	$A$ given $F$	$A = F \frac{i}{(1+i)^n - 1}$	
	$F$ given $A$	$F = A \frac{(1+i)^n - 1}{i}$	
	$P$ given $G$	$P = G \frac{1}{i} \left[ \frac{(1+i)^n - 1}{i(1+i)^n} - \frac{n}{(1+i)^n} \right]$	
	$F$ given $G$	$F = G \frac{1}{i} \left[ \frac{(1+i)^n - 1}{i} - n \right]$	
	$A$ given $G$	$A = G \left[ \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right]$	

*Example:* A rental property pays \$2,000/month with a \$10 per month increase starting the second year. Based on a 10-year period and 8% annual interest, compute the uniform average annuity  $A$  from the rental of this property, considering the gradient.

*Solution:* The gradient  $G = \$10$  per month; the interest each month is  $1/12$  of the rate  $i = 0.08$ ; the duration  $n = 120$  months (using the basis of the annuity, which is monthly rent).

$$\begin{aligned}
 A &= G \left[ \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right] + A_{\text{initial}} \\
 &= 10 \left[ \frac{1}{(.08/12)} - \frac{120}{(1 + (.08/12))^{120} - 1} \right] + 2000 \\
 &= 10(150 - 98.39) = 516 + 2000 = \$2,516
 \end{aligned}$$

### Depreciation

Depreciation is an accounting method that allocates the cost of an asset over its useful life. A machine may decline in value because it is wearing out and no longer performing its function as well as when it was new. As an economics technique, depreciation spreads the purchase price of an asset or other property over a number of years. Tax regulations do not allow the cost of an asset to be treated as a deductible expense in the year of purchase; rather, a portion of the expense is allocated to each year of the asset's depreciation period. This yearly allocation is referred to as *depreciation*.

**Straight Line Depreciation.**—Straight line depreciation is a constant depreciation charge over the period of life. If  $P$  is principal value,  $L$  is salvage value and  $n$  is period of life, then depreciation is calculated:

$$\text{Depreciated value of an asset at year } n: \quad A = P(1 - x) + L$$

$$\text{Depreciation at } x\text{th year:} \quad D_x = \frac{P - L}{n}$$

$$\text{Book value after } x \text{ years:} \quad BV_x = \frac{(P - L)(n - x)}{n} + L$$

$$\text{After tax depreciation recovery:} \quad ATDR = TR \left( \frac{P - L}{n} \right) \frac{(1 + i)^n - 1}{i(1 + i)^n}$$

**Sum of the Years Digits.**—Another method for allocating the cost of an asset minus its salvage value over useful life is *sum of the years digits depreciation*. This method results in charges that are greater than straight line depreciation charges during the early years of an asset and smaller charges near the end period.

$$\text{Depreciation at } x\text{th year:} \quad D_x = \frac{2(P - L)(n - x + 1)}{n(n + 1)}$$

$$\text{Book value after } x \text{ years:} \quad BV_x = P - (P - L)(2n - x + 1) \frac{x}{n(n + 1)}$$

**Double Declining Balance Method.**—A constant depreciation is applied to the book value of a property.

$$\text{Depreciation at } x\text{th year:} \quad D_x = 2 \left( \frac{P}{n} \right) \left( \frac{n - 2}{n} \right)^{(x - 1)}$$

$$\text{Book value after } x \text{ years:} \quad BV_x = P \left( \frac{n - 2}{n} \right)^x$$

**Statutory Depreciation System.**—A depreciation method used for income tax purposes is *accelerated cost recovery system* (ACRS) depreciation. The first step in ACRS is to determine the property class of the asset being depreciated. All personal property falls into one of six classes. Reading across Table 3 after identifying the correct property class, principal  $P$  for year  $x$  is substituted into the following formula:

$$\text{Depreciation at } x\text{th year:} \quad D_x = P \times \text{Depreciation Factor}$$

**Table 3. Property Class and Factor**

ACRS Classes of Depreciable Property		Depreciation Factor for Recovery Period ( <i>n</i> )				
Property Class	Personal Property	Year (r)	3 Years	5 Years	7 Years	10 Years
3	Handling device for food and beverage manufacture, plastic products, fabricated metal products	1	33.33%	20.00%	14.29%	10.00%
		2	44.45%	32.00%	24.49%	18.00%
		3	14.81%	19.20%	17.49%	14.40%
5	Automobiles, trucks, computer, aircraft, petroleum drilling equipment, research and experimentation equipment	4	7.41%	11.52%	12.49%	11.52%
		5		11.52%	8.93%	9.22%
7	Office furniture, fixtures, and equipment	6		5.76%	8.92%	7.37%
10	Railroad cars, manufacture of tobacco products	7			8.93%	6.55%
		8			4.46%	6.55%
15	Telephone distribution line, municipal sewers plant	9				6.56%
		10				6.55%
20	Municipal sewers	11				3.28%

### Evaluating Alternative Investments

When two or more mutually exclusive investments compete for limited funds, a number of ways are available to select the best investment options from a group of proposals. This section discusses such strategies for analyzing alternatives and making decisions to maximize net value.

**Net Present Value.**—One of the easiest ways to compare mutually exclusive investment alternatives is to calculate and compare the net present value of each. *Net present value* (NPV) is most frequently used to determine the present value of future money receipts and disbursements. Three economic criteria for present worth analysis are described: (1) If investment cost is the same, only the output money is considered. (2) If the output result is known, then the investment cost is minimized. (3) If neither input nor output is fixed, then the output minus the input is maximized. The NPV method is widely applied when the lifespans of the alternative proposals are the same.

In selecting the project with the highest NPV from several projects that all achieve the same outcome, a common rate of interest called the minimum attractive rate of return (MARR) is used. The MARR is a rate that companies strive to earn on all their investments. This rate usually is a rate above the interest rate that a company's idle cash will be earning in a risk-free environment. Small-scale companies also may seek investments based on the MARR to achieve returns slightly above the average rate the same money would earn in the stock market on a long-term basis.

The symbols used for the following calculations are defined:

$P$ = present value	$NPV$ = net present value	$AR$ = annual revenue
$AE$ = annual expense	$G_A$ = uniform gradient of expense given annual amount $A$	$TR$ = tax rate as percentage
$i$ = interest rate (as a decimal)	$n$ = number of payments or periods	$L$ = salvage value

$$\text{With uniform annual expense before tax} \quad NPV = -P + (AR - AE) \left[ \frac{(1+i)^n - 1}{i(1+i)^n} \right] + \frac{L}{(1+i)^n}$$

$$\text{With uniform gradient on annual expense before tax} \quad NPV = -P + (AR - AE - A_G) \left[ \frac{(1+i)^n - 1}{i(1+i)^n} \right] + \frac{L}{(1+i)^n}$$

$$\text{With uniform annual expense after tax} \quad NPV = -P + (AR - AE)(1 - TR) \left[ \frac{(1+i)^n - 1}{i(1+i)^n} \right] + \frac{L}{(1+i)^n}$$

$$\text{With uniform gradient on annual expense after tax} \quad NPV = -P + (AR - AE - A_G)(1 - TR) \left[ \frac{(1+i)^n - 1}{i(1+i)^n} \right] + \frac{L}{(1+i)^n}$$

To include depreciation, the after tax depreciation recovery (ATDR) must be added to get the net present value.

*Example:* A pharmaceutical company makes a product from a composition of chemicals. Two mixing processes, batch and continuous, are available.

Process	Continuous	Batch
Initial cost ( $P$ )	\$75,000	\$35,000
Lifetime (years) ( $n$ )	10	10
Maintenance (per year)	\$5,000	\$8,000
Capacity (units/year)	25,000	20,000

The company uses straight line depreciation, pays 40% of its net income as income tax, and has an after tax minimum attractive rate of return of 15%. The company can sell the product at \$1.00 per unit. Which manufacturing process should the company invest in?

*Solution:* Because the lifetimes of the batch and continuous processes are equal at 10 years each, we can make a comparison using the present worth method by applying the formulas for NPV and also for ATDR.

$$\begin{aligned}
 NPV_{\text{Continuous}} &= -P + (AR - AE)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + TR \left( \frac{P-L}{n} \right) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) \\
 &= -75000 + [(25000 \times 1) - 5000](1 - 0.40) \left( \frac{(1 + 0.15)^{10} - 1}{0.15(1 + 0.15)^{10}} \right) + 0.40 \left( \frac{75000}{10} \right) \left( \frac{(1 + 0.15)^{10} - 1}{0.15(1 + 0.15)^{10}} \right) \\
 &= -14775 + 15056 = 281 \\
 NPV_{\text{Batch}} &= -P + (AR - AE)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + TR \left( \frac{P-L}{n} \right) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) \\
 &= -35000 + [(20000 \times 1) - 8000](1 - 0.40) \left( \frac{(1 + 0.15)^{10} - 1}{0.15(1 + 0.15)^{10}} \right) + 0.40 \left( \frac{35000}{10} \right) \left( \frac{(1 + 0.15)^{10} - 1}{0.15(1 + 0.15)^{10}} \right) \\
 &= 1135 + 7026 = 8161
 \end{aligned}$$

Based on above calculations, the batch production process is selected because it gives a greater net present value (NPV) than the continuous process.

**Capitalized Cost.**—In governmental analyses, there are some circumstances where a service is required for an infinite period of time, such as with roads, dams, and pipelines. Present worth of a project with an infinite life is known as *capitalized cost* (CC). Capitalized cost is the amount of money at  $n=0$  needed to perpetually support projected expenses with earned interest only. Capitalized cost is the present sum of money that would need to be set aside now, at some interest rate, to yield the funds required to provide the service.

$$CC = P + (A)(P_{\text{given } A}) - (L)(P_{\text{given } F}) + (G)(P_{\text{given } G})$$

Without periodical replacement:  $CC = P + \frac{A}{i}$

With 100% periodical replacement:  $CC = P + \frac{P-L}{(1+i)^n - 1} + \frac{A}{i}$

With periodical renovation cost:  $CC = P + \frac{RC}{(1+i)^n - 1} + \frac{A}{i}$

where  $CC$  = capitalized cost;  $P$  = initial cost;  $L$  = salvage value;  $A$  = annual cost;  $RC$  = renovation cost;  $i$  = interest rate; and,  $n$  = effective period of time.

**Equivalent Uniform Annual Cost.**—This method is applied when the alternatives have unequal periods of life. To avoid unequal periods of time, the present value and future value is converted to an annual value. The alternatives must be mutually exclusive and repeatedly renewed up to the duration of the longest lived alternative.

$$A = (P)(A_{\text{given } P}) - (L)(A_{\text{given } F}) + (G)(A_{\text{given } G}) + AE$$

With sinking fund depreciation: 
$$A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE$$

With sinking fund depreciation and uniform gradient  $G$ : 
$$A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE + G \left[ \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right]$$

Straight line depreciation: 
$$A = \frac{P-L}{n} + Li + AE + \frac{(P-L)(n+1)i}{2n}$$

*Example:* An investment of \$15,000 is being considered to reduce labor and labor-associated costs in a materials handling operation from \$8,200 a year to \$3,300. This operation is expected to be used for 10 years before being changed or discontinued entirely. In addition to the initial investment of \$15,000 and the annual cost of \$3,300 for labor, there are additional annual combined costs for power, maintenance, insurance, and property taxes of \$1,800 associated with the revised operation. Based on comparisons of annual costs, should the \$15,000 investment be made or the present operation continued?

*Solution:* The present annual cost of the operation is \$8,200 for labor and labor-associated costs. The proposed operation has an annual cost of \$3,300 for labor and labor extras plus \$1,800 for additional power, maintenance, insurance, and taxes, plus the annual cost of recovering the initial investment of \$15,000 at some interest rate (minimum acceptable rate of return).

Assuming that 10 percent would be an acceptable rate of return on this investment over a period of 10 years, the annual amount to be recovered on the initial investment would be \$15,000 multiplied by the capital recovery factor.

Putting this value into ( $A_{\text{given } P}$ ) yields:

$$A = \frac{i(1+i)^n}{(1+i)^n - 1} P + AE = \frac{(0.10)(1+0.10)^{10}}{(1+0.10)^{10} - 1} 15000 + 5100 = 7541.18$$

This amount is less than the present annual cost of \$8,200. Thus, the investment is justified unless there are other considerations, such as the effects of income taxes, salvage values, expected life, uncertainty about the required rate of return, changes in the cost of borrowed funds, and others.

A tabulation of annual costs of alternative plans A, B, C, etc. is a good way to compare costs item by item. For this example:

	Item	Plan A	Plan B
1	Labor and labor extras	\$8,200	\$3,300
2	Annual cost of \$15,000 investment		2,442
3	Power		400
4	Maintenance		1,100
5	Property taxes and insurance		<u>300</u>
	Total annual cost	\$8,200	\$7,542

*Example, Annual Cost Considering Salvage Value:* If in the previous example the salvage value of the equipment installed was \$5,000 at the end of 10 years, what is the effect on the annual cost of the proposed investment of \$15,000?

*Solution:* The only item in the annual cost of the previous example that will be affected is the capital recovery amount of \$2,442. The following formula gives the amount of annual capital recovery when salvage value is considered:

$$A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE$$

$$= (15000 - 5000) \frac{(0.10)(1 + 0.10)^{10}}{(1 + 0.10)^{10} - 1} + 5000(0.10) + 5100 = 7227.45$$

This amount is \$315 less than the previous annual cost of \$7,542 for the proposed investment.

**Rate of Return.**—This is the estimated interest rate produced by an investment. *Rate of return (ROR)* is the interest rate at which benefits are equivalent to costs. It is defined as the interest rate paid on the unpaid balance of a loan in such a way that the payment schedule makes the unpaid loan balance equal zero when the final payment is made. It may be computed by finding the interest rate in such a way that the estimated expenditures are equal to the capital gain. *Net Present Worth* = 0, or equivalently, *PW of benefits* – *PW of costs* = 0

$$\frac{(1 + ROR)^n - 1}{ROR(1 + ROR)^n} (AR - AE) + \frac{L}{(1 + ROR)^n} = P$$

The rate of return can only be calculated through trial and error. To find out the present worth, a reasonable interest rate is selected and the present worth is calculated. Then another rate is chosen and the present worth is calculated. The value of the *ROR* is interpolated or extrapolated to find the zero value of present worth.

**Benefit-Cost Ratio.**—This is the ratio of present worth of benefit to present worth of cost. This method is applied to municipal project evaluations where benefits (*B*) and costs (*C*) accrue to different segments of the community. A project is considered acceptable if the ratio equals or exceeds 1. For fixed input,  $B/C \geq 1$  is maximized, and for fixed output,  $B/C \geq 1$  is maximized, and if neither input nor output is fixed, to compute the incremental benefit-cost ratio ( $\Delta B/\Delta C$ ), choose  $\Delta B/\Delta C \geq 1$ .

*Example:* To build a bridge over a river costs \$1,200,000, with benefits of \$2,000,000, and disbenefits of \$500,000. (a) What is the benefit-cost ratio? (b) What is the excess of benefits over costs?

*Solution:* (a) The benefit-cost ratio  $B/C$  is regarded as  $(B - D)/C$ . Here  $B$  = benefits,  $D$  = disbenefits, and  $C$  = cost.

Benefit-cost ratio:  $(2,000,000 - 500,000)/1,200,000 = 1.25$

As the ratio is greater than 1, the project is worth undertaking.

(b) The excess of benefits over cost =  $2,000,000 - 1,200,000 - 500,000 = 300,000$ .

**Payback Period.**—This is the period required to obtain benefits or cost savings equal to the initial investment made. For example, if a piece of equipment costs \$10,000 and the company can obtain cost savings of \$2,500 per year by procuring that equipment, the payback period can be said to be \$10,000 divided by \$2,500, which is 4 years. Payback period is a quick way of evaluating whether an investment is worth making. For example, a plant manager who has a payback period of 5 years in her mind might think the \$10,000 investment is worth making.

Payback period ignores the rate of interest or assumes that rate to be 0%. Also, payback period ignores benefits coming in a non-linear manner over the life of the equipment.

## MECHANICS

Throughout this section of the Handbook, both English and metric SI data and formulas are given to cover the requirements of working in either system of measurement. Except for the passage entitled *Use of Metric SI System in Mechanics Calculations*, formulas and text relating exclusively to SI are given in bold face type.

## Terms and Definitions

**Definitions.**—The science of mechanics is concerned with the effects of forces in causing or preventing motion. *Statics* is the branch of mechanics that deals with bodies in equilibrium, i.e., the forces acting on bodies cause them to remain at rest or to move with uniform velocity. *Dynamics* deals with bodies not in equilibrium, i.e., the forces acting on bodies cause them to move with non-uniform velocity. *Kinetics* is the branch of dynamics that concerns both the forces acting on bodies and the motions that they cause. *Kinematics* is the branch of dynamics that deals only with the motions of bodies without reference to the forces that cause them.

Definitions of certain terms and quantities as used in mechanics follow:

*Force* may be defined simply as a push or a pull, which may result from the force of contact between bodies or from a force, such as magnetism or gravitation, in which no direct contact takes place.

*Matter* is any substance that occupies space; gases, liquids, solids, electrons, atoms, molecules, etc., are all classified as matter.

*Inertia* is that property by which matter tends to resist any change in its motion or state of rest.

*Mass* is a measure of the inertia of a body.

*Work*, in mechanics, is the product of force and distance and is expressed by a combination of units of force and distance, expressed as foot-pound, inch-pound, meter-kilogram, etc. **The metric SI unit of work is the joule (J), which is the work done when the point of application of a force of one newton is displaced through a distance of one meter in the direction of the force.**

*Power*, in mechanics, is the rate of change of work per unit time; it is the product of force and distance divided by time; it measures the amount of work performed in a given time period. It is the rate of doing work and is expressed in foot-pound per minute, foot-pound per second, kilogram-meter per second, etc. **The metric SI unit is the watt (W), which is equivalent to one joule per second.**

*Horsepower* is the unit of power that has been adopted for engineering work. One horsepower (hp) is equal to 33,000 foot-pounds per minute or 550 foot-pounds per second. The *kilowatt* (kW), used in electrical work, equals 1.34 horsepower; or 1 horsepower equals 0.746 kilowatt. **However, in the metric SI, the term "horsepower" is not used, and the basic unit of power is the watt. This unit, and the derived units milliwatt and kilowatt, for example, are the same as those used in electrical work.**

*Torque or moment* of a force is a measure of the tendency of a force to rotate a body upon which it acts about an axis. The magnitude of the moment due to a force acting in a plane perpendicular to some axis is obtained by multiplying the force by the perpendicular distance from the axis to the line of action of the force. (If the axis of rotation is not perpendicular to the plane of the force, then the components of the force in a plane perpendicular to the axis of rotation are used to find the resultant moment of the force by finding the moment of each component and adding the component moments algebraically.) Moment or torque is commonly expressed in pound-feet, pound-inches, kilogram-meters, etc. **The metric SI unit is the newton-meter (N·m).**

*Velocity* is the rate of change of distance; it is expressed as distance divided by time, that is, feet per second, miles per hour, centimeters per second, meters per second, etc.

*Acceleration* is the time-rate of change of velocity and is expressed as velocity divided by time or as distance divided by time squared, that is, in feet per second per second or feet per second squared ( $\text{ft}/\text{sec}^2$ ); inches per second per second or inches per second squared ( $\text{in}/\text{sec}^2$ ); centimeters per second per second or centimeters per second squared ( $\text{cm}/\text{sec}^2$ ); etc. **The metric SI unit is the meter per second squared ( $\text{m}/\text{sec}^2$ ).**

**Unit Abbreviations.**—Standard abbreviations for the units of physical quantities are used throughout the Handbook. Comprehensive tables of unit abbreviations are found starting on page 2827 for US units, and on page 2832 for metric units.

**Unit Systems.**—In mechanics calculations, both *absolute* and *gravitational* systems of units are employed. The fundamental quantities in absolute systems are *length*, *time*, and *mass*, and from these the dimension of *force* is derived. Two absolute systems that have been in use for many years are the CGS (centimeter-gram-second) and the MKS (meter-kilogram-second) systems. They are named for the fundamental units of length, mass and time, respectively. Another system known as MKSA (meter-kilogram-second-ampere) links the MKS system of units of mechanics with electromagnetic units.

**The General Conference of Weights and Measures (CGPM), which is the body responsible for all international matters concerning the metric system, adopted in 1954 a rationalized and coherent system of units based on the four MKSA units, including the kelvin as the unit of temperature and the candela as the unit of luminous intensity. In 1960, the CGPM formally named this system the “Système International d’Unités,” for which the abbreviation is SI in all languages. In 1971, the 14th CGPM adopted a seventh base unit, the *mole*, which is the unit of quantity (“amount of substance”). Further details of the SI are given in the section *MEASURING UNITS* starting on page 2831, and its application in mechanics calculations, contrasted with the use of the English system, is considered below.**

The fundamental quantities in gravitational systems are *length*, *time*, and *force*, and from these units, the dimension of *mass* is derived. In the gravitational system most widely used in English measure countries, the units of length, time, and force are, respectively, the foot (ft), the second (s or sec), and the pound (lb). The corresponding unit of mass, commonly called the *slug*, is equal to  $1 \text{ lb}\cdot\text{s}^2/\text{ft}$  and is derived from the formula,  $M = W/g$  in which  $M$  = mass in slugs,  $W$  = weight in pounds, and  $g$  = acceleration due to gravity, commonly taken as  $32.16 \text{ ft}/\text{s}^2$ . A body that weighs 32.16 lbs on the surface of the earth has, therefore, a mass of 1 slug.

Many engineering calculations utilize a system of units consisting of the inch, the second, and the pound. The corresponding units of mass are pounds second squared per inch ( $\text{lb}\cdot\text{s}^2/\text{in}$ ) and the value of  $g$  is taken as  $386 \text{ in}/\text{s}^2$ .

In a gravitational system that has been widely used in metric countries, the units of length, time, and force are, respectively, the meter, the second, and the kilogram-force ( $1 \text{ kgf} = 9.80665 \text{ N}$ ). The corresponding units of mass are  $\text{kgf}\cdot\text{s}^2/\text{m}$  and the value of  $g$  is taken as  $9.81 \text{ m}/\text{s}^2$ .

**Acceleration of Gravity  $g$  Used in Mechanics Formulas.**—The acceleration of a freely falling body varies according to location on the earth's surface as well as the height from which the body falls. Its value measured at sea level at the equator is  $32.09 \text{ ft}/\text{sec}^2$  while at the poles is  $32.26 \text{ ft}/\text{sec}^2$ . In the United States it is customary to regard 32.16 as satisfactory for most practical purposes in engineering calculations.

**Standard Pound Force:** For use in defining the magnitude of a standard unit of force, known as the *pound force*, a fixed value of  $32.1740 \text{ ft}/\text{sec}^2$ , designated by the symbol  $g_0$ , has been adopted by international agreement. As a result of this agreement, whenever the term mass,  $M$ , appears in a mechanics formula and the substitution  $M = W/g$  is made, use of the standard value  $g_0 = 32.1740 \text{ ft}/\text{sec}^2$  is implied, although as stated previously, it is customary to use approximate values for  $g$  except where extreme accuracy is required.

**Use of Metric SI System in Mechanics Calculations.**—The SI system is a development of the traditional metric system based on decimal arithmetic; fractions are avoided. For each physical quantity, units of different sizes are formed by multiplying or dividing a single base value by powers of 10. Conversions can be made simply by adding zeros or shifting decimal points. For example, the meter is the basic unit of length; *kilometer* is a multiple (1000 meters); and *millimeter* is a sub-multiple (1/1000 of a meter).

In the older metric system, the simplicity of a series of units linked by powers of 10 is an advantage for plain quantities such as length, but this simplicity is lost as soon as more complex units are encountered. For example, in different branches of science and engineering, energy may appear as the erg, calorie, kilogram-meter, liter-atmosphere, or horsepower-hour. In contrast, the metric SI provides only one basic unit for each physical quantity, and universality is thus achieved.

There are seven *base units*, and in mechanics calculations three are used, which are for the basic quantities of length, mass, and time, expressed as meter (m), kilogram (kg), and second (s). The other four base-units are ampere (A) for electric current, kelvin (K) for thermodynamic temperature, candela (cd) for luminous intensity, and mole (mol) for amount of substance.

The SI is a coherent system. A system of units is said to be coherent if the product or quotient of any two unit quantities in the system is the unit of the resultant quantity. For example, in a coherent system in which the foot is a unit of length, the square foot is the unit of area, whereas the acre is not. Further details of the SI, and definitions of the units are given in the section *MEASURING UNITS* starting on page 2831, near the end of the Handbook.

Additional units of physical quantities are derived from the base-units. For example, the unit of velocity is meter per second (m/s), which is a combination of the base-units of length and time. The unit of acceleration is meter per second squared (m/s<sup>2</sup>). By applying Newton's second law of motion, *force is proportional to mass multiplied by acceleration*:

The unit of force is obtained, which is kg·m/s<sup>2</sup>. This unit is the *newton*, or N.

*Work*, the product of force and distance, has units of kg·m<sup>2</sup>/s<sup>2</sup>, which is the *joule*, or J. (1 J = 1 N·m) and energy is also expressed in these terms.

*Power*, or work per unit time, has units of kg·m<sup>2</sup>/s<sup>3</sup>, which is the *watt*, or W.

(1 W = 1 J/s = 1 N·m/s).

Information on Newton's laws may be found in *Newton's Laws of Motion* on page 182.

The coherence of SI units has two important advantages. The first, that of uniqueness and therefore universality, has been explained. The second is that it greatly simplifies technical calculations. Equations representing physical principles can be applied without introducing such numbers as 550 in power calculations, which, in the English system of measurement have to be used to convert units. Thus, conversion factors largely disappear from calculations carried out in SI units, with a great saving in time and labor.

*Mass, Weight, Force, Load:* SI is an absolute system (see *Unit Systems* on page 157), and consequently it is necessary to make a clear distinction between mass and weight. The *mass* of a body is a measure of its inertia, which is unaffected by gravity whereas the *weight* of a body is the *force* exerted on it by gravity. In a fixed gravitational field, weight is directly proportional to mass, and the distinction between mass and weight can be easily overlooked. However, if a body is moved to a different gravitational field, for example, that of the moon, its weight alters, but its mass remains unchanged. Because the gravitational field on earth varies from place to place by only a small amount, and because weight is proportional to mass, it is practical to use the weight of unit mass as a unit of force, and this procedure is adopted in both the English and older metric systems of measurement. In common usage, they are given the same names, and we say that a mass of 1 pound has a weight of 1 pound. In the former case the pound is being used as a unit of mass, and in the latter case, as a unit of force. This procedure is convenient in some branches of engineering, but leads to confusion in others.

As mentioned earlier, Newton's second law of motion states that force is proportional to mass times acceleration. Because an unsupported body on the earth's surface falls with acceleration  $g$  (32 ft/s<sup>2</sup> approximately), the pound force (lbf) is that force which will impart an acceleration of  $g$  ft/s<sup>2</sup> to a 1 pound mass (lbm). Similarly, the kilogram force (kgf) is that force which will impart an acceleration of  $g$  (9.8 m/s<sup>2</sup> approximately), to a mass of 1 kg. In the SI, the *newton* is that force which will impart *unit acceleration* (1 m/s<sup>2</sup>) to a mass of one kilogram. The newton is therefore smaller than the kilogram (force) in the ratio 1:g (about 1:9.8). This fact has important consequences in engineering calculations. The factor  $g$  now disappears from a wide range of formulas in dynamics, but appears in many formulas in statics where it was formerly absent. It is however not quite the same  $g$ , for reasons which will now be explained.

In the article on page 186, the mass of a body is referred to as  $M$ , but it is immediately replaced in subsequent formulas by  $W/g$ , where  $W$  is the weight in pounds (force), which leads to familiar expressions such as  $WV^2/2g$  for kinetic energy. In this treatment, the  $M$  is really expressed in terms of the slug (page 157), a unit normally used only in aeronautical engineering. In everyday engineers' language, weight and mass are regarded as synonymous and expressions such as  $WV^2/2g$  are used without pondering the distinction. Nevertheless, on reflection it seems odd that  $g$  should appear in a formula which has nothing to do with gravity at all. In fact the  $g$  used here is not the true, local value of the acceleration due to gravity, but an arbitrary standard value chosen as part of the definition of the pound force and is more properly designated  $g_0$  (page 157). Its function is not to indicate the strength of the local gravitational field but to convert from one unit to another.

In SI the unit of mass is the *kilogram*, and the unit of force (and weight) is the *newton*.

The following are typical statements in dynamics expressed in SI units:

A force of  $R$  newtons acting on a mass of  $M$  kilograms produces an acceleration of  $R/M$  m/s<sup>2</sup>. The kinetic energy of a mass of  $M$  kg moving with velocity  $V$  m/s is  $\frac{1}{2}MV^2$  kg (m/s)<sup>2</sup> or  $\frac{1}{2}MV^2$  joules. The work done by a force of  $R$  newtons moving a distance  $L$  meters is  $RL$  N·m, or  $RL$  joules. If this work were converted entirely into kinetic energy we could write  $RL = \frac{1}{2}MV^2$  and it is instructive to consider the units. Remembering that the N is the same as the kg·m/s<sup>2</sup>, we have (kg·m/s<sup>2</sup>) m = kg (m/s)<sup>2</sup>, which is obviously correct. It will be noted that  $g$  does not appear anywhere in these statements.

In contrast, in many branches of engineering where the weight of a body is important, rather than its mass, using SI units,  $g$  does appear where formerly it was absent. Thus, if a rope hangs vertically supporting a mass of  $M$  kilograms the tension in the rope is  $Mg$  N. Here  $g$  is acceleration due to gravity, and its units are m/s<sup>2</sup>. The ordinary numerical value of 9.81 will be sufficiently accurate for most purposes on earth. The expression is still valid elsewhere, for example, on the moon, provided the proper value of  $g$  is used. The maximum tension the rope can safely withstand (and other similar properties) will also be specified in terms of the newton, so that direct comparison may be made with the tension predicted.

Words like load and weight have to be used with greater care. In everyday language we might say "a lift carries a load of five people of average weight 70 kg," but in precise technical language we say that if the average mass is 70 kg, then the average weight is 70g N, and the total load (that is force) on the lift is 350g N.

If the lift starts to rise with acceleration  $a$  m/s<sup>2</sup>, the load becomes 350( $g + a$ ) N; both  $g$  and  $a$  have units of m/s<sup>2</sup>, the mass is in kg, so the load is in terms of kg·m/s<sup>2</sup>, which is the same as the newton.

*Pressure and stress:* These quantities are expressed in terms of force per unit area. In SI the unit is the *pascal* (Pa), which expressed in terms of SI derived and base units is the newton per meter squared (N/m<sup>2</sup>). The pascal is very small—equivalent to  $0.15 \times 10^{-3}$  lb/in<sup>2</sup>—hence the kilopascal (kPa = 1000 pascals) and the megapascal (MPa =

$10^6$  pascals) may be more convenient multiples in practice. Thus, note:  $1 \text{ N/mm}^2 = 1 \text{ MN/m}^2 = 1 \text{ MPa}$ .

In addition to the pascal, the *bar*, a non-SI unit, is in use in the field of pressure measurement in some countries, including England. Thus, in view of existing practice, the International Committee of Weights and Measures (CIPM) decided in 1969 to retain this unit for a limited time for use with those of SI.  $1 \text{ bar} = 10^5$  pascals and  $1 \text{ hectobar} = 10^7$  pascals.

### Force Systems

**Scalar and Vector Quantities.**—The quantities dealt with in mechanics are of two kinds according to whether magnitude alone or direction as well as magnitude must be known in order to completely specify them. Quantities such as time, volume and density are completely specified when their magnitude is known. Such quantities are called *scalar* quantities. Quantities such as force, velocity, acceleration, moment, and displacement must, in order to be specified completely, include direction as well as magnitude, are called *vector* quantities.

**Graphical Representation of Forces.**—A force has three characteristics which, when known, determine it. They are *direction*, *point of application*, and *magnitude*. The direction of a force is the direction it tends to move the body upon which it acts. The point of application is the place on the line of action where the force is applied. Forces may conveniently be represented by straight lines and arrow heads. The arrow head indicates the direction of the force, and the length of the line, its magnitude to any suitable scale. The point of application may be at any point on the line, but it is generally convenient to assume it to be at one end. In Fig. 1, a force is supposed to act along line *AB* in a direction from left to right. The length of line *AB* shows the magnitude of the force. If point *A* is the point of application, the force is exerted as a pull, but if point *B* be assumed to be the point of application, it would indicate that the force is exerted as a push.

Fig. 1. Vector

Velocities, moments, displacements, etc. may similarly be represented and manipulated graphically because they are all of the same class of quantities, *vectors*. (See *Scalar and Vector Quantities*.)

**Addition and Subtraction of Forces:** The resultant of two forces applied at the same point and acting in the same direction, as in Fig. 2, is equal to the sum of the forces. For example, if forces *AB* and *AC*, one equal to 2 lbs the other equal to 3 lbs, are applied at point *A*, then their resultant *AD* equals the sum of these forces, or 5 lbs.

Fig. 2.

Fig. 3.

If two forces act in opposite directions, as in Fig. 3, then their resultant is equal to their difference, and the direction of the resultant is the same as the direction of the greater of the two forces. For example, *AB* and *AC* are both applied at point *A*; then, if *AB* equals 4 N and *AC* equals 6 N, the resultant force *AD* equals 2 N and acts in the direction of *AC*.

**Parallelogram of Forces:** If two forces applied at a point are represented in magnitude and direction by the adjacent sides of a parallelogram ( $AB$  and  $AC$  in Fig. 4), their resultant will be represented in magnitude and direction by the diagonal  $AR$  drawn from the intersection of the two component forces.

Fig. 4.

Fig. 5.

Fig. 6.

If two forces  $P$  and  $Q$  do not have the same point of application, as in Fig. 5, but the lines indicating their directions intersect, the forces may be imagined as having been applied at the point of intersection between the lines (as at  $A$ ), and the resultant of the two forces may be found by constructing the parallelogram of forces. Line  $AR$  shows the direction and magnitude of the resultant, the point of application of which may be assumed to be at any point on line  $AR$  or its extension.

If the resultant of three or more forces having the same point of application is to be found, as in Fig. 6, first the resultant of any two of the forces ( $AB$  and  $AC$ ) is found. Then, the resultant of the resultant just found ( $AR_1$ ) and the third force ( $AD$ ) is found. If there are more than three forces, continue in this manner until the resultant of all remaining forces has been found.

**Parallel Forces:** If two forces are parallel and act in the same direction, as in Fig. 7, then their resultant is parallel to both lines, is located between them, and is equal to the sum of the two components. The point of application of the resultant divides the line joining the points of application of the components inversely as the magnitude of the components. Thus,

$$AB:CE = CD:AD$$

The resultant of two parallel and unequal forces acting in opposite directions, Fig. 8, is parallel to both lines, is located outside of them on the side of the greater of the components, has the same direction as the greater component, and is equal in magnitude to the difference between the two components. The point of application on the line  $AC$  produced is found from the proportion:

$$AB:CD = CE:AE$$

Fig. 7.

Fig. 8.

**Polygon of Forces:** When several forces are applied at a point and act in a single plane, Fig. 9, their resultant may be found more simply than by the method just described, as follows: From the extreme end of the line representing the first force, draw a line representing the second force, parallel to it and of the same length and in the direction of the second

force. Then through the extreme end of this line, draw a line parallel to, and of the same length and direction as the third force, and continue this until all the forces have been thus represented. Then draw a line from the point of application of the forces (as  $A$ ) to the extreme point (as  $S_1$ ) of the line last drawn. This line ( $AS_1$ ) is the resultant of the forces.

Fig. 9.

Fig. 10.

**Moment of a Force:** The moment of a force with respect to a point is the magnitude of the force multiplied by the perpendicular distance from the given point to the direction of the force. In Fig. 10, the moment of the force  $P$  with relation to point  $A$  is  $P \times AB$ . The perpendicular distance  $AB$  is called the *lever-arm* of the force. The moment is the measure of the tendency of the force to produce rotation about the given point, which is termed the *center-of-moments*. If the force is measured in pounds and the distance in inches, the moment is expressed in inch-pounds. **In metric SI units, the moment is expressed in newton-meters (N·m), or newton-millimeters (N·mm).**

The moment of the resultant of any number of forces acting together in the same plane is equal to the algebraic sum of the moments of the separate forces.

**Couples.**—Two parallel forces of equal magnitude acting parallel to one another in opposite directions are a *couple*. The *resultant force* of a couple is zero; the resultant itself is a *pure moment*. In the first example of Fig. 11, forces  $AB$  and  $CD$  are a couple. A couple tends to produce *rotation*. The measure of this tendency is called the moment of the couple; it is the product of one of the forces multiplied by the distance between the two.

Fig. 11. Two Examples of Couples

As a couple has zero resultant force, no single force can balance or counteract the tendency of the couple to produce rotation. To prevent the rotation of a body acted upon by a couple, two other forces are required, forming a second couple. In the second illustration of Fig. 11,  $E$  and  $F$  form one couple and  $G$  and  $H$  are the balancing couple. The body on which they act is in equilibrium if the moments of the two couples are equal and tend to rotate the body in opposite directions. A couple may also be represented by a vector in the direction of the axis about which the couple acts. The length of the vector, to some scale, represents the magnitude of the couple, and the direction of the vector is that in which a right-hand screw would advance if it were to be rotated by the couple.

**Composition of a Single Force and Couple.**—A single force and a couple in the same plane or in parallel planes may be replaced by another single force equal in magnitude and parallel to the first force, at a distance from it equal to the moment of the couple divided by the magnitude of the force. The new single force is located so that the moment of the resultant about the point of application of the original force is of the same sign as the moment of the couple.

Fig. 12 illustrates this relationship. Forces  $N$  and  $-N$  are a couple. The moment of this couple is  $N(ac + bc)$ . The resultant of  $N$ ,  $-N$ , and a single force  $P$  is a force  $O$ , equal in magnitude to  $P$  and acting on an axis through a point  $c$  such that the moment of  $P$  and  $-N$  are equal to the moment of  $N$ . That is:  $(P - N) \times ac = N \times bc$ .

Thus,

$$ac = \frac{N(ac + bc)}{P} = \frac{\text{Moment of Couple}}{P}$$

Fig. 12. Single Force and Couple Composition

**Algebraic Composition and Resolution of Force Systems.**—The graphical methods given beginning on page 160 are convenient for solving problems involving force systems in which all of the forces lie in the same plane and only a few forces are involved. If many forces are involved, however, or the forces do not lie in the same plane, it is better to use algebraic methods to avoid complicated space diagrams. Systematic procedures for solving force problems by algebraic methods are outlined beginning on page 163. In connection with the use of these procedures, several terms applicable to force systems in general must be defined.

As has been illustrated, single force that produces the same effect upon a body as two or more forces acting together is called their *resultant*. The separate forces which can be so combined are called the *components*. Finding the resultant of two or more forces is called the *composition* of forces, and finding two or more components of a given force, the *resolution* of forces. Forces are said to be *concurrent* when their lines of action can be extended to meet at a common point; forces that are *parallel* are, of course, *nonconcurrent*. Two forces having the same line of action are said to be *collinear*. Two forces equal in magnitude, parallel, and in opposite directions constitute a *couple*. Forces all in the same plane are said to be *coplanar*; if not in the same plane, they are called *noncoplanar* forces.

The resultant of a system of forces is the simplest equivalent system that can be determined. It may be a single force, a couple, or a noncoplanar force and a couple. This last type of resultant, a noncoplanar force and a couple, may be replaced, if desired, by two *skewed* forces (forces that are nonconcurrent, nonparallel, and noncoplanar). When the resultant of a system of forces is zero, the system is in equilibrium, that is, the body on which the force system acts remains at rest or continues to move with uniform velocity.

## Algebraic Solution of Force Systems—All Forces in the Same Plane

## Finding Two Concurrent Components of a Single Force:

	<p>Case I: To find two components <math>F_1</math> and <math>F_2</math> at angles <math>\theta</math> and <math>\phi</math>, <math>\phi</math> not being <math>90^\circ</math>.</p> $F_1 = \frac{F \sin \theta}{\sin \phi}$ $F_2 = \frac{F \sin (\phi - \theta)}{\sin \phi}$
	<p>Case II: Components <math>F_1</math> and <math>F_2</math> form <math>90^\circ</math> angle.</p> $F_1 = F \sin \theta$ $F_2 = F \cos \theta$

## Finding the Resultant of Two Concurrent Forces:

	<p>Case I: Forces <math>F_1</math> and <math>F_2</math> do not form <math>90^\circ</math> angle.</p> $R = \frac{F_1 \sin \phi}{\sin \theta} \quad \text{or} \quad R = \frac{F_2 \sin \phi}{\sin (\phi - \theta)} \quad \text{or}$ $R = \sqrt{F_1^2 + F_2^2 + 2F_1 F_2 \cos \phi}$ $\tan \theta = \frac{F_1 \sin \phi}{F_1 \cos \phi + F_2}$
	<p>Case II: Forces <math>F_1</math> and <math>F_2</math> form <math>90^\circ</math> angle.</p> $R = \frac{F_2}{\cos \theta} \quad \text{or} \quad R = \frac{F_1}{\sin \theta} \quad \text{or}$ $R = \sqrt{F_1^2 + F_2^2}$ $\tan \theta = \frac{F_1}{F_2}$

## Finding the Resultant of Three or More Concurrent Forces:

	<p>To determine resultant of forces <math>F_1, F_2, F_3</math>, etc. making angles, respectively, of <math>\theta_1, \theta_2, \theta_3</math>, etc. with the <math>x</math> axis, find the <math>x</math> and <math>y</math> components <math>F_x</math> and <math>F_y</math> of each force and arrange in a table similar to that shown below for a system of three forces. Find the algebraic sum of the <math>F_x</math> and <math>F_y</math> components (<math>\Sigma F_x</math> and <math>\Sigma F_y</math>) and use these to determine resultant <math>R</math>.</p> <table border="1" data-bbox="509 1047 888 1185"> <thead> <tr> <th>Force</th> <th><math>F_x</math></th> <th><math>F_y</math></th> </tr> </thead> <tbody> <tr> <td><math>F_1</math></td> <td><math>F_1 \cos \theta_1</math></td> <td><math>F_1 \sin \theta_1</math></td> </tr> <tr> <td><math>F_2</math></td> <td><math>F_2 \cos \theta_2</math></td> <td><math>F_2 \sin \theta_2</math></td> </tr> <tr> <td><math>F_3</math></td> <td><math>F_3 \cos \theta_3</math></td> <td><math>F_3 \sin \theta_3</math></td> </tr> <tr> <td></td> <td><math>\Sigma F_x</math></td> <td><math>\Sigma F_y</math></td> </tr> </tbody> </table> $R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2}$ $\cos \theta_R = \frac{\Sigma F_x}{R}$ <p>or <math>\tan \theta_R = \frac{\Sigma F_y}{\Sigma F_x}</math></p>	Force	$F_x$	$F_y$	$F_1$	$F_1 \cos \theta_1$	$F_1 \sin \theta_1$	$F_2$	$F_2 \cos \theta_2$	$F_2 \sin \theta_2$	$F_3$	$F_3 \cos \theta_3$	$F_3 \sin \theta_3$		$\Sigma F_x$	$\Sigma F_y$
Force	$F_x$	$F_y$														
$F_1$	$F_1 \cos \theta_1$	$F_1 \sin \theta_1$														
$F_2$	$F_2 \cos \theta_2$	$F_2 \sin \theta_2$														
$F_3$	$F_3 \cos \theta_3$	$F_3 \sin \theta_3$														
	$\Sigma F_x$	$\Sigma F_y$														

*Finding a Force and a Couple which Together Are Equivalent to a Single Force:*

	<p>To resolve a single force <math>F</math> into a couple of moment <math>M</math> and a force <math>P</math> passing through any chosen point <math>O</math> at a distance <math>d</math> from the original force <math>F</math>, use the relations</p> $P = F$ $M = F \times d$ <p>The moment <math>M</math> must, of course, tend to produce rotation about <math>O</math> in the same direction as the original force. Thus, as seen in the diagram, <math>F</math> tends to produce clockwise rotation; hence <math>M</math> is shown clockwise.</p>
--	---

*Finding the Resultant of a Single Force and a Couple:*

	<p>The resultant of a single force <math>F</math> and a couple <math>M</math> is a single force <math>R</math> equal in magnitude and direction to <math>F</math> and parallel to it at a distance <math>d</math> to the left or right of <math>F</math>.</p> $R = F$ $d = M \div R$ <p>Resultant <math>R</math> is placed to the left or right of point of application <math>O</math> of the original force <math>F</math> depending on which position will give <math>R</math> the same direction of moment about <math>O</math> as the original couple <math>M</math>.</p>
--	---

*Finding the Resultant of a System of Parallel Forces:*

	<p>To find the resultant of a system of coplanar parallel forces, proceed as indicated below.</p>
--	---

- 1) Select any convenient point  $O$  from which perpendicular distances  $d_1, d_2, d_3$ , etc. to parallel forces  $F_1, F_2, F_3$ , etc. can be specified or calculated.
- 2) Find the algebraic sum of all the forces; this will give the magnitude of the resultant of the system.
 
$$R = \Sigma F = F_1 + F_2 + F_3 + \dots$$
- 3) Find the algebraic sum of the moments of the forces about  $O$ ; clockwise moments may be taken as negative and counterclockwise moments as positive:
 
$$\Sigma M_O = F_1 d_1 + F_2 d_2 + \dots$$
- 4) Calculate the distance  $d$  from  $O$  to the line of action of resultant  $R$ :

$$d = \frac{\Sigma M_O}{R}$$

This distance is measured to the left or right from  $O$  depending on which position will give the moment of  $R$  the same direction of rotation about  $O$  as the couple  $\Sigma M_O$ , that is, if  $\Sigma M_O$  is negative, then  $d$  is left or right of  $O$  depending on which direction will make  $R \times d$  negative.

*Note Concerning Interpretation of Results:* If  $R = 0$ , then the resultant of the system is a couple  $\Sigma M_O$ ; if  $\Sigma M_O = 0$  then the resultant is a single force  $R$ ; if both  $R$  and  $\Sigma M_O = 0$ , then the system is in equilibrium.

*Finding the Resultant of Forces Not Intersecting at a Common Point:*

To determine the resultant of a coplanar, nonconcurrent, nonparallel force system as shown in the diagram, proceed as shown below.

- 1) Draw a set of  $x$  and  $y$  coordinate axes through any convenient point  $O$  in the plane of the forces as shown in the diagram.
- 2) Determine the  $x$  and  $y$  coordinates of any convenient point on the line of action of each force and the angle  $\theta$ , measured in a counterclockwise direction, that each line of action makes with the positive  $x$  axis. For example, in the diagram, coordinates  $x_4, y_4$ , and  $\theta_4$  are shown for  $F_4$ . Similar data should be known for each of the forces of the system.
- 3) Calculate the  $x$  and  $y$  components ( $F_x, F_y$ ) of each force and the moment of each component about  $O$ . Counterclockwise moments are considered positive and clockwise moments are negative. Tabulate all results in a manner similar to that shown below for a system of three forces and find  $\Sigma F_x, \Sigma F_y, \Sigma M_O$  by algebraic addition.

Force $F$	Coordinates of $F$			Components of $F$		Moment of $F$ about $O$
	$x$	$y$	$\theta$	$F_x$	$F_y$	$M_O = xF_y - yF_x$
$F_1$	$x_1$	$y_1$	$\theta_1$	$F_1 \cos \theta_1$	$F_1 \sin \theta_1$	$x_1 F_1 \sin \theta_1 - y_1 F_1 \cos \theta_1$
$F_2$	$x_2$	$y_2$	$\theta_2$	$F_2 \cos \theta_2$	$F_2 \sin \theta_2$	$x_2 F_2 \sin \theta_2 - y_2 F_2 \cos \theta_2$
$F_3$	$x_3$	$y_3$	$\theta_3$	$F_3 \cos \theta_3$	$F_3 \sin \theta_3$	$x_3 F_3 \sin \theta_3 - y_3 F_3 \cos \theta_3$
				$\Sigma F_x$	$\Sigma F_y$	$\Sigma M_O$

- 4) Compute the resultant of the system and the angle  $\theta_R$  it makes with the  $x$  axis by using the formulas:

$$R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2}$$

$$\cos \theta_R = \Sigma F_x \div R \quad \text{or} \quad \tan \theta_R = \Sigma F_y \div \Sigma F_x$$

- 5) Calculate the distance  $d$  from  $O$  to the line of action of the resultant  $R$ :

$$d = \Sigma M_O \div R$$

Distance  $d$  is in such direction from  $O$  as will make the moment of  $R$  about  $O$  have the same sign as  $\Sigma M_O$ .

*Note Concerning Interpretation of Results:* If  $R=0$ , then the resultant is a couple  $\Sigma M_O$ ; if  $\Sigma M_O=0$ , then  $R$  passes through  $O$ ; if both  $R=0$  and  $\Sigma M_O=0$ , then the system is in equilibrium.

*Example:* Find the resultant of three coplanar nonconcurrent forces for which the following data are given.

$$F_1 = 10 \text{ lbs; } x_1 = 5 \text{ in.; } y_1 = -1 \text{ in.; } \theta_1 = 270^\circ$$

$$F_2 = 20 \text{ lbs; } x_2 = 4 \text{ in.; } y_2 = 1.5 \text{ in.; } \theta_2 = 50^\circ$$

$$F_3 = 30 \text{ lbs; } x_3 = 2 \text{ in.; } y_3 = 2 \text{ in.; } \theta_3 = 60^\circ$$

$$F_{x_1} = 10 \cos 270^\circ = 10 \times 0 = 0 \text{ lbs.}$$

$$F_{x_2} = 20 \cos 50^\circ = 20 \times 0.64279 = 12.86 \text{ lbs.}$$

$$F_{x_3} = 30 \cos 60^\circ = 30 \times 0.5000 = 15.00 \text{ lbs.}$$

$$F_{y_1} = 10 \times \sin 270^\circ = 10 \times (-1) = -10.00 \text{ lbs.}$$

$$F_{y_2} = 20 \times \sin 50^\circ = 20 \times 0.76604 = 15.32 \text{ lbs.}$$

$$F_{y_3} = 30 \times \sin 60^\circ = 30 \times 0.86603 = 25.98 \text{ lbs.}$$

$$M_{O_1} = 5 \times (-10) - (-1) \times 0 = -50 \text{ in. lbs.}$$

$$M_{O_2} = 4 \times 15.32 - 1.5 \times 12.86 = 41.99 \text{ in. lbs.}$$

$$M_{O_3} = 2 \times 25.98 - 2 \times 15 = 21.96 \text{ in. lbs.}$$

**Note:** When working in metric SI units, pounds are replaced by newtons (N); inches by meters or millimeters, and inch-pounds by newton-meters (N·m) or newton-millimeters (N·mm).

Force $F$	Coordinates of $F$			Components of $F$		Moment of $F$ about $O$
	$x$	$y$	$\theta$	$F_x$	$F_y$	
$F_1 = 10$	5	-1	$270^\circ$	0	-10.00	-50.00
$F_2 = 20$	4	1.5	$50^\circ$	12.86	15.32	41.99
$F_3 = 30$	2	2	$60^\circ$	15.00	25.98	21.96
				$\Sigma F_x = 27.86$	$\Sigma F_y = 31.30$	$\Sigma M_O = 13.95$

$$R = \sqrt{(27.86)^2 + (31.30)^2}$$

$$= 41.90 \text{ lbs}$$

$$\tan \theta_R = \frac{31.30}{27.86} = 1.1235$$

$$\theta_R = 48^\circ 20'$$

$$d = \frac{13.95}{41.90} = 0.33 \text{ inch}$$

measured as shown on the diagram.

**Algebraic Solution of Force Systems — Forces Not in Same Plane***Resolving a Single Force Into Its Three Rectangular Components:*

$$F_x = F \cos \theta_x$$

$$F_y = F \cos \theta_y$$

$$F_z = F \cos \theta_z$$

$$F = \sqrt{F_x^2 + F_y^2 + F_z^2}$$

The diagram shows how a force  $F$  may be resolved at any point  $O$  on its line of action into three concurrent components each of which is perpendicular to the other two.

The  $x, y, z$  components  $F_x, F_y, F_z$  of force  $F$  are determined from the accompanying relations in which  $\theta_x, \theta_y, \theta_z$  are the angles that the force  $F$  makes with the  $x, y, z$  axes.

*Finding the Resultant of Any Number of Concurrent Forces:*

To find the resultant of any number of noncoplanar concurrent forces  $F_1, F_2, F_3$ , etc., use the procedure outlined below.

- 1) Draw a set of  $x, y, z$  axes at  $O$ , the point of concurrency of the forces. The angles each force makes measured counterclockwise from the positive  $x, y$ , and  $z$  coordinate axes must be known in addition to the magnitudes of the forces. For force  $F_2$ , for example, the angles are  $\theta_{x2}, \theta_{y2}, \theta_{z2}$  as indicated on the diagram.
- 2) Apply the first three formulas given under the heading "Resolving a Single Force Into Its Three Rectangular Components" to each force to find its  $x, y$ , and  $z$  components. Tabulate these calculations as shown below for a system of three forces. Algebraically add the calculated components to find  $\Sigma F_x, \Sigma F_y$ , and  $\Sigma F_z$  which are the components of the resultant.

Force	Angles			Components of Forces		
	$\theta_x$	$\theta_y$	$\theta_z$	$F_x$	$F_y$	$F_z$
$F_1$	$\theta_{x1}$	$\theta_{y1}$	$\theta_{z1}$	$F_1 \cos \theta_{x1}$	$F_1 \cos \theta_{y1}$	$F_1 \cos \theta_{z1}$
$F_2$	$\theta_{x2}$	$\theta_{y2}$	$\theta_{z2}$	$F_2 \cos \theta_{x2}$	$F_2 \cos \theta_{y2}$	$F_2 \cos \theta_{z2}$
$F_3$	$\theta_{x3}$	$\theta_{y3}$	$\theta_{z3}$	$F_3 \cos \theta_{x3}$	$F_3 \cos \theta_{y3}$	$F_3 \cos \theta_{z3}$
				$\Sigma F_x$	$\Sigma F_y$	$\Sigma F_z$

- 3) Find the resultant of the system from the formula  $R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2 + (\Sigma F_z)^2}$

- 4) Calculate the angles  $\theta_{xR}, \theta_{yR}$ , and  $\theta_{zR}$  that the resultant  $R$  makes with the respective coordinate axes:

$$\cos \theta_{xR} = \frac{\Sigma F_x}{R}$$

$$\cos \theta_{yR} = \frac{\Sigma F_y}{R}$$

$$\cos \theta_{zR} = \frac{\Sigma F_z}{R}$$

## Finding the Resultant of Parallel Forces Not in the Same Plane:

In the diagram, forces  $F_1, F_2$ , etc. represent a system of noncoplanar parallel forces. To find the resultant of such systems, use the procedure shown below.

- 1) Draw a set of  $x, y$ , and  $z$  coordinate axes through any point  $O$  in such a way that one of these axes, say the  $z$  axis, is parallel to the lines of action of the forces. The  $x$  and  $y$  axes then will be perpendicular to the forces.
- 2) Set the distances of each force from the  $x$  and  $y$  axes in a table as shown below. For example,  $x_1$  and  $y_1$  are the  $x$  and  $y$  distances for  $F_1$  shown in the diagram.
- 3) Calculate the moment of each force about the  $x$  and  $y$  axes and set the results in the table as shown for a system consisting of three forces. The algebraic sums of the moments  $\sum M_x$  and  $\sum M_y$  are then obtained. (In taking moments about the  $x$  and  $y$  axes, assign counterclockwise moments a plus (+) sign and clockwise moments a minus (-) sign. In deciding whether a moment is counterclockwise or clockwise, look from the positive side of the axis in question toward the negative side.)

Force $F$	Coordinates of Force $F$		Moments $M_x$ and $M_y$ due to $F$	
	$x$	$y$	$M_x$	$M_y$
$F_1$	$x_1$	$y_1$	$F_1 y_1$	$F_1 x_1$
$F_2$	$x_2$	$y_2$	$F_2 y_2$	$F_2 x_2$
$F_3$	$x_3$	$y_3$	$F_3 y_3$	$F_3 x_3$
$\Sigma F$			$\Sigma M_x$	$\Sigma M_y$

- 4) Find the algebraic sum  $\Sigma F$  of all the forces; this will be the resultant  $R$  of the system.

$$R = \Sigma F = F_1 + F_2 + \dots$$

- 5) Calculate  $x_R$  and  $y_R$ , the moment arms of the resultant:

$$x_R = \Sigma M_y \div R$$

$$y_R = \Sigma M_x \div R$$

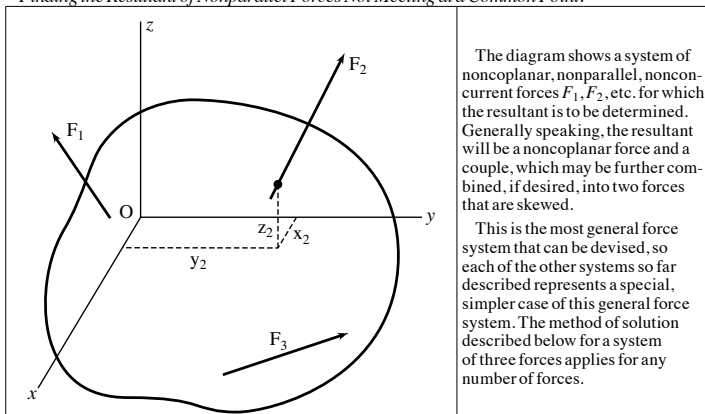

These moment arms are measured in a direction along the  $x$  and  $y$  axes as will give the resultant a moment of the same direction of rotation as  $\Sigma M_x$  and  $\Sigma M_y$ .

*Note Concerning Interpretation of Results:* If  $\Sigma M_x$  and  $\Sigma M_y$  are both 0, then the resultant is a single force  $R$  along the  $z$  axis; if  $R$  is also 0, then the system is in equilibrium. If  $R$  is 0 but  $\Sigma M_x$  and  $\Sigma M_y$  are not both 0, then the resultant is a couple

$$M_R = \sqrt{(\Sigma M_x)^2 + (\Sigma M_y)^2}$$

that lies in a plane parallel to the  $z$  axis and making an angle  $\theta_R$  measured in a counterclockwise direction from the positive  $x$  axis and calculated from the following formula:

$$\sin \theta_R = \frac{\Sigma M_y}{M_R}$$

*Finding the Resultant of Nonparallel Forces Not Meeting at a Common Point:*

The diagram shows a system of noncoplanar, nonparallel, nonconcurrent forces  $F_1, F_2$ , etc. for which the resultant is to be determined. Generally speaking, the resultant will be a noncoplanar force and a couple, which may be further combined, if desired, into two forces that are skewed.

This is the most general force system that can be devised, so each of the other systems so far described represents a special, simpler case of this general force system. The method of solution described below for a system of three forces applies for any number of forces.

- 1) Select a set of coordinate  $x, y$ , and  $z$  axes at any desired point  $O$  in the body as shown in the diagram.
- 2) Determine the  $x, y$ , and  $z$  coordinates of any convenient point on the line of action of each force as shown for  $F_2$ . Also determine the angles,  $\theta_x, \theta_y, \theta_z$ , that each force makes with each coordinate axis. These angles are measured counterclockwise from the positive direction of the  $x, y$ , and  $z$  axes. The data is tabulated, as shown in the table accompanying Step 3, for convenient use in subsequent calculations.
- 3) Calculate the  $x, y$ , and  $z$  components of each force using the formulas given in the accompanying table. Add these components algebraically to get  $\Sigma F_x, \Sigma F_y$  and  $\Sigma F_z$ , which are the components of the resultant  $R$  given by the formula,

$$R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2 + (\Sigma F_z)^2}$$

Force $F$	Coordinates of Force $F$						Components of $F$		
	$x$	$y$	$z$	$\theta_x$	$\theta_y$	$\theta_z$	$F_x$	$F_y$	$F_z$
$F_1$	$x_1$	$y_1$	$z_1$	$\theta_{x1}$	$\theta_{y1}$	$\theta_{z1}$	$F_1 \cos \theta_{x1}$	$F_1 \cos \theta_{y1}$	$F_1 \cos \theta_{z1}$
$F_2$	$x_2$	$y_2$	$z_2$	$\theta_{x2}$	$\theta_{y2}$	$\theta_{z2}$	$F_2 \cos \theta_{x2}$	$F_2 \cos \theta_{y2}$	$F_2 \cos \theta_{z2}$
$F_3$	$x_3$	$y_3$	$z_3$	$\theta_{x3}$	$\theta_{y3}$	$\theta_{z3}$	$F_3 \cos \theta_{x3}$	$F_3 \cos \theta_{y3}$	$F_3 \cos \theta_{z3}$
							$\Sigma F_x$	$\Sigma F_y$	$\Sigma F_z$

The resultant force  $R$  makes angles of  $\theta_{xR}, \theta_{yR}$ , and  $\theta_{zR}$  with the  $x, y$ , and  $z$  axes, respectively, and passes through the selected point  $O$ . These angles are determined from the formulas,

$$\cos \theta_{xR} = \Sigma F_x \div R$$

$$\cos \theta_{yR} = \Sigma F_y \div R$$

$$\cos \theta_{zR} = \Sigma F_z \div R$$

4) Calculate the moments  $M_x, M_y, M_z$  about  $x, y,$  and  $z$  axes, respectively, due to the  $F_x, F_y,$  and  $F_z$  components of each force and set them in tabular form. The formulas to use are given in the accompanying table.

In interpreting moments about the  $x, y,$  and  $z$  axes, consider counterclockwise moments a plus (+) sign and clockwise moments a minus (-) sign. In deciding whether a moment is counterclockwise or clockwise, look from the positive side of the axis in question toward the negative side.

Force	Moments of Components of $F (F_x, F_y, F_z)$ about $x, y, z$ axes		
$F$	$M_x = yF_z - zF_y$	$M_y = zF_x - xF_z$	$M_z = xF_y - yF_x$
$F_1$	$M_{x1} = y_1F_{z1} - z_1F_{y1}$	$M_{y1} = z_1F_{x1} - x_1F_{z1}$	$M_{z1} = x_1F_{y1} - y_1F_{x1}$
$F_2$	$M_{x2} = y_2F_{z2} - z_2F_{y2}$	$M_{y2} = z_2F_{x2} - x_2F_{z2}$	$M_{z2} = x_2F_{y2} - y_2F_{x2}$
$F_3$	$M_{x3} = y_3F_{z3} - z_3F_{y3}$	$M_{y3} = z_3F_{x3} - x_3F_{z3}$	$M_{z3} = x_3F_{y3} - y_3F_{x3}$
	$\Sigma M_x$	$\Sigma M_y$	$\Sigma M_z$

5) Add the component moments algebraically to get  $\Sigma M_x, \Sigma M_y$  and  $\Sigma M_z$ , which are the components of the resultant couple,  $M$ , given by the formula,

$$M = \sqrt{(\Sigma M_x)^2 + (\Sigma M_y)^2 + (\Sigma M_z)^2}$$

The resultant couple  $M$  will tend to produce rotation about an axis making angles of  $\beta_x, \beta_y,$  and  $\beta_z$  with the  $x, y, z$  axes, respectively. These angles are determined from the formulas,

$$\cos \beta_x = \frac{\Sigma M_x}{M} \quad \cos \beta_y = \frac{\Sigma M_y}{M} \quad \cos \beta_z = \frac{\Sigma M_z}{M}$$

*General Method of Locating Resultant When Its Components Are Known:* To determine the position of the resultant force of a system of forces, proceed as follows:

From the origin, point  $O$ , of a set of coordinate axes  $x, y, z$ , lay off on the  $x$  axis a length  $A$  representing the algebraic sum  $\Sigma F_x$  of the  $x$  components of all the forces. From the end of line  $A$  lay off a line  $B$  representing  $\Sigma F_y$ , the algebraic sum of the  $y$  components; this line  $B$  is drawn in a direction parallel to the  $y$  axis. From the end of line  $B$  lay off a line  $C$  representing  $\Sigma F_z$ . Finally, draw a line  $R$  from  $O$  to the end of  $C$ ;  $R$  will be the resultant of the system. Notice that  $R$  is in the three-dimensional space bounded by the  $xy, xz,$  and  $yz$  planes.

**Friction**

**Properties of Friction.**—Friction is the resistance to motion that takes place when one body is moved upon another, and is generally defined as “that force which acts between two bodies at their surface of contact, so as to resist their sliding on each other.” According to the conditions under which sliding occurs, the force of friction,  $F$ , bears a certain relation to the force between the two bodies called the normal force  $N$ . The relation between force of friction and normal force is given by the *coefficient of friction*, generally denoted by the Greek letter  $\mu$ . Thus:

$$F = \mu \times N \quad \text{and} \quad \mu = \frac{F}{N}$$

*Example:* A body weighing 28 pounds rests on a horizontal surface. The force required to keep it in motion along the surface is 7 pounds. Find the coefficient of friction.

$$\mu = \frac{F}{N} = \frac{7}{28} = 0.25$$

If a body is placed on an inclined plane, the friction between the body and the plane will prevent it from sliding down the inclined surface, provided the angle of the plane with the horizontal is not too great. There is a certain angle, however, at which the body will just barely be able to remain stationary, the frictional resistance being very nearly overcome by the tendency of the body to slide down. This angle is termed the *angle of repose*, frequently denoted by the Greek letter  $\theta$ , and the tangent of this angle is the coefficient of friction. Thus,  $\mu = \tan \theta$ .

A greater force is required to start a body moving from a state of rest than to merely keep it in motion, because *static (resting) friction* is greater than *sliding (motion) friction*.

**Laws of Friction.**—*Unlubricated or Dry Surfaces:*

1) At low pressures (low normal force per unit area) friction is directly proportional to the normal force between the two surfaces. As the pressure increases, the friction does not rise proportionally; but when pressure becomes abnormally high, friction increases at a rapid rate until seizing takes place.

2) Friction, both in its total amount and its coefficient, is independent of the area in contact, so long as the normal force remains the same. This is true for moderate pressures only. For high pressures, this law is modified in the same way as in the first case.

3) At very low velocities friction is independent of the velocity of rubbing. As velocity increases, friction decreases.

*Lubricated Surfaces:* For well-lubricated surfaces, the laws of friction are considerably different from those governing dry or poorly lubricated surfaces.

1) Frictional resistance is almost independent of pressure (normal force per unit area) if the surfaces are flooded with oil.

2) Friction varies directly with speed at low pressures; but at high pressures the friction is very great at low velocities, approaching a minimum at about 2 ft/s (0.61 m/s), linear velocity, and afterwards increasing approximately as the square root of the speed.

3) For well-lubricated surfaces frictional resistance depends, to a very great extent, on temperature, partly because of a change in the viscosity of the lubricant and partly because, for a journal bearing, bearing diameter increases with temperature rise more rapidly than does shaft diameter, thus relieving the bearing of side pressure.

4) If bearing surfaces are flooded with oil, friction is almost independent of the nature of the material of the surfaces in contact. As the lubrication becomes less ample, the coefficient of friction becomes more dependent upon the material of the surfaces.

**Influence of Friction on Efficiency of Small Machine Elements.**—Friction between machine parts lowers the efficiency of a machine. Average values of efficiency, in percent, of

the most common machine elements when carefully made are: ordinary bearings, 95 to 98; roller bearings, 98; ball bearings, 99; spur gears with cut teeth, including bearings, 99; bevel gears with cut teeth, including bearings, 98; belting, 96 to 98; high-class silent power transmission chain, 97 to 99; roller chains, 95 to 97.

**Coefficients of Friction.**—Table 1 and Table 2 provide representative values of static friction for various combinations of materials with dry (clean, unlubricated) and lubricated surfaces. The values for static, or breakaway, friction shown in these tables will generally be higher than the subsequent sliding friction. Typically, the steel-on-steel static coefficient of 0.8 unlubricated will drop to 0.4 when sliding has been initiated; with oil lubrication, the value will drop from 0.16 to 0.03.

Many factors affect friction, and even slight deviations from normal or test conditions can produce wide variations. Accordingly, when friction coefficients are used in design calculations, due allowance or factors of safety should be considered, and in critical applications, specific tests should be conducted to provide specific coefficients for material, geometry, and/or lubricant combinations.

**Table 1. Coefficients of Static Friction for Steel on Various Materials**

Material	Coefficient of Friction, $\mu$		Material	Coefficient of Friction, $\mu$	
	Clean	Lubricated		Clean	Lubricated
Steel	0.8	0.16	Hard carbon	0.14	0.11–0.14
Copper-lead alloy	0.22		Graphite	0.1	0.1
Phosphor-bronze	0.35		Tungsten carbide	0.4–0.6	0.1–0.2
Aluminum-bronze	0.45		Plexiglas	0.4–0.5	0.4–0.5
Brass	0.35	0.19	Polystyrene	0.3–0.35	0.3–0.35
Cast iron	0.4	0.21	Polythene	0.2	0.2
Bronze		0.16	Teflon	0.04	0.04
Sintered bronze		0.13			

Table 1 and Table 2 used with permission from *The Friction and Lubrication of Solids*, Vol. 1, by Bowden and Tabor, Clarendon Press, Oxford, 1950.

**Table 2. Coefficients of Static Friction for Various Materials Combinations**

Material Combination	Coefficient of Friction, $\mu$		Material Combination	Coefficient of Friction, $\mu$	
	Clean	Lubricated		Clean	Lubricated
Aluminum-aluminum	1.35	0.30	Tungsten carbide-tungsten carbide	0.2–0.25	0.12
Cadmium-cadmium	0.5	0.05	Plexiglas-Plexiglas	0.8	0.8
Chromium-chromium	0.41	0.34	Polystyrene-polystyrene	0.5	0.5
Copper-copper	1.0	0.08	Teflon-Teflon	0.04	0.04
Iron-iron	1.0	0.15–0.20	Nylon-nylon	0.15–0.25	
Magnesium-magnesium	0.6	0.08	Solids on rubber	1–4	
Nickel-nickel	0.7	0.28	Wood on wood (clean)	0.25–0.5	
Platinum-platinum	1.2	0.25	Wood on wood (wet)	0.2	
Silver-silver	1.4	0.55	Wood on metals (clean)	0.2–0.6	
Zinc-zinc	0.6	0.04	Wood on metals (wet)	0.2	
Glass-glass	0.9–1.0	0.1–0.6	Brick on wood	0.6	
Glass-metal	0.5–0.7	0.2–0.3	Leather on wood	0.3–0.4	
Diamond-diamond	0.1	0.05–0.1	Leather on metal (clean)	0.6	
Diamond-metal	0.1–0.15	0.1	Leather on metal (wet)	0.4	
Sapphire-sapphire	0.2	0.2	Leather on metal (greasy)	0.2	
Hard carbon on carbon	0.16	0.12–0.14	Brake material on cast iron	0.4	
Graphite-graphite (in vacuum)	0.5–0.8		Brake material on cast iron (wet)	0.2	
Graphite-graphite	0.1	0.1			

**Rolling Friction.**—When a body rolls on a surface, the force resisting the motion is termed *rolling friction* or *rolling resistance*. Let  $W$  = total weight of rolling body or load on wheel, in pounds (newtons);  $r$  = radius of wheel, in inches (centimeters);  $f$  = coefficient of rolling resistance, in inches (centimeters). Then, resistance to rolling, in pounds (newtons) is given as:

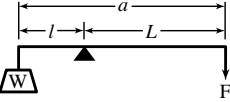

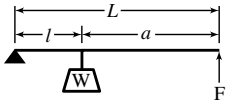

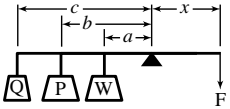

$$F_r = Wflr$$

Coefficient of rolling resistance varies with conditions. For wood on wood,  $f = 0.06$  inch (0.152 cm) may be used; for iron on iron, 0.02 inch (0.051 cm); iron on granite, 0.085 inch (0.216 cm); iron on asphalt, 0.15 inch (0.381 cm); and iron on wood, 0.22 inch (0.559 cm).

The coefficient of rolling resistance  $f$  is given in inches (or centimeters) and is not the same as the sliding or static coefficient of friction given in Table 1 and Table 2, in which  $\mu$  is a dimensionless ratio between frictional resistance and normal load. Various investigators are not in close agreement on the true values for these coefficients and the foregoing values should only be used for the approximate calculation of rolling resistance.

## Simple Mechanisms

### Lever

Types of Levers	Examples
 <p> <math>F: W = l:L</math> <math>F \times L = W \times l</math>  <math>F = \frac{W \times l}{L}</math> <math>W = \frac{F \times L}{l}</math>  <math>L = \frac{W \times a}{W + F} = \frac{W \times l}{F}</math> <math>l = \frac{F \times a}{W + F} = \frac{F \times L}{W}</math> </p>	<p>A pull of 80 pounds is exerted at the end of the lever, at <math>W</math>; <math>l = 12</math> inches and <math>L = 32</math> inches.</p> <p>Find the value of force <math>F</math> required to balance the lever.</p> $F = \frac{80 \times 12}{32} = \frac{960}{32} = 30 \text{ pounds}$ <p>If <math>F = 20</math>; <math>W = 180</math>; and <math>l = 3</math>; how long must <math>L</math> be made to secure equilibrium?</p> $L = \frac{180 \times 3}{20} = 27$
 <p> <math>F: W = l:L</math> <math>F \times L = W \times l</math>  <math>F = \frac{W \times l}{L}</math> <math>W = \frac{F \times L}{l}</math>  <math>L = \frac{W \times a}{W - F} = \frac{W \times l}{F}</math> <math>l = \frac{F \times a}{W - F} = \frac{F \times L}{W}</math> </p>	<p>Total length <math>L</math> of a lever is 25 cm. A weight of 400 N, supported at <math>W</math>; <math>l</math> is 10 cm. Find the value of <math>F</math>.</p> $F = \frac{(400)(10)}{25} = 160 \text{ N}$ <p>If <math>F = 400</math> N, <math>W = 900</math> lbs, and <math>a = 1.5</math> m, what should <math>L</math> equal to secure equilibrium?</p> $L = \frac{(900)(1.5)}{900 - 400} = 2.7 \text{ m}$
 <p>When three or more forces act on lever:</p> $F \times x = W \times a + P \times b + Q \times c$ $x = \frac{W \times a + P \times b + Q \times c}{F}$ $F = \frac{W \times a + P \times b + Q \times c}{x}$	<p>Let <math>W = 20</math>, <math>P = 30</math>, and <math>Q = 15</math> lbs; <math>a = 4</math>, <math>b = 7</math>, and <math>c = 10</math> in.</p> <p>If <math>x = 6</math> in., find <math>F</math>.</p> $F = \frac{20 \times 4 + 30 \times 7 + 15 \times 10}{6} = 73 \frac{1}{3} \text{ lbs}$ <p>Assuming <math>F = 20</math> lbs in the example above, how long must lever arm <math>x</math> be made?</p> $x = \frac{20 \times 4 + 30 \times 7 + 15 \times 10}{20} = 22 \text{ inches}$

The above formulas are valid using metric SI units, with forces expressed in newtons, and lengths in meters. However, it should be noted that the weight of a mass  $W$  kilograms

is equal to a force of  $Wg$  newtons, where  $g$  is approximately  $9.81 \text{ m/s}^2$ . Thus, supposing that in the first example  $l = 0.4 \text{ m}$ ,  $L = 1.2 \text{ m}$ , and  $W = 30 \text{ kg}$ , then the weight of  $W$  is  $30g$  newtons,

so that the force  $F$  required to balance the lever is  $F = \frac{30g \times 0.4}{1.2} = 10g = 98.1 \text{ N}$ . This force could be produced by suspending a mass of  $10 \text{ kg}$  at location  $F$ .

**Table of Forces on Inclined Planes**

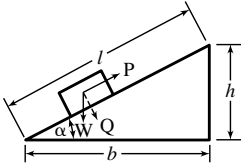

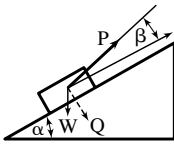

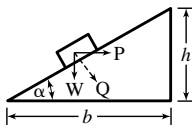

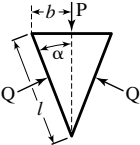

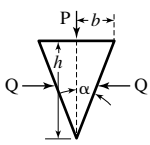

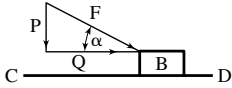

Percent of Grade, Rise in ft per 100 ft	Angle $\alpha$	Tension $P$ per Ton	Perpendicular Pressure $Q$ on Plane per Ton	Percent of Grade, Rise in ft per 100 ft	Angle $\alpha$	Tension $P$ in Cable per Ton	Perpendicular Pressure $Q$ on Plane per Ton

	<p><b>Force Moving Body on Horizontal Plane.</b>—<math>F</math> tends to move <math>B</math> along line <math>CD</math>; <math>Q</math> is the component which actually moves <math>B</math>; <math>P</math> is the pressure, due to <math>F</math>, of the body on <math>CD</math>.</p> $Q = F \times \cos \alpha \quad P = \sqrt{F^2 - Q^2}$		

Wheels and Pulleys

 <p> <math>F:W = r:R</math>  <math>F \times R = W \times r</math>  <math>F = \frac{W \times r}{R}</math>  <math>W = \frac{F \times R}{r}</math>  <math>R = \frac{W \times r}{F}</math>  <math>r = \frac{F \times R}{W}</math> </p>	<p>The radius of a drum on which is wound the lifting rope of a windlass is 2 in. What force will be exerted at the periphery of a gear of 24 in. diameter, mounted on the same shaft as the drum and transmitting power to it, if one ton (2000 lbs) is to be lifted? Here <math>W = 2000</math>; <math>R = 12</math>; <math>r = 2</math>.</p> $F = \frac{2000 \times 2}{12} = 333 \text{ lbs}$
 <p>A, B, C and D are the pitch circles of gears.</p> $F = \frac{W \times r \times r_1 \times r_2}{R \times R_1 \times R_2}$ $W = \frac{F \times R \times R_1 \times R_2}{r \times r_1 \times r_2}$	<p>Let the pitch diameters of gears A, B, C and D be 30, 28, 12 and 10 in., respectively. Then <math>R_2 = 15</math>; <math>R_1 = 14</math>; <math>r_1 = 6</math>; and <math>r = 5</math>. Let <math>R = 12</math>, and <math>r_2 = 4</math>. The force <math>F</math> required to lift a weight <math>W</math> of 2000 lbs, friction being neglected, is:</p> $F = \frac{2000 \times 5 \times 6 \times 4}{12 \times 14 \times 15} = 95 \text{ pounds}$
 <p> <math>F = \frac{1}{2} W</math> </p> <p>The velocity with which weight <math>W</math> will be raised is one-half the velocity of the force applied at <math>F</math>.</p>	 <p> <math>F:W = \sec \alpha:2</math>  <math>F = \frac{W \times \sec \alpha}{2}</math>  <math>W = 2F \times \cos \alpha</math> </p>
 <p> <math>n =</math> number of strands or parts of rope (<math>n_1, n_2</math>, etc.).  <math>F = \frac{1}{n} \times W</math> </p> <p>The velocity with which <math>W</math> will be raised equals <math>\frac{1}{n}</math> of the velocity of the force applied at <math>F</math>.</p>	<p>In the illustration is shown a combination of a double and triple block. The pulleys each turn freely on a pin as axis, and are drawn with different diameters, to show the parts of the rope more clearly. There are 5 parts of rope. Therefore, if 200 lbs is to be lifted, the force <math>F</math> required at the end of the rope is:</p> $F = \frac{1}{5} \times 200 = 40 \text{ lbs}$

Note: The above formulas are valid using metric SI units, with forces expressed in newtons, and lengths in meters or millimeters. (See note on page 174 concerning weight and mass.)

**Differential Pulley**

	<p>In the differential pulley a chain must be used, engaging sprockets, so as to prevent the chain from slipping over the pulley faces.</p> $PR = \frac{1}{2}W(R - r)$ $P = \frac{W(R - r)}{2R}$ $W = \frac{2PR}{R - r}$
<p style="text-align: center;">Chinese Windlass</p>	<p>The Chinese windlass employs the differential motion principle in that the resultant motion is the difference between two original motions. The hoisting rope is arranged to unwind from one part of a drum or pulley onto another part differing somewhat in diameter. The distance that the load or hook moves for one revolution of the compound hoisting drum is equal to half the difference between the circumferences of the two drum sections.</p>

**Screw**

	<p><math>F</math> = force at end of handle or wrench; <math>R</math> = lever-arm of <math>F</math>; <math>r</math> = pitch radius of screw; <math>p</math> = lead of thread; <math>Q</math> = load. Then, neglecting friction:</p> $F = Q \times \frac{p}{6.2832R} \quad Q = F \times \frac{6.2832R}{p}$ <p>If <math>\mu</math> is the coefficient of friction, then:</p> <p>For motion in direction of load <math>Q</math> which <i>assists</i> it:</p> $F = Q \times \frac{6.2832\mu r - p}{6.2832r + \mu p} \times \frac{r}{R}$ <p>For motion opposite load <math>Q</math> which <i>resists</i> it:</p> $F = Q \times \frac{p + 6.2832\mu r}{6.2832r - \mu p} \times \frac{r}{R}$
--	--

**Geneva Wheel**

	<p>Geneva wheels are frequently used on machine tools for indexing or rotating some part of the machine through a fractional part of a revolution.</p> <p>The driven wheel shown in the illustration has four radial slots located 90 degrees apart, and the driver carries a roller <math>k</math> which engages one of these slots each time it makes a revolution, thus turning the driven wheel one-quarter revolution. The concentric surface <math>b</math> engages the concave surface <math>c</math> between each pair of slots before the driving roller is disengaged from the driven wheel, which prevents the latter from rotating while the roller is moving around to engage the next successive slot. The circular boss <math>b</math> on the driver is cut away at <math>d</math> to provide a clearance space for the projecting arms of the driven wheel. In designing gearing of the general type illustrated, it is advisable to so proportion the driving and driven members that the angle <math>\alpha</math> will be approximately 90 degrees.</p> <p>The radial slots in the driven part will then be tangent to the circular path of the driving roller at the time the roller enters and leaves the slot. When the gearing is designed in this way, the driven wheel is started gradually from a state of rest and the motion is also gradually checked.</p>

### Toggle Joint

A link mechanism commonly known as a toggle joint is applied to machines of different types, such as drawing and embossing presses, stone crushers, etc., for securing great pressure. The principle of the toggle joint is shown by Fig. 1. There are two links, *b* and *c*, which are connected at the center. Link *b* is free to swivel about a fixed pin or bearing at *d*, and link *c* is connected to a sliding member *e*. Rod *f* joins links *b* and *c* at the central connection. When force is applied to rod *f* in a direction at right angles to centerline *xx*, along which the driven member *e* moves, this force is greatly multiplied at *e*, because a movement at the joint *g* produces a relatively slight movement at *e*. As the angle  $\alpha$  becomes less, motion at *e* decreases and the force increases until the links are in line. If *R* = the resistance at *e*, *P* = the applied power or force, and  $\alpha$  = the angle between each link, and a line *x-x* passing through the axes of the pins, then:

$$2R \sin \alpha = P \cos \alpha$$

Fig. 1. Toggle Joint Principle

If arms *ED* and *EH* are of unequal length then

$$P = \frac{Fa}{b}$$

The relation between *P* and *F* changes constantly as *F* moves downward.

If arms *ED* and *EH* are equal, then

$$P = \frac{Fa}{2h}$$

A double toggle-joint does not increase the pressure exerted so long as the relative distances moved by *F* and *P* remain the same.

### Toggle-joints with Equal Arms

$$2P \sin \alpha = F \cos \alpha$$

$$\frac{P}{F} = \frac{\cos \alpha}{2 \sin \alpha} = \text{coefficient}$$

$$P = F \times \text{coefficient}$$

where *F* = force applied; *P* = resistance; and,  $\alpha$  = given angle.

Equivalent expressions (see diagram):

$$P = \frac{FS}{4h} \quad P = \frac{FS}{H}$$

To use the table, measure angle  $\alpha$ , and find the coefficient in the table that corresponds to it. The coefficient is the ratio of the resistance to the force applied, and multiplying the force applied by the coefficient gives the resistance, neglecting friction.

### Pendulums

A *compound* or *physical* pendulum consists of any rigid body suspended from a fixed horizontal axis about which the body may oscillate in a vertical plane due to the action of gravity.

A *simple* or *mathematical* pendulum is similar to a compound pendulum except that the mass of the body is concentrated at a single point which is suspended from a fixed horizontal axis by a weightless cord. Actually, a simple pendulum cannot be constructed since it is impossible to have either a weightless cord or a body whose mass is entirely concentrated at one point. A good approximation, however, consists of a small, heavy bob suspended by a light, fine wire. A pendulum that does not meet these conditions should be considered a compound pendulum.

A *conical* pendulum is similar to a simple pendulum except that the weight suspended by the cord moves at a uniform speed around the circumference of a circle in a horizontal plane instead of oscillating back and forth in a vertical plane. The principle of the conical pendulum is employed in the Watt fly-ball governor.

#### Four Types of Pendulum

Physical Pendulum

Simple Pendulum

Conical Pendulum

Torsional Pendulum

W = Weight of Disk

A *torsional* pendulum in its simplest form consists of a disk fixed to a slender rod, the other end of which is fastened to a fixed frame. When the disc is twisted through some angle and released, it will oscillate back and forth about the axis of the rod because of the torque exerted by the rod.

**Pendulum Formulas.**—From the formulas that follow, the period of vibration or time required for one complete cycle back and forth may be determined for the types of pendulums shown in the accompanying diagram.

For a *simple* pendulum,

$$T = 2\pi \sqrt{\frac{l}{g}} \quad (1)$$

where  $T$  = period in seconds for one complete cycle;  $g$  = acceleration due to gravity = 32.17 ft/sec<sup>2</sup> (approximately); and  $l$  is the length of the pendulum in feet as shown on the accompanying diagram.

For a *physical* or *compound* pendulum,

$$T = 2\pi \sqrt{\frac{k_o^2}{gr}} \quad (2)$$

where  $k_o$  = radius of gyration of the pendulum about the axis of rotation in feet, and  $r$  is the distance from the axis of rotation to the center of gravity in feet.

**The metric SI units that can be used in the two above formulas are  $T$  = time in seconds;  $g$  = approximately 9.81 m/s<sup>2</sup>, which is the value for acceleration due to gravity;  $l$  = the length of the pendulum in meters;  $k_o$  = the radius of gyration in meters, and  $r$  = the distance from the axis of rotation to the center of gravity in meters.**

Formulas (1) and (2) are accurate when the angle of oscillation  $\theta$  shown in the diagram is very small. For  $\theta$  equal to 22 degrees, these formulas give results that are too small by 1 percent; for  $\theta$  equal to 32 degrees, by 2 percent.

For a *conical* pendulum, the time in seconds for one revolution is:

$$T = 2\pi \sqrt{\frac{l \cos \phi}{g}} \quad (3a) \quad \text{or} \quad T = 2\pi \sqrt{\frac{r \cot \phi}{g}} \quad (3b)$$

For a *torsional* pendulum consisting of a thin rod and a disk as shown in the figure

$$T = \frac{2}{3} \sqrt{\frac{\pi W r^2 l}{g d^4 G}} \quad (4)$$

where  $W$  = weight of disk in pounds;  $r$  = radius of disk in feet;  $l$  = length of rod in feet;  $d$  = diameter of rod in feet; and  $G$  = modulus of elasticity in shear of the rod material in pounds per square inch (psi or lb/in<sup>2</sup>).

**The formula using metric SI units is:**

$$T = 8 \sqrt{\frac{\pi M r^2 l}{d^4 G}}$$

where  $T$  = time in seconds for one complete oscillation;  $M$  = mass in kilograms;  $r$  = radius in meters;  $l$  = length of rod in meters;  $d$  = diameter of rod in meters;  $G$  = modulus of elasticity in shear of the rod material in pascals (newtons per meter squared). The same formula can be applied using millimeters, provided dimensions are expressed in millimeters throughout, and the modulus of elasticity in megapascals (newtons per millimeter squared).

**Harmonic.**—A harmonic is any component of a periodic quantity which is an integral multiple of the fundamental frequency. For example, a component the frequency of which is twice the fundamental frequency is called the second harmonic.

A harmonic, in electricity, is an alternating-current electromotive force wave of higher frequency than the fundamental, and superimposed on the same so as to distort it from a true sine-wave shape. It is caused by the slots, the shape of the pole pieces, and the pulsation of the armature reaction. The third and the fifth harmonics, i.e., with a frequency three and five times the fundamental, are generally the predominating ones in three-phase machines.

## VELOCITY, ACCELERATION, WORK, AND ENERGY

## Velocity and Acceleration

Motion is a progressive change of position of a body. Velocity is the rate of motion, that is, the rate of change of a body's position. It is expressed in units of distance over time, such as feet per second, miles per hour, and kilometers per second. *Uniform motion* indicates that the velocity of a body is the same at every moment during which the motion takes place. When velocity is variable and constantly increasing, the rate at which it changes is called *acceleration*. Acceleration is the rate at which the velocity of a body changes in a unit of time, as the change of feet or meters per second in one second. When the motion is decreasing instead of increasing, it is called *retarded motion*, and the rate at which the motion is retarded is frequently called *deceleration*. If the acceleration is uniform, the motion is called *uniformly accelerated motion*. An example of such motion is that of falling bodies.

**Newton's Laws of Motion.**—The first clear statement of the fundamental relations existing between force and motion was made in the seventeenth century by Sir Isaac Newton, the English mathematician and physicist. It was put in the form of three laws, which are given as originally stated by Newton:

- 1) Every body continues in its state of rest, or uniform motion in a straight line, except in so far as it may be compelled by force to change that state.
- 2) Change of motion is proportional to the force applied and takes place in the direction in which that force acts.
- 3) To every action there is always an equal reaction; or, the mutual actions of two bodies are always equal and oppositely directed.

**Motion with Constant Velocity.**—In the formulas that follow,  $S$  = distance moved;  $V$  = velocity;  $t$  = time of motion,  $\theta$  = angle of rotation, and  $\omega$  = angular velocity; the usual units for these quantities in the US customary system are, respectively, feet, feet per second, seconds, radians, and radians per second. The usual metric units are meters, meters per second, seconds, radians, and radians per second. Any consistent set of units may be employed.

$$\text{Constant Linear Velocity: } S = Vt \quad V = S/t \quad t = S/V$$

$$\text{Constant Angular Velocity: } \theta = \omega t \quad \omega = \theta/t \quad t = \theta/\omega$$

**Relation between Angular Motion and Linear Motion:** The relation between the angular velocity of a rotating body and the linear velocity of a point at a distance  $r$  from the center of rotation is:

$$V(\text{ft/s}) = r(\text{ft}) \times \omega(\text{radians/s}) \quad V(\text{m/s}) = r(\text{m}) \times \omega(\text{radians/s})$$

Similarly, the distance moved by the point during rotation through angle  $\theta$  is:

$$S(\text{ft}) = r(\text{ft}) \times \theta(\text{radians}) \quad S(\text{m}) = r(\text{m}) \times \theta(\text{radians})$$

**Linear Motion with Constant Acceleration.**—The relations between distance, velocity, and time for linear motion with constant or uniform acceleration are given by the formulas in the accompanying Table 1. In these formulas, the acceleration is assumed to be in the same direction as the initial velocity; hence, if the acceleration in a particular problem should happen to be in a direction opposite that of the initial velocity, then  $a$  should be replaced by  $-a$ . Thus, for example, the formula  $V_f = V_o + at$  becomes  $V_f = V_o - at$  when  $a$  and  $V_o$  are opposite in direction.

*Example:* A car is moving at 100 km/h when the brakes are suddenly locked and the car begins to skid. If it takes 2 seconds to slow the car to 50 km/h, at what rate is it being decelerated, how long is it before the car comes to a halt, and how far will it have traveled?

*Solution:* The initial velocity  $V_o$  of the car is 100 km/h or 27.78 m/s and the acceleration  $a$  due to braking is opposite in direction to  $V_o$ , since the car is slowed to 50 km/h or 13.89 m/s.

**Table 1. Linear Motion with Constant Acceleration**

To Find	Known	Formula	To Find	Known	Formula
Motion Uniformly Accelerated from Rest ( $V_o = 0$ )					
S	$a, t$	$S = \frac{1}{2}at^2$	t	$S, V_f$	$t = 2S \div V_f$
	$V_f, t$	$S = \frac{1}{2}V_f t$		$S, a$	$t = \sqrt{2S \div a}$
	$V_f, a$	$S = V_f^2 \div 2a$		$a, V_f$	$t = V_f \div a$
$V_f$	$a, t$	$V_f = at$	a	$S, t$	$a = 2S \div t^2$
	$S, t$	$V_f = 2S \div t$		$S, V$	$a = V_f^2 \div 2S$
	$a, S$	$V_f = \sqrt{2aS}$		$V_f, t$	$a = V_f \div t$
Motion Uniformly Accelerated from Initial Velocity $V_o$					
S	$a, t, V_o$	$S = V_o t + \frac{1}{2}at^2$	t	$V_o, V_f, a$	$t = (V_f - V_o) \div a$
	$V_o, V_f, t$	$S = (V_f + V_o)t \div 2$		$V_o, V_f, S$	$t = 2S \div (V_f + V_o)$
	$V_o, V_f, a$	$S = (V_f^2 - V_o^2) \div 2a$	a	$V_o, V_f, S$	$a = (V_f^2 - V_o^2) \div 2S$
	$V_f, a, t$	$S = V_f t - \frac{1}{2}at^2$		$V_o, V_f, t$	$a = (V_f - V_o) \div t$
$V_f$	$V_o, a, t$	$V_f = V_o + at$	a	$V_o, S, t$	$a = 2(S - V_o t) \div t^2$
	$V_o, S, t$	$V_f = (2S \div t) - V_o$		$V_f, S, t$	$a = 2(V_f t - S) \div t^2$
	$V_o, a, S$	$V_f = \sqrt{V_o^2 + 2aS}$		<i>Meanings of Symbols</i>	
	$S, a, t$	$V_f = (S \div t) + \frac{1}{2}at$	S = distance moved in ft or m $V_f$ = final velocity, ft/s or m/s $V_o$ = initial velocity, ft/s or m/s a = acceleration, ft/s <sup>2</sup> or m/s <sup>2</sup> t = time of acceleration, sec or s		
$V_o$	$V_f, a, S$	$V_o = \sqrt{V_f^2 - 2aS}$			
	$V_f, S, t$	$V_o = (2S \div t) - V_f$			
	$V_f, a, t$	$V_o = V_f - at$			
	$S, a, t$	$V_o = (S \div t) - \frac{1}{2}at$			

Since  $V_o$ ,  $V_f$ , and  $t$  are known,  $a$  can be determined from the formula

$$a = (V_f - V_o) \div t = (13.89 - 27.78) \div 2 = -6.95 \text{ m/s}^2$$

The time required to stop the car can be determined from the formula

$$t = (V_f - V_o) \div a = (0 - 27.78) \div (-6.95) = 4 \text{ seconds}$$

The distance traveled by the car is obtained from the formula

$$S = V_o t + \frac{1}{2}at^2 = (27.78)(4) + \frac{1}{2}(-6.95)4^2 = (111.12 - 55.6) = 55.52 \text{ m}$$

**Angular Velocity of a Rotating Body.**—The angular velocity of a rotating body is the angle through which the body turns in a unit of time. Angular velocity is commonly expressed in terms of revolutions per minute rpm, but in certain engineering applications it is necessary to express it as radians per second (rad/s). By definition there are  $2\pi$  radians in 360 degrees, or one revolution, so that one radian =  $360/2\pi \approx 57.3$  degrees. To convert angular velocity  $n$  in rpm to angular velocity  $\omega$  in radians per second, and vice versa, use Equation (1):

$$\omega = \frac{\pi n}{30} \text{ rad/s} \quad n = \frac{30\omega}{\pi} \text{ rpm} \quad (1)$$

Table 2 can be used to obtain angular velocity in radians per second for all whole numbers of revolutions per minute from 1 to 239.

**Table 2. Angular Velocity in Revolutions per Minute  
Converted to Radians per Second**

RPM	Angular Velocity in Radians per Second (rad/s)									
	0	1	2	3	4	5	6	7	8	9

230	24.09	24.19	24.29	24.40	24.50	24.61	24.71	24.82	24.92	25.03

*Example:* To find the angular velocity in radians per second of a flywheel making 97 revolutions per minute, locate 90 in the left-hand column and 7 at the top of the columns; at the intersection of the two lines, the angular velocity is read off as equal to 10.16 radians per second.

**Linear Velocity of Points on a Rotating Body.**—The linear velocity,  $v$ , of any point on a rotating body expressed in feet per second may be found by multiplying the angular velocity of the body in radians per second,  $\omega$ , by the radius,  $r$ , in feet from the center of rotation to the point:

$$v = \omega r \quad (2)$$

**The metric SI units are  $v$  = meters per second;  $\omega$  = radians per second,  $r$  = meters.**

**Rotary Motion with Constant Acceleration.**—The relations among angle of rotation, angular velocity, and time for rotation with constant or uniform acceleration are given in the accompanying Table 3.

In these formulas, the acceleration is assumed to be in the same direction as the initial angular velocity; hence, if the acceleration in a particular problem should happen to be in a direction opposite that of the initial angular velocity, then  $\alpha$  should be replaced by  $-\alpha$ . Thus, for example, the formula  $\omega_f = \omega_o + \alpha t$  becomes  $\omega_f = \omega_o - \alpha t$  when  $\alpha$  and  $\omega_o$  are opposite in direction.

**Linear Acceleration of a Point on a Rotating Body:** A point,  $P$ , on a body rotating about a fixed axis has a linear acceleration  $a$  that is the resultant of two component accelerations. The first component is the centripetal, or normal, acceleration, which is directed from the point  $P$  toward the axis of rotation; its magnitude is  $r\omega^2$ , where  $r$  is the radius from the axis to the point  $P$  and  $\omega$  is the angular velocity of the body at the time acceleration  $a$  is to be determined. The second component of  $a$  is the tangential acceleration, which is equal to  $r\alpha$ , where  $\alpha$  is the angular acceleration of the body.

**Table 3. Rotary Motion with Constant Acceleration**

To Find	Known	Formula	To Find	Known	Formula
Motion Uniformly Accelerated from Rest ( $\omega_o = 0$ )					
$\theta$	$\alpha, t$	$\theta = \frac{1}{2}\alpha t^2$	$t$	$\theta, \omega_f$	$t = 2\theta \div \omega_f$
	$\omega_f, t$	$\theta = \frac{1}{2}\omega_f t$		$\theta, \alpha$	$t = \sqrt{2\theta \div \alpha}$
	$\omega_f, \alpha$	$\theta = \omega_f^2 \div 2\alpha$		$\alpha, \omega_f$	$t = \omega_f \div \alpha$
$\omega_f$	$\alpha, t$	$\omega_f = \alpha t$	$\alpha$	$\theta, t$	$\alpha = 2\theta \div t^2$
	$\theta, t$	$\omega_f = 2\theta \div t$		$\theta, \omega_f$	$\alpha = \omega_f^2 \div 2\theta$
	$\alpha, \theta$	$\omega_f = \sqrt{2\alpha\theta}$		$\omega_f, t$	$\alpha = \omega_f \div t$
Motion Uniformly Accelerated from Initial Velocity $\omega_o$					
$\theta$	$\alpha, t, \omega_o$	$\theta = \omega_o t + \frac{1}{2}\alpha t^2$	$\alpha$	$\omega_o, \omega_f, \theta$	$\alpha = (\omega_f^2 - \omega_o^2) \div 2\theta$
	$\omega_o, \omega_f, t$	$\theta = (\omega_f + \omega_o)t \div 2$		$\omega_o, \omega_f, t$	$\alpha = (\omega_f - \omega_o) \div t$
	$\omega_o, \omega_f, \alpha$	$\theta = (\omega_f^2 - \omega_o^2) \div 2\alpha$		$\omega_o, \theta, t$	$\alpha = 2(\theta - \omega_o t) \div t^2$
	$\omega_f, \alpha, t$	$\theta = \omega_f t - \frac{1}{2}\alpha t^2$		$\omega_f, \theta, t$	$\alpha = 2(\omega_f t - \theta) \div t^2$
$\omega_f$	$\omega_o, \alpha, t$	$\omega_f = \omega_o + \alpha t$	<i>Meanings of Symbols</i>  $\theta$ = angle of rotation, radians $\omega_f$ = final angular velocity, rad/s $\omega_o$ = initial angular velocity, rad/s $\alpha$ = angular acceleration, rad/s <sup>2</sup> $t$ = time in seconds  1 degree = 0.01745 radian (See degree-radian conversion table on page 103)		
	$\omega_o, \theta, t$	$\omega_f = (2\theta \div t) - \omega_o$			
$\omega_o$	$\omega_o, \alpha, \theta$	$\omega_f = \sqrt{\omega_o^2 + 2\alpha\theta}$			
	$\theta, \alpha, t$	$\omega_f = (\theta \div t) + \frac{1}{2}\alpha t$			
	$\omega_f, \alpha, \theta$	$\omega_o = \sqrt{\omega_f^2 - 2\alpha\theta}$			
	$\omega_f, \theta, t$	$\omega_o = (2\theta \div t) - \omega_f$			
$t$	$\omega_f, \alpha, \theta$	$\omega_o = \omega_f - \alpha t$			
	$\theta, \alpha, t$	$\omega_o = (\theta \div t) - \frac{1}{2}\alpha t$			
	$\omega_o, \omega_f, \alpha$	$t = (\omega_f - \omega_o) \div \alpha$			
$\omega_o, \omega_f, \theta$	$t = 2\theta \div (\omega_f + \omega_o)$				

The acceleration of point  $P$  is the resultant of  $r\omega^2$  and  $r\alpha$  and is given by the formula

$$a = \sqrt{(r\omega^2)^2 + (r\alpha)^2}$$

When  $\alpha = 0$ , this formula reduces to:  $a = r\omega^2$

*Example:* A flywheel on a press rotating at 120 rpm is slowed to 102 rpm during a punching operation that requires  $\frac{3}{4}$  second for the punching portion of the cycle. What angular deceleration does the flywheel experience?

*Solution:* From the table on page 184, angular velocities corresponding to 120 and 102 rpm, respectively, are 12.57 and 10.68 radians per second. Therefore, using the formula:

$$\begin{aligned}\alpha &= (\omega_f - \omega_o) \div t \\ &= (10.68 - 12.57) \div \frac{3}{4} = -1.89 \div \frac{3}{4} \\ &= -2.52 \text{ rad/s}^2\end{aligned}$$

which is, from the table on page 184,  $-24$  rpm per second. The minus sign in the answer indicates that acceleration  $\alpha$  acts to slow the flywheel, that is, the flywheel is decelerating.

**Force, Work, Energy, and Momentum**

**Accelerations Resulting from Unbalanced Forces.**—In the section describing the resolution and composition of forces, page 163, it was stated that when the resultant of a system of forces is zero, the system is in equilibrium, that is, the body on which the force system acts remains at rest or continues to move with uniform velocity. If, however, the resultant of a system of forces is not zero, the body on which the forces act will be accelerated in the direction of the unbalanced force. To determine the relation between the unbalanced force and the resulting acceleration, Newton's laws of motion must be applied. These laws may be stated as follows:

*First Law:* Every body continues in a state of rest or in uniform motion in a straight line until it is compelled by a force to change its state of rest or motion.

*Second Law:* Change of motion is proportional to the force applied and takes place along the straight line in which the force acts. The "force applied" represents the resultant of *all* the forces acting on the body. This law is sometimes worded: An unbalanced force acting on a body causes an acceleration of the body in the direction of the force and of magnitude proportional to the force and inversely proportional to the mass of the body. Stated as a formula,  $R = Ma$  where  $R$  is the resultant of *all* the forces acting on the body,  $M$  is the mass of the body (mass = weight  $W$  divided by acceleration due to gravity  $g$ ), and  $a$  is the acceleration of the body resulting from application of force  $R$ .

*Third Law:* To every action there is always an equal reaction; or, if a force acts to change the state of motion of a body, the body offers a resistance equal and directly opposite to the force.

Newton's second law may be used to calculate linear and angular accelerations of a body produced by unbalanced forces and torques acting on the body; however, it is necessary first to use the methods described under *Algebraic Composition and Resolution of Force Systems* starting on page 163 to determine the magnitude and direction of the resultant of *all* forces acting on the body. Then, for a body moving with pure translation,

$$R = Ma = \frac{W}{g}a$$

where  $R$  is the resultant force in pounds acting on a body weighing  $W$  pounds;  $g$  is the gravitational constant, usually taken as 32.16 ft/sec<sup>2</sup>, approximately; and  $a$  is the resulting acceleration in ft/sec<sup>2</sup> of the body due to  $R$  and in the same direction as  $R$ .

**Using metric SI units, the formula is  $R = Ma$ , where  $R$  = force in newtons (N),  $M$  = mass in kilograms (kg), and  $a$  = acceleration in meters/second squared (m/s<sup>2</sup>). It should be noted that the weight of a body of mass  $M$  kg is  $Mg$  newtons, where  $g$  is approximately 9.81 m/s<sup>2</sup>.**

*Free Body Diagram:* In order to correctly determine the effect of forces on the motion of a body it is necessary to construct a *free body diagram*. This diagram shows 1) the body removed or isolated from contact with all other bodies that exert force on it; and 2) *all* the forces acting on the body.

For example, in Fig. 1a the block being pulled up the plane is acted upon by certain forces; the free body diagram of this block is shown at Fig. 1b. Note that all forces acting on the block are indicated. These forces include: 1) the force of gravity (weight); 2) the pull of the cable,  $P$ ; 3) the normal component,  $W \cos \phi$ , of the force exerted on the block by the plane; and 4) the friction force,  $\mu W \cos \phi$ , of the plane on the block.

Fig. 1a.

Fig. 1b.

In preparing a free body diagram, it is important to understand that only those forces exerted *on* the body being considered are shown; forces exerted by the body on other bodies are disregarded. This feature makes the free body diagram an invaluable aid in the solution of problems in mechanics.

*Example:* A 100-pound body is being hoisted by a winch, the tension in the hoisting cable being kept constant at 110 pounds. At what rate is the body accelerated?

*Solution:* Two forces are acting on the body, its weight, 100 pounds downward, and the pull of the cable, 110 pounds upward. The resultant force  $R$ , from a free body diagram, is therefore  $110 - 100$ . Thus, applying Newton's second law,

$$\begin{array}{c} \uparrow 110 \text{ lb} \\ \square \\ \downarrow 100 \text{ lb} \end{array} \quad 110 - 100 = \frac{100}{32.16} a$$

$$a = \frac{32.16 \times 10}{100} = 3.216 \text{ ft/sec}^2 \text{ upward}$$

It should be noted that since in this problem the resultant force  $R$  was positive ( $110 - 100 = +10$ ), the acceleration  $a$  is also positive, that is,  $a$  is in the same direction as  $R$ , which is in accord with Newton's second law.

**Example using SI metric units:** A body of mass 50 kilograms is being hoisted by a winch, and the tension in the cable is 600 newtons. What is the acceleration? The weight of the 50 kg body is 50g newtons, where  $g$  is approximately  $9.81 \text{ m/s}^2$  (see *Note* on page 194). Applying the formula  $R = Ma$ , the calculation is:  $(600 - 50g) = 50a$ . Thus,

$$a = \frac{600 - 50g}{50} = \frac{600 - (50 \times 9.81)}{50} = 2.19 \text{ m/s}^2$$

*Formulas Relating Torque and Angular Acceleration:* For a body rotating about a fixed axis the relation between the unbalanced torque acting to produce rotation and the resulting angular acceleration may be determined from any one of the following formulas, each based on Newton's second law:

$$T_o = J_M \alpha$$

$$T_o = M k_o^2 \alpha$$

$$T_o = \frac{W k_o^2 \alpha}{g} = \frac{W k_o^2 \alpha}{32.16}$$

where  $T_o$  is the unbalanced torque in pounds-feet;  $J_M$  in ft-lbs-sec<sup>2</sup> is the moment of inertia of the body about the axis of rotation;  $k_o$  in feet is the radius of gyration of the body with respect to the axis of rotation, and  $\alpha$  rad/sec<sup>2</sup>, is the angular acceleration of the body.

*Example:* A flywheel has a diameter of 3 feet and weighs 1000 pounds. What torque must be applied, neglecting bearing friction, to accelerate the fly wheel at the rate of 100 revolutions per minute per second (rpm/s)?

**Solution:** From page 253 the moment of inertia of a solid cylinder with respect to a gravity axis at right angles to the circular cross section is given as  $\frac{1}{2}Mr^2$ . From page 184, 100 rpm = 10.47 rad/sec, hence an acceleration of 100 rpm per second = 10.47 rad/sec<sup>2</sup>. Therefore, using the first of the preceding formulas,

$$T_o = J_M\alpha = \left(\frac{1}{2}\right)\frac{1000}{32.16}\left(\frac{3}{2}\right)^2 \times 10.47 = 366 \text{ ft-lbs}$$

**Using metric SI units, the formulas are:**  $T_o = J_M\alpha = Mk_o^2\alpha$ , where  $T_o$  = torque in newton-meters;  $J_M$  = the moment of inertia in kg·m<sup>2</sup>, and  $\alpha$  = the angular acceleration in rad/s<sup>2</sup>.

**Example:** A flywheel has a diameter of 1.5 m and a mass of 800 kg. What torque is needed to produce an angular acceleration of 100 rpm/s? As in the preceding example,  $\alpha = 10.47 \text{ rad/s}^2$ . Thus:

$$J_M = \frac{1}{2}Mr^2 = \frac{1}{2} \times 800 \times 0.75^2 = 225 \text{ kg} \cdot \text{m}^2$$

**Therefore:**  $T_o = J_M\alpha = 225 \times 10.47 = 2356 \text{ N} \cdot \text{m}$ .

**Energy.**—A body is said to possess energy when it is capable of doing work or overcoming resistance. The energy may be either mechanical or non-mechanical, the latter including chemical, electrical, thermal, and atomic energy.

Mechanical energy includes *kinetic energy* (energy possessed by a body because of its motion) and *potential energy* (energy possessed by a body because of its position in a field of force and/or its elastic deformation).

**Kinetic Energy:** The motion of a body may be one of pure translation, pure rotation, or a combination of rotation and translation. By translation is meant motion in which every line in the body remains parallel to its original position throughout the motion; that is, no rotation is associated with the motion of the body.

The kinetic energy of a translating body is given by the formula

$$\text{Kinetic Energy in ft-lbs due to translation} = E_{KT} = \frac{1}{2}MV^2 = \frac{WV^2}{2g} \quad (3a)$$

where  $M$  = mass of body ( $M = W/g$ );  $V$  = velocity of the center of gravity of the body in ft/sec;  $W$  = weight of body in lbs; and  $g$  = acceleration due to gravity = 32.16 ft/sec<sup>2</sup>.

The kinetic energy of a body rotating about a fixed axis  $O$  is expressed by the formula:

$$\text{Kinetic Energy in ft-lbs due to rotation} = E_{KR} = \frac{1}{2}J_{MO}\omega^2 \quad (3b)$$

where  $J_{MO}$  is the moment of inertia of the body about the fixed axis  $O$  in lbs-ft-sec<sup>2</sup>, and  $\omega$  = angular velocity in rad/sec.

For a body that is moving with both translation and rotation, the total kinetic energy is given by the following formula as the sum of the kinetic energy due to translation of the center of gravity and the kinetic energy due to rotation about the center of gravity:

$$\begin{aligned} \text{Total Kinetic Energy in ft-lbs} &= E_T = \frac{1}{2}MV^2 + \frac{1}{2}J_{MG}\omega^2 & (3c) \\ &= \frac{WV^2}{2g} + \frac{1}{2}J_{MG}\omega^2 = \frac{WV^2}{2g} + \frac{1}{2}\frac{Wk^2\omega^2}{g} = \frac{W}{2g}(V^2 + k^2\omega^2) \end{aligned}$$

where  $J_{MG}$  is the moment of inertia of the body about its gravity axis in lbs-ft-sec<sup>2</sup>,  $k$  is the radius of gyration in feet with respect to an axis through the center of gravity, and the other quantities are as previously defined.

**In the metric SI system, energy is expressed as the joule (J). One joule = 1 newton-meter. The kinetic energy of a translating body is given by the formula  $E_{KT} = \frac{1}{2}MV^2$ ,**

where  $M$  = mass in kilograms, and  $V$  = velocity in meters per second. Kinetic energy due to rotation is expressed by the formula  $E_{KR} = \frac{1}{2} J_{MO} \omega^2$ , where  $J_{MO}$  = moment of inertia in  $\text{kg}\cdot\text{m}^2$ , and  $\omega$  = the angular velocity in radians per second. Total kinetic energy  $ET = \frac{1}{2} MV^2 + \frac{1}{2} J_{MO} \omega^2$  joules =  $\frac{1}{2} M(V^2 + k^2 \omega^2)$  joules, where  $k$  = radius of gyration in meters.

*Potential Energy:* A common example of a body having potential energy because of its position in a field of force is that of a body elevated to some height above the earth. The field of force is the gravitational field of the earth. The potential energy of a body weighing  $W$  pounds elevated to height  $S$  feet above the earth's surface is  $E_{PF} = WS$  lb. If the body is permitted to drop from this height its potential energy will be converted to kinetic energy. Thus, after falling through height  $S$  the kinetic energy of the body will be  $WS$  ft-lbs.

**In metric SI units, the potential energy  $E_{PF}$  of a body of mass  $M$  kilograms elevated to a height of  $S$  meters, is  $MgS$  joules. After it has fallen a distance  $S$ , the kinetic energy gained will thus be  $MgS$  joules.**

Another type of potential energy is *elastic potential energy*, such as possessed by a spring that has been compressed or extended. The amount of work in ft-lbs done in compressing the spring  $S$  feet is equal to  $KS^2/2$ , where  $K$  is the spring constant in pounds per foot. Thus, when the spring is released to act against some resistance, it can perform  $KS^2/2$  ft-lbs of work, which is the amount of elastic potential energy  $E_{PF}$  stored in the spring.

**Using metric SI units, the amount of work done in compressing the spring a distance  $S$  meters is  $KS^2/2$  joules, where  $K$  is the spring constant in newtons per meter.**

**Work Performed by Forces and Couples.**—The work  $U$  done by a force  $F$  in moving an object along some path is the product of the distance  $S$  the body is moved and the component  $F \cos \alpha$  of the force  $F$  in the direction of  $S$ .

$$U = FS \cos \alpha$$

where  $U$  = work in ft-lbs;  $S$  = distance moved in feet;  $F$  = force in lbs; and  $\alpha$  = angle between line of action of force and the path of  $S$ .

If the force is in the same direction as the motion, then  $\cos \alpha = \cos 0 = 1$ , and this formula reduces to:

$$U = FS$$

Similarly, the work done by a couple  $T$  turning an object through an angle  $\theta$  is:

$$U = T\theta$$

where  $T$  = torque of couple in pounds-feet and  $\theta$  = the angular rotation in radians.

**The above formulas can be used with metric SI units:  $U$  in joules;  $S$  in meters;  $F$  in newtons, and  $T$  in newton-meters.**

**Relation Between Work and Energy.**—Theoretically, when work is performed on a body and there are no energy losses (such as those due to friction, air resistance, etc.), the energy acquired by the body is equal to the work performed on the body; this energy may be either potential, kinetic, or a combination of both.

In actual situations, however, there may be energy losses that must be taken into account. Thus, the relation between work done on a body, energy losses, and the energy acquired by the body can be stated as:

$$\text{Work Performed} - \text{Energy Losses} = \text{Energy Acquired}$$

$$U - \text{Losses} = E_T$$

*Example 1:* A 12-inch cube of steel weighing 490 pounds is being moved on a horizontal conveyor belt at a speed of 6 miles per hour (8.8 feet per second). What is the kinetic energy of the cube?

*Solution:* Since the block is not rotating, **Formula (3a)** for the kinetic energy of a body moving with pure translation applies:

$$\text{Kinetic Energy} = \frac{WV^2}{2g} = \frac{490 \times 8.8^2}{2 \times 32.16} = 590 \text{ ft-lbs}$$

**A similar example using metric SI units is as follows: If a cube of mass 200 kg is being moved on a conveyor belt at a speed of 3 meters per second, what is the kinetic energy of the cube? It is:**

$$\text{Kinetic Energy} = \frac{1}{2}MV^2 = \frac{1}{2} \times 200 \times 3^2 = 900 \text{ joules}$$

*Example 2:* If the conveyor in **Example 1** is brought to an abrupt stop, how long would it take for the steel block to come to a stop and how far along the belt would it slide before stopping if the coefficient of friction  $\mu$  between the block and the conveyor belt is 0.2 and the block slides without tipping over?

*Solution:* The only force acting to slow the motion of the block is the friction force between the block and the belt. This force  $F$  is equal to the weight of the block  $W$  multiplied by the coefficient of friction;  $F = \mu W = 0.2 \times 490 = 98$  lbs.

The time required to bring the block to a stop can be determined from the impulse-momentum **Formula (4c)** on page 191.

$$R \times t = \frac{W}{g}(V_f - V_o) = (-98)t = \frac{490}{32.16}(0 - 8.8)$$

$$t = \frac{490 \times 8.8}{98 \times 32.16} = 1.37 \text{ seconds}$$

The distance the block slides before stopping can be determined by equating the kinetic energy of the block and the work done by friction in stopping it:

$$\text{Kinetic energy of block} \left( \frac{WV^2}{2g} \right) = \text{Work done by friction} (F \times S)$$

$$590 = 98 \times S$$

$$S = \frac{590}{98} = 6.0 \text{ feet}$$

**If metric SI units are used, the calculation is as follows (for the cube of 200 kg mass): The friction force =  $\mu$  multiplied by the weight  $Mg$  where  $g$  = approximately 9.81 m/s<sup>2</sup>. Thus,  $\mu Mg = 0.2 \times 200g = 392.4$  newtons. The time  $t$  required to bring the block to a stop is  $(-392.4)t = 200(0 - 3)$ . Therefore,**

$$t = \frac{200 \times 3}{392.4} = 1.53 \text{ seconds}$$

**The kinetic energy of the block is equal to the work done by friction, that is 392.4  $\times$  S = 900 joules. Thus, the distance S which the block moves before stopping is**

$$S = \frac{900}{392.4} = 2.29 \text{ meters}$$

**Force of a Blow.**—A body that weighs  $W$  pounds and falls  $S$  feet from an initial position of rest is capable of doing  $WS$  foot-pounds of work. The work performed during its fall may, for example, be that necessary to drive a pile a distance  $d$  into the ground. Neglecting losses in the form of dissipated heat and strain energy, the work done in driving the pile is equal to the product of the impact force acting on the pile and the distance  $d$  which the

pile is driven. Since the impact force is not accurately known, an average value, called the "average force of the blow," may be assumed. Equating the work done on the pile and the work done by the falling body, which in this case is a pile driver:

$$\text{Average force of blow} \times d = WS$$

$$\text{or,} \quad \text{Average force of blow} = \frac{WS}{d}$$

where  $S$  = total height in feet through which the driver falls, including the distance  $d$  that the pile is driven

$W$  = weight of driver in pounds

$d$  = distance in feet which pile is driven

**When using metric SI units, it should be noted that a body of mass  $M$  kilograms has a weight of  $Mg$  newtons, where  $g$  = approximately  $9.81 \text{ m/s}^2$ . If the body falls a distance  $S$  meters, it can do work equal to  $MgS$  joules. The average force of the blow is  $MgS/d$  newtons, where  $d$  is the distance in meters that the pile is driven.**

*Example:* A pile driver weighing 200 pounds strikes the top of the pile after having fallen from a height of 20 feet. It forces the pile into the ground a distance of  $\frac{1}{2}$  foot. Before the ram is brought to rest, it will do  $200 \times (20 + \frac{1}{2}) = 4100$  foot-pounds of work, and as this energy is expended in a distance of  $\frac{1}{2}$  foot, the average force of the blow equals  $4100 \div \frac{1}{2} = 8200$  pounds.

**A similar example using metric SI units is as follows: A pile driver of mass 100 kilograms falls 10 meters and moves the pile a distance of 0.3 meter. The work done =  $100g(10 + 0.3)$  joules, and it is expended in 0.3 meter. Thus, the average force is**

$$\frac{100g \times 10.3}{0.3} = 33680 \text{ newtons or } 33.68 \text{ kN}$$

**Impulse and Momentum.**—The *linear momentum* of a body is defined as the product of the mass  $M$  of the body and the velocity  $V$  of the center of gravity of the body:

$$\text{Linear momentum} = MV \text{ or since } M = \frac{W}{g} \tag{4a}$$

$$\text{Linear momentum} = \frac{WV}{g}$$

It should be noted that linear momentum is a vector quantity, the momentum being in the same direction as  $V$ .

*Linear impulse* is defined as the product of the resultant  $R$  of all the forces acting on a body and the time  $t$  that the resultant acts:

$$\text{Linear Impulse} = Rt \tag{4b}$$

The change in the linear momentum of a body is numerically equal to the linear impulse that causes the change in momentum:

$$\text{Linear Impulse} = \text{change in Linear Momentum} \tag{4c}$$

$$Rt = \frac{W}{g}V_f - \frac{W}{g}V_o = \frac{W}{g}(V_f - V_o)$$

where  $V_f$ , the final velocity of the body after time  $t$ , and  $V_o$ , the initial velocity of the body, are both in the same direction as the applied force  $R$ . If  $V_o$  and  $V_f$  are in opposite directions, then the minus sign in the formula becomes a plus sign.

**In metric SI units, the formulas are: Linear Momentum =  $MV$  kg·m/s, where  $M$  = mass in kg, and  $V$  = velocity in meters per second; and Linear Impulse =  $Rt$  newton-seconds (N·s), where  $R$  = force in newtons, and  $t$  = time in seconds. In **Formula (4c)** above,  $W/g$  is replaced by  $M$  when SI units are used.**

*Example:* A 1000-pound block is pulled up a 2-degree incline by a cable exerting a constant force  $F$  of 600 lbs. If the coefficient of friction  $\mu$  between the block and the plane is 0.5, how fast will the block be moving up the plane 10 seconds after the pull is applied?

*Solution:* The resultant force  $R$  causing the body to be accelerated up the plane is the difference between  $F$ , the force acting up the plane, and  $P$ , the force acting to resist motion up the plane. This latter force for a body on a plane is given by the formula at the top of page 176 as  $P = W(\mu \cos \alpha + \sin \alpha)$  where  $\alpha$  is the angle of the incline.

$$\begin{aligned} \text{Thus, } R &= F - P = F - W(\mu \cos \alpha + \sin \alpha) \\ &= 600 - 1000(0.5 \cos 2^\circ + \sin 2^\circ) = 600 - 1000(0.5 \times 0.99939 + 0.03490) \\ R &= 600 - 535 = 65 \text{ pounds.} \end{aligned}$$

**Formula (4c)** can now be applied to determine the speed at which the body will be moving up the plane after 10 seconds:

$$\begin{aligned} Rt &= \frac{W}{g} V_f - \frac{W}{g} V_o \\ 65 \times 10 &= \frac{1000}{32.2} V_f - \frac{1000}{32.2} \times 0 \\ V_f &= \frac{65 \times 10 \times 32.2}{1000} = 20.9 \text{ ft/sec} = 14.3 \text{ mph} \end{aligned}$$

**A similar example using metric SI units is as follows: A 500 kg block is pulled up a 2 degree incline by a constant force  $F$  of 4 kN. The coefficient of friction  $\mu$  between the block and the plane is 0.5. How fast will the block be moving 10 seconds after the pull is applied?**

The resultant force  $R$  is:

$$\begin{aligned} R &= F - Mg(\mu \cos \alpha + \sin \alpha) \\ &= 4000 - 500 \times 9.81(0.5 \times 0.99939 + 0.03490) = 1378\text{N or } 1.378 \text{ kN} \end{aligned}$$

**Formula (4c)** can now be applied to determine the speed at which the body will be moving up the plane after 10 seconds. Replacing  $W/g$  by  $M$  in the formula, the calculation is:

$$\begin{aligned} Rt &= MV_f - MV_o \\ 1378 \times 10 &= 500(V_f - 0) \\ V_f &= \frac{1378 \times 10}{500} = 27.6 \text{ m/s} \end{aligned}$$

*Angular Impulse and Momentum:* In a manner similar to that for linear impulse and moment, the formulas for angular impulse and momentum for a body rotating about a fixed axis are:

$$\text{Angular momentum} = J_M \omega \quad (5a)$$

$$\text{Angular impulse} = T_o t \quad (5b)$$

where  $J_M$  is the moment of inertia of the body about the axis of rotation in lb-ft-sec<sup>2</sup>,  $\omega$  is the angular velocity in rad/sec,  $T_o$  is the torque in lb-ft about the axis of rotation, and  $t$  is the time in seconds that  $T_o$  acts.

The change in angular momentum of a body is numerically equal to the angular impulse that causes the change in angular momentum:

$$\begin{aligned} \text{Angular Impulse} &= \text{Change in Angular Momentum} \\ T_o t &= J_M \omega_f - J_M \omega_o = J_M (\omega_f - \omega_o) \end{aligned} \quad (5c)$$

where  $\omega_f$  and  $\omega_o$  are the final and initial angular velocities, respectively.

*Example:* A flywheel having a moment of inertia of 25 lbs-ft-sec<sup>2</sup> is revolving with an angular velocity of 10 rad/sec, when a constant torque of 20 lbs-ft is applied to reverse its direction of rotation. For what length of time must this constant torque act to stop the flywheel and bring it up to a reverse speed of 5 rad/sec?

*Solution:* Applying **Formula (5c)**,

$$\begin{aligned}T_o t &= J_M(\omega_f - \omega_o) \\20t &= 25(10 - [-5]) = 250 + 125 \\t &= 375 \div 20 = 18.8 \text{ seconds}\end{aligned}$$

**A similar example using metric SI units is as follows:** A flywheel with a moment of inertia of 20 kg-m<sup>2</sup> is revolving with an angular velocity of 10 rad/s when a constant torque of 30 N-m is applied to reverse its direction of rotation. For what length of time must this constant torque act to stop the flywheel and bring it up to a reverse speed of 5 rad/s? Applying **Formula (5c)**, the calculation is:

$$\begin{aligned}T_o t &= J_M(\omega_f - \omega_o) \\30t &= 20(10 - -5) \\ \text{Thus, } t &= \frac{20 \times 15}{30} = 10\text{s}\end{aligned}$$

**Formulas for Work and Power.**—The formulas in the accompanying **Table 4** may be used to determine work and power in terms of the applied force and the velocity at the point of application of the force.

**Table 4. Formulas<sup>a</sup> for Work and Power**

To Find	Known	Formula	To Find	Known	Formula
S	P, t, F	$S = P \times t + F$	K	F, S	$K = F \times S$
	K, F	$S = K \div F$		P, t	$K = P \times t$
t, F, hp	$S = 550 \times t \times hp \div F$	F, V, t		$K = F \times V \times t$	
		t, hp		$K = 550 \times t \times hp$	
V	P, F	$V = P \div F$	hp	F, S, t	$hp = F \times S \div (550 \times t)$
	K, F, t	$V = K \div (F \times t)$		P	$hp = P \div 550$
	F, hp	$V = 550 \times hp \div F$		F, V	$hp = F \times V \div 550$
t	F, S, P	$t = F \times S \div P$	K, t	$hp = K \div (550 \times t)$	
	K, F, V	$t = K \div (F \times V)$			
	F, S, hp	$t = F \times S \div (550 \times hp)$	<i>Meanings of Symbols:</i> (metric units see note <sup>a</sup> )		
F	P, V	$F = P \div V$			
	K, S	$F = K \div S$			
	K, V, t	$F = K \div (V \times t)$			
	V, hp	$F = 550 \times hp \div V$			
P	F, V	$P = F \times V$	S = distance in feet		
	F, S, t	$P = F \times S \div t$	V = constant or average velocity in ft/sec		
	K, t	$P = K \div t$	t = time in seconds		
	hp	$P = 550 \times hp$	F = constant or average force in pounds		
			P = power in foot-pounds per second		
			hp = horsepower		
			K = work in foot-pounds		

<sup>a</sup> **Note:** The metric SI unit of work is the joule (one joule = 1 newton-meter), and the unit of power is the watt (one watt = 1 joule per second = 1 N·m/s). The term horsepower is not used. Thus, those formulas above that involve horsepower and the factor 550 are not applicable when working in SI units. The remaining formulas can be used, and the units are:  $S$  = distance in meters;  $V$  = constant or average velocity in meters per second;  $t$  = time in seconds;  $F$  = force in newtons;  $P$  = power in watts;  $K$  = work in joules.

**Example:** A casting weighing 300 pounds is to be lifted by means of an overhead crane. The casting is lifted 10 feet in 12 seconds. What is the horsepower developed?

**Solution:** Here  $F = 300$  lbs,  $S = 10$  ft, and  $t = 12$  sec.

$$\text{hp} = \frac{F \times S}{550t} = \frac{300 \times 10}{550 \times 12} = 0.45$$

**A similar example using metric SI units is as follows:** A casting of mass 150 kg is lifted 4 meters in 15 seconds by means of a crane. What is the power? Here  $F = 150\text{g N}$ ,  $S = 4$  m, and  $t = 15$  s. Thus:

$$\text{Power} = \frac{FS}{t} = \frac{150\text{g} \times 4}{15} = \frac{150 \times 9.81 \times 4}{15} = 392 \text{ watts or } 0.392 \text{ kW}$$

### Centrifugal Force

When a body rotates about an axis other than the one at its center of mass, the inertia of its rotating body exerts an apparent outward force, drawing it away from that center. This is called *centrifugal force*.

$F$  = centrifugal force in pounds

$W$  = weight of revolving body in pounds

$v$  = velocity at radius  $R$  on body in feet/second

$n$  = number of revolutions per minute

$g$  = acceleration due to gravity = 32.16 feet/second<sup>2</sup>

$R$  = perpendicular distance in feet from axis of rotation to center of mass, or for practical use, to center of gravity of revolving body

**Note:** If a body rotates about its own center of mass,  $R$  equals zero and  $v$  equals zero. This means that the *resultant* of the centrifugal forces of all the elements of the body is equal to zero or, in other words, no centrifugal force is exerted on the axis of rotation. The centrifugal force of any part or element of such a body is found by the equations given below, where  $R$  is the radius to the center of gravity of the part or element. In a flywheel rim,  $R$  is the mean radius of the rim because it is the radius to the center of gravity of a thin radial section.

$$F = \frac{Wv^2}{gR} = \frac{Wv^2}{32.16R} = \frac{4WR\pi^2n^2}{60 \times 60g} = \frac{WRn^2}{2933} = 0.000341WRn^2$$

$$W = \frac{FRg}{v^2} = \frac{2933F}{Rn^2} \quad v = \sqrt{\frac{FRg}{W}}$$

$$R = \frac{Wv^2}{Fg} = \frac{2933F}{Wn^2} \quad n = \sqrt{\frac{2933F}{WR}}$$

(If  $n$  is the number of revolutions per second instead of per minute, then  $F = 1227WRn^2$ .)

**If metric SI units are used in the foregoing formulas,  $W/g$  is replaced by  $M$ , which is the mass in kilograms;  $F$  = centrifugal force in newtons;  $v$  = velocity in meters per second;  $n$  = number of revolutions per minute; and  $R$  = the radius in meters. Thus:**

$$F = \frac{Mv^2}{R} = \frac{Mn^2(2\pi R^2)}{60^2 R} = 0.01097 MRn^2$$

If the rate of rotation is expressed as  $n_1 =$  revolutions per second, then  $F = 39.48 MRn_1^2$ ; if it is expressed as  $\omega$  radians per second, then  $F = MR\omega^2$ .

**Calculating Centrifugal Force.**—In the ordinary formula for centrifugal force,  $F = 0.000341 WRn^2$ ; the mean radius  $R$  of the flywheel or pulley rim is given in feet. For small dimensions, it is more convenient to have the formula in the form:

$$F = 0.2842 \times 10^{-4} Wrn^2$$

in which  $F =$  centrifugal force, in pounds;  $W =$  weight of rim, in pounds;  $r =$  mean radius of rim, in inches;  $n =$  number of revolutions per minute.

In this formula let  $C = 0.000028416n^2$ . This, then, is the centrifugal force of one pound, one inch from the axis. The formula can now be written in the form,

$$F = WrC$$

$C$  is calculated for various values of the revolutions per minute  $n$ , and the calculated values of  $C$  are given in Table 5. To find the centrifugal force in any given case, simply find the value of  $C$  in the table and multiply it by the product of  $W$  and  $r$ ; the four multiplications in the original formula given are thus reduced to two.

*Example:* A cast-iron flywheel with a mean rim radius of 9 inches is rotated at a speed of 800 revolutions per minute. If the weight of the rim is 20 pounds, what is the centrifugal force?

*Solution:* From Table 5, for  $n = 800$  revolutions per minute, the value of  $C$  is 18.1862.

Thus,

$$F = WrC = 20 \times 9 \times 18.1862 = 3273.52 \text{ pounds}$$

Using metric SI units,  $0.01097n^2$  is the centrifugal force acting on a body of 1 kilogram mass rotating at  $n$  revolutions per minute at a distance of 1 meter from the axis. If this value is designated  $C_1$ , then the centrifugal force of mass  $M$  kilograms rotating at this speed at a distance from the axis of  $R$  meters is  $C_1 MR$  newtons. To simplify calculations, values for  $C_1$  are given in Table 6. If it is required to work in terms of millimeters, the force is  $0.001 C_1 MR_1$  newtons, where  $R_1$  is the radius in millimeters.

*Example:* A steel pulley with a mean rim radius of 120 mm is rotated at a speed of 1100 rpm. If the mass of the rim is 5 kg, what is the centrifugal force?

From Table 6, for  $n = 1100$  rpm, the value of  $C_1$  is 13,269.1.

Thus,

$$F = 0.001 C_1 MR_1 = 0.001 \times 13,269.1 \times 5 \times 120 = 7961.50 \text{ N}$$

**Centrifugal Casting.**—The centrifugal casting of metals is an old art. This process has become important in such work as the manufacture of paper-mill rolls, railroad car wheels, and cast-iron pipe. The centrifugal casting process has been successfully applied in the production of non-metallic tubes, such as concrete pipe, in the production of solid castings by locating the molds around the rim of a spinning wheel, and to a limited extent in the production of solid ingots by a largely similar process. Hollow objects such as cast-iron pipe are cast by introducing molten metal into a spinning mold. If the chilling of the metal is extremely rapid, for example in casting cast-iron pipe against a water-cooled chilled mold, it is imperative that a movable spout be used. The particular feature that determines the field of application of hot-mold centrifugal casting is the ability to produce long cast shapes of comparatively thin metal.

**Table 5. Factors  $C$  for Calculating Centrifugal Force (English units)**

$n$	$C$	$n$	$C$	$n$	$C$	$n$	$C$

## Balancing Rotating Parts

**Static Balancing.**—There are several methods of testing the standing or static balance of a rotating part. A simple method that is sometimes used for flywheels, etc., is illustrated by the diagram, Fig. 1. An accurate shaft is inserted through the bore of the finished wheel, which is then mounted on carefully leveled "parallels" A. If the wheel is in an unbalanced state, it will turn until the heavy side is downward. When it will stand in any position as the result of counterbalancing and reducing the heavy portions, it is said to be in standing or static balance. Another test which is used for disk-shaped parts is shown in Fig. 2. The disk D is mounted on a vertical arbor attached to an adjustable cross-slide B. The latter is carried by a table C, which is supported by a knife-edged bearing. A pendulum having an adjustable screw-weight W at the lower end is suspended from cross-slide B. To test the static balance of disk D, slide B is adjusted until pointer E of the pendulum coincides with the center of a stationary scale F. Disk D is then turned halfway around without moving the slide, and if the indicator remains stationary, it shows that the disk is in balance for this particular position. The test is then repeated for ten or twelve other positions, and the heavy sides are reduced, usually by drilling out the required amount of metal. Several other devices for testing static balance are designed on this same principle.

Fig. 1.

Fig. 2.

Fig. 3.

**Running or Dynamic Balance.**—A cylindrical body may be in perfect static balance yet not be in a balanced state when rotating at high speed. If the part is in the form of a thin disk, static balancing, if carefully done, may be accurate enough for high speeds, but if the rotating part is long in proportion to its diameter, and the unbalanced portions are at opposite ends or in different planes, the balancing must be done so as to counteract the centrifugal force of these heavy parts when they are rotating rapidly. This process is known as a *running balance* or *dynamic balancing*. To illustrate, if a heavy section is located at H (Fig. 3), and another correspondingly heavy section at  $H_1$ , one may exactly counterbalance the other when the cylinder is stationary, and this static balance may be sufficient for a part rigidly mounted and rotating at a comparatively slow speed; but when the speed is very high, as in turbine rotors, etc., the heavy masses H and  $H_1$ , being in different planes, are in an unbalanced state owing to the effect of centrifugal force, which results in excessive strains and injurious vibrations. Theoretically, to obtain a perfect running balance, the exact positions of the heavy sections should be located and the balancing effected either by reducing their weight or by adding counterweights opposite each section and in the same plane at the proper radius; but if the rotating part is rigidly mounted on a stiff shaft, a running balance that is sufficiently accurate for practical purposes can be obtained by means of comparatively few counterbalancing weights located with reference to the unbalanced parts.

**Balancing Calculations.**—As indicated previously, centrifugal forces caused by an unbalanced mass or masses in a rotating machine member cause additional loads on the bearings, which are transmitted to the housing or frame and to other machine members.

Such dynamically unbalanced conditions can occur even though static balance (balance at zero speed) exists. Dynamic balance can be achieved by the addition of one or two masses rotating about the same axis and at the same speed as the unbalanced masses. A single unbalanced mass can be balanced by one counterbalancing mass located 180 degrees opposite and in the same plane of rotation as the unbalanced mass if the product of their respective radii and masses are equal; i.e.,  $M_1 r_1 = M_2 r_2$ . Two or more unbalanced masses rotating in the same plane can be balanced by a single mass rotating in the same plane, or by two masses rotating about the same axis in two separate planes. Likewise, two or more unbalanced masses rotating in different planes about a common axis can be balanced by two masses rotating about the same axis in separate planes. When the unbalanced masses are in separate planes they may be in static balance but not in dynamic balance; i.e., they may be balanced when not rotating but unbalanced when rotating. If a system is in dynamic balance, it will remain in balance at all speeds, although this is not strictly true at the critical speed of the system. (See *Critical Speeds* on page 204.)

In all the equations that follow, the symbol  $M$  denotes either mass in kilograms or in slugs, or weight in pounds. Either mass or weight units may be used; the equations may be used with metric or with customary English units without change; however, in a given problem the units must be all metric or all customary English.

**Counterbalancing Several Masses Located in a Single Plane.**—In all balancing problems, the product of the counterbalancing mass (or weight) and its radius are calculated; it is thus necessary to select either the mass or the radius and then calculate the other value from the product of the two quantities. Design considerations usually make this decision self-evident. The angular position of the counterbalancing mass must also be calculated. Referring to Fig. 4:

$$M_B r_B = \sqrt{(\sum Mr \cos \theta)^2 + (\sum Mr \sin \theta)^2} \quad (1)$$

$$\tan \theta_B = \frac{-(\sum Mr \sin \theta)}{-(\sum Mr \cos \theta)} = \frac{y}{x} \quad (2)$$

Fig. 4.

where:

$M_1, M_2, M_3, \dots, M_n$  = any unbalanced mass or weight, kg or lb

$M_B$  = counterbalancing mass or weight, kg or lb

$r$  = radius to center of gravity of any unbalanced mass or weight, mm or inch

$r_B$  = radius to center of gravity of counterbalancing mass or weight, mm or inch

$\theta$  = angular position of  $r$  of any unbalanced mass or weight, degrees

$\theta_B$  = angular position of  $r_B$  of counterbalancing mass or weight, degrees

$x$  and  $y$  = position with sign according to Table 1

Table 1 is helpful in finding the angular position of the counterbalancing mass or weight. It indicates the range of the angles within which this angular position occurs by noting the plus and minus signs of the numerator and the denominator of the terms in Equation (2). In a like manner, Table 1 is useful in determining the *sign* of the sine or cosine functions for angles ranging from 0 to 360 degrees. Balancing problems are usually solved most conveniently by arranging the arithmetical calculations in a tabular form.

**Table 1. Relationship of Angle Function Signs to Quadrant in Which They Occur**

	Angle $\theta$			
	0° to 90°	90° to 180°	180° to 270°	270° to 360°
	Signs of the Functions			
tan	$\frac{+y}{+x}$	$\frac{+y}{-x}$	$\frac{-y}{-x}$	$\frac{-y}{+x}$
sine	$\frac{+y}{+r}$	$\frac{+y}{+r}$	$\frac{-y}{+r}$	$\frac{-y}{+r}$
cosine	$\frac{+x}{+r}$	$\frac{-x}{+r}$	$\frac{-x}{+r}$	$\frac{+x}{+r}$

*Example:* Referring to Fig. 4, particular values of unbalanced weights  $M_1, M_2, M_3$  are entered in the table below. Calculate the magnitude of the counterbalancing weight  $M_B$  if its radius  $r$  is to be 10 inches.

*Solution:* The table is arranged with the given masses  $M$ , their radii  $r$ , and their angular positions  $\theta$ . The angle functions  $\sin \theta$  and  $\cos \theta$  are determined from the angles using a calculator or trig table. Finally, the quantities are used to fill in the last two columns.

$M$		$r$	$\theta$	$\cos \theta$	$\sin \theta$	$Mr \cos \theta$	$Mr \sin \theta$
No.	lb.	in.	deg.				
1	10	10	30	0.8660	0.5000	86.6	50.0
2	5	20	120	-0.5000	0.8660	-50.0	86.6
3	15	15	200	-0.9397	-0.3420	-211.4	-77.0
						-174.8 = $\sum Mr \cos \theta$	59.6 = $\sum Mr \sin \theta$

$$M_B = \frac{\sqrt{(\sum Mr \cos \theta)^2 + (\sum Mr \sin \theta)^2}}{r_B} = \frac{\sqrt{(-174.8)^2 + (59.6)^2}}{10}$$

$$M_B = 18.5 \text{ lbs}$$

$$\tan \theta_B = \frac{-(\sum Mr \sin \theta)}{-(\sum Mr \cos \theta)} = \frac{-(59.6)}{-(-174.8)} = \frac{-y}{+x}, \quad \theta_B = 341^\circ 10'$$

Fig. 5.

**Counterbalancing Masses Located in Two or More Planes.**—Unbalanced masses or weights rotating about a common axis in two separate planes of rotation form a couple, which must be counterbalanced by masses or weights, also located in two separate planes, say, planes A and B, and rotating about a common axis (see *Couples* on page 162). In addition, they must be balanced in the direction perpendicular to the axis, as before. Since two counterbalancing masses are required, two separate equations are required to calculate the product of each mass or weight and its radius, and two additional equations are required to calculate the angular positions. The planes A and B selected as balancing planes may be any two planes separated by any convenient distance  $c$ , along the axis of rotation. In Fig. 5:

For balancing plane A:

$$M_A r_A = \frac{\sqrt{(\sum Mrb \cos \theta)^2 + (\sum Mrb \sin \theta)^2}}{c} \quad (3)$$

$$\tan \theta_A = \frac{-(\sum Mrb \sin \theta)}{-(\sum Mrb \cos \theta)} = \frac{y}{x} \quad (4)$$

For balancing plane B:

$$M_B r_B = \frac{\sqrt{(\sum Mra \cos \theta)^2 + (\sum Mra \sin \theta)^2}}{c} \quad (5)$$

$$\tan \theta_B = \frac{-(\sum Mra \sin \theta)}{-(\sum Mra \cos \theta)} = \frac{y}{x} \quad (6)$$

where:  $M_A$  and  $M_B$  are the mass or weight of the counterbalancing masses in the balancing planes A and B, respectively;  $r_A$  and  $r_B$  are the radii; and  $\theta_A$  and  $\theta_B$  are the angular positions of the balancing masses in these planes.  $M$ ,  $r$ , and  $\theta$  are the mass or weight, radius, and angular positions of the unbalanced masses, with the subscripts defining the particular mass to which the values are assigned. The distance,  $c$ , between the balancing planes is always a positive value. The axial dimensions,  $a$  and  $b$ , may be either positive or negative, depending upon their position relative to the balancing plane; for example, in Fig. 5, the dimension  $b_2$  would be negative.

*Example:* Referring to Fig. 5, a set of values for the masses and dimensions has been selected and put into convenient table form below. The separation of balancing planes,  $c$ , is chosen as 15 inches. If in balancing plane A, the radius of the counterbalancing weight

is selected to be 10 inches; calculate the magnitude of the counterbalancing mass and its position. In balancing plane *B* the counterbalancing mass is selected to be 10 lb; calculate its radius and position.

*Solution:* For balancing plane *A*:

Plane	<i>M</i> lb	<i>r</i> in.	$\theta$ deg.	Balancing Plane <i>A</i>			
				<i>b</i> in.	<i>Mrb</i>	<i>Mrb</i> cos $\theta$	<i>Mrb</i> sin $\theta$
1	10	8	30	6	480	415.7	240.0
2	8	10	135	-6	-480	339.4	-339.4
3	12	9	270	12	1296	<u>0.0</u>	<u>-1296.0</u>
<i>A</i>	?	10	?	15 <sup>a</sup>		755.1	-1395.4
<i>B</i>	10	?	?	0		= $\Sigma Mrb$ cos $\theta$	= $\Sigma Mrb$ sin $\theta$

<sup>a</sup> 15 inches = distance *c* between planes *A* and *B*.

$$M_A = \frac{\sqrt{(\Sigma Mrb \cos \theta)^2 + (\Sigma Mrb \sin \theta)^2}}{r_A c} = \frac{\sqrt{(755.1)^2 + (-1395.4)^2}}{10(15)}$$

$$M_A = 10.6 \text{ lb}$$

$$\tan \theta_A = \frac{-\Sigma Mrb \sin \theta}{-\Sigma Mrb \cos \theta} = \frac{-(-1395.4)}{-(755.1)} = \frac{+y}{-x}$$

$$\theta_A = 118^\circ 25'$$

For balancing plane *B*:

Plane	<i>M</i> lb	<i>r</i> in.	$\theta$ deg.	Balancing Plane <i>B</i>			
				<i>a</i> in.	<i>Mra</i>	<i>Mra</i> cos $\theta$	<i>Mra</i> sin $\theta$
1	10	8	30	9	720	623.5	360.0
2	8	10	135	21	1680	-1187.9	1187.9
3	12	9	270	3	324	<u>0.0</u>	<u>-324.0</u>
<i>A</i>	?	10	?	0		-564.4	1223.9
<i>B</i>	10	?	?	15 <sup>a</sup>		= $\Sigma Mra$ cos $\theta$	= $\Sigma Mra$ sin $\theta$

<sup>a</sup> 15 inches = distance *c* between planes *A* and *B*.

$$r_B = \frac{\sqrt{(\Sigma Mra \cos \theta)^2 + (\Sigma Mra \sin \theta)^2}}{M_B c} = \frac{\sqrt{(-564.4)^2 + (1223.9)^2}}{10(15)}$$

$$= 8.985 \text{ in.}$$

$$\tan \theta_B = \frac{-\Sigma Mra \sin \theta}{-\Sigma Mra \cos \theta} = \frac{-(1223.9)}{-(-564.4)} = \frac{-y}{+x}$$

$$\theta_B = 294^\circ 45'$$

**Balancing Lathe Fixtures.**—Lathe fixtures rotating at a high speed require balancing. Often it is assumed that the center of gravity of the workpiece and fixture and of the counterbalancing masses are in the same plane; however, this is not usually the case. Counterbalancing masses are required in two separate planes to prevent excessive vibration or bearing loads at high speeds.

Fig. 6.

Usually a single counterbalancing mass is placed in one plane selected to be 180 degrees directly opposite the combined center of gravity of the workpiece and the fixture. Two equal counterbalancing masses are then placed in the second counterbalancing plane, equally spaced on each side of the fixture. Referring to Fig. 6, the two counterbalancing masses  $M_A$  and the two angles  $\theta$  are equal. For the design in this illustration, the following formulas can be used to calculate the magnitude of the counterbalancing masses. Since their angular positions are fixed by the design, they are not calculated.

$$M_B = \frac{M_W r_W (l_1 + l_2)}{r_B l_1} \quad (7)$$

$$M_A = \frac{M_B r_B - M_W r_W}{2r_A \sin \theta} \quad (8)$$

In these formulas  $M_W$  and  $r_W$  denote the mass or weight and the radius of the combined center of gravity of the workpiece and the fixture.

*Example:* In Fig. 6 the combined weight of the workpiece and the fixture is 18.5 lb. The following dimensions were determined from the layout of the fixture and by calculating the centers of gravity:  $r_W = 2$  in.;  $r_A = 6.25$  in.;  $r_B = 6$  in.;  $l_1 = 3$  in.;  $l_2 = 5$  in.; and  $\theta = 30^\circ$ . Calculate the weights of the counterbalancing masses.

$$M_B = \frac{M_W r_W (l_1 + l_2)}{r_B l_1} = \frac{18.5 \times 2 \times 8}{6 \times 3} = 16.44 \text{ lb}$$

$$M_A = \frac{M_B r_B - M_W r_W}{2r_A \sin \theta} = \frac{(16.44 \times 6) - (18.5 \times 2)}{(2 \times 6.25) \sin 30^\circ} = 9.86 \text{ lb (each weight)}$$

### Critical Speeds

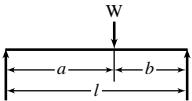

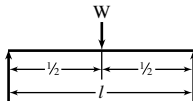

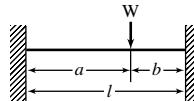

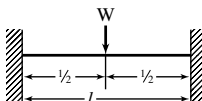

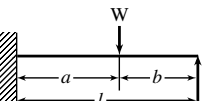

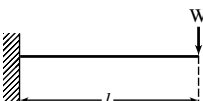

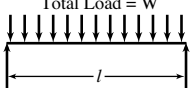

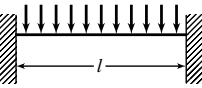

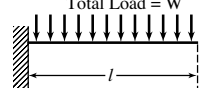

**Critical Speeds of Rotating Bodies and Shafts.**—If a body or disk mounted upon a shaft rotates about it, the center of gravity of the body or disk must be at the center of the shaft if a perfect running balance is to be obtained. In most cases, however, the center of gravity of the disk will be slightly removed from the center of the shaft, owing to the difficulty of perfect balancing. Now, if the shaft and disk are rotated, the centrifugal force generated by the heavier side will be greater than that generated by the lighter side geometrically opposite to it, and the shaft will deflect toward the heavier side, causing the center of the disk to rotate in a small circle. A rotating shaft without a body or disk mounted on it can also become dynamically unstable, and the resulting vibrations and deflections can result in damage not only to the shaft but to the machine of which it is a part. These conditions hold true up to a comparatively high speed, but a point is eventually reached (at several thousand revolutions per minute) when momentarily there will be excessive vibration, and then the parts will run quietly again. The speed at which this occurs is called the *critical speed* of the wheel or shaft, and the phenomenon itself for the shaft-mounted disk or body is called the *settling* of the wheel. The explanation of the settling is that at this speed the axis of rotation changes, and the wheel and shaft, instead of rotating about their geometrical center, begin to rotate about an axis through their center of gravity. The shaft itself is then deflected so that for every revolution its geometrical center traces a circle around the center of gravity of the rotating mass.

Critical speeds depend upon the magnitude or location of the load or loads carried by the shaft, the length of the shaft, its diameter and the kind of supporting bearings. The normal operating speed of a machine may or may not be higher than the critical speed. For instance, some steam turbines exceed the critical speed, although they do not run long enough at the critical speed for the vibrations to build up to an excessive amplitude. The practice of the General Electric Co. at Schenectady is to keep below the critical speeds. It is assumed that the maximum speed of a machine may be within 20 percent above or below the critical speed without vibration troubles. Thus, in a design of steam turbine sets, critical speed is a factor that determines the size of the shafts for both the generators and turbines. Although a machine may run very close to the critical speed, the alignment and play of the bearings, the balance and construction generally will require extra care, resulting in a more expensive machine; moreover, while such a machine may run smoothly for a considerable time, any looseness or play that may develop later, causing a slight imbalance, will immediately set up excessive vibrations.

The formulas commonly used to determine critical speeds are sufficiently accurate for general purposes. There are cases, however, where the torque applied to a shaft has an important effect on its critical speed. Investigations have shown that the critical speeds of a uniform shaft are decreased as the applied torque is increased and that there exist critical torques which will reduce the corresponding critical speed of the shaft to zero. A detailed analysis of the effects of applied torques on critical speeds may be found in a paper, "Critical Speeds of Uniform Shafts under Axial Torque," by Golumb and Rosenberg, presented at the First US National Congress of Applied Mechanics in 1951.

**Formulas for Critical Speeds.**—The critical speed formulas given in the accompanying table (from the paper on Critical Speed Calculation presented before the ASME by S. H. Weaver) apply to (1) shafts with single concentrated loads and (2) shafts carrying uniformly distributed loads. These formulas also cover different conditions as regards bearings. If the bearings are self-aligning or very short, the shaft is considered to be supported at the ends; whereas, if the bearings are long and rigid, the shaft is considered fixed. These formulas, for both concentrated and distributed loads, apply to vertical shafts as well as horizontal shafts, the critical speeds having the same value in both cases. The data required for the solution of critical speed problems are the same as for shaft deflection. As the shaft is usually of variable diameter and its stiffness is increased by a long hub, an ideal shaft of uniform diameter and equal stiffness must be assumed.

## Critical Speed Formulas

Formulas for Single Concentrated Load		
 $N = 387,000 \frac{d^2}{ab} \sqrt{\frac{l}{W}}$ Bearings supported	 $N = 1,550,500 \frac{d^2}{l\sqrt{Wl}}$ Bearings supported	 $N = 387,000 \frac{d^2 l}{ab} \sqrt{\frac{l}{Wab}}$ Bearings fixed
 $N = 3,100,850 \frac{d^2}{l\sqrt{Wl}}$ Bearings fixed	 $N = 775,200 \frac{d^2 l}{ab} \sqrt{\frac{l}{Wa(3l+b)}}$ One-fixed — One supported	 $N = 387,000 \frac{d^2}{l\sqrt{Wl}}$ One fixed — One free end
Formulas for Distributed Loads—First Critical Speed		
 $N = 2,232,500 \frac{d^2}{l\sqrt{Wl}}$ $N_1 = 4,760,000 \frac{d}{l^2}$ Bearings supported	 $N = 4,979,250 \frac{d^2}{l\sqrt{Wl}}$ $N_1 = 10,616,740 \frac{d}{l^2}$ Bearings fixed	 $N = 795,200 \frac{d^2}{l\sqrt{Wl}}$ $N_1 = 1,695,500 \frac{d}{l^2}$ One fixed—One free end

$N$  = critical speed, RPM

$N_1$  = critical speed of shaft alone

$d$  = diameter of shaft, in inches

$W$  = load applied to shaft, in pounds

$l$  = distance between centers of bearings, in inches

$a$  and  $b$  = distances from bearings to load

In calculating critical speeds, the weight of the shaft is either neglected or, say,  $\frac{1}{2}$  to  $\frac{2}{3}$  of the weight is added to the concentrated load. The formulas apply to steel shafts having a modulus of elasticity  $E = 29,000,000$ . Although a shaft carrying a number of loads or a distributed load may have an infinite number of critical speeds, ordinarily it is the first critical speed that is of importance in engineering work. The first critical speed is obtained by the formulas given in the distributed loads portion of the table *Critical Speed Formulas*.

## STRENGTH OF MATERIALS

Strength of materials deals with the relations between elastic bodies, external forces applied, and resulting deformations and stresses. In the design of structures and machines, mechanical engineering must consider the behavior of chosen materials when under load and apply strength of materials principles, including static strength and fatigue strength. Optimizing mechanical properties, load characteristics, and part shapes helps ensure expected behavior and life of a part or machine.

Forces are produced by the action of gravity, by accelerations and impacts of moving parts, by gasses and fluids under pressure, and by the transmission of mechanical power, among others. In order to analyze the stresses and deflections of a body, the magnitudes, directions and points of application of forces acting on the body must be known. Information given previously in the Mechanics section provides the basis for evaluating force systems.

The time element in the application of a force on a body is an important consideration. Thus, a force may be static or change so slowly that its maximum value can be treated as if it were static; it may be suddenly applied, as with an impact; or it may have a repetitive or cyclic behavior.

The environment in which forces act on a machine or part is also important. Such factors as high and low temperatures; the presence of corrosive gases, vapors and liquids; radiation, etc. may have a marked effect on how well parts are able to resist stresses.

**Throughout this and other sections of the Handbook, both English and metric SI data and formulas are given to cover the requirements of working in either system of measurement. In many cases, formulas and text relating exclusively to SI units are given in bold-face type.**

**Mechanical Properties of Materials.**—Many mechanical properties of materials are determined from tests such as tensile testing, which subjects a uniform sample of a material to controlled axial tension. Strain (elongation) is measured as well as stress at the point of rupture.

*Engineering stress* is the applied load on a tensile specimen divided by its original cross-sectional area. *True stress* uses the actual cross-sectional area. The maximum stress a material can withstand before breaking may be called *ultimate tensile stress* or *breaking stress*. *Engineering strain* is the amount by which a tensile specimen of a given material changes when the body is subjected to a load, divided by the original value of the dimension. *True strain* is the natural log of the ratio of current length over original length. Instead of *unit strain*, the simpler term *strain* often is used.

The shape of an engineering stress-strain curve (see Fig. 1) reveals how material will behave under tensile loading, assuming the tensile specimen has a constant cross-sectional area as loading is applied. (True stress and strain both reference the instantaneous cross-sectional area, which can be more accurate, but in practice, engineering stress-strain curves are used almost exclusively.) Values beyond the elastic limit must be used with caution, as the cross-sectional area begins to change and introduce error.

Fig. 1 (1) shows the curve shape for a ductile ferrous material similar to low-carbon steel. The (upper or first) yield point is well defined and followed by some elongation with little additional stress. Then the curve turns upward again, toward an inflection point; strain hardening accounts for the increasing stress in this segment. When the curve again turns downward at the ultimate strength point, necking has begun. Fig. 1 (2) shows a curve typical of a ductile non-ferrous material such as annealed copper. A well-defined yield point is absent, so an offset yield point is constructed. Fig. 1 (3) illustrates an offset yield point, as discussed below.

Fig. 1. Stress-Strain Curves

**In the SI, the unit of stress is the pascal (Pa), the newton per meter squared (N/m<sup>2</sup>). The megapascal (newtons per millimeter squared) is often an appropriate submultiple for use in practice.**

*Proportional limit* is the point on a stress-strain curve at which it begins to deviate from the straight-line relationship between stress and strain. Prior to this point, the curve has a constant slope equal to the modulus of elasticity for that material.

*Elastic limit* is the maximum tensile stress to which a test specimen may be subjected and still return to its original length upon release of the load. A material is said to be stressed within the *elastic region* when the working stress does not exceed the elastic limit, and to be stressed in the *plastic region* when the working stress does exceed the elastic limit. The elastic limit for steel is for all practical purposes the same as its proportional limit.

*Yield point* is a point on the stress-strain curve at which there is a sudden increase in strain without a corresponding increase in stress. While not all materials have a yield point, for those that do, this point tends to occur at or near the onset of plastic or permanent deformation. Modern standards may refer to this as *upper yield strength*.

*Yield strength*,  $S_y$ , is the stress associated with a specified small amount of permanent strain. Ideally, this is the maximum stress that can be applied with no permanent deformation of the material; in practice, it is not easily measurable. When a material does not have a clearly defined upper yield strength (yield point), an offset yield strength may be defined instead, as illustrated in Fig. 1 (3). In such cases, yield strength is the stress value on the stress-strain curve corresponding to a defined amount of permanent set or strain, usually 0.1%, 0.2%, or 0.5% of the original dimension. A line drawn parallel to the elastic range curve (with slope equal to the modulus of elasticity) intersects the X-axis at the target strain. The intersection of the stress-strain curve with that offset line is the offset yield point (again 0.2%). Yield strength data for various materials are given in tables starting on pages 388, 390, 418, 419, 421, 423, 427, 510, 512, 516, 525, 526, 531, 532, 536, 544, 546, 547, and elsewhere.

*Ultimate tensile strength*,  $S_u$  (also called *ultimate strength*), is the maximum stress value obtained in a tensile test for a given material. This value has significance in designs with brittle materials; design calculations for ductile materials use yield strength instead.

*Modulus of elasticity*,  $E$  (also called *Young's modulus*), is a measurement of the elasticity of a given material. Calculated according to Hooke's law by dividing stress by the corresponding strain within a material's elastic range, this value is equal to the slope of the linear portion of the stress-strain curve. Smaller  $E$  values indicate larger deflections under a given stress. Young's modulus has significant implications for parts in use, as well as those being machined or processed. Some representative values of Young's modulus in both US customary and metric units are as follows:

Material	Young's Modulus		Material	Young's Modulus	
	10 <sup>6</sup> psi	10 <sup>9</sup> Pa		10 <sup>6</sup> psi	10 <sup>9</sup> Pa
Aluminum, cast, pure	9	62.1	Magnesium, AZ80A-T5	6.5	44.8
Aluminum, wrought, 2014-T6	10.6	73.1	Titanium, pure	15.5	106.9
Beryllium copper	19	131	Titanium, alloy, 5 Al, 2.5 Sn	17	117.2
Brass, naval	15	103.4	Steel for bridges and buildings, ASTM A7-61T, all shapes	29	199.9
Bronze, phosphor, ASTM B159	15	103.4	Steel, castings, high strength, for structural purposes, ASTM A148-60	29	199.9
Cast iron, malleable	26	179.3			
Cast iron, nodular	23.5	162			

*Modulus of rigidity,  $G$*  (also called *modulus of elasticity in shear* or *shear modulus*), is shear stress divided by corresponding shear strain. (Shear may be applied directly or through torsion. Strain torsion is measured in radians.) As with modulus of elasticity, this value is only meaningful within the elastic range of the material, where it is equal to the slope of the straight-line portion of the stress-strain curve. Smaller  $G$  values also are associated with larger deflections, given the same stress. This value is important to consider in shaft designs where windup is a concern.

*Poisson's ratio,  $\mu$* , is the value of the strain transverse to the load direction, divided by the strain in the load direction. This ratio is determined when uniaxial force is applied, with tensile force having a negative sign and compressive force a positive sign. Values of Poisson's ratio for common materials are as follows:

Aluminum	0.334	Nickel silver	0.322
Beryllium copper	0.285	Phosphor bronze	0.349
Brass	0.340	Rubber	0.500
Cast iron, gray	0.211	Steel, cast	0.265
Copper	0.340	high carbon	0.295
Inconel	0.290	mild	0.303
Lead	0.431	nickel	0.291
Magnesium	0.350	Wrought iron	0.278
Monel metal	0.320	Zinc	0.331

**Compressive and Shear Properties.**—*Compressive yield strength,  $S_{cy}$* , and *compressive ultimate strength,  $S_{cu}$* , are determined from compression tests. It is common to assume that ultimate compressive strength is equal to ultimate tensile strength. But ductile materials in compression usually fail by excessive yielding well before they fracture; as they are weaker in shear than in tension/compression, shear failure is more likely to occur. For brittle materials, which are stronger in shear, tensile and compressive stresses are of particular concern.

The properties of *shear yield strength,  $S_{sy}$* , and *shear ultimate strength,  $S_{su}$* , are determined by direct shear and torsional tests. The shear yield strength of ductile materials is approximated as 0.577 times the tensile yield strength.

**Creep.**—Continuing changes in dimensions of a stressed material over time is called creep; it varies with different materials and periods under stress, and with temperature. Creep tests may take some time, as it is necessary to apply a constant tensile load to a specimen under a selected temperature. Measurements are taken to record the resulting elongation at time periods sufficiently long for a relationship to be established. The data are then plotted as elongation against time. The load is applied to the specimen only after it has reached the testing temperature, and causes an initial elastic elongation that includes some plastic deformation if the load is above the proportional limit for the material.

Some combinations of stress and temperature may cause failure of the specimen. Others show initial high rates of deformation, followed by decreasing, then constant, rates over long periods. Generally, testing times to arrive at the constant rate of deformation are over 1000 hours.

**Creep Rupture.**—Tests for creep rupture are similar to creep tests but are prolonged until the specimen fails. Further data to be obtained from these tests include time to rupture, amount of elongation, and reduction of area. Stress-rupture tests are performed without measuring the elongation, so that no strain data are recorded, time to failure, elongation and reduction of area being sufficient. Sometimes, a V-notch is cut in the specimen to allow measurement of notch sensitivity under the testing conditions.

**Stress and Strain Analysis.**—Stresses, deflections (strains), and loads may be characterized by applying strain gages or indicating coatings to the surface of a part and then subjecting it to loads simulating those encountered in service. Strain gages, available in various configurations, are attached to the part's surface and often calibrated before use. Such gages convert tension, pressure, force, and so on into electrical resistance, which can be measured to indicate strain. Indicating coatings include brittle lacquers that crack in

patterns indicative of strain direction and magnitude, as well as color-changing coatings that indicate the amount of strain at each point, identifying areas requiring component modification. Alternatively, modern materials testing systems offer automated, multi-axial, and high-precision capabilities. Testing may involve use of specific wavelengths of light or be performed at extreme temperatures.

Most of these tests have been standardized by the American Society for Testing and Materials (ASTM) and are published in their *Book of Standards* in separate sections for metals, plastics, rubber, and wood. Many of the test methods are also adopted by the American National Standards Institute (ANSI).

**Fatigue Properties.**—When a material is subjected to many cycles of stress reversal or fluctuation (variation in magnitude without reversal), failure may occur, even though the maximum stress at any cycle is considerably less than the value at which failure would occur if the stress were constant. Fatigue properties are determined by subjecting test specimens to stress cycles and counting the number of cycles to failure. From a series of such tests in which maximum stress values are progressively reduced, diagrams of stress versus number of cycles until failure (*S-N* diagrams) can be plotted as illustrated by the accompanying figures. The *S-N* diagram Fig. 2a shows the behavior of a material for which there is an *endurance limit*  $S_{en}$ . Endurance limit is the stress value at which the number of cycles to failure is infinite. Steels have endurance limits that vary according to hardness, composition, and quality, but many nonferrous metals do not. The *S-N* diagram Fig. 2b does not have an endurance limit. For a metal that does not have an endurance limit, it is standard practice to specify fatigue strength as the stress value corresponding to a specific number of stress reversals, usually 100,000,000 or 500,000,000.

Fig. 2a. *S-N* Endurance LimitFig. 2b. *S-N* No Endurance Limit

**Influence of Mean Stress on Fatigue.**—Most published data on the fatigue properties of metals are for completely reversed alternating stresses, that is, the mean stress of the cycle is equal to zero. However, if a structure is subjected to stresses that fluctuate between different values of tension and compression, then the mean stress is not zero.

When fatigue data for a specified mean stress and design life are not available for a material, the influence of nonzero mean stress can be estimated from empirical relationships that relate failure at a given life, under zero mean stress, to failure at the same life under zero mean cyclic stress. One widely used formula is Goodman's linear relationship,

$$S_a = S \left( 1 - S_m / S_u \right)$$

where  $S_a$  is the alternating stress associated with some nonzero mean stress  $S_m$ .  $S$  is the alternating fatigue strength at zero mean stress.  $S_u$  is the ultimate tensile strength.

Goodman's linear relationship is usually represented graphically on a so-called *Goodman Diagram*, shown in Fig. 3a. The alternating fatigue strength or the alternating stress for a given number of endurance cycles is plotted on the ordinate (*y*-axis) and the static tensile strength is plotted on the abscissa (*x*-axis). The straight line joining the alternating fatigue strength  $S$  and the tensile strength  $S_u$  is the Goodman line.

The value of an alternating stress  $S_{ax}$  at a known value of mean stress  $S_{mx}$  is determined as shown by the dashed lines on the diagram.

Fig. 3a. Goodman Diagram

Fig. 3b. Mean Tensile Stress

For ductile materials, the Goodman law is usually conservative, since approximately 90 percent of actual test data for most ferrous and nonferrous alloys fall above the Goodman line, even at low endurance values where the yield strength is exceeded. For many brittle materials, however, actual test values can fall below the Goodman line, as illustrated in Fig. 3b.

As a rule of thumb, materials having an elongation of less than 5 percent in a tensile test may be regarded as brittle. Those having an elongation of 5 percent or more may be regarded as ductile.

**Cumulative Fatigue Damage.**—Most data are determined from tests at a constant stress amplitude. This is easy to do experimentally, and the data can be presented in a straightforward manner. In actual engineering applications, however, the alternating stress amplitude usually changes in some way during service operation. Such changes, referred to as “spectrum loading,” make direct use of standard  $S-N$  fatigue curves inappropriate. A problem exists, therefore, in predicting the fatigue life under varying stress amplitude from conventional, constant-amplitude  $S-N$  fatigue data.

The assumption in predicting spectrum loading effects is that operation at a given stress amplitude and number of cycles will produce a certain amount of permanent fatigue damage and that subsequent operation at different stress amplitude and number of cycles will produce additional fatigue damage and a sequential accumulation of total damage, which at a critical value will cause fatigue failure. Although the assumption appears simple, the amount of damage incurred at any stress amplitude and number of cycles has proven difficult to determine, and several “cumulative damage” theories have been advanced.

One of the first and simplest methods for evaluating cumulative damage is known as *Miner's law* or the *linear damage rule*, where it is assumed that  $n_1$  cycles at a stress of  $S_1$ , for which the average number of cycles to failure is  $N_1$ , causes an amount of damage  $n_1/N_1$ . Failure is predicted to occur when

$$\sum_1^N \frac{n_i}{N_i} = 1$$

The term  $n/N$  is known as the “cycle ratio” or the damage fraction.

The greatest advantages of the Miner rule are its simplicity and prediction reliability, which approximates that of more complex theories. For these reasons the rule is widely used. It should be noted, however, that it does not account for all influences, and errors are to be expected in failure prediction ability.

**Modes of Fatigue Failure.**—Several modes of fatigue failure are:

*Low/High-Cycle Fatigue:* This fatigue process covers cyclic loading in two significantly different domains, with different physical mechanisms of failure. One domain is characterized by relatively low cyclic loads, strain cycles confined largely to the elastic range, and long lives, that is, a high number of cycles to failure; traditionally, this has been called “high-cycle fatigue.” The other domain has cyclic loads that are relatively high, significant amounts of plastic strain induced during each cycle, and short lives, that is, a low

number of cycles to failure. This domain has commonly been called "low-cycle fatigue" or cyclic strain-controlled fatigue.

The transition from low- to high-cycle fatigue behavior occurs in the range from approximately 10,000 to 100,000 cycles. Many define low-cycle fatigue as failure that occurs in 50,000 cycles or less.

**Thermal Fatigue:** Cyclic temperature changes in a machine part will produce cyclic stresses and strains if natural thermal expansions and contractions are either wholly or partially constrained. These cyclic strains produce fatigue failure just as if they were produced by external mechanical loading. When strain cycling is produced by a fluctuating temperature field, the failure process is termed "thermal fatigue."

While thermal fatigue and mechanical fatigue phenomena are very similar, and can be mathematically expressed by the same types of equations, the use of mechanical fatigue results to predict thermal fatigue performance must be done with care. For equal values of plastic strain range, the number of cycles to failure is usually up to 2.5 times lower for thermally cycled than for mechanically cycled samples.

**Corrosion Fatigue:** Corrosion fatigue is a failure mode where cyclic stresses and a corrosion-producing environment combine to initiate and propagate cracks in fewer stress cycles and at lower stress amplitudes than would be required in a more inert environment. The corrosion process forms pits and surface discontinuities that act as stress raisers to accelerate fatigue cracking. Cyclic loads may also cause cracking and flaking of the corrosion layer, baring fresh metal to the corrosive environment. Each process accelerates the other, making the cumulative result more serious.

**Surface or Contact Fatigue:** Surface fatigue failure is usually associated with rolling surfaces in contact, and results in pitting, cracking, and spalling of the contacting surfaces from cyclic Hertz contact stresses that cause the maximum values of cyclic shear stresses to be slightly below the surface. The cyclic subsurface shear stresses generate cracks that propagate to the contacting surface, dislodging particles in the process.

**Combined Creep and Fatigue:** In this failure mode, all of the conditions for both creep failure and fatigue failure exist simultaneously. Each process influences the other in producing failure, but this interaction is not well understood.

**Factors of Safety.**—There is always a risk that the working stress to which a member is subjected will exceed the strength of its material. The purpose of a factor of safety is to minimize this risk.

Factors of safety can be incorporated into design calculations in many ways. For most calculations the following equation is used:

$$s_w = \frac{S_m}{f_s} \quad (1)$$

where  $f_s$  is the factor of safety,  $S_m$  is the strength of the material in pounds per square inch, and  $s_w$  is the allowable working stress, also in pounds per square inch. Since the factor of safety is greater than 1, the allowable working stress will be less than the strength of the material.

In general,  $S_m$  is based on yield strength for ductile materials, ultimate strength for brittle materials, and fatigue strength for parts subjected to cyclic stressing. Most strength values are obtained by testing standard specimens at 68°F in normal atmospheres. If, however, the character of the stress or environment differs significantly from that used in obtaining standard strength data, then special data must be obtained. If special data are not available, standard data must be suitably modified.

General recommendations for values of factors of safety  $f_s$  are given in the following list.

$f_s$	Application
1.3–1.5	For use with highly reliable materials where loading and environmental conditions are not severe, and where weight is an important consideration.
1.5–2	For applications using reliable materials where loading and environmental conditions are not severe.

- 2-2.5 For use with ordinary materials where loading and environmental conditions are not severe.
- 2.5-3 For less tried and for brittle materials where loading and environmental conditions are not severe.
- 3-4 For applications in which material properties are not reliable and where loading and environmental conditions are not severe, or where reliable materials are to be used under difficult loading and environmental conditions.

**Stress and Strain.**—Stress is force per unit area of a material associated with a given strain (stress = force/area), normally expressed in pounds per square inch (psi) or newtons per square meter ( $N/m^2$ , or pascals, Pa). Strain is the deformation or extension of a material or part under load (strain = extension/length). Stress and strain are linearly related in some materials over all or part of their elastic ranges. This linear relationship is expressed as Hooke's law, where stress/strain =  $E$ , with  $E$  being the elastic modulus of the material. Stresses can be axial (tensile or compressive), shear (simple or torsional), isotropic (uniform loading on all surfaces), or combined (any combination of types). Tensile and compressive stress act at right angles to (normal to) the stressed area; shear stress acts along the plane of the affected area (at right angles to compressive or tensile stresses).

**Working Stress.**—Calculated working stresses are the products of calculated nominal stress values and stress concentration factors. Calculated nominal stress values are based on the assumption of idealized stress distributions. Such nominal stresses may be simple stresses, combined stresses, or cyclic stresses. Depending on the nature of the nominal stress, one of the following equations applies:

$$s_w = K\sigma \quad (2) \qquad s_w = K\sigma' \quad (4) \qquad s_w = K\sigma_{cy} \quad (6)$$

$$s_w = K\tau \quad (3) \qquad s_w = K\tau' \quad (5) \qquad s_w = K\tau_{cy} \quad (7)$$

where  $K$  is a stress concentration factor;  $\sigma$  and  $\tau$  are, respectively, simple normal (tensile or compressive) and shear stresses;  $\sigma'$  and  $\tau'$  are combined normal and shear stresses;  $\sigma_{cy}$  and  $\tau_{cy}$  are cyclic normal and shear stresses.

Where uneven stress distribution occurs, as illustrated in the table (on page 216) of simple stresses for Cases 3, 4 and 6, the maximum stress is the one to which the stress concentration factor is applied in computing working stresses. The location of the maximum stress in each case is discussed under the section *Simple Stresses* and the formulas for these maximum stresses are given in the *Table of Simple Stresses* on page 216.

**Stress Concentration Factors.**—Stress concentration is related to type of material, the nature of the stress, environmental conditions, and the geometry of parts. When stress concentration factors that specifically match all of the foregoing conditions are not available, the following equation may be used:

$$K = 1 + q(K_t - 1) \quad (8)$$

$K_t$  is a theoretical stress concentration factor that is a function only of the geometry of a part and the nature of the stress;  $q$  is the *index of sensitivity* of the material. If the geometry is such as to provide no theoretical stress concentration,  $K_t = 1$ .

Curves for evaluating  $K_t$  are on pages 213 through 216. For constant stresses in cast iron and in ductile materials,  $q = 0$  (hence,  $K = 1$ ). For constant stresses in brittle materials such as hardened steel,  $q$  may be taken as 0.15; for very brittle materials such as steels that have been quenched but not drawn,  $q$  may be taken as 0.25. When stresses are suddenly applied (impact stresses)  $q$  ranges from 0.4 to 0.6 for ductile materials; for cast iron it is taken as 0.5; and, for brittle materials, 1.

**Simple Stresses.**—Simple stresses are produced by constant conditions of loading on elements that can be represented as beams, rods, or bars. Table 2 summarizes information pertaining to the calculation of simple stresses, including symbols used in simple stress formulae:

$\sigma$  = simple normal (tensile or compressive) stress, in psi (Mpa)

$\tau$  = simple shear stress, in psi (Mpa)

$F$  = external force in pounds (Newtons, or N)

$V$  = shearing force in pounds (N)

$M$  = bending moment in inch-pounds (N-mm)

$T$  = torque in inch-pounds (N-mm)

$A$  = cross-sectional area perpendicular to the axial force or parallel to the shear force, in in<sup>2</sup> (mm<sup>2</sup>)

$Z$  = section modulus in in<sup>3</sup> (mm<sup>3</sup>)

$Z_p$  = polar section modulus in in<sup>3</sup> (mm<sup>3</sup>)

$I$  = moment of inertia in in<sup>4</sup> (mm<sup>4</sup>)

$J$  = polar moment of inertia in in<sup>4</sup> (mm<sup>4</sup>)

$a$  = area of the web of wide flange and I beams in in<sup>2</sup> (mm<sup>2</sup>)

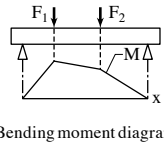

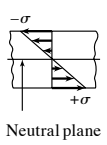

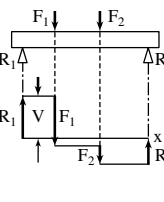

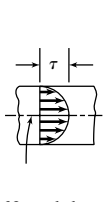

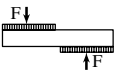

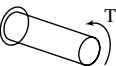

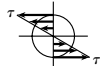

$y$  = perpendicular distance from axis through center of gravity of cross-sectional area to the most-stressed fiber in inches (mm)

$c$  = radial distance from center of gravity to the most-stressed fiber (usually the farthest point from the neutral axis) in in. (mm).

**Table 2. Table of Simple Stresses**

Case	Type of Loading	Illustration	Stress Distribution	Stress Equations
1	Direct tension		Uniform	$\sigma = \frac{F}{A}$ (9)
2	Direct compression		Uniform	$\sigma = -\frac{F}{A}$ (10)

Table 2. (Continued) Table of Simple Stresses

Case	Type of Loading	Illustration	Stress Distribution	Stress Equations
3	Bending	 <p>Bending moment diagram</p>	 <p>Neutral plane</p>	$\sigma = \pm \frac{M}{Z} = \pm \frac{My}{I} \quad (11)$
4	Shear	 <p>Shearing force diagram</p>	 <p>Neutral plane</p>	<p>For beams of rectangular cross section:</p> $\tau = \frac{3V}{2A} \quad (12)$ <p>For beams of solid circular cross section:</p> $\tau = \frac{4V}{3A} \quad (13)$ <p>For wide flange and I beams (approximately):</p> $\tau = \frac{V}{a} \quad (14)$
5	Direct shear		Uniform	$\tau = \frac{F}{A} \quad (15)$
6	Torsional Shear			$\tau = \frac{T}{Z_p} = \frac{Tc}{J} \quad (16)$

For direct tension and direct compression loading, Cases 1 and 2 in the table on page 216, the force  $F$  must act along a line through the center of gravity of the section at which the stress is calculated. The equation for direct compression loading applies only to members for which the ratio of length to least radius of gyration is relatively small, approximately 20; otherwise the member must be treated as a column.

The table *Stresses and Deflections in Beams* starting on page 257 give equations for calculating stresses due to bending for common types of beams and conditions of loading. Where these tables are not applicable, stress may be calculated using Equation (11) in the table on page 216. In using this equation it is necessary to determine the value of the bending moment at the point where the stress is to be calculated. For beams of constant cross-section, stress is ordinarily calculated at the point coinciding with the maximum value of bending moment. Bending loading results in the characteristic stress distribution shown in the table for Case 3. It will be noted that the maximum stress values are at the surfaces farthest from the neutral plane. One of the surfaces is stressed in tension and the other in compression. It is for this reason that the  $\pm$  sign is used in Equation (11). Numerous tables for evaluating section moduli are given in the section starting on page 239.

Shear stresses caused by bending have maximum values at neutral planes and zero values at the surfaces farthest from the neutral axis, as indicated by the stress distribution diagram shown for Case 4 in the *Table of Simple Stresses*. Values for  $V$  in Equations (12), (13) and (14) can be determined from shearing force diagrams. The shearing force diagram shown in Case 4 corresponds to the bending moment diagram for Case 3. As shown in this diagram, the value taken for  $V$  is represented by the greatest vertical distance from the

$x$ -axis. The shear stress caused by direct shear loading, Case 5, has a uniform distribution. However, the shear stress caused by torsion loading, Case 6, has a zero value at the axis and a maximum value at the surface farthest from the axis.

**Deflections.**—For direct tension and direct compression loading on members with uniform cross sections, deflection can be calculated using Equation (17). For direct tension loading,  $e$  is an elongation; for direct compression loading,  $e$  is a contraction. Deflection is in inches when the load  $F$  is in pounds, the length  $L$  over which deflection occurs is in inches, the cross-sectional area  $A$  is in square inches, and the modulus of elasticity  $E$  is in pounds per square inch. The angular deflection of members with uniform circular cross sections subject to torsion loading can be calculated with Equation (18).

$$e = \frac{FL}{AE} \quad (17) \quad \theta = \frac{TL}{GJ} \quad (18)$$

The angular deflection  $\theta$  is in radians when the applied torsion  $T$  is in inch-pounds, the length  $L$  over which the member is twisted is in inches, the modulus of rigidity  $G$  is in pounds per square inch, and the polar moment of inertia  $J$  is in in.<sup>4</sup>

**Metric SI units can be used in Equations (17) and (18), where  $F$  = force in newtons (N);  $L$  = length over which deflection or twisting occurs in meters;  $A$  = cross-sectional area in meters<sup>2</sup>;  $E$  = the modulus of elasticity in N/m<sup>2</sup>;  $\theta$  = radians;  $T$  = the applied torsion in newton-meters (N·m);  $G$  = modulus of rigidity, in pascals (Pa); and  $J$  = the polar moment of inertia in meters<sup>4</sup>. If the load ( $F$ ) is applied as a weight, it should be noted that the weight of a mass  $M$  kilograms is  $Mg$  newtons, where  $g = 9.81$  m/s<sup>2</sup>. Millimeters can be used in the calculations in place of meters, provided the treatment is consistent throughout.**

**Combined Stresses.**—A member may be loaded in such a way that a combination of simple stresses acts at a point. Three general cases are shown in the accompanying illustration, Fig. 11. Strength data is widely available for tensile performance, and the *von Mises stress* method and other methods can be used to calculate effective tensile stress at a point under combined loading.

*von Mises Effective Tensile Stress:* This method of calculating an equivalent tensile stress for combined stress scenarios is applicable to ductile material. The von Mises effective tensile stress,  $\sigma'$ , can be directly compared to the tensile yield strength of the material to predict performance for two-dimensional loading (Equation 19) and three-dimensional loading (Equation 20):

$$\sigma' = \sqrt{\sigma_x^2 + \sigma_y^2 - \sigma_x\sigma_y + 3\tau_{xy}^2} \quad (19)$$

$$\sigma' = \sqrt{\frac{(\sigma_x - \sigma_y)^2 + (\sigma_y - \sigma_z)^2 + (\sigma_z - \sigma_x)^2 + 6(\tau_{xy}^2 + \tau_{yz}^2 + \tau_{zx}^2)}{2}} \quad (20)$$

*Superposition of Stresses:* This method may be used in cases where the deformations are small and within the elastic range. Fig. 11 at (1) illustrates a common situation that results in simple stresses combining by superposition at points **a** and **b**. The equal and opposite forces  $F_1$  will cause a compressive stress  $\sigma_1 = -F_1/A$ . Force  $F_2$  will cause a bending moment  $M$  to exist in the plane of points **a** and **b**. The resulting stress  $\sigma_2 = \pm M/Z$ . The combined stress at point **a**,

$$\sigma'_a = -\frac{F_1}{A} - \frac{M}{Z} \quad (21) \quad \text{and at } \mathbf{b}, \quad \sigma'_b = -\frac{F_1}{A} + \frac{M}{Z} \quad (22)$$

where the minus sign indicates a compressive stress and the plus sign a tensile stress. Thus, the stress at **a** will be compressive and at **b** either tensile or compressive, depending on which term in the equation for  $\sigma'_b$  has the greatest value.

**Normal Stresses at Right Angles:** This is shown in Fig. 11 at (2). This combination of stresses occurs, for example, in tanks subjected to internal or external pressure. According to the Maximum Shear Stress theory, failure will occur in ductile materials due to shear, so this stress is critical to evaluate. The principal normal stresses are  $\sigma_x = F_1/A_1$ ,  $\sigma_y = F_2/A_2$ , and  $\sigma_z = 0$  in this plane stress problem. Determine the values of these three stresses with their signs, order them algebraically, and then calculate the maximum shear stress:

$$\tau = \frac{\sigma_{\text{largest}} - \sigma_{\text{smallest}}}{2} \quad (23)$$

**Normal and Shear Stresses:** The example in Fig. 11 at (3) shows a member subjected to a torsional shear stress,  $\tau = T/Z_p$ , and a direct compressive stress,  $\sigma = -F/A$ . At some point **a** on the member the principal normal stresses are calculated using the equation,

$$\sigma' = \frac{\sigma}{2} \pm \sqrt{\left(\frac{\sigma}{2}\right)^2 + \tau^2} \quad (24)$$

The maximum shear stress is calculated by using the equation,

$$\tau' = \sqrt{\left(\frac{\sigma}{2}\right)^2 + \tau^2} \quad (25)$$

The point **a** should ordinarily be selected where stress is a maximum value. For the example shown in Fig. 11 at (3), the point **a** can be anywhere on the cylindrical surface because the combined stress has the same value anywhere on that surface.

Fig. 11. Types of Combined Loading

**Tables of Combined Stresses.**—Beginning on page 220, these tables list equations for maximum nominal tensile or compressive (normal) stresses, and maximum nominal shear stresses for common machine elements. These equations were derived using general Equations (21), (22), (24), and (25). The equations apply to the critical points indicated on the figures. Cases 1, 2, 3, and 4 are cantilever beams. These may be loaded with a combination of a vertical and horizontal force, or by a single oblique force. If the single oblique force  $F$  and the angle  $\theta$  are given, then horizontal and vertical forces can be calculated using the equations  $F_x = F\cos\theta$  and  $F_y = F\sin\theta$ . In cases 9 and 10 of the table, the equations for  $\sigma_a'$  can give a tensile and a compressive stress because of the  $\pm$  sign in front of the radical. Equations involving direct compression are valid only if machine elements have relatively short lengths with respect to their sections; otherwise column equations apply.

**Calculation of Worst Stress Condition:** Stress failure can occur at any critical point if either the tensile, compressive, or shear stress properties of the material are exceeded by the corresponding working stress. It is necessary to evaluate the factor of safety for each possible failure condition. If working with the von Mises equivalent stress, only tensile yield need be considered.

The following rules apply to calculations using equations in the *Table of Simple Stresses* on page 216 and to calculations based on Equations (21) and (22). **Rule 1:** For every calculated normal stress there is a corresponding induced shear stress; the value of the shear stress is equal to half that of the normal stress. **Rule 2:** For every calculated shear stress there is a corresponding induced normal stress; the value of the normal stress is equal to that of the shear stress. The tables of combined stress formulas below include equations for calculating both maximum nominal tensile or compressive stresses, and maximum nominal shear stresses.

**Formulas for Combined Stresses**

**(1) Circular Cantilever Beam in Direct Compression and Bending:**

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1.273}{d^2} \left( \frac{8LF_y}{d} - F_x \right)$ $\sigma'_b = -\frac{1.273}{d^2} \left( \frac{8LF_y}{d} + F_x \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

**(2) Circular Cantilever Beam in Direct Tension and Bending:**

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1.273}{d^2} \left( F_x + \frac{8LF_y}{d} \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( F_x - \frac{8LF_y}{d} \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

**(3) Rectangular Cantilever Beam in Direct Compression and Bending:**

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1}{bh} \left( \frac{6LF_y}{h} - F_x \right)$ $\sigma'_b = -\frac{1}{bh} \left( \frac{6LF_y}{h} + F_x \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

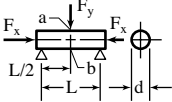

**(4) Rectangular Cantilever Beam in Direct Tension and Bending:**

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1}{bh} \left( F_x + \frac{6LF_y}{h} \right)$ $\sigma'_b = \frac{1}{bh} \left( F_x - \frac{6LF_y}{h} \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

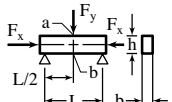

**(5) Circular Beam or Shaft in Direct Compression and Bending:**

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = -\frac{1.273}{d^2} \left( \frac{2LF_y}{d} + F_x \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( \frac{2LF_y}{d} - F_x \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

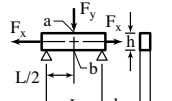

(6) *Circular Beam or Shaft in Direct Tension and Bending:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1.273}{d^2} \left( F_x - \frac{2LF_y}{d} \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( F_x + \frac{2LF_y}{d} \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

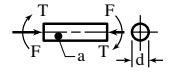

(7) *Rectangular Beam or Shaft in Direct Compression and Bending:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = -\frac{1}{bh} \left( \frac{3LF_y}{2h} + F_x \right)$ $\sigma'_b = \frac{1}{bh} \left( -\frac{3LF_y}{2h} - F_x \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

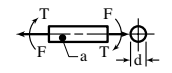

(8) *Rectangular Beam or Shaft in Direct Tension and Bending:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1}{bh} \left( F_x - \frac{3LF_y}{2h} \right)$ $\sigma'_b = \frac{1}{bh} \left( F_x + \frac{3LF_y}{2h} \right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

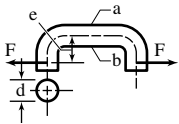

(9) *Circular Shaft in Direct Compression and Torsion:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
 <p>a anywhere on surface</p>	$\sigma'_a = -\frac{0.637}{d^2} \left[ F \pm \sqrt{F^2 + \left( \frac{8T}{d} \right)^2} \right]$	$\tau'_a = -\frac{0.637}{d^2} \sqrt{F^2 + \left( \frac{8T}{d} \right)^2}$

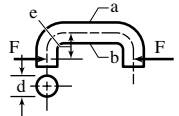

(10) *Circular Shaft in Direct Tension and Torsion:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
 <p>a anywhere on surface</p>	$\sigma'_a = \frac{0.637}{d^2} \left[ F \pm \sqrt{F^2 + \left( \frac{8T}{d} \right)^2} \right]$	$\tau'_a = \frac{0.637}{d^2} \sqrt{F^2 + \left( \frac{8T}{d} \right)^2}$

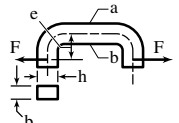

(11) *Offset Link, Circular Cross Section, in Direct Tension:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1.273F}{d^2} \left(1 - \frac{8e}{d}\right)$ $\sigma'_b = \frac{1.273F}{d^2} \left(1 + \frac{8e}{d}\right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

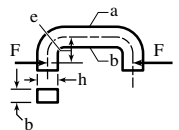

(12) *Offset Link, Circular Cross Section, in Direct Compression:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{1.273F}{d^2} \left(\frac{8e}{d} - 1\right)$ $\sigma'_b = -\frac{1.273F}{d^2} \left(\frac{8e}{d} + 1\right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

(13) *Offset Link, Rectangular Section, in Direct Tension:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{F}{bh} \left(1 - \frac{6e}{h}\right)$ $\sigma'_b = \frac{F}{bh} \left(1 + \frac{6e}{h}\right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

(14) *Offset Link, Rectangular Section, in Direct Compression:*

Type of Beam and Loading	Maximum Nominal Tensile or Compressive Stress	Maximum Nominal Shear Stress
	$\sigma'_a = \frac{F}{bh} \left(\frac{6e}{h} - 1\right)$ $\sigma'_b = -\frac{F}{bh} \left(\frac{6e}{h} + 1\right)$	$\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$

**Formulas from the simple and combined stress tables, as well as tension and shear factors, can be applied without change in calculations using metric SI units. Stresses are given in N/m<sup>2</sup> or in N/mm<sup>2</sup>.**

**Three-Dimensional Stress.**—Three-dimensional or triaxial stress occurs in assemblies such as a shaft press-fitted into a gear bore, or in pipes and cylinders subjected to internal or external fluid pressure. Triaxial stress also occurs in two-dimensional stress problems if the loads produce normal stresses that are either both tensile or both compressive. In either case the calculated maximum shear stress, based on the corresponding two-dimensional theory, will be less than the true maximum value because of three-dimensional effects.

Fig. 12.  $x, y, z$ -Coordinate System Showing Positive Directions of Stresses

The von Mises effective tensile stress method can be used to evaluate three-dimensional stress failure of ductile materials. If stress analysis is based on the maximum-shear-stress theory of failure, the triaxial stress cubic equation is used first to calculate the three principal stresses; true maximum shear stress can then be determined. The following procedure provides the principal maximum normal tensile and compressive stresses and the true maximum shear stress at any point on a body subjected to any combination of loads. The basis for the procedure is the stress cubic equation

$$S^3 - AS^2 + BS - C = 0$$

in which:

$$A = S_x + S_y + S_z$$

$$B = S_x S_y + S_y S_z + S_z S_x - S_{xy}^2 - S_{yz}^2 - S_{zx}^2$$

$$C = S_x S_y S_z + 2S_{xy} S_{yz} S_{zx} - S_x S_{yz}^2 - S_y S_{zx}^2 - S_z S_{xy}^2$$

and  $S_x, S_y, S_z$ , etc. are as shown in Fig. 12.

The  $x, y, z$  coordinate system in Fig. 12 shows the positive directions of the normal and shear stress components on an elementary cube of material. Only six of the nine components shown are needed for the calculations: the normal stresses  $S_x, S_y$ , and  $S_z$  on three of the faces of the cube; and the three shear stresses  $S_{xy}, S_{yz}$ , and  $S_{zx}$ . The remaining three shear stresses are known because  $S_{yx} = S_{xy}$ ,  $S_{zy} = S_{yz}$ , and  $S_{xz} = S_{zx}$ . The normal stresses  $S_x, S_y$ , and  $S_z$  are shown as positive (tensile) stresses; the opposite direction is negative (compressive). The first subscript of each shear stress identifies the coordinate axis perpendicular to the plane of the shear stress; the second subscript identifies the axis to which the stress is parallel. Thus,  $S_{xy}$  is the shear stress in the  $yz$ -plane to which the  $x$ -axis is perpendicular, and the stress is parallel to the  $y$ -axis.

Step 1. Draw a diagram of the hardware to be analyzed, and show the applied loads  $P, T$ , and any others.

Step 2. For any point at which the stresses are to be analyzed, draw a coordinate diagram similar to Fig. 12 and show the magnitudes of the stresses resulting from the applied loads (these stresses may be calculated by using standard basic equations from strength of materials, and should include any stress concentration factors).

Step 3. Substitute the values of the six stresses  $S_x, S_y, S_z, S_{xy}, S_{yz}$ , and  $S_{zx}$ , including zero values, into the formulas for the quantities  $A$  through  $K$ . The quantities  $I, J$ , and  $K$  represent the principal normal stresses at the point analyzed. As a check, if the algebraic sum  $I + J + K$  equals  $A$ , within rounding errors, then the calculations up to this point should be correct.

$$\begin{aligned}
 D &= \frac{A^2}{3} - B & E &= \frac{AB}{3} - C - \frac{2A^3}{27} & F &= \sqrt{\frac{D^3}{27}} \\
 G &= \arccos\left(\frac{-E}{2F}\right) & H &= \sqrt{\frac{D}{3}} & I &= 2H \cos\left(\frac{G}{3}\right) + \frac{A}{3} \\
 J &= 2H \cos\left(\frac{G}{3} + 120^\circ\right) + \frac{A}{3} & & & K &= 2H \cos\left(\frac{G}{3} + 240^\circ\right) + \frac{A}{3}
 \end{aligned}$$

Step 4. Calculate the true maximum shear stress  $S_{s(\max)}$  using the formula

$$S_{s(\max)} = 0.5(S_{\text{large}} - S_{\text{small}})$$

in which  $S_{\text{large}}$  is equal to the algebraically largest of the calculated principal stresses  $I, J$ , or  $K$  and  $S_{\text{small}}$  is algebraically the smallest.

The maximum principal normal stresses and the maximum true shear stress calculated above may be used with any of the various theories of failure.

**Sample Calculations.**—The following examples illustrate some typical strength of materials calculations, using both English and metric SI units of measurement.

*Example 1(a):* A round bar made from SAE 1025 low carbon steel is to support a direct tension load of 50,000 lbs. Using a factor of safety of 4, and assuming that the stress concentration factor  $K = 1$ , a suitable standard diameter is to be determined. Calculations are to be based on a yield strength of 40,000 psi.

*Solution:* Because the factor of safety and strength of the material are known, the allowable working stress  $s_w$  may be calculated using Equation (1):  $40,000/4 = 10,000$  psi. The relationship between working stress  $s_w$  and nominal stress  $\sigma$  is given by Equation (2). Since  $K = 1$ ,  $\sigma = 10,000$  psi. Applying Equation (9) in the *Table of Simple Stresses* on page 216, the area of the bar can be solved for:  $A = 50,000/10,000$  or 5 square inches. The next largest standard diameter corresponding to this area is  $2\frac{9}{16}$  inches.

*Example 1(b):* A similar example to that given in Example 1(a), using metric SI units, is as follows. A round steel bar of 300 meganewtons/meter<sup>2</sup> yield strength is to withstand a direct tension of 200 kilonewtons. Using a safety factor of 4, and assuming that the stress concentration factor  $K = 1$ , a suitable diameter is to be determined.

Because the factor of safety and the strength of the material are known, the allowable working stress  $s_w$  may be calculated using Equation (1):  $300/4 = 75$  meganewtons/meter<sup>2</sup>. The relationship between working stress and nominal stress  $\sigma$  is given by Equation (2). Since  $K = 1$ ,  $\sigma = 75$  MN/m<sup>2</sup>. Applying Equation (9) in the *Table of Simple Stresses* on page 216, the area of the bar can be determined from:

$$A = \frac{200 \text{ kN}}{75 \text{ MN/m}^2} = \frac{200,000 \text{ N}}{75,000,000 \text{ N/m}^2} = 0.00267 \text{ m}^2$$

The diameter corresponding to this area is 0.058 meters, or approximately 0.06 m. Millimeters can be employed in the calculations in place of meters, provided the treatment is consistent throughout. In this instance the diameter would be 60 mm.

*Note:* If the tension in the bar is produced by hanging a mass of  $M$  kilograms from its end, the value is  $Mg$  newtons, where  $g$  = approximately 9.81 meters per second<sup>2</sup>.

*Example 2(a):* What would the total elongation of the bar in Example 1(a) be if its length were 60 inches? Applying Equation (18) on page 218,

$$e = \frac{50,000 \times 60}{5.157 \times 30,000,000} = 0.019 \text{ inch}$$

*Example 2(b):* What would be the total elongation of the bar in Example 1(b) if its length were 1.5 meters? The problem is solved by applying Equation (17) in which  $F = 200$  kilonewtons;  $L = 1.5$  meters;  $A = \pi(0.06)^2/4 = 0.00283 \text{ m}^2$ . Assuming a modulus of elasticity  $E$  of 200 giganewtons/meter<sup>2</sup>, then the calculation is:

$$e = \frac{200,000 \times 1.5}{0.00283 \times 200,000,000} = 0.000530 \text{ m}$$

The calculation is less unwieldy if carried out using millimeters in place of meters; then  $F = 200 \text{ kN}$ ;  $L = 1500 \text{ mm}$ ;  $A = 2830 \text{ mm}^2$ , and  $E = 200,000 \text{ N/mm}^2$ . Thus:

$$e = \frac{200,000 \times 1500}{2830 \times 200,000} = 0.530 \text{ mm}$$

*Example 3(a):* Determine the size for the section of a square bar which is to be held firmly at one end and is to support a load of 3000 pounds at the other end. The bar is to be 30 inches long and is to be made from SAE 1045 medium carbon steel with a yield point of 60,000 psi. A factor of safety of 3 and a stress concentration factor of 1.3 are to be used.

*Solution:* From Equation (1) the allowable working stress  $s_w = 60,000/3 = 20,000$  psi. The applicable equation relating working stress and nominal stress is Equation (2); hence,  $\sigma = 20,000/1.3 = 15,400$  psi. The member must be treated as a cantilever beam subject to a bending moment of  $30 \times 3000$  or 90,000 inch-pounds. Solving Equation (11) in the *Table of Simple Stresses* for section modulus:  $Z = 90,000/15,400 = 5.85 \text{ inch}^3$ . The section modulus for a square section with neutral axis equidistant from either side is  $a^3/6$ , where  $a$  is the dimension of the square, so  $a = \sqrt[3]{35.1} = 3.27$  inches. The bar size can be  $3\frac{3}{16}$  inches.

*Example 3(b):* A similar example to that given in Example 3(a), using metric SI units is as follows. Determine the size for the section of a square bar which is to be held firmly at one end and is to support a load of 1600 kilograms at the other end. The bar is to be 1 meter long and is to be made from steel with a yield strength of 500 newtons/mm<sup>2</sup>. A factor of safety of 3 and a stress concentration factor of 1.3 are to be used. The calculation can be performed using millimeters throughout.

*Solution:* From Equation (1) the allowable working stress  $s_w = 500 \text{ N/mm}^2/3 = 167 \text{ N/mm}^2$ . The formula relating working stress and nominal stress is Equation (2); hence  $\sigma = 167/1.3 = 128 \text{ N/mm}^2$ . Since a mass of 1600 kg equals a weight of 1600g newtons, where  $g = 9.81 \text{ meters/second}^2$ , the force acting on the bar is 15,700 newtons. The bending moment on the bar, which must be treated as a cantilever beam, is thus  $1000 \text{ mm} \times 15,700 \text{ N} = 15,700,000 \text{ N}\cdot\text{mm}$ . Solving Equation (11) in the *Table of Simple Stresses* for section modulus:  $Z = M/\sigma = 15,700,000/128 = 123,000 \text{ mm}^3$ . Since the section modulus for a square section with neutral axis equidistant from either side is  $a^3/6$ , where  $a$  is the dimension of the square,

$$a = \sqrt[3]{6 \times 123,000} = 90.4 \text{ mm}$$

*Example 4(a):* Find the working stress in a 2-inch diameter shaft through which a transverse hole  $\frac{1}{4}$  inch in diameter has been drilled. The shaft is subject to a torsional moment of 80,000 inch-pounds and is made from hardened steel so that the index of sensitivity  $q = 0.2$ .

*Solution:* The polar section modulus is calculated using the equation shown in the stress concentration curve for a Round Shaft in Torsion with Transverse Hole, Fig. 7, page 214.

$$\frac{J}{c} = Z_p = \frac{\pi \times 2^3}{16} - \frac{2^2}{4 \times 6} = 1.4 \text{ inches}^3$$

The nominal shear stress due to torsion loading is computed using Equation (16) in the *Table of Simple Stresses*:

$$\tau = \frac{80,000}{1.4} = 57,200 \text{ psi}$$

Referring to the previously mentioned stress concentration curve on page 214,  $K_t$  is 2.82 since  $d/D$  is 0.125. The stress concentration factor may now be calculated by means of Equation (8):  $K = 1 + 0.2(2.82 - 1) = 1.36$ . Working stress calculated with Equation (3) is  $s_w = 1.36 \times 57,200 = 77,800$  psi.

*Example 4(b):* A similar example to that given in Example 4(a), using metric SI units, is as follows. Find the working stress in a 50 mm diameter shaft through which a transverse hole 6 mm in diameter has been drilled. The shaft is subject to a torsional moment of 8000 N·m, and has an index of sensitivity of  $q = 0.2$ . If the calculation is made in millimeters, the torsional moment is 8,000,000 N·mm.

**Solution:** The polar section modulus is calculated using the equation shown in the stress concentration curve for a Round Shaft in Torsion with Transverse Hole, Fig. 7, page 214:

$$\frac{J}{c} = Z_p = \frac{\pi \times 50^3}{16} - \frac{6 \times 50^2}{6} = 24,544 - 2500 = 22,044 \text{ mm}^3$$

The nominal shear stress due to torsion loading is computed using Equation (16) in the Table of Simple Stresses:

$$\tau = \frac{8,000,000}{22,000} = 363 \frac{\text{N}}{\text{mm}^2} = 363 \text{ megapascals}$$

Referring to the previously mentioned stress concentration curve on page 214,  $K_t$  is 2.85, since  $a/d = 6/50 = 0.12$ . The stress concentration factor may now be calculated by means of Equation (8):  $K = 1 + 0.2(2.85 - 1) = 1.37$ . From Equation (3), working stress  $s_w = 1.37 \times 363 = 497 \text{ N/mm}^2 = 497 \text{ MPa}$ .

**Example 5(a):** For Case 3 in the Tables of Combined Stresses, calculate the least factor of safety for a 5052-H32 aluminum beam that is 10 inches long, 1 inch wide, and 2 inches high. Yield strengths are 23,000 psi tension; 21,000 psi compression; 13,000 psi shear. The stress concentration factor is 1.5;  $F_x$  is 600 lbs;  $F_y$  500 lbs.

**Solution:** From Tables of Combined Stresses, Case 3:

$$\sigma_b' = -\frac{1}{1 \times 2} \left( \frac{6 \times 10 \times 600}{2} + 500 \right) = -9250 \text{ psi (in compression)}$$

The other formulas for Case 3 give  $\sigma_a' = 8750$  psi (in tension);  $\tau_a' = 4375$  psi, and  $\tau_b' = 4625$  psi. Using Equation (4) for the nominal compressive stress of 9250 psi:  $S_w = 1.5 \times 9250 = 13,900$  psi. From Equation (1)  $f_s = 21,000/13,900 = 1.51$ . Applying Equations (1), (4) and (5) in appropriate fashion to the other calculated nominal stress values for tension and shear will show that the factor of safety of 1.51, governed by the compressive stress at  $b$  on the beam, is minimum.

**Example 5(b):** What maximum  $F$  can be applied in Case 3 if the aluminum beam is 200 mm long; 20 mm wide; 40 mm high;  $\theta = 30^\circ$ ;  $f_s = 2$ , governing for compression,  $K = 1.5$ , and  $S_m = 144 \text{ N/mm}^2$  for compression.

**Solution:** From Equation (1)  $S_w = -144 \text{ N/mm}^2$ . Therefore, from Equation (4),  $\sigma_b' = -72/1.5 = -48 \text{ N/mm}^2$ . Since  $F_x = F \cos 30^\circ = 0.866F$ , and  $F_y = F \sin 30^\circ = 0.5F$ :

$$-48 = -\frac{1}{20 \times 40} \left( 0.866F + \frac{6 \times 200 \times 0.5F}{40} \right) \quad F = 2420 \text{ N}$$

**Stresses and Deflections in a Loaded Ring.**—For thin rings, that is, rings in which the dimension  $d$  shown in the accompanying diagram is small compared with  $D$ , the maximum stress in the ring is due primarily to bending moments produced by the forces  $P$ . The maximum stress due to bending is:

$$S = \frac{PDd}{4\pi I} \quad (26)$$

For a ring of circular cross section where  $d$  is the diameter of the bar from which the ring is made,

$$S = \frac{1.621PD}{d^3} \quad \text{or} \quad P = \frac{0.617Sd^3}{D} \quad (27)$$

The increase in the vertical diameter of the ring due to load  $P$  is:

$$\text{Increase in vertical diameter} = \frac{0.0186PD^3}{EI} \text{ inches} \quad (28)$$

The *decrease* in the horizontal diameter will be about 92 percent of the increase in the vertical diameter given by **Formula (28)**. In the above formulas,  $P$  = load on ring in pounds;  $D$  = mean diameter of ring in inches;  $S$  = tensile stress in psi,  $I$  = moment of inertia of section in inches<sup>4</sup>; and  $E$  = modulus of elasticity of material in psi.

**Strength of Taper Pins.**—The mean diameter of taper pin required to safely transmit a known torque may be found from the formulas:

$$d = 1.13\sqrt{\frac{T}{DS}} \quad (29) \quad \text{and} \quad d = 283\sqrt{\frac{HP}{NDS}} \quad (30a)$$

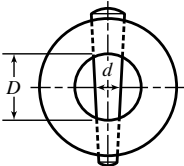

where  $T$  = torque in inch-pounds;  $S$  = safe unit stress in psi; HP = horsepower transmitted;  $N$  = number of revolutions per minute; and  $d$  and  $D$  denote dimensions shown in the figure.

**Formula (29)** can be used with metric SI units where  $d$  and  $D$  denote dimensions shown in the figure in millimeters;  $T$  = torque in newton-millimeters (N·mm); and  $S$  = safe unit stress in newtons per millimeter<sup>2</sup> (N/mm<sup>2</sup>). **Formula (30a)** is replaced by:

$$d = 110.3\sqrt{\frac{\text{Power}}{NDS}} \quad (30b)$$

where  $d$  and  $D$  denote dimensions shown in the figure in millimeters;  $S$  = safe unit stress in N/mm<sup>2</sup>;  $N$  = number of revolutions per minute, and Power = power transmitted in watts.

**Example 6(a):** A lever secured to a 2-inch round shaft by a steel tapered pin (dimension  $d = \frac{3}{8}$  inch) has a pull of 50 pounds at a 30-inch radius from shaft center. Find  $S$ , the unit working stress on the pin. By rearranging **Formula (29)**:

$$S = \frac{1.27T}{Dd^2} = \frac{1.27 \times 50 \times 30}{2 \times \left(\frac{3}{8}\right)^2} \cong 6770 \text{ psi}$$

6770 psi is a safe unit working stress for machine steel in shear.

Let  $P = 50$  pounds,  $R = 30$  inches,  $D = 2$  inches, and  $S = 6000$  pounds unit working stress. Using **Formula (29)** to find  $d$ :

$$d = 1.13\sqrt{\frac{T}{DS}} = 1.13\sqrt{\frac{50 \times 30}{2 \times 6000}} = 1.13\sqrt{\frac{1}{8}} = 0.4 \text{ inch}$$

**Example 6(b):** A similar example using SI units is as follows: A lever secured to a 50 mm round shaft by a steel tapered pin ( $d = 10$  mm) has a pull of 200 newtons at a radius of 800 mm. Find  $S$ , the working stress on the pin. By rearranging **Formula (29)**:

$$S = \frac{1.27T}{Dd^2} = \frac{1.27 \times 200 \times 800}{50 \times 10^2} = 40.6 \text{ N/mm}^2 = 40.6 \text{ megapascals}$$

If a shaft of 50 mm diameter is to transmit power of 12 kilowatts at a speed of 500 rpm, find the mean diameter of the pin for a material having a safe unit stress of 40 N/mm<sup>2</sup>. Using **Equation (30b)**:

$$\begin{aligned} d &= 110.3\sqrt{\frac{\text{Power}}{NDS}} \quad \text{then} \quad d = 110.3\sqrt{\frac{12,000}{500 \times 50 \times 40}} \\ &= 110.3 \times 0.1096 = 12.09 \text{ mm} \end{aligned}$$

## RIGID BODY PARAMETERS

## Center of Gravity

The center of gravity of a body, volume, area, or line is that point at which if the body, volume, area, or line were suspended it would be perfectly balanced in all positions. For symmetrical bodies of uniform material it is at the geometric center. The center of gravity of a uniform round rod, for example, is at the center of its diameter halfway along its length; the center of gravity of a sphere is at the center of the sphere. For solids, areas, and arcs that are not symmetrical, the determination of the center of gravity may be made experimentally or may be calculated by the use of formulas.

The tables that follow give such formulas for some of the more important shapes. For more complicated and unsymmetrical shapes the methods outlined on page 234 may be used.

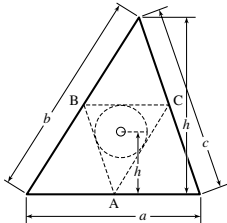

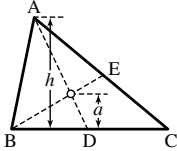

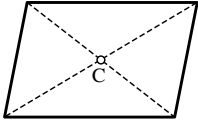

*Example:* A piece of wire is bent into the form of a semi-circular arc of 10-inch (25.4 cm) radius. How far from the center of the arc is the center of gravity located?

*Solution:* Accompanying the *Circular Arc* diagram on page 229 is a formula for the distance from the center of gravity of an arc to the center of the arc:  $a = 2r + \pi$ . Therefore,

$$a = \frac{2 \times 10}{3.1416} = 6.366 \text{ inches} \quad a = \frac{2 \times 25.4}{3.1416} = 16.17 \text{ cm}$$

## Formulas for Center of Gravity

*Triangle:*

	<p><i>Perimeter</i></p> <p>If <math>A</math>, <math>B</math> and <math>C</math> are the midpoints of the sides of the triangle, then the center of gravity is at the center of the circle that can be inscribed in triangle <math>ABC</math>. The distance <math>d</math> of the center of gravity from side <math>a</math> is:</p> $d = \frac{h(b+c)}{2(a+b+c)}$ <p>where <math>h</math> is the height perpendicular to <math>a</math>.</p>
	<p><i>Area</i></p> <p>The center of gravity is at the intersection of lines <math>AD</math> and <math>BE</math>, which bisect the sides <math>BC</math> and <math>AC</math>. The perpendicular distance from the center of gravity to any one of the sides is equal to one-third the height perpendicular to that side. Hence, <math>a = h \div 3</math>.</p>
<p><i>Perimeter or Area of a Parallelogram:</i></p>	
	<p>The center of gravity is at the intersection of the diagonals.</p>

Area of Trapezoid:

	<p>The center of gravity is on the line joining the midpoints of parallel lines <math>AB</math> and <math>DE</math>.</p> $c = \frac{h(a+2b)}{3(a+b)} \quad d = \frac{h(2a+b)}{3(a+b)}$ $e = \frac{a^2+ab+b^2}{3(a+b)}$ <p>The trapezoid can also be divided into two triangles. The center of gravity is at the intersection of the line joining the centers of gravity of the triangles and the middle line <math>FG</math>.</p>
--	---

Any Four-sided Figure:

	<p>Two cases are possible, as shown in the illustration. To find the center of gravity of the four-sided figure <math>ABCD</math>, each of the sides is divided into three equal parts. A line is then drawn through each pair of division points next to the points of intersection <math>A, B, C</math>, and <math>D</math> of the sides of the figure. These lines form a parallelogram <math>EFGH</math>; the intersection of the diagonals <math>EG</math> and <math>FH</math> locates center of gravity.</p>
--	--

Circular Arc:

	<p>The center of gravity is on the line that bisects the arc, at a distance <math>a = \frac{r \times c}{l} = \frac{c(c^2+4h^2)}{8lh}</math> from the center of the circle.</p> <p>For an arc equal to <math>1/2</math> the periphery:  <math>a = 2r \div \pi = 0.6366r</math></p> <p>For an arc equal to <math>1/4</math> of the periphery:  <math>a = 2r\sqrt{2} \div \pi = 0.9003r</math></p> <p>For an arc equal to <math>1/6</math> of the periphery:  <math>a = 3r \div \pi = 0.9549r</math></p>
--	---

	<p>An approximate formula is very nearly exact for all arcs less than <math>1/4</math> the periphery is:  <math>a = \frac{2}{3}h</math></p> <p>The error is only about 1 percent for a quarter circle, and it decreases for smaller arcs.</p>
--	---

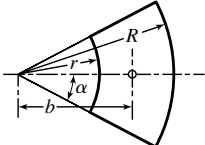

Circle Segment:

	<p>The distance of the center of gravity from the center of the circle is:</p> $b = \frac{c^3}{12A} = \frac{2}{3} \times \frac{r^3 \sin \alpha^3}{A}$ <p>in which <math>A</math> = area of segment.</p>
--	---

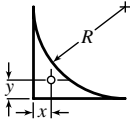

Circle Sector:

	<p>Distance <math>b</math> from center of gravity to center of circle is:</p> $b = \frac{2rc}{3l} = \frac{r^2c}{3A} = 38.197 \frac{r \sin \alpha}{\alpha}$ <p>in which <math>A</math> = area of sector, and <math>\alpha</math> is expressed in degrees.</p> <p>For the area of a half-circle:</p> $b = 4r \div 3\pi = 0.4244r$ <p>For the area of a quarter-circle:</p> $b = 4\sqrt{2} \times r \div 3\pi = 0.6002r$ <p>For the area of a sixth of a circle:</p> $b = 2r \div \pi = 0.6366r$
---	---

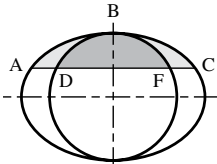

Part of Circle Ring:

	<p>Distance <math>b</math> from center of gravity to center of circle is:</p> $b = 38.197 \frac{(R^3 - r^3) \sin \alpha}{(R^2 - r^2) \alpha}$ <p>Angle <math>\alpha</math> is expressed in degrees.</p>
---	---

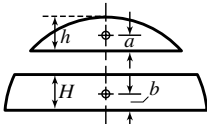

Spandrel or Fillet:

	<p>Area = <math>0.2146R^2</math>      <math>x = 0.2234R</math>  <math>y = 0.2234R</math></p>
---	--

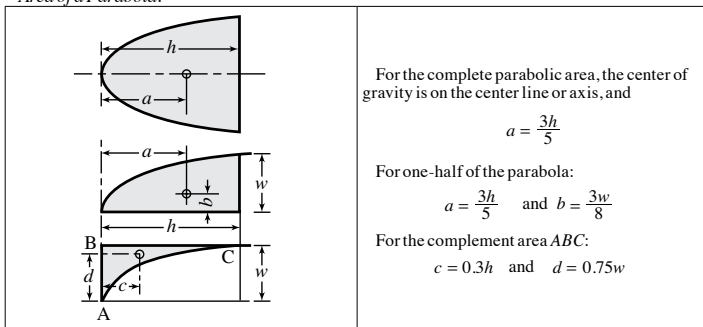

Segment of an Ellipse:

	<p>The center of gravity of an elliptical segment <math>ABC</math>, symmetrical about one of the axes, coincides with the center of gravity of the segment <math>DBF</math> of a circle, the diameter of which is equal to that axis of the ellipse about which the elliptical segment is symmetrical.</p>
--	--

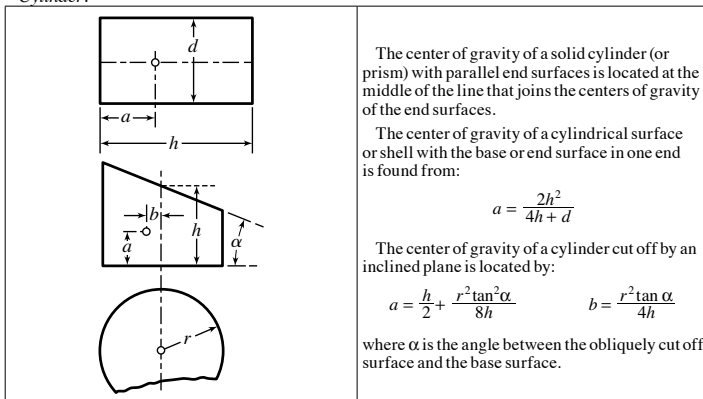

Spherical Surface of Segments and Zones of Spheres:

	<p>Distances <math>a</math> and <math>b</math> which determine the center of gravity are:</p> $a = \frac{h}{2} \qquad b = \frac{H}{2}$
---	--

## Area of a Parabola:

## Cylinder:

## Portion of Cylinder:

*Center of Gravity of Two Bodies:*

If the weights of the bodies are  $P$  and  $Q$ , and the distance between their centers of gravity is  $a$ , then:

$$b = \frac{Qa}{P+Q} \quad c = \frac{Pa}{P+Q}$$

*Pyramid:*

In a solid pyramid the center of gravity is located on the line joining the apex with the center of gravity of the base surface, at a distance from the base equal to one-quarter of the height; or  $a = \frac{1}{4}h$ .

The center of gravity of the triangular surfaces forming the pyramid is located on the line joining the apex with the center of gravity of the base surface at a distance from the base equal to one-third the height:  $a = \frac{1}{3}h$ .

*Frustum of Pyramid:*

The center of gravity is located on the line that joins the centers of gravity of the end surfaces. If  $A_1$  = area of base surface, and  $A_2$  area of top surface,

$$a = \frac{h(A_1 + 2\sqrt{A_1 \times A_2} + 3A_2)}{4(A_1 + \sqrt{A_1 \times A_2} + A_2)}$$

*Cone:*

The same rules apply as for the pyramid. For the solid cone:

$$a = \frac{1}{4}h$$

For the conical surface:

$$a = \frac{1}{3}h$$

*Frustum of Cone:*

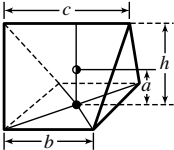

The same rules apply as for the frustum of a pyramid. For a solid frustum of a circular cone the formula below is also used:

$$a = \frac{h(R^2 + 2Rr + 3r^2)}{4(R^2 + Rr + r^2)}$$

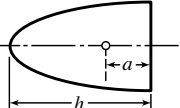

The location of the center of gravity of the conical surface of a frustum of a cone is determined by:

$$a = \frac{h(R + 2r)}{3(R + r)}$$

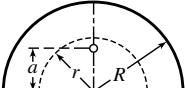

Wedge:

	<p>The center of gravity is on the line joining the center of gravity of the base with the middle point of the edge, and is located at:</p> $a = \frac{h(b+c)}{2(2b+c)}$
---	--

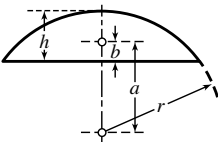

Paraboloid:

	<p>The center of gravity of a solid paraboloid of rotation is at:</p> $a = \frac{1}{3}h$
---	--

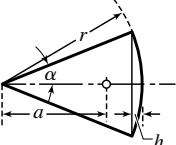

Half of a Hollow Sphere:

	<p>The center of gravity is located at:</p> $a = \frac{3(R^4 - r^4)}{8(R^3 - r^3)}$
---	---

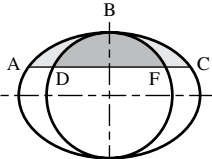

Spherical Segment:

	<p>The center of gravity of a solid segment is determined by:</p> $a = \frac{3(2r-h)^2}{4(3r-h)}$ $b = \frac{h(4r-h)}{4(3r-h)}$ <p>For a half-sphere, <math>a = b = \frac{3}{8}r</math></p>
---	---

Spherical Sector:

	<p>The center of gravity of a solid sector is at:</p> $a = \frac{3}{8}(1 + \cos \alpha)r = \frac{3}{8}(2r - h)$
--	---

Segment of Ellipsoid or Spheroid:

	<p>The center of gravity of a solid segment <math>ABC</math>, symmetrical about the axis of rotation, coincides with the center of gravity of the segment <math>DBF</math> of a sphere, the diameter of which is equal to the axis of rotation of the spheroid.</p>
---	---

**Center of Gravity of Figures of Any Outline.**—If the figure is symmetrical about a center line, as in Fig. 1, the center of gravity will be located on that line. To find the exact location on that line, the simplest method is by taking moments with reference to any convenient axis at right angles to this center line. Divide the area into geometrical figures the centers of gravity of which can be easily found. In the example shown, divide the figure into three rectangles KLMN, EFGH and OPRS. Call the areas of these rectangles  $A$ ,  $B$  and  $C$ , respectively, and find the center of gravity of each. Then select any convenient axis, such as X-X, at right angles to the center line Y-Y, and determine distances  $a$ ,  $b$  and  $c$ . The distance  $y$  of the center of gravity of the complete figure from the axis X-X is then found from the equation:

$$y = \frac{Aa + Bb + Cc}{A + B + C}$$

Fig. 1.

Fig. 2.

*Example 1:* Assume that the area  $A$  is 24 square inches,  $B$ , 14 square inches, and  $C$ , 16 square inches, and that  $a = 3$  inches,  $b = 7.5$  inches, and  $c = 12$  inches. Then:

$$y = \frac{24 \times 3 + 14 \times 7.5 + 16 \times 12}{24 + 14 + 16} = \frac{369}{54} = 6.83 \text{ inches}$$

If the figure whose center of gravity is to be found is not symmetrical about any axis, as in Fig. 2, then moments must be taken with relation to two axes X-X and Y-Y, centers of gravity of which can be easily found, the same as before. The center of gravity is determined by the equations:

$$x = \frac{Aa_1 + Bb_1 + Cc_1}{A + B + C} \quad y = \frac{Aa + Bb + Cc}{A + B + C}$$

*Example 2:* In Fig. 2, let  $A = 14 \text{ cm}^2$ ,  $B = 18 \text{ cm}^2$ , and  $C = 20 \text{ cm}^2$ . Let  $a = 3 \text{ cm}$ ,  $b = 7 \text{ cm}$ , and  $c = 11.5 \text{ cm}$ . Let  $a_1 = 6.5 \text{ cm}$ ,  $b_1 = 8.5 \text{ cm}$ , and  $c_1 = 7 \text{ cm}$ . Then:

$$x = \frac{14 \times 6.5 + 18 \times 8.5 + 20 \times 7}{14 + 18 + 20} = \frac{384}{52} = 7.38 \text{ cm}$$

$$y = \frac{14 \times 3 + 18 \times 7 + 20 \times 11.5}{14 + 18 + 20} = \frac{398}{52} = 7.65 \text{ cm}$$

In other words, the center of gravity is located at a distance of 7.65 cm from the axis X-X and 7.38 cm from the axis Y-Y.

### Radius of Gyration

The radius of gyration with reference to an axis is that distance from the axis at which the entire mass of a body may be considered as concentrated, the moment of inertia, meanwhile, remaining unchanged. If  $W$  is the weight of a body;  $J_M$  its moment of inertia with respect to some axis; and  $k_o$  the radius of gyration with respect to the same axis, then:

$$k_o = \sqrt{\frac{J_M g}{W}} \quad \text{and} \quad J_M = \frac{W k_o^2}{g}$$

When using metric SI units, the formulas are:

$$k_o = \sqrt{\frac{J_M}{M}} \quad \text{and} \quad J_M = M k_o^2$$

where  $k_o$  = the radius of gyration in meters,  $J_M$  = moment of inertia in kilogram-meter<sup>2</sup> (kg·m<sup>2</sup>), and  $M$  = mass in kilograms.

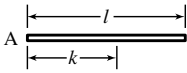

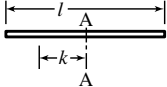

To find the radius of gyration of an area, such as for the cross section of a beam, divide the moment of inertia of the area by the area and extract the square root.

When the axis, the reference to which the radius of gyration is taken, passes through the center of gravity, the radius of gyration is the least possible and is called the *principal* radius of gyration. If  $k$  is the radius of gyration with respect to such an axis passing through the center of gravity of a body, then the radius of gyration  $k_o$  with respect to a parallel axis at a distance  $d$  from the gravity axis is given by:  $k_o = \sqrt{k^2 + d^2}$

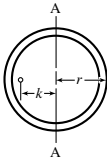

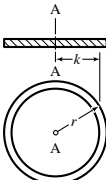

Tables of radii of gyration for various bodies and axes follows.

### Formulas for Radius of Gyration

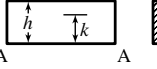

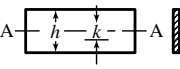

*Bar of Small Diameter:*

 <p>Axis at end</p> $k = 0.5773l$ $k^2 = \frac{1}{3}l^2$	 <p>Axis at center</p> $k = 0.2886l$ $k^2 = \frac{1}{12}l^2$
---	---

*Bar of Small Diameter Bent to Circular Shape:*

 <p>Axis, a diameter of the ring</p> $k = 0.7071r$ $k^2 = \frac{1}{2}r^2$	 <p>Axis through center of ring</p> $k = r$ $k^2 = r^2$
--	--

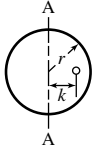

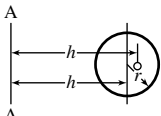

*Parallelogram (Thin Flat Plate):*

 <p>Axis at base</p> $k = 0.5773h$ $k^2 = \frac{1}{3}h^2$	 <p>Axis at mid-height</p> $k = 0.2886h$ $k^2 = \frac{1}{12}h^2$
--	---

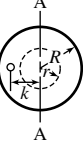

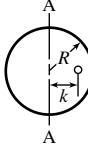

*Thin Circular Disk:**Thin, Flat, Circular Ring:**Cylinder:**Parallelepiped:*

**Rectangular Prism:****Thin Hollow Cylinder:****Hollow Cylinder:****Cone:****Frustum of Cone:**

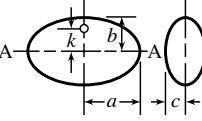

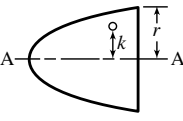

## Sphere:

 $k = 0.6325r$ $k^2 = \frac{2}{5}r^2$ <p>Axis its diameter</p>	 $k = \sqrt{a^2 + \frac{2}{5}r^2}$ $k^2 = a^2 + \frac{2}{5}r^2$ <p>Axis at a distance</p>
---	--

## Hollow Sphere and Thin Spherical Shell:

 $k = 0.6325\sqrt{\frac{R^5 - r^5}{R^3 - r^3}}$ $k^2 = \frac{2(R^5 - r^5)}{5(R^3 - r^3)}$ <p>Hollow Sphere Axis its diameter</p>	 $k = 0.8165r$ $k^2 = \frac{2}{3}r^2$ <p>Thin Spherical Shell</p>
---	--

---	--

**Center and Radius of Oscillation.**—If a body oscillates about a horizontal axis which does not pass through its center of gravity, there will be a point on the line drawn from the center of gravity, perpendicular to the axis, the motion of which will be the same as if the whole mass were concentrated at that point. This point is called the *center of oscillation*. The *radius of oscillation* is the distance between the center of oscillation and the point of suspension. In a straight line, or in a bar of small diameter suspended at one end and oscillating about it, the center of oscillation is at  $\frac{2}{3}$  the length of the rod from the end by which it is suspended.

When the vibrations are perpendicular to the plane of the figure, and the figure is suspended by the vertex of an angle or its uppermost point, the radius of oscillation of an isosceles triangle is equal to  $\frac{3}{4}$  of the height of the triangle; of a circle,  $\frac{5}{8}$  of the diameter; of a parabola,  $\frac{5}{7}$  of the height.

If the vibrations are in the plane of the figure, then the radius of oscillation of a circle equals  $\frac{3}{4}$  of the diameter; of a rectangle suspended at the vertex of one angle,  $\frac{1}{3}$  of the diagonal.

**Center of Percussion.**—For a body that moves without rotation, the resultant of all the forces acting on the body passes through the center of gravity. On the other hand, for a body that rotates about some *fixed axis*, the resultant of all the forces acting on it does not pass through the center of gravity of the body but through a point called the *center of*

*percussion.* The center of percussion is useful in determining the position of the resultant in mechanics problems involving angular acceleration of bodies about a fixed axis.

*Finding the Center of Percussion when Radius of Gyration and Location of Center of Gravity are Known:* The center of percussion lies on a line drawn through the center of rotation and the center of gravity. The distance from the axis of rotation to the center of percussion may be calculated from the following formula

$$q = k_o^2 \div r$$

in which  $q$  = distance from the axis of rotation to the center of percussion;  $k_o$  = radius of gyration of the body with respect to the axis of rotation; and  $r$  = distance from the axis of rotation to the center of gravity of the body.

### Moment of Inertia

An important property of areas and solid bodies is moment of inertia. Standard formulas are derived by multiplying elementary particles of area or mass by the squares of their distances from reference axes. Moments of inertia, therefore, depend on the location of reference axes. Values are minimum when these axes pass through the centers of gravity.

Three kinds of moments of inertia occur in engineering formulas:

1) *Moments of inertia of plane area,  $I$* , in which the axis is in the plane of the area are found in formulas for calculating deflections and stresses in beams. When dimensions are given in inches, the units of  $I$  are inches<sup>4</sup>. A table of formulas for calculating the  $I$  of common areas can be found beginning on page 241.

2) *Polar moments of inertia of plane areas,  $J$* , in which the axis is at right angles to the plane of the area, occur in formulas for the torsional strength of shafting. When dimensions are given in inches, the units of  $J$  are inches<sup>4</sup>. If moments of inertia,  $I$ , are known for a plane area with respect to both  $x$  and  $y$  axes, then the polar moment for the  $z$  axis may be calculated using the equation,  $J_z = I_x + I_y$

A table of formulas for calculating  $J$  for common areas can be found on page 252 in this section.

**When metric SI units are used, the formulas referred to in (1) and (2) above are valid if the dimensions are given consistently in meters or millimeters. If meters are used, the units of  $I$  and  $J$  are in meters<sup>4</sup>; if millimeters are used, these units are in millimeters<sup>4</sup>.**

3) *Polar moments of inertia of masses,  $J_M$* <sup>\*</sup>, appear in dynamics equations involving rotational motion.  $J_M$  bears the same relationship to angular acceleration as mass does to linear acceleration. If units are in the foot-pound-second system, the units of  $J_M$  are ft-lbs-sec<sup>2</sup> or slug-ft<sup>2</sup> (1 slug = 1 lb-sec<sup>2</sup>/ft). If units are in the inch-pound-second system, the units of  $J_M$  are inch-lbs-sec<sup>2</sup>.

**If metric SI values are used, the units of  $J_M$  are kilogram-meter squared (kg-m<sup>2</sup>).** Formulas for calculating  $J_M$  for various bodies are given beginning on page 253. If the polar moment of inertia  $J$  is known for the area of a body of constant cross section,  $J_M$  may be calculated using the equation,

$$J_M = \frac{\rho L}{g} J$$

where  $\rho$  is the density of the material,  $L$  the length of the part, and  $g$  the gravitational constant. If dimensions are in the foot-pound-second system,  $\rho$  is in lbs/ft<sup>3</sup>,  $L$  is in ft,  $g$  is

\* In some books the symbol  $I$  denotes the polar moment of inertia of masses;  $J_M$  is used in this Handbook to avoid confusion with moments of inertia of plane areas.

32.16 ft/sec<sup>2</sup>, and  $J$  is in ft<sup>4</sup>. If dimensions are in the inch-pound-second system,  $\rho$  is in lbs/in<sup>3</sup>,  $L$  is in inches,  $g$  is 386 in/sec<sup>2</sup>, and  $J$  is in inches<sup>4</sup>.

Using metric SI units, the above formula becomes  $J_M = \rho L J$ , where  $\rho$  = density in kilograms/meter<sup>3</sup>,  $L$  = length in meters, and  $J$  = polar moment of inertia in meters<sup>4</sup>. The units of  $J_M$  are kg·m<sup>2</sup>.

**Moment of Inertia of Built-Up Sections.**—The usual method of calculating the moment of inertia of a built-up section involves the calculations of the moment of inertia for each element of the section about its own neutral axis and the transferring of this moment of inertia to the previously found neutral axis of the whole built-up section. A much simpler method, called the tabular method, can be used in the case of any section that can be divided into rectangular elements bounded by lines parallel and perpendicular to the neutral axis. It is based upon the formula:  $I = b(h_1^3 - h^3)/3$  in which  $I$  = the moment of inertia about axis  $DE$ , Fig. 1, and  $b, h$  and  $h_1$  are dimensions as given in the same illustration.

The method may be illustrated by applying it to the section shown in Fig. 2, and for simplicity of calculation shown “massed” in Fig. 3. The calculation may then be tabulated as shown in the accompanying table. The distance from the axis  $DE$  to the neutral axis  $xx$  (which will be designated as  $d$ ) is found by dividing the sum of the geometrical moments by the area. The moment of inertia about the neutral axis is then found in the usual way by subtracting the area multiplied by  $d^2$  from the moment of inertia about the axis  $DE$ .

**Tabulated Calculation of Moment of Inertia**

Section	Breadth $b$	Height $h_1$	Area $b(h_1 - h)$	$h_1^2$	Moment $\frac{b(h_1^2 - h^2)}{2}$	$h_1^3$	$I$ about axis $DE$ $\frac{b(h_1^3 - h^3)}{3}$
A	1.500	0.125	0.187	0.016	0.012	0.002	0.001
B	0.531	0.625	0.266	0.391	0.100	0.244	0.043
C	0.219	1.500	0.191	2.250	0.203	3.375	0.228
			$\Sigma A = 0.644$		$\Sigma M = 0.315$		$\Sigma I_{DE} = 0.272$

The distance  $d$  from  $DE$ , the axis at the base of the configuration, to the neutral axis  $xx$  is:

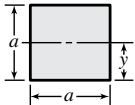

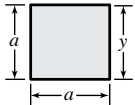

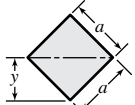

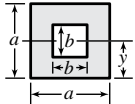

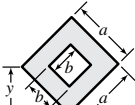

$$d = \frac{M}{A} = \frac{0.315}{0.644} = 0.49$$

The moment of inertia of the entire section with reference to the neutral axis  $xx$  is:

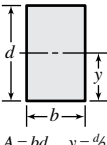

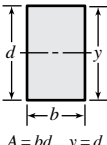

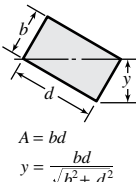

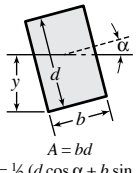

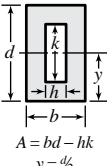

$$\begin{aligned} I_N &= I_{DE} - Ad^2 \\ &= 0.272 - 0.644 \times 0.49^2 \\ &= 0.117 \end{aligned}$$

**Formulas for Moments of Inertia, Section Moduli, etc.**—On the following pages are given formulas for moments of inertia and other properties of forty-two different cross sections. The formulas give the area of the section  $A$ , and the distance  $y$  from the neutral axis to the extreme fiber, for each example. Where the formulas for the section modulus and radius of gyration are very lengthy, the formula for the section modulus, for example, has been simply given as  $I \div y$ . The radius of gyration is sometimes given as  $\sqrt{I \div A}$  to save space.

### Moments of Inertia, Section Moduli, and Radii of Gyration

Section $A$ = area $y$ = distance from axis to extreme fiber	Moment of Inertia $I$	Section Modulus $Z = \frac{I}{y}$	Radius of Gyration $k = \sqrt{\frac{I}{A}}$
Square and Rectangular Sections			
 $A = a^2 \quad y = \frac{a}{2}$	$\frac{a^4}{12}$	$\frac{a^3}{6}$	$\frac{a}{\sqrt{12}} = 0.289a$

**Polar Area Moment of Inertia and Section Modulus.**—The *polar moment of inertia*  $J$  of a cross section with respect to a polar axis, that is, an axis at right angles to the plane of the cross section, is defined as the moment of inertia of the cross section with respect to the point of intersection of the axis and the plane. The polar moment of inertia may be found by taking the sum of the moments of inertia about two perpendicular axes lying in the plane of the cross section and passing through this point. Thus, for example, the polar moment of inertia of a circular or a square area with respect to a polar axis through the center of gravity is equal to twice the moment of inertia with respect to an axis lying in the plane of the cross section and passing through the center of gravity.

The polar moment of inertia with respect to a polar axis through the center of gravity is required for problems involving the torsional strength of shafts since this axis is usually the axis about which twisting of the shaft takes place.

The *polar section modulus* (also called section modulus of torsion)  $Z_p$  for circular sections may be found by dividing the polar moment of inertia  $J$  by the distance  $c$  from the center of gravity to the most remote fiber. This method may be used to find the *approximate* value of the polar section modulus of sections that are *nearly* round. For other than circular cross sections, however, the polar section modulus *does not* equal the polar moment of inertia divided by the distance  $c$ .

The accompanying table *Polar Moment of Inertia and Polar Section Modulus* on page 252 gives formulas for the polar section modulus for several different cross sections. The polar section modulus multiplied by the allowable torsional shearing stress gives the allowable twisting moment to which a shaft may be subjected; see [Formula \(7\)](#) on page 296.

**Polar Mass Moment of Inertia.**—Starting on page 253, formulas for mass moment of inertia\*  $J_M$  of various solids are given in a series of tables. The example that follows illustrates the derivation of  $J_M$  for one of the bodies given on page 253.

*Example, Polar Mass Moment of Inertia of a Hollow Circular Section:* Referring to the figure *Hollow Cylinder* on page 253, consider a strip of width  $dr$  on a hollow circular section whose inner radius is  $r$  and outer radius is  $R$ .

The mass of the strip =  $2\pi r \rho dr$ , where  $\rho$  is the density of material. In order to get the mass of an individual section, integrate the mass of the strip from  $r$  to  $R$ .

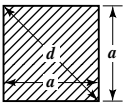

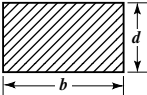

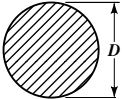

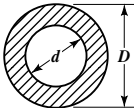

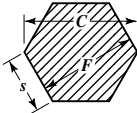

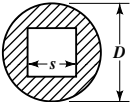

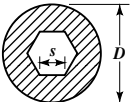

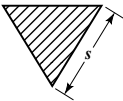

$$\begin{aligned} M &= \int_r^R 2\pi \rho r dr = 2\pi \rho \int_r^R r dr = 2\pi \rho \left[ \frac{r^2}{2} \right]_r^R \\ &= 2\pi \rho \left( \frac{R^2}{2} - \frac{r^2}{2} \right) = \pi \rho (R^2 - r^2) \end{aligned}$$

The second moment of the strip about the AA axis =  $2\pi r dr \rho r^2$ . To find the polar moment of inertia about the AA axis, integrate the 2nd moment from  $r$  to  $R$ .

$$\begin{aligned} J_M &= \int_r^R 2\pi r (dr) \rho r^2 = 2\pi \rho \int_r^R r^3 (dr) = 2\pi \rho \left[ \frac{r^4}{4} \right]_r^R \\ &= 2\pi \rho \left( \frac{R^4}{4} - \frac{r^4}{4} \right) = \frac{\pi \rho}{2} (R^2 - r^2)(R^2 + r^2) \\ &= \pi \rho (R^2 - r^2) \frac{(R^2 + r^2)}{2} = \frac{M(R^2 + r^2)}{2} \end{aligned}$$

\*In some books the symbol  $I$  denotes the polar moment of inertia of masses;  $J_M$  is used in this Handbook to avoid confusion with moments of inertia of plane areas.

**Polar Moment of Inertia and Polar Section Modulus**

Section	Polar Moment of Inertia, $J$	Polar Section Modulus, $Z_p$
	$\frac{a^4}{6} = 0.1667a^4$	$0.208a^3 = 0.074d^3$
	$\frac{bd(b^2 + d^2)}{12}$	$\frac{bd^2}{3 + 1.8\frac{d}{b}}$ ( $d$ is the shorter side)
	$\frac{\pi D^4}{32} = 0.098D^4$	$\frac{\pi D^3}{16} = 0.196D^3$
	$\frac{\pi}{32}(D^4 - d^4)$ $= 0.098(D^4 - d^4)$	$\frac{\pi}{16}\left(\frac{D^4 - d^4}{D}\right)$ $= 0.196\left(\frac{D^4 - d^4}{D}\right)$
	$\frac{5\sqrt{3}}{8}s^4 = 1.0825s^4$ $= 0.12F^4$	$0.20F^3$
	$\frac{\pi D^4}{32} - \frac{s^4}{6}$ $= 0.098D^4 - 0.167s^4$	$\frac{\pi D^3}{16} - \frac{s^4}{3D}$ $= 0.196D^3 - 0.333\frac{s^4}{D}$
	$\frac{\pi D^4}{32} - \frac{5\sqrt{3}}{8}s^4$ $= 0.098D^4 - 1.0825s^4$	$\frac{\pi D^3}{16} - \frac{5\sqrt{3}}{4D}s^4$ $= 0.196D^3 - 2.165\frac{s^4}{D}$
	$\frac{\sqrt{3}}{48}s^4 = 0.036s^4$	$\frac{s^3}{20} = 0.05s^3$

*Polar Section Modulus* for a shaft of given diameter can be obtained by multiplying its section modulus by 2. *Polar Moment of Inertia* can be obtained by multiplying its moment of inertia by 2.

**Formulas for Polar Moment of Inertia of Masses,  $J_M$**

*Prism:*

	<p>With reference to axis AA: <math>J_M = \frac{M}{12}(h^2 + b^2)</math></p> <p>With reference to axis BB: <math>J_M = M\left(\frac{l^2}{3} + \frac{h^2}{12}\right)</math></p>
--	--

*Cylinder:*

	<p>With reference to axis AA: <math>J_M = \frac{1}{2}Mr^2</math></p> <p>With reference to axis BB: <math>J_M = M\left(\frac{l^2}{3} + \frac{r^2}{4}\right)</math></p>
--	---

*Hollow Cylinder:*

	<p>With reference to axis AA: <math>J_M = \frac{1}{2}M(R^2 + r^2)</math></p> <p>With reference to axis BB:</p> $J_M = M\left(\frac{l^2}{3} + \frac{R^2 + r^2}{4}\right)$
--	--

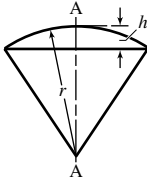

*Pyramid, Rectangular Base:*

	<p>With reference to axis AA: <math>J_M = \frac{M}{20}(a^2 + b^2)</math></p> <p>With reference to axis BB (through the center of gravity):</p> $J_M = M\left(\frac{3}{80}h^2 + \frac{b^2}{20}\right)$
--	---

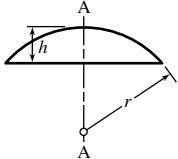

*Sphere:*

	<p>With reference to any axis through the center:</p> $J_M = \frac{2}{5}Mr^2$
--	---

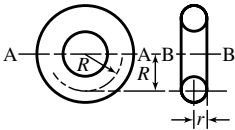

*Spherical Sector:*

	<p>With reference to axis AA: <math>J_M = \frac{M}{5}(3rh - h^2)</math></p>
---	---

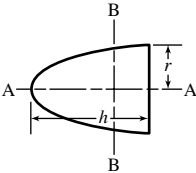

*Spherical Segment:*

	<p>Spherical Segment: With reference to axis AA:</p> $J_M = M\left(r^2 - \frac{3rh}{4} + \frac{3h^2}{20}\right) \frac{2h}{3r-h}$
---	--

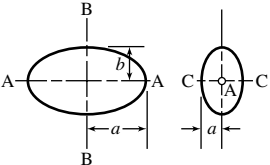

*Torus:*

	<p>With reference to axis AA: <math>J_M = M\left(\frac{R^2}{2} + \frac{5r^2}{8}\right)</math></p> <p>With reference to axis BB: <math>J_M = M\left(R^2 + \frac{3}{4}r^2\right)</math></p>
---	---

*Paraboloid:*

	<p>With reference to axis AA: <math>J_M = \frac{1}{3}Mr^2</math></p> <p>With reference to axis BB (through the center of gravity):</p> $J_M = M\left(\frac{r^2}{6} + \frac{h^2}{18}\right)$
--	---

	<p>With reference to axis AA: <math>J_M = \frac{M}{5}(b^2 + c^2)</math></p> <p>With reference to axis BB: <math>J_M = \frac{M}{5}(a^2 + c^2)</math></p> <p>With reference to axis CC: <math>J_M = \frac{M}{5}(a^2 + b^2)</math></p>
---	---

Cone:

	<p>With reference to axis AA: <math>J_M = \frac{3M}{10} r^2</math></p> <p>With reference to axis BB (through the center of gravity):</p> $J_M = \frac{3M}{20} \left( r^2 + \frac{h^2}{4} \right)$
--	---

Frustum of Cone:

	<p>With reference to axis AA: <math>J_M = \frac{3M(R^5 - r^5)}{10(R^3 - r^3)}</math></p>
--	--

Moments of Inertia of Complex Areas and Masses may be evaluated by the addition and subtraction of elementary areas and masses. For example, the accompanying figure shows a complex mass at (1); its mass polar moment of inertia can be determined by adding the moments of inertia of the bodies shown at (2) and (3), and subtracting that at (4). Thus,  $J_{M1} = J_{M2} + J_{M3} - J_{M4}$ . All of these moments of inertia are with respect to the axis of rotation  $z-z$ . Formulas for  $J_{M2}$  and  $J_{M3}$  can be obtained from the tables beginning on page 253. The moment of inertia for the body at (4) can be evaluated by using the following transfer-axis equation:  $J_{M4} = J_{M4}' + d^2M$ . The term  $J_{M4}'$  is the moment of inertia with respect to axis  $z'-z'$ ; it may be evaluated using the same equation that applies to  $J_{M2}$  where  $d$  is the distance between the  $z-z$  and the  $z'-z'$  axes, and  $M$  is the mass of the body (= weight in lbs ÷  $g$ ).

Moments of Inertia of Complex Masses

Similar calculations can be made when calculating  $I$  and  $J$  for complex areas using the appropriate transfer-axis equations  $I = I' + d^2A$  and  $J = J' + d^2A$ . The primed term,  $I'$  or  $J'$ , is with respect to the center of gravity of the corresponding area  $A$ ;  $d$  is the distance between the axis through the center of gravity and the axis to which  $I$  or  $J$  is referred.

## BEAMS

## Beam Calculations

**Reaction at the Supports.**—When a beam is loaded by vertical loads or forces, the sum of the reactions at the supports equals the sum of the loads. In a simple beam, when the loads are symmetrically placed with reference to the supports, or when the load is uniformly distributed, the reaction at each end will equal one-half the sum of the loads. When the loads are not symmetrically placed, the reaction at each support may be ascertained from the fact that the algebraic sum of the moments must equal zero. In the accompanying illustration, if moments are taken about the support to the left, then:  $R_2 \times 40 - 8000 \times 10 - 10,000 \times 16 - 20,000 \times 20 = 0$ ;  $R_2 = 16,000$  pounds. In the same way, moments taken about the support at the right give  $R_1 = 22,000$  pounds.

The sum of the reactions equals 38,000 pounds, which is also the sum of the loads. If part of the load is uniformly distributed over the beam, this part is first equally divided between the two supports, or the uniform load may be considered as concentrated at its center of gravity.

**If metric SI units are used for the calculations, distances may be expressed in meters or millimeters, provided the treatment is consistent, and loads in newtons. Note: If the load is given in kilograms, the value referred to is the mass. A mass of  $M$  kilograms has a weight (applies a force) of  $Mg$  newtons, where  $g =$  approximately  $9.81 \text{ m/s}^2$ .**

**Stresses and Deflections in Beams.**—On the following pages Table 1 gives an extensive list of formulas for stresses and deflections in beams, shafts, etc. It is assumed that all the dimensions are in inches, all loads in pounds, and all stresses in pounds per square inch. **The formulas are also valid using metric SI units, with all dimensions in millimeters, all loads in newtons, and stresses and moduli in newtons per millimeter<sup>2</sup> (N/mm<sup>2</sup>).** **Note: A load due to the weight of a mass of  $M$  kilograms is  $Mg$  newtons, where  $g =$  approximately  $9.81 \text{ m/s}^2$ .** In the tables:

$E =$  modulus of elasticity of the material

$I =$  moment of inertia of the cross section of the beam

$Z =$  section modulus of the cross section of the beam  $= I \div$  distance from neutral axis to extreme fiber

$W =$  load on beam

$s =$  stress in extreme fiber, or maximum stress in the cross section considered, due to load  $W$ . A positive value of  $s$  denotes tension in the upper fibers and compression in the lower ones (as in a cantilever). A negative value of  $s$  denotes the reverse (as in a beam supported at the ends). The greatest safe load is that value of  $W$  which causes a maximum stress equal to, but not exceeding, the greatest safe value of  $s$

$y =$  deflection measured from the position occupied if the load causing the deflection were removed. A positive value of  $y$  denotes deflection below this position; a negative value, deflection upward

$u, v, w, x =$  variable distances along the beam from a given support to any point

 <p>Total Load on Each Span, <math>W</math></p>	$s = \frac{W(l-x)}{2ZI} \left( \frac{1}{4}l - x \right)$	Maximum stress at point A, $\frac{WL}{8Z}$ Stress is zero at $x = \frac{1}{2}l$ Greatest negative stress is at $x = \frac{3}{8}l$ and is, $-\frac{9}{128} \frac{WL}{Z}$	$y = \frac{Wx^2(l-x)}{48EI}(3l-2x)$	Maximum deflection is at $x = 0.5785l$ , and is $\frac{WL^3}{185EI}$ Deflection at center of span, $\frac{WL^3}{192EI}$ Deflection at point of greatest negative stress, at $x = \frac{3}{8}l$ is $\frac{WL^3}{187EI}$
Case 23. — Continuous Beam, with Two Equal Spans, Equal Loads at Center of Each				
	Between point A and load, $s = \frac{W}{16Z} (3l - 11x)$ Between point B and load, $s = -\frac{5}{16} \frac{WV}{Z}$	Maximum stress at point A, $\frac{3}{16} \frac{WL}{Z}$ Stress is zero at $x = \frac{11}{11}l$ Greatest negative stress at center of span, $-\frac{5}{32} \frac{WL}{Z}$	Between point A and load, $y = \frac{Wx^2}{96EI} (9l - 11x)$ Between point B and load, $y = \frac{WV}{96EI} (3l^2 - 5V^2)$	Maximum deflection is at $v = 0.4472l$ , and is $\frac{WL^3}{107.33EI}$ Deflection at load, $\frac{7}{768} \frac{WL^3}{EI}$

**Table 1. (Continued) Stresses and Deflections in Beams**

Type of Beam	Stresses		Deflections	
	General Formula for Stress at any Point	Stresses at Critical Points	General Formula for Deflection at any Point <sup>a</sup>	Deflections at Critical Points <sup>a</sup>
Case 24. — Continuous Beam, with Two Unequal Spans, Unequal Loads at any Point of Each				
	Between $R_1$ and $W_1$ , $s = -\frac{W_1 r_1}{Z}$	Stress at load $W_1$ , $-\frac{a_1 r_1}{Z}$	Between $R_1$ and $W_1$ , $y = \frac{w}{6EI} \left\{ (l_1 - w)(l_1 + w)r_1 - \frac{W_1 b_1^3}{l_1} \right\}$	Deflection at load $W_1$ , $\frac{a_1 b_1}{6EI l_1} \left[ 2a_1 b_1 W_1 - m(l_1 + a_1) \right]$
	Between $R$ and $W_1$ , $s =$ $\frac{1}{l_1 Z} [m(l_1 - u) - W_1 a_1 u]$	Stress at support $R$ , $\frac{m}{Z}$	Between $R$ and $W_1$ , $y = \frac{u}{6EI l_1} [W_1 a_1 b_1 (l_1 + a_1) - W_1 a_1 u^2 - m(2l_1 - u)(l_1 - u)]$	Deflection at load $W_2$ , $\frac{a_2 b_2}{6EI l_2} \left[ 2a_2 b_2 W_2 - m(l_2 + a_2) \right]$
Between $R$ and $W_2$ , $s =$ $\frac{1}{l_2 Z} [m(l_2 - x) - W_2 a_2 x]$	Stress at load $W_2$ , $-\frac{a_2 r_2}{Z}$	Between $R$ and $W_2$ , $y = \frac{x}{6EI l_2} [W_2 a_2 b_2 (l_2 + a_2) - W_2 a_2 x^2 - m(2l_2 - x)(l_2 - x)]$	This case is so complicated that convenient general expressions for the maximum deflections cannot be obtained.	
Between $R_2$ and $W_2$ , $s = -\frac{v r_2}{Z}$	The greatest of these is the maximum stress.	Between $R_2$ and $W_2$ , $y = \frac{v}{6EI} \left\{ (l_2 - v)(l_2 + v)r_2 - \frac{W_2 b_2^3}{l_2} \right\}$		

<sup>a</sup>The deflections apply only to cases where the cross section of the beam is constant for its entire length.

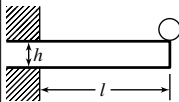

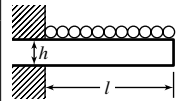

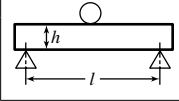

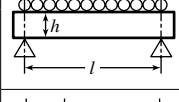

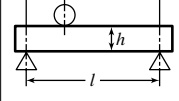

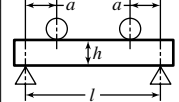

In the diagrammatical illustrations of the beams and their loading, the values indicated near, but below, the supports are the “reactions” or upward forces at the supports. For Cases 1 to 12, inclusive, the reactions, as well as the formulas for the stresses, are the same whether the beam is of constant or variable cross section. For the other cases, the reactions and the stresses given are for constant cross section beams only.

The bending moment at any point in inch-pounds (newton-meters if metric units are used) is  $s \times Z$  and can be found by omitting the divisor  $Z$  in the formula for the stress given in the tables. A positive value of the bending moment denotes tension in the upper fibers and compression in the lower ones. A negative value denotes the reverse. The value of  $W$  corresponding to a given stress is found by transposition of the formula. For example, in Case 1, the stress at the critical point is  $s = -Wl \div 8Z$ . From this formula we find  $W = -8Zs \div l$ . Of course, the negative sign of  $W$  may be ignored.

In Table 1, if there are several kinds of loads, as, for instance, a uniform load and a load at any point, or separate loads at different points, the total stress and the total deflection at any point is found by adding together the various stresses or deflections at the point considered due to each load acting by itself. If the stress or deflection due to any one of the loads is negative, it must be subtracted instead of added.

Table 2a and Table 2b give expressions for determining dimensions of rectangular and round beams in terms of beam stresses and load.

**Table 2a. Rectangular Solid Beams**

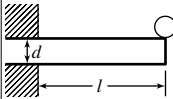

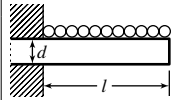

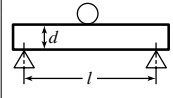

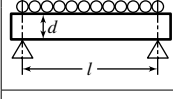

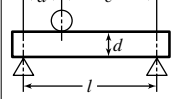

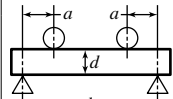

Style of Loading and Support	Breadth of Beam, $b$ inch (mm)	Beam Height, $h$ inch (mm)	Stress in Extreme Fibers, $f$ lb/in <sup>2</sup> (N/mm <sup>2</sup> )	Beam Length, $l$ inch (mm)	Total Load, $W$ lb (N)
Beam fixed at one end, loaded at the other					
	$\frac{6IW}{fh^2} = b$	$\sqrt{\frac{6IW}{bf}} = h$	$\frac{6IW}{bh^2} = f$	$\frac{bfh^2}{6W} = l$	$\frac{bfh^2}{6l} = W$
Beam fixed at one end, uniformly loaded					
	$\frac{3IW}{fh^2} = b$	$\sqrt{\frac{3IW}{bf}} = h$	$\frac{3IW}{bh^2} = f$	$\frac{bfh^2}{3W} = l$	$\frac{bfh^2}{3l} = W$
Beam supported at both ends, single load in middle					
	$\frac{3IW}{2fh^2} = b$	$\sqrt{\frac{3IW}{2bf}} = h$	$\frac{3IW}{2bh^2} = f$	$\frac{2bfh^2}{3W} = l$	$\frac{2bfh^2}{3l} = W$
Beam supported at both ends, uniformly loaded					
	$\frac{3IW}{4fh^2} = b$	$\sqrt{\frac{3IW}{4bf}} = h$	$\frac{3IW}{4bh^2} = f$	$\frac{4bfh^2}{3W} = l$	$\frac{4bfh^2}{3l} = W$
Beam supported at both ends, single unsymmetrical load					
	$\frac{6Wac}{fh^2l} = b$	$\sqrt{\frac{6Wac}{bfl}} = h$	$\frac{6Wac}{bh^2l} = f$	$a + c = l$	$\frac{bh^2fl}{6ac} = W$
Beam supported at both ends, two symmetrical loads					
	$\frac{3Wa}{fh^2} = b$	$\sqrt{\frac{3Wa}{bf}} = h$	$\frac{3Wa}{bh^2} = f$	$l$ , any length $\frac{bh^2f}{3W} = a$	$\frac{bh^2f}{3a} = W$

**Deflection of Beam Uniformly Loaded for Part of Its Length.**—In the following formulas, lengths are in inches, weights in pounds.  $W$  = total load;  $L$  = total length between supports;  $E$  = modulus of elasticity;  $I$  = moment of inertia of beam section;  $a$  = fraction of length of beam at each end, that is not loaded =  $b \div L$ ; and  $f$  = deflection.

$$f = \frac{WL^3}{384EI(1 - 2a)}(5 - 24a^2 + 16a^4)$$

The expression for maximum bending moment is:  $M_{\max} = \frac{1}{8}WL(1 + 2a)$ .

Table 2b. Round Solid Beams

Style of Loading and Support	Diameter of Beam, $d$ inch (mm)	Stress in Extreme Fibers, $f$ lb/in <sup>2</sup> (N/mm <sup>2</sup> )	Beam Length, $l$ inch (mm)	Total Load, $W$ lb (N)
	Beam fixed at one end, loaded at the other			
	$\sqrt[3]{\frac{10.18W}{f}} = d$	$\frac{10.18W}{d^3} = f$	$\frac{d^3 f}{10.18W} = l$	$\frac{d^3 f}{10.18l} = W$
	Beam fixed at one end, uniformly loaded			
	$\sqrt[3]{\frac{5.092Wl}{f}} = d$	$\frac{5.092Wl}{d^3} = f$	$\frac{d^3 f}{5.092W} = l$	$\frac{d^3 f}{5.092l} = W$
	Beam supported at both ends, single load in middle			
	$\sqrt[3]{\frac{2.546Wl}{f}} = d$	$\frac{2.546Wl}{d^3} = f$	$\frac{d^3 f}{2.546W} = l$	$\frac{d^3 f}{2.546l} = W$
	Beam supported at both ends, uniformly loaded			
	$\sqrt[3]{\frac{1.273Wl}{f}} = d$	$\frac{1.273Wl}{d^3} = f$	$\frac{d^3 f}{1.273W} = l$	$\frac{d^3 f}{1.273l} = W$
	Beam supported at both ends, single unsymmetrical load			
	$\sqrt[3]{\frac{10.18Wac}{fl}} = d$	$\frac{10.18Wac}{d^3 l} = f$	$a + c = l$	$\frac{d^3 fl}{10.18ac} = W$
	Beam supported at both ends, two symmetrical loads			
	$\sqrt[3]{\frac{5.092Wa}{f}} = d$	$\frac{5.092Wa}{d^3} = f$	$l, \text{ any length}$ $\frac{d^3 f}{5.092W} = a$	$\frac{d^3 f}{5.092a} = W$

These formulas apply to simple beams resting on supports at the ends.

If the formulas are used with metric SI units,  $W$  = total load in newtons (N);  $L$  = total length between supports in millimeters;  $E$  = modulus of elasticity in newtons per millimeter<sup>2</sup> (N/mm<sup>2</sup>);  $I$  = moment of inertia of beam section in mm<sup>4</sup>;  $a$  = fraction of length of beam at each end, that is not loaded =  $b \div L$ ; and  $f$  = deflection in mm. The bending moment  $M_{\max}$  is in newton-millimeters (N-mm).

*Note:* A load due to the weight of a mass of  $M$  kilograms is  $Mg$  newtons, where  $g$  = approximately 9.81 m/s<sup>2</sup>.

**Bending Stress Due to an Oblique Transverse Force.**—The following illustration shows a beam and a channel being subjected to a transverse force acting at an angle  $\phi$  to the center of gravity. To find the bending stress, the moments of inertia  $I$  around axes 3-3 and 4-4 are computed from the following equations:  $I_3 = I_x \sin^2 \phi + I_y \cos^2 \phi$ , and  $I_4 = I_x \cos^2 \phi + I_y \sin^2 \phi$ .

The computed bending stress  $f_b$  is then found from  $f_b = M \left( \frac{y}{I_x} \sin \phi + \frac{x}{I_y} \cos \phi \right)$  where  $M$  is the bending moment due to force  $F$ .

**Beams of Uniform Strength Throughout Their Length.**—The bending moment in a beam is generally not uniform throughout its length, but varies. Therefore, a beam of uniform cross section which is made strong enough at its most strained section will have an excess of material at every other section. Sometimes it may be desirable to have the cross section uniform, but at other times the metal can be more advantageously distributed if the beam is so designed that its cross section varies from point to point, so that it is at every point just great enough to take care of the bending stresses at that point. Table 3a and Table 3b are given showing beams in which the load is applied in different ways and which are supported by different methods, and the shape of the beam required for uniform strength is indicated. It should be noted that the shape given is the theoretical shape required to resist bending only. It is apparent that sufficient cross section of beam must also be added either at the points of support (in beams supported at both ends), or at the point of application of the load (in beams loaded at one end), to take care of the vertical shear.

It should be noted that the theoretical shapes of the beams given in the two tables that follow are based on the stated assumptions of uniformity of width or depth of cross section, and unless these are observed in the design the theoretical outlines do not apply without modifications. For example, in a cantilever with the load at one end, the outline is a parabola only when the width of the beam is uniform. It is not correct to use a strictly parabolic shape when the thickness is not uniform, as, for instance, when the beam is made of an I- or T-section. In such cases, some modification may be necessary; but it is evident that whatever the shape adopted, the correct depth of the section can be obtained by an investigation of the bending moment and the shearing load at a number of points, and then a line can be drawn through the points thus ascertained, which will provide for a beam of practically uniform strength whether the cross section be of uniform width or not.

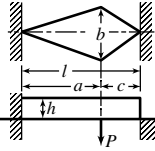

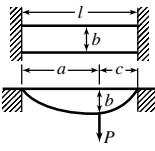

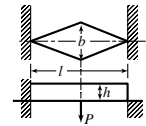

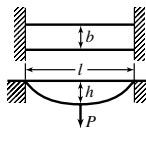

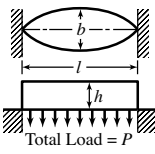

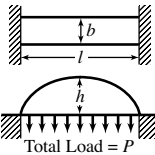

Table 3a. Beams of Uniform Strength Throughout Their Length

Type of Beam	Description	Formula <sup>a</sup>
	Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam-shape, parabola with vertex at loaded end.	$P = \frac{Sbh^2}{6l}$
	Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam, one-half of a parabola with vertex at loaded end. Beam may be reversed so that upper edge is parabolic.	$P = \frac{Sbh^2}{6l}$
	Load at one end. Depth of beam uniform. Width of beam decreasing towards loaded end. Outline of beam triangular, with apex at loaded end.	$P = \frac{Sbh^2}{6l}$
	Beam of <i>approximately</i> uniform strength. Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end, but not tapering to a sharp point.	$P = \frac{Sbh^2}{6l}$
	Uniformly distributed load. Width of beam uniform. Depth of beam decreasing towards outer end. Outline of beam, right-angle triangle. Total Load = $P$	$P = \frac{Sbh^2}{3l}$
	Uniformly distributed load. Depth of beam uniform. Width of beam gradually decreasing towards outer end. Outline of beam is formed by two parabolas which are tangent to each other at their vertexes at the outer end of the beam. Total Load = $P$	$P = \frac{Sbh^2}{3l}$

<sup>a</sup>In the formulas,  $P$  = load in pounds;  $S$  = safe stress in lb/in<sup>2</sup>; and  $a, b, c, h,$  and  $l$  are in inches. If metric SI units are used,  $P$  is in newtons (N);  $S$  = safe stress in N/mm<sup>2</sup>; and  $a, b, c, h,$  and  $l$  are in millimeters.

**Table 3b. Beams of Uniform Strength Throughout Their Length**

Type of Beam	Description	Formula <sup>a</sup>
	<p>Beam supported at both ends. Load concentrated at any point. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.</p>	$P = \frac{Sbh^2l}{6ac}$
	<p>Beam supported at both ends. Load concentrated at any point. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam is formed by two parabolas with their vertexes at points of support.</p>	$P = \frac{Sbh^2l}{6ac}$
	<p>Beam supported at both ends. Load concentrated in the middle. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.</p>	$P = \frac{2Sbh^2}{3l}$
	<p>Beam supported at both ends. Load concentrated at center. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam, two parabolas with vertexes at points of support.</p>	$P = \frac{2Sbh^2}{3l}$
 <p>Total Load = P</p>	<p>Beam supported at both ends. Load uniformly distributed. Depth of beam uniform. Width of beam maximum at center. Outline of beam, two parabolas with vertexes at middle of beam.</p>	$P = \frac{4Sbh^2}{3l}$
 <p>Total Load = P</p>	<p>Beam supported at both ends. Load uniformly distributed. Width of beam uniform. Depth of beam maximum at center. Outline of beam one-half of an ellipse.</p>	$P = \frac{4Sbh^2}{3l}$

<sup>a</sup>For details of English and metric SI units used in the formulas, see footnote on page 271.

**Deflection as a Limiting Factor in Beam Design.**—For some applications, a beam must be stronger than required by the maximum load it is to support in order to prevent excessive deflection. Maximum allowable deflections vary widely for different classes of service, so a general formula for determining them cannot be given. When exceptionally stiff girders are required, one rule is to limit the deflection to 1 inch per 100 feet of span; hence, if  $l$  = length of span in inches, deflection =  $l \div 1200$ . According to another formula, deflection limit =  $l \div 360$  where beams are adjacent to materials like plaster, which would be broken by excessive beam deflection. Some machine parts of the beam type must be very rigid to maintain alignment under load. For example, the deflection of a punch press column may be limited to 0.010 inch or less. These examples merely illustrate variations in practice. It is impracticable to give general formulas for determining the allowable deflection in any specific application because the allowable amount depends on the conditions governing each class of work.

*Procedure in Designing for Deflection:* Assume that a deflection equal to  $l \div 1200$  is to be the limiting factor in selecting a wide-flange (W-shape) beam having a span length of 144 inches. Supports are at both ends and load at center is 15,000 pounds. Deflection  $y$  is to be limited to  $144 \div 1200 = 0.12$  inch. According to the formula on page 257 (Case 2), in which  $W$  = load on beam in pounds,  $l$  = length of span in inches,  $E$  = modulus of elasticity of material in psi, and  $I$  = moment of inertia of cross section in inches<sup>4</sup>:

$$\text{Deflection } y = \frac{Wl^3}{48EI} \text{ hence, } I = \frac{Wl^3}{48yE} = \frac{15,000 \times 144^3}{48 \times 0.12 \times 29,000,000} = 268.1$$

A structural wide-flange beam, see *Steel Wide-Flange Sections* on page 2694, having a depth of 12 inches and weighing 35 pounds per foot has a moment of inertia  $I$  of 285 and a section modulus ( $Z$  or  $S$ ) of 45.6. Checking now for maximum stress  $s$  (Case 2, page 257):

$$s = \frac{Wl}{4Z} = \frac{15,000 \times 144}{4 \times 46.0} = 11,842 \text{ lbs/in}^2$$

Although deflection is the limiting factor in this case, the maximum stress is checked to make sure that it is within the allowable limit. As the limiting deflection is decreased, for a given load and length of span, the beam strength and rigidity must be increased, and, consequently, the maximum stress is decreased. Thus, in the preceding example, if the maximum deflection is 0.08 inch instead of 0.12 inch, then the calculated value for the moment of inertia  $I$  will be 402; hence a W 12  $\times$  53 beam having an  $I$  value of 426 could be used (nearest value above 402). The maximum stress then would be reduced to 7640 lb/in<sup>2</sup> and the calculated deflection is 0.076 inch.

A similar example using metric SI units is as follows. Assume that a deflection equal to  $l \div 1000$  mm is to be the limiting factor in selecting a W-beam having a span length of 5 meters. Supports are at both ends and the load at the center is 30 kN. Deflection  $y$  is to be limited to  $5000 \div 1000 = 5$  mm. The formula on page 257 (Case 2) is applied, and  $W$  = load on beam in N;  $l$  = length of span in mm;  $E$  = modulus of elasticity (assume 200,000 N/mm<sup>2</sup> in this example); and  $I$  = moment of inertia of cross section in mm<sup>4</sup>. Thus,

$$\text{Deflection } y = \frac{Wl^3}{48EI}$$

hence

$$I = \frac{Wl^3}{48yE} = \frac{30,000 \times 5000^3}{48 \times 5 \times 200,000} = 78,125,000 \text{ mm}^4$$

Although deflection is the limiting factor in this case, the maximum stress is checked to make sure that it is within the allowable limit using the formula from page 257 (Case 2):

$$s = \frac{Wl}{4Z}$$

The units of  $s$  are newtons per square millimeter;  $W$  is the load in newtons;  $l$  is the length in mm; and  $Z$  = section modulus of the cross section of the beam =  $I \div$  distance in mm from neutral axis to extreme fiber.

**Curved Beams.**—The formula  $S = Mc/I$  used to compute stresses due to bending of beams is based on the assumption that the beams are straight before any loads are applied. In beams having initial curvature, however, the stresses may be considerably higher than predicted by the ordinary straight-beam formula because the effect of initial curvature is to shift the neutral axis of a curved member in from the gravity axis toward the center of curvature (the concave side of the beam). This shift in the position of the neutral axis causes an increase in the stress on the concave side of the beam and decreases the stress at the outside fibers.

Hooks, press frames, and other machine members which as a rule have a rather pronounced initial curvature may have a maximum stress at the inside fibers of up to about  $3\frac{1}{2}$  times that predicted by the ordinary straight-beam formula.

*Stress Correction Factors for Curved Beams:* A simple method for determining the maximum fiber stress due to bending of curved members consists of 1) calculating the maximum stress using the straight-beam formula  $S = Mc/I$ ; and; and 2) multiplying the calculated stress by a stress correction factor. Table 4 on page 275 gives stress correction factors for some of the common cross sections and proportions used in the design of curved members.

An example in the application of the method using English units of measurement is given at the bottom of the table. **A similar example using metric SI units is as follows: The fiber stresses of a curved rectangular beam are calculated as 40 newtons per millimeter<sup>2</sup>, using the straight beam formula,  $S = Mc/I$ . If the beam is 150 mm deep and its radius of curvature is 300 mm, what are the true stresses?  $R/c = 300/75 = 4$ . From Table 4 on page 275, the  $K$  factors corresponding to  $R/c = 4$  are 1.20 and 0.85. Thus, the inside fiber stress is  $40 \times 1.20 = 48 \text{ N/mm}^2 = 48 \text{ megapascals (MPa)}$ ; and the outside fiber stress is  $40 \times 0.85 = 34 \text{ N/mm}^2 = 34 \text{ MPa}$ .**

*Approximate Formula for Stress Correction Factor:* The stress correction factors given in Table 4 on page 275 were determined by Wilson and Quereau and published in the University of Illinois Engineering Experiment Station Circular No. 16, "A Simple Method of Determining Stress in Curved Flexural Members." In this same publication the authors indicate that the following empirical formula may be used to calculate the value of the stress correction factor for the *inside* fibers of sections not covered by the tabular data to within 5 percent accuracy, except in triangular sections where up to 10 percent deviation may be expected. However, for most engineering calculations, this formula should prove satisfactory for general use in determining the factor for the inside fibers.

$$K = 1.00 + 0.5 \frac{I}{bc^2} \left[ \frac{1}{R-c} + \frac{1}{R} \right]$$

(Use 1.05 instead of 0.5 in this formula for circular and elliptical sections.)

$I$  = moment of inertia of section about centroidal axis

$b$  = maximum width of section

$c$  = distance from centroidal axis to inside fiber, i.e., to the extreme fiber nearest the center of curvature

$R$  = radius of curvature of centroidal axis of beam

**Table 4. Values of Stress Correction Factor  $K$  for Various Curved Beam Sections**

<sup>a</sup> $y_0$  is the distance from the centroidal axis to the neutral axis of curved beams subjected to pure bending and is measured from the centroidal axis toward the center of curvature.

The accompanying diagram shows the dimensions of a clamp frame of rectangular cross section. Determine the maximum stress at points *A* and *B* due to a clamping force of 1000 pounds.

The cross-sectional area =  $2 \times 4 = 8$  square inches; the bending moment at section *AB* is  $1000(24 + 6 + 2) = 32,000$  inch pounds; the distance from the center of gravity of the section at *AB* to point *B* is  $c = 2$  inches; and using the formula on page 242, the moment of inertia of the section is  $2 \times (4)^3 / 12 = 10.667$  inches<sup>4</sup>.

Using the straight-beam formula, page 274, the stress at points *A* and *B* due to the bending moment is:

$$S = \frac{Mc}{I} = \frac{32,000 \times 2}{10.667} = 6000 \text{ psi}$$

The stress at *A* is a compressive stress of 6000 psi and that at *B* is a tensile stress of 6000 psi.

These values must be corrected to account for the curvature effect. In Table 4 on page 275 for  $R/c = (6 + 2)/2 = 4$ , the value of *K* is found to be 1.20 and 0.85 for points *B* and *A* respectively. Thus, the actual stress due to bending at point *B* is  $1.20 \times 6000 = 7200$  psi in tension, and the stress at point *A* is  $0.85 \times 6000 = 5100$  psi in compression.

To these stresses at *A* and *B* must be added, algebraically, the direct stress on section *AB* due to the 1000-pound clamping force. The direct stress on section *AB* will be a tensile stress equal to the clamping force divided by the section area. Thus  $1000 \div 8 = 125$  psi in tension.

The maximum unit stress at *A* is, therefore,  $5100 - 125 = 4975$  psi in compression, and the maximum unit stress at *B* is  $7200 + 125 = 7325$  psi in tension.

The following is a similar calculation using metric SI units, assuming that it is required to determine the maximum stress at points *A* and *B* due to clamping force of 4 kN acting on the frame. The frame cross section is 50 by 100 mm, the radius  $R = 200$  mm, and the length of the straight portions is 600 mm. Thus, the cross-sectional area =  $50 \times 100 = 5000$  mm<sup>2</sup>; the bending moment at *AB* is  $4000(600 + 200) = 3,200,000$  newton-millimeters; the distance from the center of gravity of the section at *AB* to point *B* is  $c = 50$  mm; and the moment of inertia of the section is (from the formula on page 242),  $50(100^3)/12 = 4,170,000$  mm<sup>4</sup>.

Using the straight-beam formula, page 274, the stress at points *A* and *B* due to the bending moment is:

$$\begin{aligned} s &= \frac{Mc}{I} = \frac{3,200,000 \times 50}{4,170,000} \\ &= 38.4 \text{ newtons per millimeter}^2 = 38.4 \text{ megapascals} \end{aligned}$$

The stress at *A* is a compressive stress of 38.4 N/mm<sup>2</sup>, while that at *B* is a tensile stress of 38.4 N/mm<sup>2</sup>. These values must be corrected to account for the curvature

effect. From the table on page 275, the  $K$  factors are 1.20 and 0.85 for points  $A$  and  $B$ , respectively, derived from  $R/c = 200/50 = 4$ . Thus, the actual stress due to bending at point  $B$  is  $1.20 \times 38.4 = 46.1 \text{ N/mm}^2$  (46.1 MPa) in tension; and the stress at point  $A$  is  $0.85 \times 38.4 = 32.6 \text{ N/mm}^2$  (32.6 MPa) in compression.

To these stresses at  $A$  and  $B$  must be added, algebraically, the direct stress at section  $AB$  due to the 4 kN clamping force. The direct stress on section  $AB$  will be a tensile stress equal to the clamping force divided by the section area. Thus,  $4000/5000 = 0.8 \text{ N/mm}^2$ . The maximum unit stress at  $A$  is, therefore,  $32.61 - 0.8 = 31.8 \text{ N/mm}^2$  (31.8 MPa) in compression, and the maximum unit stress at  $B$  is  $46.1 + 0.8 = 46.9 \text{ N/mm}^2$  (46.9 MPa) in tension.

**Size of Rail Necessary to Carry a Given Load.**—The following formulas may be employed for determining the size of rail and wheel suitable for carrying a given load. Let  $A$  = the width of the head of the rail in inches;  $B$  = width of the tread of the rail in inches;  $C$  = the wheel-load in pounds;  $D$  = the diameter of the wheel in inches.

Then the width of the tread of the rail in inches is found from the formula:

$$B = \frac{C}{1250D} \quad (1)$$

The width  $A$  of the head equals  $B + \frac{5}{8}$  inch. The diameter  $D$  of the smallest track wheel that will safely carry the load is found from the formula:

$$D = \frac{C}{A \times K} \quad (2)$$

in which  $K = 600$  to  $800$  for steel castings;  $K = 300$  to  $400$  for cast iron.

As an example, assume that the wheel-load is 10,000 pounds; the diameter of the wheel is 20 inches; and the material is cast steel. Determine the size of rail necessary to carry this load. From **Formula (1)**:

$$B = \frac{10,000}{1250 \times 20} = 0.4 \text{ inch}$$

The width of the rail required equals  $0.4 + \frac{5}{8}$  inch = 1.025 inch. Determine also whether a wheel 20 inches in diameter is large enough to safely carry the load. From **Formula (2)**:

$$D = \frac{10,000}{1.025 \times 600} = 16\frac{1}{4} \text{ inches}$$

This is the smallest diameter of track wheel that will safely carry the load; hence a 20-inch wheel is ample.

**American Railway Engineering Association Formulas.**—The American Railway Engineering Association recommends for safe operation of steel cylinders rolling on steel plates that the allowable load  $p$  in pounds per inch of length of the cylinder should not exceed the value calculated from the formula

$$p = \frac{y.s. - 13,000}{20,000} 600d \text{ for diameter } d \text{ less than 25 inches}$$

This formula is based on steel having a yield strength, *y.s.*, of 32,000 pounds per square inch. For roller or wheel diameters of up to 25 inches, the Hertz stress (contact stress) resulting from the calculated load *p* will be approximately 76,000 pounds per square inch.

For a 10-inch diameter roller the safe load per inch of roller length is

$$p = \frac{32,000 - 13,000}{20,000} 600 \times 10 = 5700 \text{ lbs per inch of length}$$

Therefore, to support a 10,000 pound load the roller or wheel would need to be  $10,000/5700 = 1.75$  inches wide.

### Stresses Produced by Shocks

**Stresses in Beams Produced by Shocks.**—Any elastic structure subjected to a shock will deflect until the product of the average resistance developed by the deflection and the distance through which it has been overcome has reached a value equal to the energy of the shock. It follows that for a given shock, the average resisting stresses are inversely proportional to the deflection. If the structure were perfectly rigid, the deflection would be zero and the stress infinite. The effect of a shock is, therefore, to a great extent dependent upon the elastic property (the springiness) of the structure subjected to the impact.

The energy of a body in motion, such as a falling body, may be spent in each of four ways:

- 1) In deforming the body struck as a whole.
- 2) In deforming the falling body as a whole.
- 3) In partial deformation of both bodies on the surface of contact (most of this energy will be transformed into heat).
- 4) Part of the energy will be taken up by the supports, if these are not perfectly rigid and inelastic.

How much energy is spent in the last three ways is usually difficult to determine, and for this reason it is safest to figure as if the whole amount were spent as in Case 1. If a reliable judgment is possible as to what percentage of the energy is spent in other ways than the first, a corresponding fraction of the total energy can be assumed as developing stresses in the body subjected to shocks.

One investigation into the stresses produced by shocks led to the following conclusions:

- 1) A suddenly applied load will produce the same deflection, and, therefore, the same stress as a static load twice as great; and 2) the unit stress *p* (see formulas in [Table 1, Stresses Produced in Beams by Shocks](#)) for a given load producing a shock varies directly as the square root of the modulus of elasticity *E* and inversely as the square root of the length *L* of the beam and the area of the section.

Thus, for instance, if the sectional area of a beam is increased by four times, the unit stress will diminish only by half. This result is entirely different from those produced by static loads where the stress would vary inversely with the area, and within certain limits be practically independent of the modulus of elasticity.

In [Table 1](#), the expression for the approximate value of *p*, which is applicable whenever the deflection of the beam is small as compared with the total height *h* through which the body producing the shock is dropped, is always the same for beams supported at both ends and subjected to shock at *any* point between the supports. In the formulas all dimensions are in inches and weights in pounds.

**Table 1. Stresses Produced in Beams by Shocks**

Method of Support and Point Struck by Falling Body	Fiber (Unit) Stress $p$ Produced by Weight $Q$ Dropped Through a Distance $h$	Approximate Value of $p$
Supported at both ends; struck in center.	$p = \frac{QaL}{4I} \left( 1 + \sqrt{1 + \frac{96hEI}{QL^3}} \right)$	$p = a\sqrt{\frac{6QhE}{LI}}$
Fixed at one end; struck at the other.	$p = \frac{QaL}{I} \left( 1 + \sqrt{1 + \frac{6hEI}{QL^3}} \right)$	$p = a\sqrt{\frac{6QhE}{LI}}$
Fixed at both ends; struck in center.	$p = \frac{QaL}{8I} \left( 1 + \sqrt{1 + \frac{384hEI}{QL^3}} \right)$	$p = a\sqrt{\frac{6QhE}{LI}}$

$I$  = moment of inertia of section;  $a$  = distance of extreme fiber from neutral axis;  $L$  = length of beam;  $E$  = modulus of elasticity.

If metric SI units are used,  $p$  is in newtons per square millimeter;  $Q$  is in newtons;  $E$  = modulus of elasticity in N/mm<sup>2</sup>;  $I$  = moment of inertia of section in mm<sup>4</sup>; and  $h$ ,  $a$ , and  $L$  in mm. Note: If  $Q$  is given in kilograms, the value referred to is mass. The weight  $Q$  of a mass  $M$  kilograms is  $Mg$  newtons, where  $g$  = approximately 9.81 m/s<sup>2</sup>.

Examples of How Formulas for Stresses Produced by Shocks are Derived: The general formula from which specific formulas for shock stresses in beams, springs, and other machine and structural members are derived is:

$$p = p_s \left( 1 + \sqrt{1 + \frac{2h}{y}} \right) \quad (1)$$

In this formula,  $p$  = stress in psi due to shock caused by impact of a moving load;  $p_s$  = stress in psi resulting when moving load is applied statically;  $h$  = distance in inches that load falls before striking beam, spring, or other member;  $y$  = deflection in inches resulting from static load.

As an example of how Formula (1) may be used to obtain a formula for a specific application, suppose that the load  $W$  shown applied to the beam in Case 2 on page 257 were dropped on the beam from a height of  $h$  inches instead of being gradually applied (static loading). The maximum stress  $p_s$  due to load  $W$  for Case 2 is given as  $Wl \div 4Z$  and the maximum deflection  $y$  is given as  $Wl^3 \div 48EI$ . Substituting these values in Formula (1),

$$p = \frac{Wl}{4Z} \left( 1 + \sqrt{1 + \frac{2h}{Wl^3 \div 48EI}} \right) = \frac{Wl}{4Z} \left( 1 + \sqrt{1 + \frac{96hEI}{Wl^3}} \right) \quad (2)$$

If in Formula (2) the letter  $Q$  is used in place of  $W$  and if  $Z$ , the section modulus, is replaced by its equivalent,  $I \div$  distance  $a$  from neutral axis to extreme fiber of beam, then Formula (2) becomes the first formula given in the accompanying Table 1, *Stresses Produced in Beams by Shocks*.

**Stresses in Helical Springs Produced by Shocks.**—A load suddenly applied on a spring will produce the same deflection, and, therefore, also the same unit stress, as a static load twice as great. When the load drops from a height  $h$ , the stresses are as given in the accompanying Table 2. The approximate values are applicable when the deflection is small as compared with the height  $h$ . The formulas show that the fiber stress for a given shock will be greater in a spring made from a square bar than in one made from a round bar, if the diameter of coil is the same and the side of the square bar equals the diameter of the round

bar. It is, therefore, more economical to use round stock for springs which must withstand shocks, due to the fact that the deflection for the same fiber stress for a square bar spring is smaller than that for a round bar spring, the ratio being as 4 to 5. The round bar spring is therefore capable of storing more energy than a square bar spring for the same stress.

**Table 2. Stresses Produced in Springs by Shocks**

Form of Bar from Which Spring is Made	Fiber (Unit) Stress $f$ Produced by Weight $Q$ Dropped a Height $h$ on a Helical Spring	Approximate Value of $f$
Round	$f = \frac{8QD}{\pi d^3} \left( 1 + \sqrt{1 + \frac{Ghd^4}{4QD^3n}} \right)$	$f = 1.27 \sqrt{\frac{QhG}{Dd^2n}}$
Square	$f = \frac{9QD}{4d^3} \left( 1 + \sqrt{1 + \frac{Ghd^4}{0.9\pi QD^3n}} \right)$	$f = 1.34 \sqrt{\frac{QhG}{Dd^2n}}$

$G$  = modulus of elasticity for torsion;  $d$  = diameter or side of bar;  $D$  = mean diameter of spring;  $n$  = number of coils in spring.

**Shocks from Bodies in Motion.**—The formulas given can be applied, in general, to shocks from bodies in motion. A body of weight  $W$  moving horizontally with the velocity of  $v$  feet per second has a stored-up energy:

$$E_k = \frac{1}{2} \times \frac{Wv^2}{g} \text{ foot-pounds} \quad \text{or} \quad \frac{6Wv^2}{g} \text{ inch-pounds}$$

This expression may be substituted for  $Qh$  in the tables in the equations for unit stresses containing this quantity, and the stresses produced by the energy of the moving body thereby determined.

The formulas in the tables give the maximum value of the stresses, providing the designer with some definitive guidance even where there may be justification for assuming that only a part of the energy of the shock is taken up by the member under stress.

**The formulas can also be applied using metric SI units. The stored-up energy of a body of mass  $M$  kilograms moving horizontally with the velocity of  $v$  meters per second is:**

$$E_k = \frac{1}{2} Mv^2 \text{ newton-meters}$$

**This expression may be substituted for  $Qh$  in the appropriate equations in the tables. For calculation in millimeters,  $Qh = 1000 E_k$  newton-millimeters.**

**Fatigue Stresses.**—So-called "fatigue ruptures" occur in parts that are subjected to continually repeated shocks or stresses of small magnitude. Machine parts that are subjected to continual stresses in varying directions, or to repeated shocks, even if of comparatively small magnitude, may fail ultimately if designed from a mere knowledge of the behavior of the material under a steady stress, such as is imposed upon it by ordinary tensile stress testing machines. Examinations of numerous cases of machine parts, broken under actual working conditions, indicate that at least 80 percent of these ruptures are caused by fatigue stresses. Most fatigue ruptures are caused by bending stresses, and frequently by a revolving bending stress. Hence, to test materials for this class of stress the tests should be made to stress the material in a manner similar to that in which it will be stressed under actual working conditions. See *Fatigue Properties* on page 209 for more on this topic.

## COLUMNS

## Strength of Columns or Struts

Structural members which are subject to compression may be so long in proportion to their diameter or lateral dimensions that failure may be the result 1) of both compression and bending; and 2) of bending or buckling to such a degree that compression stress may be ignored.

In such cases, the *slenderness ratio* is important. This ratio equals the length  $l$  of the column in inches or millimeters, according to the unit system in use, divided by the least radius of gyration  $r$  of the cross section. Various formulas have been used for designing columns which are too slender to be designed for compression only.

**Rankine or Gordon Formula.**—This formula is generally applied when slenderness ratios range between 20 and 100, and sometimes for ratios up to 120. The notation, in English and metric SI units of measurement, is given on page 283.

$$p = \frac{S}{1 + K\left(\frac{l}{r}\right)^2} = \text{ultimate load, lb/in}^2 \text{ or N/mm}^2$$

Factor  $K$  may be established by tests with a given material and end condition, and for the probable range of  $l/r$ . If determined by calculation,  $K = S/C\pi^2E$ . Factor  $C$  equals 1 for either rounded or pivoted column ends, 4 for fixed ends, and 1 to 4 for square flat ends. The factors 25,000, 12,500, etc., in the Rankine formulas, arranged as on page 283, equal  $1/K$ , and have been used extensively.

**Straight-Line Formula.**—This general type of formula is often used in designing compression members for buildings, bridges, or similar structural work. It is convenient especially in designing a number of columns that are made of the same material but vary in size, assuming that factor  $B$  is known. This factor is determined by tests.

$$p = S_y - B\left(\frac{l}{r}\right) = \text{ultimate load, lb/in}^2$$

$S_y$  equals yield point, lb/in<sup>2</sup>, and factor  $B$  ranges from 50 to 100. Safe unit stress =  $p$  + factor of safety.

**Formulas of American Railway Engineering Association.**—The formulas that follow apply to structural steel having an ultimate strength of 60,000 to 72,000 lb/in<sup>2</sup>.

For building columns having  $l/r$  ratios not greater than 120:

$$\text{allowable unit stress} = 17,000 - 0.485 l^2/r^2$$

For columns having  $l/r$  ratios greater than 120:

$$\text{allowable unit stress} = \frac{18,000}{1 + l^2/18,000r^2}$$

For bridge compression members centrally loaded and values of  $l/r$  not greater than 140:

$$\text{Allowable unit stress, riveted ends} = 15,000 - \frac{1}{4} \frac{l^2}{r^2}$$

$$\text{Allowable unit stress, pin ends} = 15,000 - \frac{1}{3} \frac{l^2}{r^2}$$

**Euler Formula.**—This formula is for columns that are so slender that bending or buckling action predominates and compressive stresses are not taken into account.

$$P = \frac{C\pi^2 IE}{l^2} = \text{total ultimate load, in pounds or newtons}$$

The notation, in English and metric SI units of measurement, is given in the table *Rankine and Euler Formulas for Columns* on page 283. Factors  $C$  for different end conditions are included in the Euler formulas at the bottom of the table. According to a series of experiments, Euler formulas should be used if the values of  $l/r$  exceed the following ratios: Structural steel and flat ends, 195; hinged ends, 155; round ends, 120; cast iron with flat ends, 120; hinged ends, 100; round ends, 75; oak with flat ends, 130. The *critical slenderness ratio*, which marks the dividing line between the shorter columns and those slender enough to warrant using the Euler formula, depends upon the column material and its end conditions. If the Euler formula is applied when the slenderness ratio is too small, the *calculated* ultimate strength will exceed the yield point of the material and, obviously, will be incorrect.

**Eccentrically Loaded Columns.**—In the application of the column formulas previously referred to, it is assumed that the action of the load coincides with the axis of the column. If the load is offset relative to the column axis, the column is said to be eccentrically loaded, and its strength is then calculated by using a modification of the Rankine formula, the quantity  $cz/r^2$  being added to the denominator, as shown in the table on the next page. This modified formula is applicable to columns having a slenderness ratio varying from 20 or 30 to about 100.

**Machine Elements Subjected to Compressive Loads.**—As in structural compression members, an unbraced machine member that is relatively slender (i.e., its length is more than, say, six times the least dimension perpendicular to its longitudinal axis) is usually designed as a column because failure due to overloading (assuming a compressive load centrally applied in an axial direction) may occur by buckling or a combination of buckling and compression rather than by direct compression alone. In the design of unbraced steel machine “columns” which are to carry compressive loads applied along their longitudinal axes, two formulas are in general use:

$$\text{(Euler)} \quad P_{cr} = \frac{S_y A r^2}{Q} \quad (1)$$

$$\text{(J. B. Johnson)} \quad P_{cr} = AS_y \left( 1 - \frac{Q}{4r^2} \right) \quad (2) \quad \text{where} \quad Q = \frac{S_y l^2}{n\pi^2 E} \quad (3)$$

In these formulas,  $P_{cr}$  = critical load in pounds that would result in failure of the column;  $A$  = cross sectional area, inches<sup>2</sup>;  $S_y$  = yield point of material, psi;  $r$  = least radius of gyration of cross section, inches;  $E$  = modulus of elasticity, psi;  $l$  = column length, inches; and  $n$  = coefficient for end conditions. For both ends fixed,  $n = 4$ ; for one end fixed, one end free,  $n = 0.25$ ; for one end fixed and the other end free but guided,  $n = 2$ ; for round or pinned ends, free but guided,  $n = 1$ ; and for flat ends,  $n = 1$  to 4. It should be noted that these values of  $n$  represent ideal conditions that are seldom attained in practice; for example, for both ends fixed, a value of  $n = 3$  to 3.5 may be more realistic than  $n = 4$ .

**If metric SI units are used in these formulas,  $P_{cr}$  = critical load in newtons that would result in failure of the column;  $A$  = cross-sectional area, mm<sup>2</sup>;  $S_y$  = yield point of the material, N/mm<sup>2</sup>;  $r$  = least radius of gyration of cross section, mm;  $E$  = modulus of elasticity, N/mm<sup>2</sup>;  $l$  = column length, mm; and  $n$  = a coefficient for end conditions. The coefficients given are valid for calculations in metric units.**

## Rankine and Euler Formulas for Columns

Symbol	Quantity	English Unit	Metric SI Units
$p$	Ultimate unit load	Lbs/in <sup>2</sup>	Newtons/mm <sup>2</sup>
$P$	Total ultimate load	Pounds	Newtons
$S$	Ultimate compressive strength of material	Lbs/in <sup>2</sup>	Newtons/mm <sup>2</sup>
$l$	Length of column or strut	Inches	Millimeters
$r$	Least radius of gyration	Inches	Millimeters
$I$	Least moment of inertia	Inches <sup>4</sup>	Millimeters <sup>4</sup>
$r^2$	Moment of inertia/area of section	Inches <sup>2</sup>	Millimeters <sup>2</sup>
$E$	Modulus of elasticity of material	Lbs/in <sup>2</sup>	Newtons/mm <sup>2</sup>
$c$	Distance from neutral axis of cross section to side under compression	Inches	Millimeters
$z$	Distance from axis of load to axis coinciding with center of gravity of cross section	Inches	Millimeters

## Rankine Formulas

Material	Both Ends of Column Fixed	One End Fixed and One End Rounded	Both Ends Rounded
Steel	$p = \frac{S}{1 + \frac{l^2}{25,000r^2}}$	$p = \frac{S}{1 + \frac{l^2}{12,500r^2}}$	$p = \frac{S}{1 + \frac{l^2}{6250r^2}}$
Cast Iron	$p = \frac{S}{1 + \frac{l^2}{5000r^2}}$	$p = \frac{S}{1 + \frac{l^2}{2500r^2}}$	$p = \frac{S}{1 + \frac{l^2}{1250r^2}}$
Wrought Iron	$p = \frac{S}{1 + \frac{l^2}{35,000r^2}}$	$p = \frac{S}{1 + \frac{l^2}{17,500r^2}}$	$p = \frac{S}{1 + \frac{l^2}{8750r^2}}$
Timber	$p = \frac{S}{1 + \frac{l^2}{3000r^2}}$	$p = \frac{S}{1 + \frac{l^2}{1500r^2}}$	$p = \frac{S}{1 + \frac{l^2}{750r^2}}$

## Formulas Modified for Eccentrically Loaded Columns

Material	Both Ends of Column Fixed	One End Fixed and One End Rounded	Both Ends Rounded
Steel	$p = \frac{S}{1 + \frac{l^2}{25,000r^2} + \frac{cz}{r^2}}$	$p = \frac{S}{1 + \frac{l^2}{12,500r^2} + \frac{cz}{r^2}}$	$p = \frac{S}{1 + \frac{l^2}{6250r^2} + \frac{cz}{r^2}}$

For materials other than steel, such as cast iron, use the Rankine formulas given in the upper table and add to the denominator the quantity  $cz/r^2$

## Euler Formulas for Slender Columns

Both Ends of Column Fixed	One End Fixed and One End Rounded	Both Ends Rounded	One End Fixed and One End Free
$P = \frac{4\pi^2IE}{l^2}$	$P = \frac{2\pi^2IE}{l^2}$	$P = \frac{\pi^2IE}{l^2}$	$P = \frac{\pi^2IE}{4l^2}$

*Allowable Working Loads for Columns:* To find the total allowable working load for a given section, divide the total ultimate load  $P$  (or  $p \times$  area), as found by the appropriate formula above, by a suitable factor of safety.

**Factor of Safety for Machine Columns:** When the conditions of loading and the physical qualities of the material used are accurately known, a factor of safety as low as 1.25 is sometimes used when minimum weight is important. Usually, however, a factor of safety of 2 to 2.5 is applied for steady loads. The factor of safety represents the ratio of the critical load  $P_{cr}$  to the working load.

**Application of Euler and Johnson Formulas:** To determine whether the Euler or Johnson formula is applicable in any particular case, it is necessary to determine the value of the quantity  $Q \div r^2$ . If  $Q \div r^2$  is greater than 2, then the Euler Formula (1) should be used; if  $Q \div r^2$  is less than 2, then the J. B. Johnson formula is applicable. Most compression members in machine design are in the range of proportions covered by the Johnson formula. For this reason a good procedure is to design machine elements on the basis of the Johnson formula and then as a check calculate  $Q \div r^2$  to determine whether the Johnson formula applies or the Euler formula should have been used.

**Example 1, Compression Member Design:** A rectangular machine member 24 inches long and  $\frac{1}{2} \times 1$  inch in cross section is to carry a compressive load of 4000 pounds along its axis. What is the factor of safety for this load if the material is machinery steel having a yield point of 40,000 psi, the load is steady, and each end of the rod has a ball connection so that  $n = 1$ ?

**Solution:** From Formula (3)

$$Q = \frac{40,000 \times 24 \times 24}{1 \times 3.1416 \times 3.1416 \times 30,000,000} = 0.0778$$

(The values 40,000 and 30,000,000 were obtained from the table *Strength Data for Iron and Steel* on page 429.)

The radius of gyration  $r$  for a rectangular section (page 242) is  $0.289 \times$  the dimension in the direction of bending. In columns, bending is most apt to occur in the direction in which the section is the weakest, the  $\frac{1}{2}$ -inch dimension in this example. Hence, least radius of gyration  $r = 0.289 \times \frac{1}{2} = 0.145$  inch.

$$\frac{Q}{r^2} = \frac{0.0778}{(0.145)^2} = 3.70$$

which is more than 2, so the Euler formula will be used.

$$P_{cr} = \frac{s_y A r^2}{Q} = \frac{40,000 \times \frac{1}{2} \times 1}{3.70} \\ = 5400 \text{ pounds so that the factor of safety is } 5400 \div 4000 = 1.35$$

**Example 2, Compression Member Design:** In the preceding example, the column formulas were used to check the adequacy of a column of known dimensions. The more usual problem involves determining what the dimensions should be to resist a specified load. For example:

A 24-inch long bar of rectangular cross section with width  $w$  twice its depth  $d$  is to carry a load of 4000 pounds. What must the width and depth be if a factor of safety of 1.35 is to be used?

**Solution:** First determine the critical load  $P_{cr}$ :

$$P_{cr} = \text{working load} \times \text{factor of safety} \\ = 4000 \times 1.35 = 5400 \text{ pounds}$$

Next determine  $Q$ , which is found as in **Example 1**, and will again be 0.0778.

Assume **Formula (2)** applies:

$$P_{cr} = A_s y \left( 1 - \frac{Q}{4r^2} \right)$$

$$5400 = w \times d \times 40,000 \left( 1 - \frac{0.0778}{4r^2} \right)$$

$$= 2d^2 \times 40,000 \left( 1 - \frac{0.01945}{r^2} \right)$$

$$\frac{5400}{40,000 \times 2} = d^2 \left( 1 - \frac{0.01945}{r^2} \right)$$

As mentioned in **Example 1** the least radius of gyration  $r$  of a rectangle is equal to 0.289 times the least dimension,  $d$ , in this case. Therefore, substituting for  $d$  the value  $r \div 0.289$ ,

$$\frac{5400}{40,000 \times 2} = \left( \frac{r}{0.289} \right)^2 \left( 1 - \frac{0.01945}{r^2} \right)$$

$$\frac{5400 \times 0.289 \times 0.289}{40,000 \times 2} = r^2 - 0.01945$$

$$0.005638 = r^2 - 0.01945$$

$$r^2 = 0.0251$$

Checking to determine if  $Q \div r^2$  is greater or less than 2,

$$\frac{Q}{r^2} = \frac{0.0778}{0.0251} = 3.1$$

Therefore, **Formula (1)** should have been used to determine  $r$  and dimensions  $w$  and  $d$ . Using **Formula (1)**,

$$5400 = \frac{40,000 \times 2d^2 \times r^2}{Q} = \frac{40,000 \times 2 \times \left( \frac{r}{0.289} \right)^2 r^2}{0.0778}$$

$$r^4 = \frac{5400 \times 0.0778 \times 0.289 \times 0.289}{40,000 \times 2} = 0.0004386$$

$$d = \frac{0.145}{0.289} = 0.50 \text{ inch}$$

and  $w = 2d = 1$  inch as in the previous example.

**American Institute of Steel Construction.**—For main or secondary compression members with  $l/r$  ratios up to 120, safe unit stress =  $17,000 - 0.485l^2/r^2$ . For columns and bracing or other secondary members with  $l/r$  ratios above 120,

$$\text{For bracing and secondary members, safe unit stress, psi} = \frac{18,000}{1 + l^2/18,000r^2}$$

$$\text{For main members, safe unit stress, psi} = \frac{18,000}{1 + l^2/18,000r^2} \times \left( 1.6 - \frac{l/r}{200} \right)$$

*Pipe Columns:* Allowable concentric loads for steel pipe columns based on the above formulas are given in the table on page 286.

<sup>a</sup> With respect to radius of gyration. The effective length (KL) is the actual unbraced length, L, in feet, multiplied by the effective length factor (K), which is dependent upon the restraint at the ends of the unbraced length and the means available to resist lateral movements. K may be determined by referring to the last portion of this table.

			Rotation free and translation free			

Load tables are given for 36 ksi yield stress steel. No load values are given below the heavy horizontal lines, because the  $Kl/r$  ratios (where  $l$  is the actual unbraced length in inches and  $r$  is the governing radius of gyration in inches) would exceed 200.

## PLATES, SHELLS, AND CYLINDERS

**Flat Stayed Surfaces.**—Large flat areas are often held against pressure by stays distributed at regular intervals over the surface. In boiler work, these stays are usually screwed into the plate and the projecting end riveted over to insure steam tightness. The US Board of Supervising Inspectors and the American Boiler Manufacturers Association (ABMA) rules give the following formula for flat stayed surfaces:

$$P = \frac{C \times t^2}{S^2}$$

in which  $P$  = pressure in pounds per square inch

$C$  = a constant, which equals

112 for plates  $\frac{7}{16}$  inch and under

120, for plates over  $\frac{7}{16}$  inch thick

140, for plates with stays having a nut and bolt on the inside and outside

160, for plates with stays having washers of at least one-half the plate thickness, and with a diameter at least one-half of the greatest pitch

$t$  = thickness of plate in 16ths of an inch (thickness =  $\frac{7}{16}$ ,  $t = 7$ )

$S$  = greatest pitch of stays in inches

**Strength and Deflection of Flat Plates.**—Generally, the formulas used to determine stresses and deflections in flat plates are based on certain assumptions that can be closely approximated in practice. These assumptions are:

- 1) the thickness of the plate is not greater than one-quarter the least width of the plate;
- 2) the greatest deflection when the plate is loaded is less than one-half the plate thickness;
- 3) the maximum tensile stress resulting from the load does not exceed the elastic limit of the material; and
- 4) all loads are perpendicular to the plane of the plate.

Plates of ductile materials fail when the maximum stress resulting from deflection under load exceeds the yield strength; for brittle materials, failure occurs when the maximum stress reaches the ultimate tensile strength of the material involved.

**Square and Rectangular Flat Plates.**—The formulas that follow give the maximum stress and deflection of flat steel plates supported in various ways and subjected to the loading indicated. These formulas are based upon a modulus of elasticity for steel of 30,000,000 psi and a value of Poisson's ratio of 0.3. If the formulas for maximum stress,  $S$ , are applied without modification to other materials, such as cast iron, aluminum, and brass, for which the range of Poisson's ratio is about 0.26 to 0.34, the maximum stress calculations will be in error by not more than about 3 percent. The deflection formulas may also be applied to materials other than steel by substituting in these formulas the appropriate value for  $E$ , the modulus of elasticity of the material (see pages 429 and 510). The deflections thus obtained will not be in error by more than about 3 percent.

In the stress and deflection formulas that follow,

$p$  = uniformly distributed load acting on plate, psi

$W$  = total load on plate, pounds;  $W = p \times$  area of plate

$L$  = distance between supports (length of plate), inches. For rectangular plates,

$L$  = long side,  $l$  = short side

$t$  = thickness of plate, inches

$S$  = maximum tensile stress in plate, psi

$d$  = maximum deflection of plate, in.

$E$  = modulus of elasticity in tension.  $E = 30,000,000$  psi for steel

**If metric SI units are used in the formulas, then,**

$W$  = total load on plate, newtons

$L$  = distance between supports (length of plate), mm. For rectangular plates,  $L$  = long side,  $l$  = short side

$t$  = thickness of plate, mm

$S$  = maximum tensile stress in plate, N/mm<sup>2</sup>

$d$  = maximum deflection of plate, mm

$E$  = modulus of elasticity, N/mm<sup>2</sup>

a) Square flat plate supported at top and bottom of all four edges and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.29W}{t^2} \quad (1) \qquad d = \frac{0.0443WL^2}{Et^3} \quad (2)$$

b) Square flat plate supported at the bottom only of all four edges and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.28W}{t^2} \quad (3) \qquad d = \frac{0.0443WL^2}{Et^3} \quad (4)$$

c) Square flat plate with all edges firmly fixed and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.31W}{t^2} \quad (5) \qquad d = \frac{0.0138WL^2}{Et^3} \quad (6)$$

d) Square flat plate with all edges firmly fixed and a uniform load over small circular area at the center. In Equations (7) and (9),  $r_0$  = radius of area to which load is applied.

If  $r_0 < 1.7t$ , use  $r_s$  where  $r_s = \sqrt{1.6r_0^2 + t^2} - 0.675t$ .

$$S = \frac{0.62W}{t^2} \log_e \left( \frac{L}{2r_0} \right) \quad (7) \qquad d = \frac{0.0568WL^2}{Et^3} \quad (8)$$

e) Square flat plate with all edges supported above and below, or below only, and a concentrated load at the center. See Item d), above, for definition of  $r_0$ .

$$S = \frac{0.62W}{t^2} \left[ \log_e \left( \frac{L}{2r_0} \right) + 0.577 \right] \quad (9) \qquad d = \frac{0.1266WL^2}{Et^3} \quad (10)$$

f) Rectangular plate with all edges supported at top and bottom and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.75W}{t^2 \left( \frac{L}{l} + 1.61 \frac{l^2}{L^2} \right)} \quad (11) \qquad d = \frac{0.1422W}{Et^3 \left( \frac{L}{l^3} + \frac{2.21}{L^2} \right)} \quad (12)$$

g) Rectangular plate with all edges fixed and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.5W}{t^2 \left( \frac{L}{l} + \frac{0.623l^2}{L^2} \right)} \quad (13) \qquad d = \frac{0.0284W}{Et^3 \left( \frac{L}{l^3} + \frac{1.056l^2}{L^4} \right)} \quad (14)$$

**Circular Flat Plates.**—In the following formulas,  $R$  = radius of plate to supporting edge in inches;  $W$  = total load in pounds; and other symbols are the same as used for square and rectangular plates.

**If metric SI units are used,  $R$  = radius of plate to supporting edge in mm, and the values of other symbols are the same as those used for square and rectangular plates.**

a) Edge supported around the circumference and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.39W}{t^2} \quad (15) \quad d = \frac{0.221WR^2}{Et^3} \quad (16)$$

b) Edge fixed around circumference and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.24W}{t^2} \quad (17) \quad d = \frac{0.0543WR^2}{Et^3} \quad (18)$$

c) Edge supported around the circumference and a concentrated load at the center.

$$S = \frac{0.48W}{t^2} \left[ 1 + 1.3 \log_e \frac{R}{0.325t} - 0.0185 \frac{t^2}{R^2} \right] \quad (19) \quad d = \frac{0.55WR^2}{Et^3} \quad (20)$$

d) Edge fixed around circumference and a concentrated load at the center.

$$S = \frac{0.62W}{t^2} \left[ \log_e \frac{R}{0.325t} + 0.0264 \frac{t^2}{R^2} \right] \quad (21) \quad d = \frac{0.22WR^2}{Et^3} \quad (22)$$

**Strength of Cylinders Subjected to Internal Pressure.**—In designing a cylinder to withstand internal pressure, the choice of formula to be used depends on 1) the kind of material of which the cylinder is made (whether brittle or ductile); 2) the construction of the cylinder ends (whether open or closed); and 3) whether the cylinder is classed as a thin- or a thick-walled cylinder.

A cylinder is considered to be thin-walled when the ratio of wall thickness to inside diameter is 0.1 or less and thick-walled when this ratio is greater than 0.1. Materials such as cast iron, hard steel, and cast aluminum are considered to be brittle materials; low-carbon steel, brass, bronze, etc. are considered to be ductile.

In the formulas that follow,  $p$  = internal pressure, psi;  $D$  = inside diameter of cylinder, inches;  $t$  = wall thickness of cylinder, inches;  $\mu$  = Poisson's ratio, = 0.3 for steel, 0.26 for cast iron, 0.34 for aluminum and brass; and  $S$  = allowable tensile stress, psi.

**Metric SI units can be used in Formulas (23), (25), (26), and (27), where  $p$  = internal pressure in N/mm<sup>2</sup>;  $D$  = inside diameter of cylinder, mm;  $t$  = wall thickness, mm;  $\mu$  = Poisson's ratio, = 0.3 for steel, 0.26 for cast iron, and 0.34 for aluminum and brass; and  $S$  = allowable tensile stress, N/mm<sup>2</sup>. For the use of metric SI units in Formula (24), see below.**

*Thin-walled Cylinders:*

$$t = \frac{Dp}{2S} \quad (23)$$

For low-pressure cylinders of cast iron such as are used for certain engine and press applications, a formula in common use is

$$t = \frac{Dp}{2500} + 0.3 \quad (24)$$

This formula is based on allowable stress of 1250 pounds per square inch (psi) and will give a wall thickness 0.3 inch greater than **Formula (23)** to allow for variations in metal thickness that may result from the casting process.

**If metric SI units are used in **Formula (24)**,  $t$  = cylinder wall thickness in mm;  $D$  = inside diameter of cylinder, mm; and the allowable stress is in  $\text{N/mm}^2$ . The value of 0.3 inches additional wall thickness is 7.62 mm, and the next highest number in preferred metric basic sizes is 8 mm.**

*Thick-walled Cylinders of Brittle Material, Ends Open or Closed:* Lamé's equation is used when cylinders of this type are subjected to internal pressure.

$$t = \frac{D}{2} \left( \sqrt{\frac{S+p}{S-p}} - 1 \right) \quad (25)$$

The table *Ratio of Outside Radius to Inside Radius, Thick Cylinders* on page 292 is for convenience in calculating the dimensions of cylinders under high internal pressure without the use of **Formula (25)**.

*Example, Use of the Table:* Assume that a cylinder of 10 inches inside diameter is to withstand a pressure of 2500 psi; the material is cast iron and the allowable stress is 6000 psi. To solve the problem, locate the allowable stress per square inch in the left-hand column of the table and the working pressure at the top of the columns. Then find the ratio between the outside and inside radii in the body of the table. In this example, the ratio is 1.558, and hence the outside diameter of the cylinder should be  $10 \times 1.558$ , or about  $15\frac{5}{8}$  inches. The thickness of the cylinder wall will therefore be  $(15.58 - 10)/2 = 2.79$  inches.

Unless very high-grade material is used and sound castings assured, cast iron should not be used for pressures exceeding 2000 pounds psi ( $13.75 \text{ N/mm}^2$ ). It is well to leave more metal in the bottom of a hydraulic cylinder than is indicated by the results of calculations because a hole of some size must be cored in the bottom to permit the entrance of a boring bar when finishing the cylinder, and when this hole is subsequently tapped and plugged it often gives trouble if there is too little thickness.

For steady or gradually applied stresses, the maximum allowable fiber stress  $S$  may be assumed to be from 3500 to 4000 psi ( $24\text{--}27 \text{ N/mm}^2$ ) for cast iron; from 6000 to 7000 psi ( $41\text{--}48 \text{ N/mm}^2$ ) for brass; and 12,000 psi ( $82 \text{ N/mm}^2$ ) for steel castings. For intermittent stresses, such as in cylinders for steam and hydraulic work, 3000 psi ( $20 \text{ N/mm}^2$ ) for cast iron; 5000 psi ( $34 \text{ N/mm}^2$ ) for brass; and 10,000 psi ( $69 \text{ N/mm}^2$ ) for steel castings is ordinarily used. These values give ample factors of safety.

**Note: In metric SI units, 1000 pounds per square inch equals 6.895 newtons per square millimeter ( $1000 \text{ lb/in}^2 = 6.895 \text{ N/mm}^2$ ). Also, one newtons per square millimeter equals one megapascal ( $1 \text{ N/mm}^2 = 1 \text{ MPa}$ ).**

*Thick-walled Cylinders of Ductile Material, Closed Ends:* Clavarino's equation is used:

$$t = \frac{D}{2} \left[ \sqrt{\frac{S + (1 - 2\mu)p}{S - (1 + \mu)p}} - 1 \right] \quad (26)$$

*Thick-walled Cylinders of Ductile Material, Open Ends:* Birnie's equation is used:

$$t = \frac{D}{2} \left[ \sqrt{\frac{S + (1 - \mu)p}{S - (1 + \mu)p}} - 1 \right] \quad (27)$$

**Spherical Shells Subjected to Internal Pressure.**—Let:

$D$  = internal diameter of shell in inches

$p$  = internal pressure in psi

$S$  = safe tensile stress per square inch

$t$  = thickness of metal in the shell, in inches. Then,  $t = pD \div 4S$  (28)

**Ratio of Outside Radius to Inside Radius, Thick Cylinders**

**Formula (28)** also applies to hemi-spherical shells, such as the hemi-spherical head of a cylindrical container subjected to internal pressure, etc.

**If metric SI units are used, then:**

$D$  = internal diameter of shell in millimeters

$p$  = internal pressure in newtons per square millimeter

$S$  = safe tensile stress in newtons per square millimeter

$t$  = thickness of metal in the shell, in millimeters. Use **Formula (28)**.

**Meters can be used in the formula in place of millimeters, provided the treatment is consistent throughout.**

*Example:* Find the thickness of metal required in the hemi-spherical end of a cylindrical vessel, 2 feet in diameter, subjected to an internal pressure of 500 pounds per square inch.

*Solution:* The material is mild steel and a tensile stress of 10,000 psi is allowable.

$$t = \frac{500 \times 2 \times 12}{4 \times 10,000} = 0.3 \text{ inch}$$

**Example:** A similar example using metric SI units is as follows: find the thickness of metal required in the hemi-spherical end of a cylindrical vessel, 750 mm in diameter, subjected to an internal pressure of 3 newtons/mm<sup>2</sup>. The material is mild steel and a tensile stress of 70 newtons/mm<sup>2</sup> is allowable.

$$t = \frac{3 \times 750}{4 \times 70} = 8.04 \text{ mm}$$

If the radius of curvature of the domed head of a boiler or container subjected to internal pressure is made equal to the diameter of the boiler, the thickness of the cylindrical shell and of the spherical head should be made the same. For example, if a boiler is 3 feet in diameter, the radius of curvature of its head should also be 3 feet, if material of the same thickness is to be used and the stresses are to be equal in both the head and cylindrical portion.

**Collapsing Pressure of Cylinders and Tubes Subjected to External Pressures.**—The following formulas may be used for finding the collapsing pressures of lap-welded Bessemer steel tubes:

$$P = 86,670 \frac{t}{D} - 1386 \quad (29)$$

$$P = 50,210,000 \left( \frac{t}{D} \right)^3 \quad (30)$$

in which  $P$  = collapsing pressure in psi;  $D$  = outside diameter of tube or cylinder in inches;  $t$  = thickness of wall in inches.

Formula (29) is for values of  $P$  greater than 580 pounds per square inch, and Formula (30) is for values of  $P$  less than 580 pounds per square inch. These formulas are substantially correct for all lengths of pipe greater than six diameters between transverse joints that tend to hold the pipe to a circular form. The pressure  $P$  found is the actual collapsing pressure, and a suitable factor of safety must be used. Ordinarily, a factor of safety of 5 is sufficient. In cases where there are repeated fluctuations of the pressure, vibration, shocks and other stresses, a factor of safety of from 6 to 12 should be used.

**If metric SI units are used the formulas are:**

$$P = 597.6 \frac{t}{D} - 9.556 \quad (31)$$

$$P = 346,200 \left( \frac{t}{D} \right)^3 \quad (32)$$

where  $P$  = collapsing pressure in newtons per square millimeter;  $D$  = outside diameter of tube or cylinder in millimeters; and  $t$  = thickness of wall in millimeters. Formula (31) is for values of  $P$  greater than 4 N/mm<sup>2</sup>, and Formula (32) is for values of  $P$  less than 4 N/mm<sup>2</sup>.

The table *Tubes Subjected to External Pressure* is based upon the requirements of the Steam Boat Inspection Service of the Department of Commerce and Labor and gives the permissible working pressures and corresponding minimum wall thickness for long, plain, lap-welded and seamless steel flues subjected to external pressure only. The table thicknesses have been calculated from the formula:

$$t = \frac{[(F \times p) + 1386]D}{86,670}$$

in which  $D$  = outside diameter of flue or tube in inches;  $t$  = thickness of wall in inches;  $p$  = working pressure in pounds per square inch;  $F$  = factor of safety. The formula is applicable to working pressures greater than 100 pounds per square inch, to outside diameters from 7 to 18 inches, and to temperatures less than 650°F.

The preceding **Formulas (29) and (30)** were determined by Prof. R. T. Stewart, Dean of the Mechanical Engineering Department of the University of Pittsburgh, in a series of experiments carried out at the plant of the National Tube Co., McKeesport, Pennsylvania.

The apparent fiber stress under which the different tubes failed varied from about 7000 pounds per square inch for the relatively thinnest to 35,000 pounds per square inch for the relatively thickest walls. The average yield point of the material tested was 37,000 pounds and the tensile strength 58,000 pounds per square inch, so it is evident that the strength of a tube subjected to external fluid collapsing pressure is not dependent alone upon the elastic limit or ultimate strength of the material from which it is made.

### Tubes Subjected to External Pressure

Outside Diameter of Tube, Inches	Working Pressure in Pounds per Square Inch						
	100	120	140	160	180	200	220

## SHAFTS

## Shaft Calculations

**Torsional Strength of Shafting.**—In the formulas that follow,

$\alpha$  = angular deflection of shaft in degrees

$c$  = distance from center of gravity to extreme fiber

$D$  = diameter of shaft in inches

$G$  = torsional modulus of elasticity = 11,500,000 pounds per square inch for steel

$J$  = polar moment of inertia of shaft cross section (see table)

$l$  = length of shaft in inches

$N$  = angular velocity of shaft in revolutions per minute

$P$  = power transmitted in horsepower

$S_s$  = allowable torsional shearing stress in pounds per square inch

$T$  = torsional or twisting moment in inch-pounds

$Z_p$  = polar section modulus (see table page 252)

The allowable twisting moment for a shaft of any cross section such as circular, square, etc., is:

$$T = S_s \times Z_p \quad (1)$$

For a shaft delivering  $P$  horsepower at  $N$  revolutions per minute the twisting moment  $T$  being transmitted is:

$$T = \frac{63,000P}{N} \quad (2)$$

The twisting moment  $T$  as determined by **Formula (2)** should be less than the value determined by using **Formula (1)** if the maximum allowable stress  $S_s$  is not to be exceeded.

The diameter of a solid circular shaft required to transmit a given torque  $T$  is:

$$D = \sqrt[3]{\frac{5.1T}{S_s}} \quad (3a) \quad \text{or} \quad D = \sqrt[3]{\frac{321,000P}{NS_s}} \quad (3b)$$

The allowable stresses that are generally used in practice are: 4000 pounds per square inch for main power-transmitting shafts; 6000 pounds per square inch for lineshafts carrying pulleys; and 8500 pounds per square inch for small, short shafts, countershafts, etc. Using these allowable stresses, the horsepower  $P$  transmitted by a shaft of diameter  $D$ , or the diameter  $D$  of a shaft to transmit a given horsepower  $P$  may be determined from the following formulas:

For main power-transmitting shafts:

$$P = \frac{D^3 N}{80} \quad (4a) \quad \text{or} \quad D = \sqrt[3]{\frac{80P}{N}} \quad (4b)$$

For lineshafts carrying pulleys:

$$P = \frac{D^3 N}{53.5} \quad (5a) \quad \text{or} \quad D = \sqrt[3]{\frac{53.5P}{N}} \quad (5b)$$

For small, short shafts:

$$P = \frac{D^3 N}{38} \quad (6a) \quad \text{or} \quad D = \sqrt[3]{\frac{38P}{N}} \quad (6b)$$

Shafts that are subjected to shocks, such as sudden starting and stopping, should be given a greater factor of safety resulting in the use of lower allowable stresses than those just mentioned.

*Example:* What should be the diameter of a lineshaft to transmit 10 horsepower if the shaft is to make 150 revolutions per minute? Using [Formula \(5b\)](#),

$$D = \sqrt[3]{\frac{53.5 \times 10}{150}} = 1.53 \text{ or, say, } 1 \frac{9}{16} \text{ inches}$$

*Example:* What horsepower would be transmitted by a short shaft, 2 inches in diameter, carrying two pulleys close to the bearings, if the shaft makes 300 revolutions per minute? Using [Formula \(6a\)](#),

$$P = \frac{2^3 \times 300}{38} = 63 \text{ horsepower}$$

**Torsional Strength of Shafting, Calculations in Metric SI Units.**—The allowable twisting moment for a shaft of any cross section such as circular, square, etc. can be calculated from:

$$T = S_s \times Z_p \quad (7)$$

where  $T$  = torsional or twisting moment in N-mm;  $S_s$  = allowable torsional shearing stress in N/mm<sup>2</sup>; and  $Z_p$  = polar section modulus in mm<sup>3</sup>.

For a shaft delivering power of  $P$  kilowatts at  $N$  revolutions per minute, the twisting moment  $T$  being transmitted is:

$$T = \frac{9.55 \times 10^6 P}{N} \quad (8a) \quad \text{or} \quad T = \frac{10^6 P}{\omega} \quad (8b)$$

where  $T$  is in newton-millimeters, and  $\omega$  = angular velocity in radians per second.

The diameter  $D$  of a solid circular shaft required to transmit a given torque  $T$  is:

$$D = \sqrt[3]{\frac{5.1T}{S_s}} \quad (9a) \quad \text{or} \quad D = \sqrt[3]{\frac{48.7 \times 10^6 P}{NS_s}} \quad (9b)$$

$$\text{or} \quad D = \sqrt[3]{\frac{5.1 \times 10^6 P}{\omega S_s}} \quad (9c)$$

where  $D$  is in millimeters;  $T$  is in newton-millimeters;  $P$  is power in kilowatts;  $N$  = revolutions per minute;  $S_s$  = allowable torsional shearing stress in newtons per square millimeter, and  $\omega$  = angular velocity in radians per second.

If 28 newtons/mm<sup>2</sup> and 59 newtons/mm<sup>2</sup> are taken as the generally allowed stresses for main power-transmitting shafts and small short shafts, respectively, then using these allowable stresses, the power  $P$  transmitted by a shaft of diameter  $D$ , or the diameter  $D$  of a shaft to transmit a given power  $P$  may be determined from the following formulas:

For main power-transmitting shafts:

$$P = \frac{D^3 N}{1.77 \times 10^6} \quad (10a) \quad \text{or} \quad D = \sqrt[3]{\frac{1.77 \times 10^6 P}{N}} \quad (10b)$$

For small, short shafts:

$$P = \frac{D^3 N}{0.83 \times 10^6} \quad (11a) \quad \text{or} \quad D = \sqrt[3]{\frac{0.83 \times 10^6 P}{N}} \quad (11b)$$

where  $P$  is in kilowatts,  $D$  is in millimeters, and  $N$  = revolutions per minute.

*Example:* What should be the diameter of a power-transmitting shaft to transmit 150 kW at 500 rpm?

$$D = \sqrt[3]{\frac{1.77 \times 10^6 \times 150}{500}} = 81 \text{ millimeters}$$

*Example:* What power would a short shaft, 50 millimeters in diameter, transmit at 400 rpm?

$$P = \frac{50^3 \times 400}{0.83 \times 10^6} = 60 \text{ kilowatts}$$

**Torsional Deflection of Circular Shafts.**—Shafting must often be proportioned not only to provide the strength required to transmit a given torque, but also to prevent torsional deflection (twisting) through a greater angle than has been found satisfactory for a given type of service.

For a solid circular shaft the torsional deflection in degrees is given by:

$$\alpha = \frac{584 T l}{D^4 G} \quad (12)$$

*Example:* Find the torsional deflection for a solid steel shaft 4 inches in diameter and 48 inches long, subjected to a twisting moment of 24,000 inch-pounds. By **Formula (12)**,

$$\alpha = \frac{584 \times 24,000 \times 48}{4^4 \times 11,500,000} = 0.23 \text{ degree}$$

**Formula (12)** can be used with metric SI units, where  $\alpha$  = angular deflection of shaft in degrees;  $T$  = torsional moment in newton-millimeters;  $l$  = length of shaft in millimeters;  $D$  = diameter of shaft in millimeters; and  $G$  = torsional modulus of elasticity in newtons per square millimeter.

*Example:* Find the torsional deflection of a solid steel shaft, 100 mm in diameter and 1300 mm long, subjected to a twisting moment of  $3 \times 10^6$  newton-millimeters. The torsional modulus of elasticity is 80,000 newtons/mm<sup>2</sup>. By **Formula (12)**

$$\alpha = \frac{584 \times 3 \times 10^6 \times 1300}{100^4 \times 80,000} = 0.285 \text{ degree}$$

The diameter of a shaft that is to have a maximum torsional deflection  $\alpha$  is given by:

$$D = 4.9 \times \sqrt[4]{\frac{T l}{G \alpha}} \quad (13)$$

**Formula (13)** can be used with metric SI units, where  $D$  = diameter of shaft in millimeters;  $T$  = torsional moment in newton-millimeters;  $l$  = length of shaft in

millimeters;  $G$  = torsional modulus of elasticity in newtons per square millimeter; and  $\alpha$  = angular deflection of shaft in degrees.

According to some authorities, the allowable twist in steel transmission shafting should not exceed 0.08 degree per foot length of the shaft. The diameter  $D$  of a shaft that will permit a maximum angular deflection of 0.08 degree per foot of length for a given torque  $T$  or for a given horsepower  $P$  can be determined from the formulas:

$$D = 0.29 \sqrt[4]{T} \quad (14a) \quad \text{or} \quad D = 4.6 \times \sqrt[4]{\frac{P}{N}} \quad (14b)$$

Using metric SI units and assuming an allowable twist in steel transmission shafting of 0.26 degree per meter length, Formulas (14a) and (14b) become:

$$D = 2.26 \sqrt[4]{T} \quad \text{or} \quad D = 125.7 \times \sqrt[4]{\frac{P}{N}}$$

where  $D$  = diameter of shaft in millimeters;  $T$  = torsional moment in newton-millimeters;  $P$  = power in kilowatts; and  $N$  = revolutions per minute.

Another rule that has been generally used in mill practice limits the deflection to 1 degree in a length equal to 20 times the shaft diameter. For a given torque or horsepower, the diameter of a shaft having this maximum deflection is given by:

$$D = 0.1 \sqrt[3]{T} \quad (15a) \quad \text{or} \quad D = 4.0 \times \sqrt[3]{\frac{P}{N}} \quad (15b)$$

*Example:* Find the diameter of a steel lineshaft to transmit 10 horsepower at 150 revolutions per minute with a torsional deflection not exceeding 0.08 degree per foot of length.

*Solution:* By Formula (14b),

$$D = 4.6 \times \sqrt[4]{\frac{10}{150}} = 2.35 \text{ inches}$$

This diameter is larger than that obtained for the same horsepower and rpm in the example given for Formula (5b) in which the diameter was calculated for strength considerations only. The usual procedure in the design of shafting which is to have a specified maximum angular deflection is to compute the diameter first by means of Formulas (13), (14a), (14b), (15a), or (15b) and then by means of Formulas (3a), (3b), (4b), (5b), or (6b), using the larger of the two diameters thus found.

**Linear Deflection of Shafting.**—For steel line shafting, it is considered good practice to limit the linear deflection to a maximum of 0.010 inch per foot of length. The maximum distance in feet between bearings for average conditions, in order to avoid excessive linear deflection, is determined by the formulas:

$$L = 8.95 \sqrt[3]{D^2} \text{ for shafting subject to no bending action except its own weight}$$

$$L = 5.2 \sqrt[3]{D^2} \text{ for shafting subject to bending action of pulleys, etc.}$$

in which  $D$  = diameter of shaft in inches and  $L$  = maximum distance between bearings in feet. Pulleys should be placed as close to the bearings as possible.

In general, shafting up to 3 inches in diameter is almost always made from cold-rolled steel. This shafting is true and straight and needs no turning, but if keyways are cut in the shaft, it must usually be straightened afterwards, as the cutting of the keyways relieves the tension on the surface of the shaft produced by the cold-rolling process. Sizes of shafting from 3 to 5 inches in diameter may be either cold-rolled or turned, more frequently the latter, and all larger sizes of shafting must be turned because cold-rolled shafting is not available in diameters larger than 5 inches.

**Diameters of Finished Shafting** (former American Standard ASA B17.1)

Diameters, Inches		Minus Tolerances, Inches <sup>a</sup>	Diameters, Inches		Minus Tolerances, Inches <sup>a</sup>	Diameters, Inches		Minus Tolerances, Inches <sup>a</sup>
Transmission Shafting	Machinery Shafting		Transmission Shafting	Machinery Shafting		Transmission Shafting	Machinery Shafting

	1 3/4	0.003		3 5/8	0.004	...	...	...

<sup>a</sup>Note:—These tolerances are *negative* or minus and represent the maximum allowable variation *below* the exact nominal size. For instance the maximum diameter of the 1 15/16 inch shaft is 1.938 inch and its minimum allowable diameter is 1.935 inch. Stock lengths of finished transmission shafting shall be: 16, 20 and 24 feet.

**Design of Transmission Shafting.**—The following guidelines for the design of shafting for transmitting a given amount of power under various conditions of loading are based upon formulas given in the former American Standard ASA B17c Code for the Design of Transmission Shafting. These formulas are based on the *maximum-shear theory* of failure which assumes that the elastic limit of a *ductile* ferrous material in shear is practically one-half its elastic limit in tension. This theory agrees, very nearly, with the results of tests on ductile materials and has gained wide acceptance in practice.

The formulas given apply in all shaft designs including shafts for special machinery. The limitation of these formulas is that they provide only for the strength of shafting and are not concerned with the torsional or lineal deformations which may, in shafts used in machine design, be the controlling factor (see *Torsional Deflection of Circular Shafts* on page 297 and *Linear Deflection of Shafting* on page 298 for deflection considerations). In the formulas that follow,

$$B = \sqrt[3]{1 \div (1 - K^4)} \quad (\text{see Table 3})$$

$D$  = outside diameter of shaft in inches

$D_1$  = inside diameter of a hollow shaft in inches

$K_m$  = shock and fatigue factor to be applied in every case to the computed bending moment (see Table 1)

$K_t$  = combined shock and fatigue factor to be applied in every case to the computed torsional moment (see Table 1)

$M$  = maximum bending moment in inch-pounds

$N$  = revolutions per minute

$P$  = maximum power to be transmitted by the shaft in horsepower

$p_t$  = maximum allowable shearing stress under combined loading conditions in pounds per square inch (see Table 2)

$S$  = maximum allowable flexural (bending) stress, in either tension or compression in pounds per square inch (see Table 2)

$S_s$  = maximum allowable torsional shearing stress in pounds per square inch (see Table 2)

$T$  = maximum torsional moment in inch-pounds

$V$  = maximum transverse shearing load in pounds

For shafts subjected to pure torsional loads only,

$$D = B \sqrt[3]{\frac{5.1K_t T}{S_s}} \quad (16a) \quad \text{or} \quad D = B \sqrt[3]{\frac{321,000K_t P}{S_s N}} \quad (16b)$$

For stationary shafts subjected to bending only,

$$D = B \sqrt[3]{\frac{10.2K_b M}{S}} \quad (17)$$

For shafts subjected to combined torsion and bending,

$$D = B \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_b M)^2 + (K_t T)^2}} \quad (18a)$$

or

$$D = B \times \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_b M)^2 + \left(\frac{63,000K_t P}{N}\right)^2}} \quad (18b)$$

Formulas (16a) to (18b) may be used for solid shafts or for hollow shafts. For solid shafts the factor  $B$  is equal to 1, whereas for hollow shafts the value of  $B$  depends on the value of  $K$  which, in turn, depends on the ratio of the inside diameter of the shaft to the outside diameter ( $D_1 \div D = K$ ). Table 3 gives values of  $B$  corresponding to various values of  $K$ .

For short solid shafts subjected only to heavy transverse shear, the diameter of shaft required is:

$$D = \sqrt{\frac{1.7V}{S_s}} \quad (19)$$

Formulas (16a), (17), (18a) and (19), can be used unchanged with metric SI units. Formula (16b) becomes:

$$D = B \sqrt[3]{\frac{48.7K_t P}{S_s N}} \quad \text{and Formula (18b) becomes:}$$

$$D = B \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_b M)^2 + \left(\frac{9.55K_t P}{N}\right)^2}}$$

Throughout the formulas,  $D$  = outside diameter of shaft in millimeters;  $T$  = maximum torsional moment in newton-millimeters;  $S_s$  = maximum allowable torsional shearing stress in newtons per millimeter squared (see Table 2);  $P$  = maximum power to be transmitted in milliwatts;  $N$  = revolutions per minute;  $M$  = maximum bending moment in newton-millimeters;  $S$  = maximum allowable flexural (bending) stress, either in tension or compression in newtons per millimeter squared (see Table 2);  $p_t$  = maximum allowable shearing stress under combined loading conditions in newtons per millimeter squared; and  $V$  = maximum transverse shearing load in

kilograms. The factors  $K_m$ ,  $K_T$ , and  $B$  are unchanged, and  $D_1$  = the inside diameter of a hollow shaft in millimeters.

**Table 1. Recommended Values of the Combined Shock and Fatigue Factors for Various Types of Load**

Type of Load	Stationary Shafts		Rotating Shafts	
	$K_m$	$K_T$	$K_m$	$K_T$
Gradually applied and steady	1.0	1.0	1.5	1.0
Suddenly applied, minor shocks only	1.5–2.0	1.5–2.0	1.5–2.0	1.0–1.5
Suddenly applied, heavy shocks	...	...	2.0–3.0	1.5–3.0

**Table 2. Recommended Maximum Allowable Working Stresses for Shafts Under Various Types of Load**

Material	Type of Load		
	Simple Bending	Pure Torsion	Combined Stress
"Commercial Steel" shafting without keyways	$S = 16,000$	$S_s = 8000$	$p_T = 8000$
"Commercial Steel" shafting with keyways	$S = 12,000$	$S_s = 6000$	$p_T = 6000$
Steel purchased under definite physical specs.	(See note a)	(See note b)	(See note b)

<sup>a</sup>  $S = 60$  percent of the elastic limit in tension but not more than 36 percent of the ultimate tensile strength.

<sup>b</sup>  $S_s$  and  $p_T = 30$  percent of the elastic limit in tension but not more than 18 percent of the ultimate tensile strength.

If the values in the Table are converted to metric SI units, note that 1000 pounds per square inch = 6.895 newtons per square millimeter.

**Table 3. Values of the Factor  $B$  Corresponding to Various Values of  $K$  for Hollow Shafts**

$K = \frac{D_1}{D}$	0.95	0.90	0.85	0.80	0.75	0.70	0.65	0.60	0.55	0.50
$B = \sqrt[3]{1 \div (1 - K^4)}$	1.75	1.43	1.28	1.19	1.14	1.10	1.07	1.05	1.03	1.02

For solid shafts,  $B = 1$  because  $K = 0$ , as follows:  $B = \sqrt[3]{1 \div (1 - K^4)} = \sqrt[3]{1 \div (1 - 0)} = 1$

**Effect of Keyways on Shaft Strength.**—Keyways cut into a shaft reduce its load carrying ability, particularly when impact loads or stress reversals are involved. To ensure an adequate factor of safety in the design of a shaft with standard keyway (width, one-quarter, and depth, one-eighth of shaft diameter), the former Code for Transmission Shafting tentatively recommended that shafts with keyways be designed on the basis of a solid circular shaft using not more than 75 percent of the working stress recommended for the solid shaft. See also page 2539.

**Formula for Shafts of Brittle Materials.**—The preceding formulas are applicable to ductile materials and are based on the *maximum-shear theory* of failure which assumes that the elastic limit of a *ductile* material in shear is one-half its elastic limit in tension.

Brittle materials are generally stronger in shear than in tension; therefore, the maximum-shear theory is not applicable. The *maximum-normal-stress theory* of failure is now generally accepted for the design of shafts made from brittle materials. A material may be considered brittle if its elongation in a 2-inch gage length is less than 5 percent. Materials such as cast iron, hardened tool steel, hard bronze, etc. conform to this rule. The diameter of a shaft made of a brittle material may be determined from the following formula which is based on the maximum-normal-stress theory of failure:

$$D = B \sqrt[3]{\frac{5.1}{S_t} [(K_m M) + \sqrt{(K_m M)^2 + (K_T T)^2}]}$$

where  $S_t$  is the maximum allowable tensile stress in pounds per square inch and the other quantities are as previously defined.

**The formula can be used unchanged with metric SI units, where  $D$  = outside diameter of shaft in millimeters;  $S_t$  = the maximum allowable tensile stress in newtons per millimeter squared;  $M$  = maximum bending moment in newton-millimeters; and  $T$  = maximum torsional moment in newton-millimeters. The factors  $K_m$ ,  $K_t$ , and  $B$  are unchanged.**

**Critical Speed of Rotating Shafts.**—At certain speeds, a rotating shaft will become dynamically unstable and the resulting vibrations and deflections can result in damage not only to the shaft but to the machine of which it is a part. The speeds at which such dynamic instability occurs are called the *critical speeds* of the shaft. On page 205 are given formulas for the critical speeds of shafts subject to various conditions of loading and support. A shaft may be safely operated either above or below its critical speed, good practice indicating that the operating speed be at least 20 percent above or below the critical.

The formulas commonly used to determine critical speeds are sufficiently accurate for general purposes. However, the torque applied to a shaft has an important effect on its critical speed. Investigations have shown that the critical speeds of a uniform shaft are decreased as the applied torque is increased, and that there exist critical torques which will reduce the corresponding critical speed of the shaft to zero. A detailed analysis of the effects of applied torques on critical speeds may be found in a paper, "Critical Speeds of Uniform Shafts under Axial Torque," by Golomb and Rosenberg, presented at the First US National Congress of Applied Mechanics in 1951.

**Shaft Couplings.**—A shaft coupling is a device for fastening together the ends of two shafts, so that the rotary motion of one causes rotary motion of the other. One of the most simple and common forms of coupling is the flange coupling Fig. 1a and Fig. 1b. It consists of two flanged sleeves or hubs, each of which is keyed to the end of one of the two shafts to be connected. The sleeves are held together and prevented from rotating relative to each other by bolts through the flanges as indicated.

#### Flange Coupling

Fig. 1a.

Fig. 1b.

**Flexible Couplings:** Flexible couplings are the most common mechanical means of compensating for unavoidable errors in alignment of shafts and shafting. When correctly applied, they are highly efficient for joining lengths of shafting without causing loss of power from bearing friction due to misalignment, and for use in direct motor drives for all kinds of machinery. Flexible couplings are not intended to be used for connecting a driven shaft and a driving shaft that are purposely placed in different planes or at an angle but are intended simply to overcome slight unavoidable errors in alignment that develop in service. There is a wide variety of flexible coupling designs; most of them consist essentially of two flanged members or hubs, fastened to the shafts and connected by some yielding arrangement. Balance is an important factor in coupling selection or design; it is not sufficient that the coupling be perfectly balanced when installed, but it must remain in balance after wear has taken place.

**Comparison of Hollow and Solid Shafting with Same Outside Diameter.**—Table 4 that follows gives the percent decrease in strength and weight of a hollow shaft relative to the strength and weight of a solid shaft of the same diameter. The upper figures in each line give the percent decrease in strength and the lower figures give the percent decrease in weight.

*Example:* A 4-inch shaft, with a 2-inch hole through it, has a weight 25 percent less than a solid 4-inch shaft, but its strength is decreased only 6.25 percent.

**Table 4. Comparative Torsional Strengths and Weights of Hollow and Solid Shafting with Same Outside Diameter**

The upper figures in each line give number of percent decrease in strength; the lower figures give percent decrease in weight.

## SPRINGS

## Introduction to Spring Design

Many advances have been made in the spring industry in recent years. For example: developments in materials permit longer fatigue life at higher stresses; simplified design procedures reduce the complexities of design, and improved methods of manufacture help to speed up some of the complicated fabricating procedures and increase production. New types of testing instruments and revised tolerances also permit higher standards of accuracy. Designers should also consider the possibility of using standard springs now available from stock. They can be obtained from spring manufacturing companies located in different areas, and small shipments usually can be made quickly.

Designers of springs require information in the following order of precedence to simplify design procedures.

- 1) Spring materials and their applications
- 2) Allowable spring stresses
- 3) Spring design data with tables of spring characteristics, tables of formulas, and tolerances.

Only the more commonly used types of springs are covered in detail here. Special types and designs rarely used such as torsion bars, volute springs, Belleville washers, constant force, ring and spiral springs and those made from rectangular wire are only described briefly. Belleville and disc springs are discussed in the section *DISC SPRINGS* starting on page 350.

**Notation.**—The following symbols are used in spring equations:

- $AC$  = Active coils
- $b$  = Widest width of rectangular wire, inches
- $CL$  = Compressed length, inches
- $D$  = Mean coil diameter, inches =  $OD - d$
- $d$  = Diameter of wire or side of square, inches
- $E$  = Modulus of elasticity in tension, pounds per square inch
- $F$  = Deflection, for  $N$  coils, inches
- $F^\circ$  = Deflection, for  $N$  coils, rotary, degrees
- $f$  = Deflection, for one active coil
- $FL$  = Free length, unloaded spring, inches
- $G$  = Modulus of elasticity in torsion, pounds per square inch
- $IT$  = Initial tension, pounds
- $K$  = Curvature stress correction factor
- $L$  = Active length subject to deflection, inches
- $N$  = Number of active coils, total
- $P$  = Load, pounds
- $p$  = Pitch, inches
- $R$  = Distance from load to central axis, inches
- $S$  or  $S_t$  = Stress, torsional, pounds per square inch
- $S_b$  = Stress, bending, pounds per square inch
- $SH$  = Solid height
- $S_{it}$  = Stress, torsional, due to initial tension, pounds per square inch
- $T$  = Torque =  $P \times R$ , pound-inches
- $TC$  = Total coils
- $t$  = Thickness, inches
- $U$  = Number of revolutions =  $F^\circ/360^\circ$

### Spring Materials

The spring materials most commonly used include high-carbon spring steels, alloy spring steels, stainless spring steels, copper-base spring alloys, and nickel-base spring alloys.

**High-Carbon Spring Steels in Wire Form.**—These spring steels are the most commonly used of all spring materials because they are the least expensive, are easily worked, and are readily available. However, they are not satisfactory for springs operating at high or low temperatures or for shock or impact loading. The following wire forms are available:

*Music Wire, ASTM A228:* (0.80–0.95 percent carbon) This is the most widely used of all spring materials for small springs operating at temperatures up to about 250°F. It is tough, has a high tensile strength, and can withstand high stresses under repeated loading. The material is readily available in round form in diameters ranging from 0.005 to 0.125 inch and in some larger sizes up to  $\frac{3}{16}$  inch. It is not available with high tensile strengths in square or rectangular sections. Music wire can be plated easily and is obtainable pretinned or preplated with cadmium, but plating after spring manufacture is usually preferred for maximum corrosion resistance.

*Oil-Tempered MB Grade, ASTM A229:* (0.60–0.70 percent carbon) This general-purpose spring steel is commonly used for many types of coil springs where the cost of music wire is prohibitive and in sizes larger than are available in music wire. It is readily available in diameters ranging from 0.125 to 0.500 inch, but both smaller and larger sizes may be obtained. The material should not be used under shock and impact loading conditions, at temperatures above 350°F, or at temperatures in the sub-zero range. Square and rectangular sections of wire are obtainable in fractional sizes. Annealed stock also can be obtained for hardening and tempering after coiling. This material has a heat-treating scale that must be removed before plating.

*Oil-Tempered HB Grade, SAE 1080:* (0.75–0.85 percent carbon) This material is similar to the MB Grade except that it has a higher carbon content and a higher tensile strength. It is obtainable in the same sizes and is used for more accurate requirements than the MB Grade, but is not so readily available. In lieu of using this material it may be better to use an alloy spring steel, particularly if a long fatigue life or high endurance properties are needed. Round and square sections are obtainable in the oil-tempered or annealed conditions.

*Hard-Drawn MB Grade, ASTM A227:* (0.60–0.70 percent carbon) This grade is used for general-purpose springs where cost is the most important factor. Although increased use in recent years has resulted in improved quality, it is best not to use this grade where long life and accuracy of loads and deflections are important. It is available in diameters ranging from 0.031 to 0.500 inch and in some smaller and larger sizes also. The material is available in square sections but at reduced tensile strengths. It is readily plated. Applications should be limited to those in the temperature range of 0 to 250°F.

**High-Carbon Spring Steels in Flat Strip Form.**—Two types of thin, flat, high-carbon spring steel strip are most widely used although several other types are obtainable for specific applications in watches, clocks, and certain instruments. These two compositions are used for over 95 percent of all such applications. Thin sections of these materials under 0.015 inch having a carbon content of over 0.85 percent and a hardness of over 47 RC (Rockwell C scale) are susceptible to hydrogen-embrittlement, even though special plating and heating operations are employed. The two types are described as follows:

*Cold-Rolled Spring Steel, Blue-Tempered or Annealed, SAE 1074, also 1064, and 1070:* (0.60 to 0.80 percent carbon) This very popular spring steel is available in thicknesses ranging from 0.005 to 0.062 inch and in some thinner and thicker sections. The material is available in the annealed condition for forming in 4-slide machines and in presses, and can readily be hardened and tempered after forming. It is also available in the heat-treated

or blue-tempered condition. The steel is obtainable in several finishes, such as straw color, blue color, black, or plain. Hardnesses ranging from 42 to 46 RC (Rockwell C scale) are recommended for spring applications. Uses include spring clips, flat springs, clock springs, and motor, power, and spiral springs.

*Cold-Rolled Spring Steel, Blue-Tempered Clock Steel, SAE 1095:* (0.90 to 1.05 percent carbon) This popular type should be used principally in the blue-tempered condition. Although obtainable in the annealed condition, it does not always harden properly during heat treatment as it is a "shallow" hardening type. It is used principally in clocks and motor springs. End sections of springs made from this steel are annealed for bending or piercing operations. Hardnesses usually range from 47 to 51 RC.

Other materials available in strip form and used for flat springs are brass, phosphor-bronze, beryllium-copper, stainless steels, and nickel alloys.

**Alloy Spring Steels.**—These spring steels are used for conditions of high stress, and shock or impact loadings. They can withstand both higher and lower temperatures than the high-carbon steels and are obtainable in either the annealed or pretempered conditions.

*Chromium Vanadium, ASTM A231:* This very popular spring steel is used under conditions involving higher stresses than those for which the high-carbon spring steels are recommended and is also used where good fatigue strength and endurance are needed. It behaves well under shock and impact loading. The material is available in diameters ranging from 0.031 to 0.500 inch and in some larger sizes also. In square sections it is available in fractional sizes. Both the annealed and pretempered types are available in round, square, and rectangular sections. It is used extensively in aircraft-engine valve springs and for springs operating at temperatures up to 425°F.

*Silicon Manganese:* This alloy steel is quite popular in Great Britain. It is less expensive than chromium-vanadium steel and is available in round, square, and rectangular sections in both annealed and pretempered conditions in sizes ranging from 0.031 to 0.500 inch. It was formerly used for knee-action springs in automobiles. It is used in flat leaf springs for trucks and as a substitute for more expensive spring steels.

*Chromium Silicon, ASTM A401:* This alloy is used for highly stressed springs that require long life and are subjected to shock loading. It can be heat treated to higher hardnesses than other spring steels so that high tensile strengths are obtainable. The most popular sizes range from 0.031 to 0.500 inch in diameter. Very rarely are square, flat, or rectangular sections used. Hardnesses ranging from 50 to 53 RC are quite common and the alloy may be used at temperatures up to 475°F. This material is usually ordered specially for each job.

**Stainless Spring Steels.**—The use of stainless spring steels has increased and several compositions are available all of which may be used for temperatures up to 550°F. They are all corrosion resistant. Only the stainless 18-8 compositions should be used at sub-zero temperatures.

*Stainless Type 302, ASTM A313:* (18 percent chromium, 8 percent nickel) This stainless spring steel is very popular because it has the highest tensile strength and quite uniform properties. It is cold-drawn to obtain its mechanical properties and cannot be hardened by heat treatment. This material is nonmagnetic only when fully annealed and becomes slightly magnetic due to the cold-working performed to produce spring properties. It is suitable for use at temperatures up to 550°F. and for sub-zero temperatures. It is very corrosion resistant. The material best exhibits its desirable mechanical properties in diameters ranging from 0.005 to 0.1875 inch although some larger diameters are available. It is also available as hard-rolled flat strip. Square and rectangular sections are available but are infrequently used.

*Stainless Type 304, ASTM A313:* (18 percent chromium, 8 percent nickel) This material is quite similar to Type 302, but has better bending properties and about 5 percent lower tensile strength. It is a little easier to draw, due to the slightly lower carbon content.

*Stainless Type 316, ASTM A313:* (18 percent chromium, 12 percent nickel, 2 percent molybdenum) This material is quite similar to Type 302 but is slightly more corrosion resistant because of its higher nickel content. Its tensile strength is 10 to 15 percent lower than Type 302. It is used for aircraft springs.

*Stainless Type 17-7 PH ASTM A313:* (17 percent chromium, 7 percent nickel) This alloy, which also contains small amounts of aluminum and titanium, is formed in a moderately hard state and then precipitation hardened at relatively low temperatures for several hours to produce tensile strengths nearly comparable to music wire. This material is not readily available in all sizes, and has limited applications due to its high manufacturing cost.

*Stainless Type 414, SAE 51414:* (12 percent chromium, 2 percent nickel) This alloy has tensile strengths about 15 percent lower than Type 302 and can be hardened by heat-treatment. For best corrosion resistance it should be highly polished or kept clean. It can be obtained hard drawn in diameters up to 0.1875 inch and is commonly used in flat cold-rolled strip for stampings. The material is not satisfactory for use at low temperatures.

*Stainless Type 420, SAE 51420:* (13 percent chromium) This is the best stainless steel for use in large diameters above 0.1875 inch and is frequently used in smaller sizes. It is formed in the annealed condition and then hardened and tempered. It does not exhibit its stainless properties until after it is hardened. Clean bright surfaces provide the best corrosion resistance, therefore the heat-treating scale must be removed. Bright hardening methods are preferred.

*Stainless Type 431, SAE 51431:* (16 percent chromium, 2 percent nickel) This spring alloy acquires high tensile properties (nearly the same as music wire) by a combination of heat-treatment to harden the wire plus cold-drawing after heat treatment. Its corrosion resistance is not equal to Type 302.

**Copper-Base Spring Alloys.**—Copper-base alloys are important spring materials because of their good electrical properties combined with their good resistance to corrosion. Although these materials are more expensive than the high-carbon and the alloy steels, they nevertheless are frequently used in electrical components and in sub-zero temperatures.

*Spring Brass, ASTM B134:* (70 percent copper, 30 percent zinc) This material is the least expensive and has the highest electrical conductivity of the copper-base alloys. It has a low tensile strength and poor spring qualities, but is extensively used in flat stampings and where sharp bends are needed. It cannot be hardened by heat treatment and should not be used at temperatures above 150°F, but is especially good at sub-zero temperatures. Available in round sections and flat strips, this hard-drawn material is usually used in the “spring hard” temper.

*Phosphor Bronze, ASTM B159:* (95 percent copper, 5 percent tin) This alloy is the most popular of this group because it combines the best qualities of tensile strength, hardness, electrical conductivity, and corrosion resistance with the least cost. It is more expensive than brass, but can withstand stresses 50 percent higher. The material cannot be hardened by heat treatment. It can be used at temperatures up to 212°F and at sub-zero temperatures. It is available in round sections and flat strip, usually in the “extra-hard” or “spring hard” tempers. It is frequently used for contact fingers in switches because of its low arcing properties. An 8 percent tin composition is used for flat springs and a superfine grain composition called “Duraflex” has good endurance properties.

*Beryllium Copper, ASTM B197:* (98 percent copper, 2 percent beryllium) This alloy can be formed in the annealed condition and then precipitation hardened after forming at

temperatures around 600°F, for 2 to 3 hours. This treatment produces a high hardness combined with a high tensile strength. After hardening, the material becomes quite brittle and can withstand very little or no forming. It is the most expensive alloy in the group and heat treating is expensive due to the need for holding the parts in fixtures to prevent distortion. The principal use of this alloy is for carrying electric current in switches and in electrical components. Flat strip is frequently used for contact fingers.

**Nickel-Base Spring Alloys.**—Nickel-base alloys are corrosion resistant, withstand both elevated and sub-zero temperatures, and their non-magnetic characteristic makes them useful for such applications as gyroscopes, chronoscopes, and indicating instruments. These materials have a high electrical resistance and therefore should not be used for conductors of electrical current.

*Monel*<sup>®</sup>: (67 percent nickel, 30 percent copper) This material is the least expensive of the nickel-base alloys. It also has the lowest tensile strength but is useful due to its resistance to the corrosive effects of sea water and because it is nearly non-magnetic. The alloy can be subjected to stresses slightly higher than phosphor bronze and nearly as high as beryllium copper. Its high tensile strength and hardness are obtained as a result of cold-drawing and cold-rolling only, since it can not be hardened by heat treatment. It can be used at temperatures ranging from -100 to +425°F at normal operating stresses and is available in round wires up to  $\frac{3}{16}$  inch in diameter with quite high tensile strengths. Larger diameters and flat strip are available with lower tensile strengths.

*"K" Monel*<sup>®</sup>: (66 percent nickel, 29 percent copper, 3 percent aluminum) This material is quite similar to Monel except that the addition of the aluminum makes it a precipitation-hardening alloy. It may be formed in the soft or fairly hard condition and then hardened by a long-time age-hardening heat treatment to obtain a tensile strength and hardness above Monel and nearly as high as stainless steel. It is used in sizes larger than those usually used with Monel, is non-magnetic and can be used in temperatures ranging from -100 to +450°F at normal working stresses under 45,000 pounds per square inch.

*Inconel*<sup>®</sup>: (78 percent nickel, 14 percent chromium, 7 percent iron) This is one of the most popular of the non-magnetic nickel-base alloys because of its corrosion resistance and because it can be used at temperatures up to 700°F. It is more expensive than stainless steel but less expensive than beryllium copper. Its hardness and tensile strength is higher than that of "K" Monel and is obtained as a result of cold-drawing and cold-rolling only. It cannot be hardened by heat treatment. Wire diameters up to  $\frac{1}{4}$  inch have the best tensile properties. It is often used in steam valves, regulating valves, and for springs in boilers, compressors, turbines, and jet engines.

*Inconel "X"*<sup>™</sup>: (70 percent nickel, 16 percent chromium, 7 percent iron) This material is quite similar to Inconel but the small amounts of titanium, columbium and aluminum in its composition make it a precipitation-hardening alloy. It can be formed in the soft or partially hard condition and then hardened by holding it at 1200°F for 4 hours. It is non-magnetic and is used in larger sections than Inconel. This alloy is used at temperatures up to 850°F and at stresses up to 55,000 pounds per square inch.

*Duranickel*<sup>®</sup>: ("Z" Nickel) (98 percent nickel) This alloy is non-magnetic, corrosion resistant, has a high tensile strength and is hardenable by precipitation hardening at 900°F for 6 hours. It may be used at the same stresses as Inconel but should not be used at temperatures above 500°F.

**Nickel-Base Spring Alloys with Constant Moduli of Elasticity.**—Some special nickel alloys have a constant modulus of elasticity over a wide temperature range. These materials are especially useful where springs undergo temperature changes and must exhibit uniform spring characteristics. These materials have a low or zero thermo-elastic coefficient

\*Trade name of the International Nickel Company.

and therefore do not undergo variations in spring stiffness because of modulus changes due to temperature differentials. They also have low hysteresis and creep values which makes them preferred for use in food-weighing scales, precision instruments, gyroscopes, measuring devices, recording instruments and computing scales where the temperature ranges from  $-50$  to  $+150^{\circ}\text{F}$ . These materials are expensive, none being regularly stocked in a wide variety of sizes. They should not be specified without prior discussion with spring manufacturers because some suppliers may not fabricate springs from these alloys due to the special manufacturing processes required. All of these alloys are used in small wire diameters and in thin strip only and are covered by US patents. They are more specifically described as follows:

*Elinvar*<sup>\*</sup>: (nickel, iron, chromium) This alloy, the first constant-modulus alloy used for hairsprings in watches, is an austenitic alloy hardened only by cold-drawing and cold-rolling. Additions of titanium, tungsten, molybdenum and other alloying elements have brought about improved characteristics and precipitation-hardening abilities. These improved alloys are known by the following trade names: Elinvar Extra, Durinval, Modulvar and Nivarox.

*Ni-Span C*<sup>\*</sup>: (nickel, iron, chromium, titanium) This very popular constant-modulus alloy is usually formed in the 50 percent cold-worked condition and precipitation-hardened at  $900^{\circ}\text{F}$  for 8 hours, although heating up to  $1250^{\circ}\text{F}$  for 3 hours produces hardnesses on the Rockwell C scale of 40 to 44 RC, permitting safe torsional stresses of 60,000 to 80,000 pounds per square inch. This material is ferromagnetic up to  $400^{\circ}\text{F}$ ; above that temperature it becomes non-magnetic.

*Iso-Elastic*<sup>†</sup>: (nickel, iron, chromium, molybdenum) This popular alloy is relatively easy to fabricate and is used at safe torsional stresses of 40,000 to 60,000 pounds per square inch and hardnesses of 30 to 36 RC. It is used principally in dynamometers, instruments, and food-weighing scales.

*Elgiloy*<sup>‡</sup>: (nickel, iron, chromium, cobalt) This alloy, also known by the trade names 8J Alloy, Durapower, and Cobenium, is a non-magnetic alloy suitable for sub-zero temperatures and temperatures up to about  $1000^{\circ}\text{F}$ , provided that torsional stresses are kept under 75,000 pounds per square inch. It is precipitation-hardened at  $900^{\circ}\text{F}$  for 8 hours to produce hardnesses of 48 to 50 RC. The alloy is used in watch and instrument springs.

*Dynavar*<sup>§</sup>: (nickel, iron, chromium, cobalt) This alloy is a non-magnetic, corrosion-resistant material suitable for sub-zero temperatures and temperatures up to about  $750^{\circ}\text{F}$ , provided that torsional stresses are kept below 75,000 pounds per square inch. It is precipitation-hardened to produce hardnesses of 48 to 50 RC and is used in watch and instrument springs.

### Spring Stresses

**Allowable Working Stresses for Springs.**—The safe working stress for any particular spring depends to a large extent on the following items:

- 1) Type of spring — whether compression, extension, torsion, etc.
- 2) Size of spring — small or large, long or short
- 3) Spring material
- 4) Size of spring material
- 5) Type of service — light, average, or severe
- 6) Stress range — low, average, or high

\*Trade name of Soc. Anon. de Commeny Fourchambault et Decazeville, Paris, France.

†Trade name of John Chatillon & Sons.

‡Trade name of Elgin National Watch Company.

§Trade name of Hamilton Watch Company.

- 7) Loading — static, dynamic, or shock
- 8) Operating temperature
- 9) Design of spring — spring index, sharp bends, hooks.

Consideration should also be given to other factors that affect spring life: corrosion, buckling, friction, and hydrogen embrittlement decrease spring life; manufacturing operations such as high-heat stress-equalizing, presetting, and shot-peening increase spring life.

Item 5, the type of service to which a spring is subjected, is a major factor in determining a safe working stress once consideration has been given to type of spring, kind and size of material, temperature, type of loading, and so on. The types of service are:

*Light Service:* This includes springs subjected to static loads or small deflections and seldom-used springs, such as those in bomb fuses, projectiles, and safety devices. This service is for 1000 to 10,000 deflections.

*Average Service:* This includes springs in general use in machine tools, mechanical products, and electrical components. Normal frequency of deflections not exceeding 18,000 per hour permit such springs to withstand 100,000 to 1,000,000 deflections.

*Severe Service:* This includes springs subjected to rapid deflections over long periods of time and to shock loading, such as in pneumatic hammers, hydraulic controls and valves. This service is for 1,000,000 deflections, and above. Lowering the values 10 percent permits 10,000,000 deflections.

Fig. 1 through Fig. 6 show curves that relate the three types of service conditions to allowable working stresses and wire sizes for compression and extension springs, and safe values are provided. Fig. 7 through Fig. 10 provide similar information for helical torsion springs. In each chart, the values obtained from the curves may be increased by 20 percent (but not beyond the top curves on the charts if permanent set is to be avoided) for springs that are baked, and shot-peened, and compression springs that are pressed. Springs stressed slightly above the Light Service curves will take a permanent set.

A curvature correction factor is included in all curves, and is used in spring design calculations (see examples beginning page 317). The curves may be used for materials other than those designated in Fig. 1 through Fig. 10, by applying multiplication factors as given in Table 1.

<sup>a</sup>Although Fig. 1 through Fig. 6 are for compression springs, they may also be used for extension springs; for extension springs, *reduce* the values obtained from the curves by 10 to 15 percent.

**Table 1. Correction Factors for Other Materials**

Compression and Tension Springs			
Material	Factor	Material	Factor
Silicon-manganese	Multiply the values in the chromium-vanadium curves (Fig. 6) by 0.90	Stainless Steel, 316	Multiply the values in the corrosion-resisting steel curves (Fig. 5) by 0.90
Valve-spring quality wire	Use the values in the chromium-vanadium curves (Fig. 6)		
Stainless Steel, 304 and 420	Multiply the values in the corrosion-resisting steel curves (Fig. 5) by 0.95	Stainless Steel, 431 and 17-7PH	Multiply the values in the music wire curves (Fig. 2) by 0.90

Helical Torsion Springs			
Material	Factor <sup>a</sup>	Material	Factor <sup>a</sup>
Hard Drawn MB	0.70	Stainless Steel, 431	
Stainless Steel, 316		Up to 1/2 inch diameter	0.80
Up to 1/2 inch diameter	0.75	Over 1/2 to 1/6 inch	0.85
Over 1/2 to 3/6 inch	0.70	Over 1/6 to 1/8 inch	0.95
Over 3/6 to 1/4 inch	0.65	Over 1/8 inch	1.00
Over 1/4 inch	0.50	Chromium-Vanadium	
Stainless Steel, 17-7 PH		Up to 1/6 inch diameter	1.05
Up to 1/8 inch diameter	1.00	Over 1/6 inch	1.10
Over 1/8 to 3/6 inch	1.07	Phosphor Bronze	
Over 3/6 inch	1.12	Up to 1/8 inch diameter	0.45
Stainless Steel, 420		Over 1/8 inch	0.55
Up to 1/2 inch diameter	0.70	Beryllium Copper <sup>b</sup>	
Over 1/2 to 1/6 inch	0.75	Up to 1/2 inch diameter	0.55
Over 1/6 to 1/8 inch	0.80	Over 1/2 to 1/6 inch	0.60
Over 1/8 to 3/6 inch	0.90	Over 1/6 to 1/8 inch	0.70
Over 3/6 inch	1.00	Over 1/8 inch	0.80

<sup>a</sup> Multiply the values in the curves for oil-tempered MB grade ASTM A229 Type 1 steel (Fig. 8) by these factors to obtain required values.

<sup>b</sup> Hard drawn and heat treated after coiling.

For use with design stress curves shown in Fig. 2, Fig. 5, Fig. 6, and Fig. 8.

**Endurance Limit for Spring Materials.**—When a spring is deflected continually it will become “tired” and fail at a stress far below its elastic limit. This type of failure is called *fatigue failure* and usually occurs without warning. *Endurance limit* is the highest stress, or range of stress, in pounds per square inch that can be repeated indefinitely without failure of the spring. Usually ten million cycles of deflection is called “infinite life” and is satisfactory for determining this limit.

For severely worked springs of long life, such as those used in automobile or aircraft engines and in similar applications, it is best to determine the allowable working stresses by referring to the endurance limit curves seen in Fig. 11. These curves are based principally upon the range or difference between the stress caused by the first or initial load and the stress caused by the final load. Experience with springs designed to stresses within the limits of these curves indicates that they should have infinite or unlimited fatigue life. All values include Wahl curvature correction factor. The stress ranges shown may be increased 20 to 30 percent for springs that have been properly heated, pressed to remove set, and then shot peened, provided that the increased values are lower than the torsional elastic limit by at least 10 percent.

Fig. 11. Endurance Limit Curves for Compression Springs

Notes: For commercial spring materials with wire diameters up to  $\frac{1}{4}$  inch except as noted. Stress ranges may be increased by approximately 30 percent for properly heated, preset, shot-peened springs.

Materials preceded by \* are not ordinarily recommended for long continued service under severe operating conditions.

**Working Stresses at Elevated Temperatures.**—Since modulus of elasticity decreases with increase in temperature, springs used at high temperatures exert less load and have larger deflections under load than at room temperature. The torsional modulus of elasticity for steel may be 11,200,000 pounds per square inch at room temperature, but it will drop to 10,600,000 pounds per square inch at 400°F. and will be only 10,000,000 pounds per square inch at 600°F. Also, the elastic limit is reduced, thereby lowering the permissible working stress.

Design stresses should be as low as possible for all springs used at elevated temperatures. In addition, corrosive conditions that usually exist at high temperatures, especially with steam, may require the use of corrosion-resistant material. Table 2 shows the permissible elevated temperatures at which various spring materials may be operated, together with the maximum recommended working stresses at these temperatures. The loss in load at the temperatures shown is less than 5 percent in 48 hours; however, if the temperatures listed are increased by 20 to 40 degrees, the loss of load may be nearer 10 percent. Maximum stresses shown in the table are for compression and extension springs and may be

increased by 75 percent for torsion and flat springs. In using the data in Table 2 it should be noted that the values given are for materials in the heat-treated or spring temper condition.

**Table 2. Recommended Maximum Working Temperatures and Corresponding Maximum Working Stresses for Springs**

Spring Material	Max. Working Temp., °F	Max. Working Stress, psi	Spring Material	Max. Working Temp., °F	Max. Working Stress, psi
Brass Spring Wire	150	30,000	Permanickel <sup>a</sup>	500	50,000
Phosphor Bronze	225	35,000	Stainless Steel 18-8	550	55,000
Music Wire	250	75,000	Stainless Chromium 431	600	50,000
Beryllium-Copper	300	40,000	Inconel	700	50,000
Hard Drawn Steel Wire	325	50,000	High-Speed Steel	775	70,000
Carbon Spring Steels	375	55,000	Inconel X	850	55,000
Alloy Spring Steels	400	65,000	Chromium-Molybdenum-Vanadium	900	55,000
Monel	425	40,000	Cobenium, Elgiloy	1000	75,000
K-Monel	450	45,000			

<sup>a</sup> Formerly called Z-Nickel, Type B.

Loss of load at temperatures shown is less than 5 percent in 48 hours.

### Spring Design Data

**Spring Characteristics.**—This section provides tables of spring characteristics, tables of principal formulas, and other information of a practical nature for designing the more commonly used types of springs.

*Standard wire gages for springs:* Information on wire gages is given in the section beginning on page 2702, and gages in decimals of an inch are given in the table on page 2703. It should be noted that the range in this table extends from Number 7/0 through Number 80. However, in spring design, the range most commonly used extends only from Gage Number 4/0 through Number 40. When selecting wire use Steel Wire Gage or Washburn and Moen gage for all carbon steels and alloy steels except music wire; use Brown & Sharpe gage for brass and phosphor bronze wire; use Birmingham gage for flat spring steels, and cold rolled strip; and use piano or music wire gage for music wire.

*Spring index:* The spring index is the ratio of the mean coil diameter of a spring to the wire diameter ( $D/d$ ). This ratio is one of the most important considerations in spring design because the deflection, stress, number of coils, and selection of either annealed or tempered material depend to a considerable extent on this ratio. The best proportioned springs have an index of 7 through 9. Indexes of 4 through 7, and 9 through 16 are often used. Springs with values larger than 16 require tolerances wider than standard for manufacturing; those with values less than 5 are difficult to coil on automatic coiling machines.

*Direction of helix:* Unless functional requirements call for a definite hand, the helix of compression and extension springs should be specified as optional. When springs are designed to operate, one inside the other, the helices should be opposite hand to prevent intermeshing. For the same reason, a spring that is to operate freely over a threaded member should have a helix of opposite hand to that of the thread. When a spring is to engage with a screw or bolt, it should, of course, have the same helix as that of the thread.

**Helical Compression Spring Design.**—After selecting a suitable material and a safe stress value for a given spring, designers should next determine the type of end coil formation best suited for the particular application. Springs with unground ends are less expensive but they do not stand perfectly upright; if this requirement has to be met, closed ground ends are used. Helical compression springs with different types of ends are shown in Fig. 12.

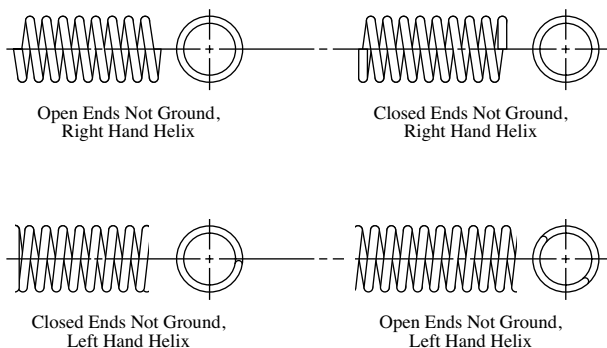

Fig. 12. Types of Helical Compression Spring Ends

*Spring design formulas:* Table 3 gives formulas for compression spring dimensional characteristics, and Table 4 gives design formulas for compression and extension springs.

*Curvature correction:* In addition to the stress obtained from the formulas for load or deflection, there is a direct shearing stress and an increased stress on the inside of the section due to curvature. Therefore, the stress obtained by the usual formulas should be multiplied by a factor  $K$  taken from the curve in Fig. 13. The corrected stress thus obtained is used only for comparison with the allowable working stress (fatigue strength) curves to determine if it is a safe stress and should not be used in formulas for deflection. The curvature correction factor  $K$  is for compression and extension springs made from round wire. For square wire reduce the  $K$  value by approximately 4 percent.

*Design procedure:* The limiting dimensions of a spring are often determined by the available space in the product or assembly in which it is to be used. The loads and deflections on a spring may also be known or can be estimated, but the wire size and number of coils are usually unknown. Design can be carried out with the aid of the tabular data that appears later in this section (see Table 5, which is a simple method, or by calculation alone using the formulas in Table 3 and Table 4.

*Example:* A compression spring with closed and ground ends is to be made from ASTM A229 high carbon steel wire, as shown in Fig. 14. Determine the wire size and number of coils.

*Method 1, using table:* Referring to Table 5, starting on page 321, locate the spring outside diameter ( $1\frac{3}{16}$  inches, from Fig. 14 on page 319) in the left-hand column. Note from the drawing that the spring load is 36 pounds. Move to the right in the table to the figure nearest this value, which is 41.7 pounds. This is somewhat above the required value but safe. Immediately above the load value, the deflection  $f$  is given, which in this instance is 0.1594 inch. This is the deflection of one coil under a load of 41.7 pounds with an uncorrected torsional stress  $S$  of 100,000 pounds per square inch for ASTM A229 oil-tempered MB steel. For other spring materials, see the footnotes to Table 5. Moving vertically in Table 5 from the load entry, the wire diameter is found to be 0.0915 inch.

The remaining spring design calculations are completed as follows:

*Step 1:* The stress with a load of 36 pounds is obtained by proportion, as follows: The 36 pound load is 86.3 percent of the 41.7 pound load; therefore, the stress  $S$  at 36 pounds =  $0.863 \times 100,000 = 86,300$  pounds per square inch.

**Table 3. Formulas for Compression Springs**

Feature	Type of End			
	Open or Plain (not ground)	Open or Plain (with ends ground)	Squared or Closed (not ground)	Closed and Ground
	Formula <sup>a</sup>			
Pitch ( $p$ )	$\frac{FL-d}{N}$	$\frac{FL}{TC}$	$\frac{FL-3d}{N}$	$\frac{FL-2d}{N}$
Solid Height ( $SH$ )	$(TC+1)d$	$TC \times d$	$(TC+1)d$	$TC \times d$
Number of Active Coils ( $N$ )	$N = TC = \frac{FL-d}{p}$	$N = TC - 1 = \frac{FL}{p} - 1$	$N = TC - 2 = \frac{FL-3d}{p}$	$N = TC - 2 = \frac{FL-2d}{p}$
Total Coils ( $TC$ )	$\frac{FL-d}{p}$	$\frac{FL}{p}$	$\frac{FL-3d}{p} + 2$	$\frac{FL-2d}{p} + 2$
Free Length ( $FL$ )	$(p \times TC) + d$	$p \times TC$	$(p \times N) + 3d$	$(p \times N) + 2d$

<sup>a</sup>The symbol notation is given on page 304.

**Table 4. Formulas for Compression and Extension Springs**

Feature	Formula <sup>a, b</sup>	
	Springs made from round wire	Springs made from square wire
Load, $P$ Pounds	$P = \frac{0.393Sd^3}{D} = \frac{Gd^4F}{8ND^3}$	$P = \frac{0.416Sd^3}{D} = \frac{Gd^4F}{5.58ND^3}$
Stress, Torsional, $S$ Pounds per square inch	$S = \frac{GdF}{\pi ND^2} = \frac{PD}{0.393d^3}$	$S = \frac{GdF}{2.32ND^2} = P \frac{D}{0.416d^3}$
Deflection, $F$ Inch	$F = \frac{8PND^3}{Gd^4} = \frac{\pi SND^2}{Gd}$	$F = \frac{5.58PND^3}{Gd^4} = \frac{2.32SND^2}{Gd}$
Number of Active Coils, $N$	$N = \frac{Gd^4F}{8PD^3} = \frac{GdF}{\pi SD^2}$	$N = \frac{Gd^4F}{5.58PD^3} = \frac{GdF}{2.32SD^2}$
Wire Diameter, $d$ Inch	$d = \frac{\pi SND^2}{GF} = \sqrt[3]{\frac{2.55PD}{S}}$	$d = \frac{2.32SND^2}{GF} = \sqrt[3]{\frac{PD}{0.416S}}$
Stress due to Initial Tension, $S_{it}$	$S_{it} = \frac{S}{P} \times IT$	$S_{it} = \frac{S}{P} \times IT$

<sup>a</sup>The symbol notation is given on page 304.

<sup>b</sup>Two formulas are given for each feature, and designers can use the one found to be appropriate for a given design. The end result from either of any two formulas is the same.

Step 2: The 86.3 percent figure is also used to determine the deflection per coil  $f$  at 36 pounds load:  $0.863 \times 0.1594 = 0.1375$  inch.

Step 3: The number of active coils  $AC = \frac{F}{f} = \frac{1.25}{0.1375} = 9.1$

Fig. 13. Compression and Extension Spring-Stress Correction for Curvature<sup>a</sup>

<sup>a</sup>For springs made from round wire. For springs made from square wire, reduce the *K* factor values by approximately 4 percent.

Fig. 14. Compression Spring Design Example

Step 4: Total Coils  $TC = AC + 2$  (Table 3) =  $9 + 2 = 11$

Therefore, a quick answer is: 11 coils of 0.0915 inch diameter wire. However, the design procedure should be completed by carrying out these remaining steps:

Step 5: From Table 3, Solid Height =  $SH = TC \times d = 11 \times 0.0915 \cong 1$  inch

Therefore, Total Deflection =  $FL - SH = 1.5$  inches

$$\text{Step 6: Stress Solid} = \frac{86,300}{1.25} \times 1.5 = 103,500 \text{ pounds per square inch}$$

$$\text{Step 7: Spring Index} = \frac{O.D.}{d} - 1 = \frac{0.8125}{0.0915} - 1 = 7.9$$

Step 8: From Fig. 13 on page 319, the curvature correction factor  $K = 1.185$

Step 9: Total Stress at 36 pounds load  $= S \times K = 86,300 \times 1.185 = 102,300$  pounds per square inch. This stress is below the 117,000 pounds per square inch permitted for 0.0915 inch wire shown on the middle curve in Fig. 3 on page 311, so it is a safe working stress.

Step 10: Total Stress at Solid  $= 103,500 \times 1.185 = 122,800$  pounds per square inch. This stress is also safe, as it is below the 131,000 pounds per square inch shown on the top curve of Fig. 3, and therefore the spring will not set.

*Method 2, using formulas:* The procedure for design using formulas is as follows (the design example is the same as in Method 1, and the spring is shown in Fig. 14):

Step 1: Select a safe stress  $S$  below the middle fatigue strength curve Fig. 3 on page 311 for ASTM A229 steel wire, say 90,000 pounds per square inch. Assume a mean diameter  $D$  slightly below the  $\frac{13}{16}$ -inch  $O.D.$ , say 0.7 inch. Note that the value of  $G$  is 11,200,000 pounds per square inch (Table 20 on page 346).

Step 2: A trial wire diameter  $d$  and other values are found by formulas from Table 4 as follows:

$$\begin{aligned} d &= \sqrt[3]{\frac{2.55PD}{S}} = \sqrt[3]{\frac{2.55 \times 36 \times 0.7}{90,000}} \\ &= \sqrt[3]{0.000714} = 0.0894 \text{ inch} \end{aligned}$$

Note: Table 21 on page 347 can be used to avoid solving the cube root.

Step 3: From Table 21 (also see the table on page 2703), select the nearest wire gauge size, which is 0.0915 inch diameter. Using this value, the mean diameter  $D = \frac{13}{16}$  inch  $- 0.0915 = 0.721$  inch.

$$\text{Step 4: The stress } S = \frac{PD}{0.393d^3} = \frac{36 \times 0.721}{0.393 \times 0.0915^3} = 86,300 \text{ lb/in}^2$$

Step 5: The number of active coils is

$$N = \frac{GdF}{\pi SD^2} = \frac{11,200,000 \times 0.0915 \times 1.25}{3.1416 \times 86,300 \times 0.721^2} = 9.1 \text{ (say 9)}$$

The answer is the same as before, which is to use 11 total coils of 0.0915-inch diameter wire. The total coils, solid height, etc., are determined in the same manner as in Method 1.

**Table of Spring Characteristics.**—Table 5 gives characteristics for compression and extension springs made from ASTM A229 oil-tempered MB spring steel having a torsional modulus of elasticity  $G$  of 11,200,000 pounds per square inch, and an uncorrected torsional stress  $S$  of 100,000 pounds per square inch. The deflection  $f$  for one coil under a load  $P$  is shown in the body of the table. The method of using these data is explained in the problems for compression and extension spring design. The table may be used for other materials by applying factors to  $f$ . The factors are given in a footnote to the table.

<sup>a</sup>This table is for ASTM A 229 oil tempered spring steel with a torsional modulus *G* of 11,200,000 psi, and an uncorrected torsional stress of 100,000 psi. For other materials use the following factors: stainless steel, multiply *f* by 1.067; spring brass, multiply *f* by 2.24; phosphor bronze, multiply *f* by 1.867; Monel metal, multiply *f* by 1.244; beryllium copper, multiply *f* by 1.725; Inconel (non-magnetic), multiply *f* by 1.045.

<sup>b</sup>Round wire. For square wire, multiply *f* by 0.707, and *p*, by 1.2

<sup>c</sup>The upper figure is the deflection and the lower figure the load as read against each spring size. *Note:* Intermediate values can be obtained within reasonable accuracy by interpolation.

<sup>a</sup>This table is for ASTM A229 oil tempered spring steel with a torsional modulus *G* of 11,200,000 psi, and an uncorrected torsional stress of 100,000 psi. For other materials, and other important footnotes, see page 321.

**Extension Springs.**—About 10 percent of all springs made by many companies are of this type, and they frequently cause trouble because insufficient consideration is given to stress due to initial tension, stress and deflection of hooks, special manufacturing methods, secondary operations and overstretching at assembly. Fig. 15 shows types of ends used on these springs.

All the Above Ends are Standard Types for Which No Special Tools are Required

This Group of Special Ends Requires Special Tools

Fig. 15. Types of Helical Extension Spring Ends

**Initial tension:** In the spring industry, the term "Initial tension" is used to define a force or load, measurable in pounds or ounces, which presses the coils of a close wound extension spring against one another. This force must be overcome before the coils of a spring begin to open up.

Initial tension is wound into extension springs by bending each coil as it is wound away from its normal plane, thereby producing a slight twist in the wire which causes the coil to spring back tightly against the adjacent coil. Initial tension can be wound into cold-coiled

extension springs only. Hot-wound springs and springs made from annealed steel are hardened and tempered after coiling, and therefore initial tension cannot be produced. It is possible to make a spring having initial tension only when a high tensile strength, obtained by cold drawing or by heat treatment, is possessed by the material as it is being wound into springs. Materials that possess the required characteristics for the manufacture of such springs include hard-drawn wire, music wire, pre-tempered wire, 18-8 stainless steel, phosphor-bronze, and many of the hard-drawn copper-nickel, and nonferrous alloys. Permissible torsional stresses resulting from initial tension for different spring indexes are shown in Fig. 16.

Fig. 16. Permissible Torsional Stress Caused by Initial Tension in Coiled Extension Springs for Different Spring Indexes

**Hook failure:** The great majority of breakages in extension springs occurs in the hooks. Hooks are subjected to both bending and torsional stresses and have higher stresses than the coils in the spring.

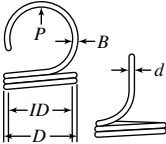

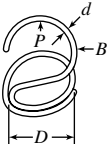

**Stresses in regular hooks:** The calculations for the stresses in hooks are quite complicated and lengthy. Also, the radii of the bends are difficult to determine and frequently vary between specifications and actual production samples. However, regular hooks are more highly stressed than the coils in the body and are subjected to a bending stress at section B

(see Table 6.) The bending stress  $S_b$  at section B should be compared with allowable stresses for torsion springs and with the elastic limit of the material in tension (See Fig. 7 through Fig. 10.)

**Stresses in cross-over hooks:** Results of tests on springs having a normal average index show that the cross-over hooks last longer than regular hooks. These results may not occur on springs of small index or if the cross-over bend is made too sharply.

In as much as both types of hooks have the same bending stress, it would appear that the fatigue life would be the same. However, the large bend radius of the regular hooks causes some torsional stresses to coincide with the bending stresses, thus explaining the earlier breakages. If sharper bends were made on the regular hooks, the life should then be the same as for cross-over hooks.

**Table 6. Formula for Bending Stress at Section B**

Type of Hook	Stress in Bending
 <p style="text-align: center;">Regular Hook</p>	$S_b = \frac{5PD^2}{IDd^3}$
 <p style="text-align: center;">Cross-over Hook</p>	

**Stresses in half hooks:** The formulas for regular hooks can also be used for half hooks, because the smaller bend radius allows for the increase in stress. It will therefore be observed that half hooks have the same stress in bending as regular hooks.

Frequently overlooked facts by many designers are that one full hook deflects an amount equal to one half a coil and each half hook deflects an amount equal to one tenth of a coil. Allowances for these deflections should be made when designing springs. Thus, an extension spring, with regular full hooks and having 10 coils, will have a deflection equal to 11 coils, or 10 percent more than the calculated deflection.

**Extension Spring Design.**—The available space in a product or assembly usually determines the limiting dimensions of a spring, but the wire size, number of coils, and initial tension are often unknown.

*Example:* An extension spring is to be made from spring steel ASTM A229, with regular hooks as shown in Fig. 17. Calculate the wire size, number of coils and initial tension.

*Note:* Allow about 20 to 25 percent of the 9 pound load for initial tension, say 2 pounds, and then design for a 7 pound load (not 9 pounds) at  $\frac{3}{8}$  inch deflection. Also use lower stresses than for a compression spring to allow for overstretching during assembly and to obtain a safe stress on the hooks. Proceed as for compression springs, but locate a load in the tables somewhat higher than the 9 pound load.

*Method 1, using table:* From Table 5 locate  $\frac{3}{8}$  inch outside diameter in the left column and move to the right to locate a load  $P$  of 13.94 pounds. A deflection  $f$  of 0.212 inch appears above this figure. Moving vertically from this position to the top of the column a suitable wire diameter of 0.0625 inch is found.

The remaining design calculations are completed as follows:

*Step 1:* The stress with a load of 7 pounds is obtained as follows:

The 7 pound load is 50.2 percent of the 13.94 pound load. Therefore, the stress  $S$  at 7 pounds = 0.502 percent  $\times$  100,000 = 50,200 pounds per square inch.

*Step 2:* The 50.2 percent figure is also used to determine the deflection per coil  $f$ : 0.502 percent  $\times$  0.212 = 0.1062 inch.

Fig. 17. Extension Spring Design Example

Step 3: The number of active coils (say 6)

$$AC = \frac{F}{f} = \frac{0.625}{0.1062} = 5.86$$

This result should be reduced by 1 to allow for deflection of 2 hooks (see notes 1 and 2 that follow these calculations.) Therefore, a quick answer is: 5 coils of 0.0625 inch diameter wire. However, the design procedure should be completed by carrying out the following steps:

Step 4: The body length =  $(TC + 1) \times d = (5 + 1) \times 0.0625 = \frac{3}{8}$  inch.

Step 5: The length from the body to inside hook

$$= \frac{FL - \text{Body}}{2} = \frac{1.4375 - 0.375}{2} = 0.531 \text{ inch}$$

$$\text{Percentage of ID} = \frac{0.531}{ID} = \frac{0.531}{0.625} = 85 \text{ percent}$$

This length is satisfactory, see Note 3 following this procedure.

Step 6:

$$\text{The spring index} = \frac{OD}{d} - 1 = \frac{0.75}{0.0625} - 1 = 11$$

Step 7: The initial tension stress is

$$S_{ii} = \frac{S \times IT}{P} = \frac{50,200 \times 2}{7} = 14,340 \text{ pounds per square inch}$$

This stress is satisfactory, as checked against curve in Fig. 16.

Step 8: The curvature correction factor  $K = 1.12$  (Fig. 13).

Step 9: The total stress =  $(50,200 + 14,340) \times 1.12 = 72,285$  pounds per square inch

This result is less than 106,250 pounds per square inch permitted by the middle curve for 0.0625 inch wire in Fig. 3 and therefore is a safe working stress that permits some additional deflection that is usually necessary for assembly purposes.

*Step 10:* The large majority of hook breakage is due to high stress in bending and should be checked as follows:

From Table 6, stress on hook in bending is:

$$S_b = \frac{5PD^2}{IDd^3} = \frac{5 \times 9 \times 0.6875^2}{0.625 \times 0.0625^3} = 139,200 \text{ pounds per square inch}$$

This result is less than the top curve value, Fig. 8, for 0.0625 inch diameter wire, and is therefore safe. Also see Note 5 that follows.

*Notes:* The following points should be noted when designing extension springs:

- 1) All coils are active and thus  $AC = TC$ .
- 2) Each full hook deflection is approximately equal to  $\frac{1}{2}$  coil. Therefore for 2 hooks, reduce the total coils by 1. (Each half hook deflection is nearly equal to  $\frac{1}{10}$  of a coil.)
- 3) The distance from the body to the inside of a regular full hook equals 75 to 85 percent (90 percent maximum) of the ID. For a cross-over center hook, this distance equals the ID.
- 4) Some initial tension should usually be used to hold the spring together. Try not to exceed the maximum curve shown on Fig. 16. Without initial tension, a long spring with many coils will have a different length in the horizontal position than it will when hung vertically.
- 5) The hooks are stressed in bending, therefore their stress should be less than the maximum bending stress as used for torsion springs—use top fatigue strength curves Fig. 7 through Fig. 10.

*Method 2, using formulas:* The sequence of steps for designing extension springs by formulas is similar to that for compression springs. The formulas for this method are given in Table 3.

**Tolerances for Compression and Extension Springs.**—Tolerances for coil diameter, free length, squareness, load, and the angle between loop planes for compression and extension springs are given in Table 7 through Table 12. To meet the requirements of load, rate, free length, and solid height, it is necessary to vary the number of coils for compression springs by  $\pm 5$  percent. For extension springs, the tolerances on the numbers of coils are: for 3 to 5 coils,  $\pm 20$  percent; for 6 to 8 coils,  $\pm 30$  percent; for 9 to 12 coils,  $\pm 40$  percent. For each additional coil, a further  $\frac{1}{2}$  percent tolerance is added to the extension spring values. Closer tolerances on the number of coils for either type of spring lead to the need for trimming after coiling, and manufacturing time and cost are increased. Fig. 18 shows deviations allowed on the ends of extension springs, and variations in end alignments.

<sup>a</sup>Slenderness Ratio =  $FL \div D$

Springs with closed and ground ends, in the free position. Squareness tolerances closer than those shown require special process techniques which increase cost. Springs made from fine wire sizes, and with high spring indices, irregular shapes or long free lengths, require special attention in determining appropriate tolerance and feasibility of grinding ends.

**Torsion Spring Design.**—Fig. 19 shows the types of ends most commonly used on torsion springs. To produce them requires only limited tooling. The straight torsion end is the least expensive and should be used whenever possible. After determining the spring load or torque required and selecting the end formations, the designer usually estimates suitable space or size limitations. However, the space should be considered approximate until the wire size and number of coils have been determined. The wire size is dependent principally upon the torque. Design data can be developed with the aid of the tabular data, which is a simple method, or by calculation alone, as shown in the following sections. Many other factors affecting the design and operation of torsion springs are also covered in the section, *Torsion Spring Design Recommendations* on page 337. Design formulas are shown in Table 13.

**Curvature correction:** In addition to the stress obtained from the formulas for load or deflection, there is a direct shearing stress on the inside of the section due to curvature. Therefore, the stress obtained by the usual formulas should be multiplied by the factor  $K$  obtained from the curve in Fig. 20. The corrected stress thus obtained is used only for comparison with the allowable working stress (fatigue strength) curves to determine if it is a safe value, and should not be used in the formulas for deflection.

$FL/F$  = the ratio of the spring free length  $FL$  to the deflection  $F$ .

Fig. 19. The Most Commonly Used Types of Ends for Torsion Springs

Fig. 20. Torsion Spring Stress Correction for Curvature

**Torque:** Torque is a force applied to a moment arm and tends to produce rotation. Torsion springs exert torque in a circular arc and the arms are rotated about the central axis. It should be noted that the stress produced is in bending, not in torsion. In the spring industry it is customary to specify torque in conjunction with the deflection or with the arms of a spring at a definite position. Formulas for torque are expressed in pound-inches. If ounce-inches are specified, it is necessary to divide this value by 16 in order to use the formulas.

When a load is specified at a distance from a centerline, the torque is, of course, equal to the load multiplied by the distance. The load can be in pounds or ounces with the distances in inches or the load can be in grams or kilograms with the distance in centimeters or millimeters, but to use the design formulas, all values must be converted to pounds and inches. Design formulas for torque are based on the tangent to the arc of rotation and presume that a rod is used to support the spring. The stress in bending caused by the moment  $P \times R$  is identical in magnitude to the torque  $T$ , provided a rod is used.

Theoretically, it makes no difference how or where the load is applied to the arms of torsion springs. Thus, in Fig. 21, the loads shown multiplied by their respective distances produce the same torque; i.e.,  $20 \times 0.5 = 10$  pound-inches;  $10 \times 1 = 10$  pound-inches; and  $5 \times 2 = 10$  pound-inches. To further simplify the understanding of torsion spring torque, observe in both Fig. 22 and Fig. 23 that although the turning force is in a circular arc the torque is not equal to  $P$  times the radius. The torque in both designs equals  $P \times R$  because the spring rests against the support rod at point  $a$ .

**Table 13. Formulas for Torsion Springs**

Feature	Springs made from round wire	Springs made from square wire
	Formula <sup>a, b</sup>	
$d =$ Wire diameter, Inches	$\sqrt[3]{\frac{10.18T}{S_b}}$	$\sqrt[3]{\frac{6T}{S_b}}$
	$\sqrt[4]{\frac{4000TND}{EF^\circ}}$	$\sqrt[4]{\frac{2375TND}{EF^\circ}}$
$S_b =$ Stress, bending pounds per square inch	$\frac{10.18T}{d^3}$	$\frac{6T}{d^3}$
	$\frac{EdF^\circ}{392ND}$	$\frac{EdF^\circ}{392ND}$
$N =$ Active Coils	$\frac{EdF^\circ}{392S_bD}$	$\frac{EdF^\circ}{392S_bD}$
	$\frac{Ed^4F^\circ}{4000TD}$	$\frac{Ed^4F^\circ}{2375TD}$
$F^\circ =$ Deflection	$\frac{392S_bND}{Ed}$	$\frac{392S_bND}{Ed}$
	$\frac{4000TND}{Ed^4}$	$\frac{2375TND}{Ed^4}$
$T =$ Torque Inch lbs. (Also = $P \times R$ )	$0.0982S_b d^3$	$0.1666S_b d^3$
	$\frac{Ed^4F^\circ}{4000ND}$	$\frac{Ed^4F^\circ}{2375ND}$
$ID_1 =$ Inside Diameter After Deflection, Inches	$\frac{N(ID \text{ free})}{N + \frac{F^\circ}{360}}$	$\frac{N(ID \text{ free})}{N + \frac{F^\circ}{360}}$

<sup>a</sup> Where two formulas are given for one feature, the designer should use the one found to be appropriate for the given design. The end result from either of any two formulas is the same.

<sup>b</sup> The symbol notation is given on page 304.

*Design Procedure:* Torsion spring designs require more effort than other kinds because consideration has to be given to more details, such as the proper size of a supporting rod, reduction of the inside diameter, increase in length, deflection of arms, allowance for friction, and method of testing.

*Example:* What music wire diameter and how many coils are required for the torsion spring shown in Fig. 24, which is to withstand at least 1000 cycles? Determine the corrected stress and the reduced inside diameter after deflection.

Fig. 21. Right-Hand Torsion Spring

Fig. 22. Left-Hand Torsion Spring

The Torque is  $T = P \times R$ , Not  $P \times \text{Radius}$ , because the Spring is Resting Against the Support Rod at Point  $a$ .

Fig. 23. Left-Hand Torsion Spring

As with the Spring in Fig. 22, the Torque is  $T = P \times R$ , Not  $P \times \text{Radius}$ , Because the Support Point Is at  $a$ .

Fig. 24. Torsion Spring Design Example. The Spring is to be Assembled on a  $\frac{7}{16}$ -Inch Support Rod.

*Method 1, using table:* From Table 14, page 339, locate the  $\frac{1}{2}$  inch inside diameter for the spring in the left-hand column. Move to the right and then vertically to locate a torque value nearest to the required 10 pound-inches, which is 10.07 pound-inches. At the top of the same column, the music wire diameter is found, which is Number 31 gauge (0.085 inch). At the bottom of the same column the deflection for one coil is found, which is 15.81 degrees. As a 90-degree deflection is required, the number of coils needed is  $\frac{90}{15.81} = 5.69$  (say  $5\frac{3}{4}$  coils).

The spring index  $\frac{D}{d} = \frac{0.500 + 0.085}{0.085} = 6.88$  and thus the curvature correction factor  $K$  from Fig. 20 = 1.13. Therefore the corrected stress equals  $167,000 \times 1.13 = 188,700$  pounds per square inch which is below the Light Service curve (Fig. 7) and therefore should provide a fatigue life of over 1,000 cycles. The reduced inside diameter due to deflection is found from the formula in Table 13:

$$ID_1 = \frac{N(ID \text{ free})}{N + \frac{F}{360}} = \frac{5.75 \times 0.500}{5.75 + \frac{90}{360}} = 0.479 \text{ in.}$$

This reduced diameter easily clears a suggested  $\frac{7}{16}$  inch diameter supporting rod:  $0.479 - 0.4375 = 0.041$  inch clearance, and it also allows for the standard tolerance. The overall length of the spring equals the total number of coils plus one, times the wire diameter. Thus,  $6\frac{3}{4} \times 0.085 = 0.574$  inch. If a small space of about  $\frac{1}{4}$  in. is allowed between the coils to eliminate coil friction, an overall length of  $2\frac{1}{32}$  inch results.

Although this completes the design calculations, other tolerances should be applied in accordance with the Torsion Spring Tolerance Table 16 through Table 17 shown at the end of this section.

*Longer fatigue life:* If a longer fatigue life is desired, use a slightly larger wire diameter. Usually the next larger gage size is satisfactory. The larger wire will reduce the stress and still exert the same torque, but will require more coils and a longer overall length.

*Percentage method for calculating longer life:* The spring design can be easily adjusted for longer life as follows:

1) Select the next larger gage size, which is Number 32 (0.090 inch) from Table 14. The torque is 11.88 pound-inches, the design stress is 166,000 pounds per square inch, and the deflection is 14.9 degrees per coil. As a percentage the torque is  $10/11.88 \times 100 = 84$  percent.

2) The new stress is  $0.84 \times 166,000 = 139,440$  pounds per square inch. This value is under the bottom or Severe Service curve, Fig. 7, and thus assures longer life.

3) The new deflection per coil is  $0.84 \times 14.97 = 12.57$  degrees. Therefore, the total number of coils required =  $90/12.57 = 7.16$  (say  $7\frac{1}{8}$ ). The new overall length =  $8\frac{1}{8} \times 0.090 = 0.73$  inch (say  $\frac{3}{4}$  inch). A slight increase in the overall length and new arm location are thus necessary.

*Method 2, using formulas:* When using this method, it is often necessary to solve the formulas several times because assumptions must be made initially either for the stress or for a wire size. The procedure for design using formulas is as follows (the design example is the same as in Method 1, and the spring is shown in Fig. 24):

*Step 1:* Note from Table 13, page 334 that the wire diameter formula is:

$$d = \sqrt[3]{\frac{10.18T}{S_b}}$$

*Step 2:* Referring to Fig. 7, select a trial stress, say 150,000 pounds per square inch.

*Step 3:* Apply the trial stress, and the 10 pound-inches torque value in the wire diameter formula:

$$d = \sqrt[3]{\frac{10.18T}{S_b}} = \sqrt[3]{\frac{10.18 \times 10}{150,000}} = \sqrt[3]{0.000679} = 0.0879 \text{ inch}$$

The nearest gage sizes are 0.085 and 0.090 inch diameter. *Note:* Table 21, page 347, can be used to avoid solving the cube root.

*Step 4:* Select 0.085 inch wire diameter and solve the equation for the actual stress:

$$S_b = \frac{10.18T}{d^3} = \frac{10.18 \times 10}{0.085^3} = 165,764 \text{ pounds per square inch}$$

*Step 5:* Calculate the number of coils from the equation, Table 13:

$$N = \frac{EdF^\circ}{392S_bD} = \frac{28,500,000 \times 0.085 \times 90}{392 \times 165,764 \times 0.585} = 5.73 \text{ (say } 5\frac{3}{4}\text{)}$$

*Step 6:* Calculate the total stress. The spring index is 6.88, and the correction factor  $K$  is 1.13 therefore total stress =  $165,764 \times 1.13 = 187,313$  pounds per square inch. *Note:* The corrected stress should not be used in any of the formulas as it does not determine the torque or the deflection.

**Torsion Spring Design Recommendations.**—The following recommendations should be taken into account when designing torsion springs:

*Hand:* The hand or direction of coiling should be specified and the spring designed so deflection causes the spring to wind up and to have more coils. This increase in coils and overall length should be allowed for during design. Deflecting the spring in an unwinding direction produces higher stresses and may cause early failure. When a spring is sighted down the longitudinal axis, it is "right hand" when the direction of the wire into the spring takes a clockwise direction or if the angle of the coils follows an angle similar to the threads of a standard bolt or screw, otherwise it is "left hand." A spring must be coiled right-handed to engage the threads of a standard machine screw.

*Rods:* Torsion springs should be supported by a rod running through the center whenever possible. If unsupported, or if held by clamps or lugs, the spring will buckle and the torque will be reduced or unusual stresses may occur.

*Diameter Reduction:* The inside diameter reduces during deflection. This reduction should be computed and proper clearance provided over the supporting rod. Also, allowances should be considered for normal spring diameter tolerances.

*Winding:* The coils of a spring may be closely or loosely wound, but they seldom should be wound with the coils pressed tightly together. Tightly wound springs with initial tension on the coils do not deflect uniformly and are difficult to test accurately. A small space between the coils of about 20 to 25 percent of the wire thickness is desirable. Square and rectangular wire sections should be avoided whenever possible as they are difficult to wind, expensive, and are not always readily available.

*Arm Length:* All the wire in a torsion spring is active between the points where the loads are applied. Deflection of long extended arms can be calculated by allowing one third of the arm length, from the point of load contact to the body of the spring, to be converted into coils. However, if the length of arm is equal to or less than one-half the length of one coil, it can be safely neglected in most applications.

*Total Coils:* Torsion springs having less than three coils frequently buckle and are difficult to test accurately. When thirty or more coils are used, light loads will not deflect all the coils simultaneously due to friction with the supporting rod. To facilitate manufacturing it is usually preferable to specify the total number of coils to the nearest fraction in eighths or quarters, such as  $5\frac{1}{8}$ ,  $5\frac{1}{4}$ ,  $5\frac{1}{2}$ , etc.

*Double Torsion:* This design consists of one left-hand-wound series of coils and one series of right-hand-wound coils connected at the center. These springs are difficult to manufacture and are expensive, so it often is better to use two separate springs. For torque and stress calculations, each series is calculated separately as individual springs; then the torque values are added together, but the deflections are not added.

*Bends:* Arms should be kept as straight as possible. Bends are difficult to produce and often are made by secondary operations, so they are therefore expensive. Sharp bends raise stresses that cause early failure. Bend radii should be as large as practicable. Hooks tend to open during deflection; their stresses can be calculated by the same procedure as that for tension springs.

*Spring Index:* The spring index must be used with caution. In design formulas it is  $D/d$ . For shop measurement it is  $OD/d$ . For arbor design it is  $ID/d$ . Conversions are easily performed by either adding or subtracting 1 from  $D/d$ .

*Proportions:* A spring index between 4 and 14 provides the best proportions. Larger ratios may require more than average tolerances. Ratios of 3 or less often cannot be coiled on automatic spring coiling machines because of arbor breakage. Also, springs with smaller or larger spring indexes often do not give the same results as are obtained using the design formulas.

**Table of Torsion Spring Characteristics.**—Table 14 shows design characteristics for the most commonly used torsion springs made from wire of standard gauge sizes. The deflection for one coil at a specified torque and stress is shown in the body of the table. The figures are based on music wire (ASTM A228) and oil-tempered MB grade (ASTM A229), and can be used for several other materials which have similar values for the modulus of elasticity  $E$ . However, the design stress may be too high or too low, and the design stress, torque, and deflection per coil should each be multiplied by the appropriate correction factor in Table 15 when using any of the materials given in that table.

<sup>a</sup>For sizes up to 26 gauge, the table values are for music wire with a modulus  $E$  of 29,500,000 psi; for sizes from 27 gauge to 1/8 inch diameter the table values are for music wire with a modulus of 28,500,000 psi; for sizes from 10 gauge to 1/8 inch diameter, the values are for oil-tempered MB with a modulus of 28,500,000 psi.

For an example in the use of the table, see the example starting on page 334. Note: Intermediate values may be interpolated within reasonable accuracy.

**Table 15. Correction Factors for Other Materials**

Material <sup>a</sup>	Factor	Material <sup>a</sup>	Factor
Hard Drawn MB	0.75	Stainless 316	
Chrome-vanadium	1.10	Up to 1/8 inch diameter	0.75
Chrome-silicon	1.20	Over 1/8 to 1/4 inch diameter	0.65
Stainless 302 and 304		Over 1/4 inch diameter	0.65
Up to 1/8 inch diameter	0.85	Stainless 17-7 PH	
Over 1/8 to 1/4 inch diameter	0.75	Up to 1/8 inch diameter	1.00
Over 1/4 inch diameter	0.65	Over 1/8 to 3/16 inch diameter	1.07
Stainless 431	0.80	Over 3/16 inch diameter	1.12
Stainless 420	0.85	...	...

<sup>a</sup>For use with values in Table 14. Note: The figures in Table 14 are for music wire (ASTM A228) and oil-tempered MB grade (ASTM A229) and can be used for several other materials that have a similar modulus of elasticity  $E$ . However, the design stress may be too high or too low, and therefore the design stress, torque, and deflection per coil should each be multiplied by the appropriate correction factor when using any of the materials given in this table (Table 15).

**Torsion Spring Tolerances.**—Torsion springs are coiled in a different manner from other types of coiled springs and therefore different tolerances apply. The commercial tolerance on loads is  $\pm 10$  percent and is specified with reference to the angular deflection. For example: 100 pound-inches  $\pm 10$  percent at 45 degrees deflection. One load specified usually suffices. If two loads and two deflections are specified, the manufacturing and testing times are increased. Tolerances smaller than  $\pm 10$  percent require each spring to be individually tested and adjusted, which adds considerably to manufacturing time and cost. Table 16, Table 17, and Table 18 give, respectively, free angle tolerances, tolerances on the number of coils, and coil diameter tolerances.

**Table 16. Torsion Spring Tolerances for Angular Relationship of Ends**

Number of Coils ( $N$ )	Spring Index								
	4	6	8	10	12	14	16	18	20
	Free Angle Tolerance, $\pm$ degrees								
1	2	3	3.5	4	4.5	5	5.5	5.5	6

**Miscellaneous Springs.**—This section provides information on various springs, some in common use, some less commonly used.

*Conical compression:* These springs taper from top to bottom and are useful where an increasing (instead of a constant) load rate is needed, where solid height must be small, and where vibration must be damped. Conical springs with a uniform pitch are easiest to coil. Load and deflection formulas for compression springs can be used—using the average mean coil diameter, and provided the deflection does not cause the largest active coil to lie against the bottom coil. When this happens, each coil must be calculated separately, using the standard formulas for compression springs.

*Constant force springs:* Those springs are made from flat spring steel and are finding more applications each year. Complicated design procedures can be eliminated by selecting a standard design from thousands now available from several spring manufacturers.

*Spiral, clock, and motor springs:* Although often used in wind-up type motors for toys and other products, these springs are difficult to design and results cannot be calculated with precise accuracy. However, many useful designs have been developed and are available from spring manufacturing companies.

*Flat springs:* These springs are often used to overcome operating space limitations in various products such as electric switches and relays. Table 19 lists formulas for designing flat springs. The formulas are based on standard beam formulas where the deflection is small.

**Table 19. Formulas for Flat Springs**

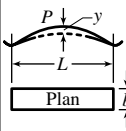

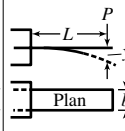

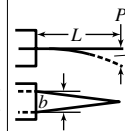

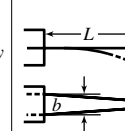

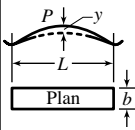

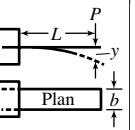

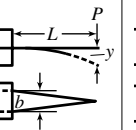

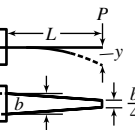

Feature				
Deflection, y Inches	$y = \frac{PL^3}{4Ebt^3}$ $= \frac{S_b L^2}{6Et}$	$y = \frac{4PL^3}{Ebt^3}$ $= \frac{2S_b L^2}{3Et}$	$y = \frac{6PL^3}{Ebt^3}$ $= \frac{S_b L^2}{Et}$	$y = \frac{5.22PL^3}{Ebt^3}$ $= \frac{0.87S_b L^2}{Et}$
Load, P, Pounds	$P = \frac{2S_b bt^2}{3L}$ $= \frac{4Ebt^3 y}{L^3}$	$P = \frac{S_b bt^2}{6L}$ $= \frac{Ebt^3 y}{4L^3}$	$P = \frac{S_b bt^2}{6L}$ $= \frac{Ebt^3 y}{6L^3}$	$P = \frac{S_b bt^2}{6L}$ $= \frac{Ebt^3 y}{5.22L^3}$

Table 19. (Continued) Formulas for Flat Springs

Feature				
Stress, $S_b$ Bending psi	$S_b = \frac{3PL}{2bt^2}$ $= \frac{6Ery}{L^2}$	$S_b = \frac{6PL}{bt^2}$ $= \frac{3Ery}{2L^2}$	$S_b = \frac{6PL}{bt^2}$ $= \frac{Ery}{L^2}$	$S_b = \frac{6PL}{bt^2}$ $= \frac{Ery}{0.87L^2}$
Thickness, $t$ Inches	$t = \frac{S_b L^2}{6E_y}$ $= \sqrt[3]{\frac{PL^3}{4Eby}}$	$t = \frac{2S_b L^2}{3E_y}$ $= \sqrt[3]{\frac{4PL^3}{Eby}}$	$t = \frac{S_b L^2}{E_y}$ $= \sqrt[3]{\frac{6PL^3}{Eby}}$	$t = \frac{0.87S_b L^2}{E_y}$ $= \sqrt[3]{\frac{5.22PL^3}{Eby}}$

Based on standard beam formulas where the deflection is small.

$y$  is deflection, see page 304 for other notation.

Note: Where two formulas are given for one feature, the designer should use the one found to be appropriate for the given design. The result from either of any two formulas is the same.

**Belleville washers or disc springs:** These washer type springs can sustain relatively large loads with small deflections, and the loads and deflections can be increased by stacking the springs.

Information on springs of this type is given in the section **DISC SPRINGS** starting on page 350.

**Volute springs:** These springs are often used on army tanks and heavy field artillery, and seldom find additional uses because of their high cost, long production time, difficulties in manufacture, and unavailability of a wide range of materials and sizes. Small volute springs are often replaced with standard compression springs.

**Torsion bars:** Although the more simple types are often used on motor cars, the more complicated types with specially forged ends are finding fewer applications.

**Moduli of Elasticity of Spring Materials.**—The modulus of elasticity in tension, denoted by the letter  $E$ , and the modulus of elasticity in torsion, denoted by the letter  $G$ , are used in formulas relating to spring design. Values of these moduli for various ferrous and nonferrous spring materials are given in Table 20.

**General Heat Treating Information for Springs.**—The following is general information on the heat treatment of springs, and is applicable to pre-tempered or hard-drawn spring materials only.

**Compression springs** are baked after coiling (before setting) to relieve residual stresses and thus permit larger deflections before taking a permanent set.

**Extension springs** also are baked, but heat removes some of the initial tension. Allowance should be made for this loss. Baking at 500 degrees F for 30 minutes removes approximately 50 percent of the initial tension. The shrinkage in diameter however, will slightly increase the load and rate.

**Outside diameters shrink** when springs of music wire, pretempered MB, and other carbon or alloy steels are baked. Baking also slightly increases the free length and these changes produce a little stronger load and increase the rate.

**Outside diameters expand** when springs of stainless steel (18-8) are baked. The free length is also reduced slightly and these changes result in a little lighter load and a decrease in the spring rate.

**Inconel, Monel, and nickel alloys** do not change much when baked.

*Beryllium-copper shrinks and deforms* when heated. Such springs usually are baked in fixtures or supported on arbors or rods during heating.

*Brass and phosphor bronze* springs should be given a light heat only. Baking above 450°F will soften the material. Do not heat in salt pots.

*Torsion springs* do not require baking because coiling causes residual stresses in a direction that is helpful, but such springs frequently are baked so that jarring or handling will not cause them to lose the position of their ends.

**Table 20. Moduli of Elasticity in Torsion and Tension of Spring Materials**

Ferrous Materials			Nonferrous Materials		
Material (Commercial Name)	Modulus of Elasticity <sup>a</sup> , psi		Material (Commercial Name)	Modulus of Elasticity <sup>a</sup> , psi

<sup>a</sup> *Note:* Modulus *G* (shear modulus) is used for compression and extension springs; modulus *E* (Young's modulus) is used for torsion, flat, and spiral springs.

<sup>b</sup> Trade name of International Nickel Company.

<sup>c</sup> May be 2,000,000 pounds per square inch less if material is not fully hard.

<sup>d</sup> Trade name of Hamilton Watch Company.

<sup>e</sup> Trade name of John Chatillon & Sons.

*Spring brass and phosphor bronze* springs that are not very highly stressed and are not subject to severe operating use may be stress relieved after coiling by immersing them in boiling water for a period of 1 hour.

*Positions of loops* will change with heat. Parallel hooks may change as much as 45 degrees during baking. Torsion spring arms will alter position considerably. These changes should be allowed for during looping or forming.

*Quick heating* after coiling either in a high-temperature salt pot or by passing a spring through a gas flame is not good practice. Samples heated in this way will not conform with production runs that are properly baked. A small, controlled-temperature oven should be used for samples and for small lot orders.

*Plated springs* should always be baked before plating to relieve coiling stresses and again after plating to relieve hydrogen embrittlement.

*Hardness* values fall with high heat—but music wire, hard drawn, and stainless steel will increase 2 to 4 points on the Rockwell C scale.

**Spring Failure.**—Spring failure may be breakage, high permanent set, or loss of load. The causes are listed in groups in **Table 22**. Group 1 covers causes that occur most frequently; Group 2 covers causes that are less frequent; and Group 3 lists causes that occur occasionally.

**Table 22. Causes of Spring Failure**

	Cause	Comments and Recommendations
Group 1	High stress	The majority of spring failures are due to high stresses caused by large deflections and high loads. High stresses should be used only for statically loaded springs. Low stresses lengthen fatigue life.
	Hydrogen embrittlement	Improper electroplating methods and acid cleaning of springs, without proper baking treatment, cause spring steels to become brittle, and are a frequent cause of failure. Nonferrous springs are immune.
	Sharp bends and holes	Sharp bends on extension, torsion, and flat springs, and holes or notches in flat springs, cause high concentrations of stress, resulting in failure. Bend radii should be as large as possible, and tool marks avoided.
	Fatigue	Repeated deflections of springs, especially above 1,000,000 cycles, even with medium stresses, may cause failure. Low stresses should be used if a spring is to be subjected to a very high number of operating cycles.
Group 2	Shock loading	Impact, shock, and rapid loading cause far higher stresses than those computed by the regular spring formulas. High-carbon spring steels do not withstand shock loading as well as do alloy steels.
	Corrosion	Slight rusting or pitting caused by acids, alkalis, galvanic corrosion, stress corrosion cracking, or corrosive atmosphere weakens the material and causes higher stresses in the corroded area.
	Faulty heat treatment	Keeping spring materials at the hardening temperature for longer periods than necessary causes an undesirable growth in grain structure, resulting in brittleness, even though the hardness may be correct.
	Faulty material	Poor material containing inclusions, seams, slivers, and flat material with rough, slit, or torn edges is a cause of early failure. Overdrawn wire, improper hardness, and poor grain structure also cause early failure.
Group 3	High temperature	High operating temperatures reduce spring temper (or hardness) and lower the modulus of elasticity, thereby causing lower loads, reducing the elastic limit, and increasing corrosion. Corrosion-resisting or nickel alloys should be used.
	Low temperature	Temperatures below $-40$ degrees F reduce the ability of carbon steels to withstand shock loads. Carbon steels become brittle at $-70$ degrees F. Corrosion-resisting, nickel, or nonferrous alloys should be used.
	Friction	Close fits on rods or in holes result in a wearing away of material and occasional failure. The outside diameters of compression springs expand during deflection but they become smaller on torsion springs.
	Other causes	Enlarged hooks on extension springs increase the stress at the bends. Carrying too much electrical current will cause failure. Welding and soldering frequently destroy the spring temper. Tool marks, nicks, and cuts often raise stresses. Deflecting torsion springs outwardly causes high stresses and winding them tightly causes binding on supporting rods. High speed of deflection, vibration, and surging due to operation near natural periods of vibration or their harmonics cause increased stresses.

## DISC SPRINGS

## Performance of Disc Springs

**Introduction.**—Disc springs, also known as *Belleville springs*, are conically formed from washers and have rectangular cross section. The disc spring concept was invented by a Frenchman Louis Belleville in 1865. His springs were relatively thick and had a small amount of cone height or “dish”, which determined axial deflection. At that time, these springs were used in the buffer parts of railway rolling stock, for recoil mechanisms of guns, and some other applications. The use of disc springs will be advantageous when space is limited and high force is required, as these conditions cannot be satisfied by using coil springs. Load-deflection characteristics of disc springs are linear and regressive depending on their dimensions and the type of stacking. A large number of standard sizes are available from disc spring manufacturers and distributors, so that custom sizes may not be required. Therefore, disc springs are widely used today in virtually all branches of engineering with possibilities of new applications.

**Disc Spring Nomenclature.**—Disc spring manufacturers assign their own part number for each disc spring, but the catalog numbers for disc springs are similar, so each item can often be identified regardless of manufacturer. The disc spring identification number is a numerical code that provides basic dimensions in millimeters. Identification numbers represent the primary dimensions of the disc spring and consist of one, two, or three numbers separated from each other by dash marks or spaces. Disc spring manufacturers in the United States also provide dimensions in inches. Dimensions of several typical disc springs are shown in the following table. Basic nomenclature is illustrated in Fig. 1.

Catalog Number (mm)	Outside Diameter $D$ (mm)	Inside Diameter $d$ (mm)	Thickness $t$ (mm)	Equivalent Catalog Number (inch)
8-4.2-0.4	8	4.2	0.4	0.315-0.165-0.0157
50-25.4-2	50	25.4	2	1.97-1.00-0.0787
200-102-12	200	102	12	7.87-4.02-0.472

Additional dimensions shown in catalogs are cone (dish) height  $h$  at unloaded condition, and overall height  $H = h + t$ , that combines the cone height and the thickness of a disc spring.

Fig. 1. Disc Spring Nomenclature

**Disc Spring Group Classification.**—Forces and stresses generated by compression depend on disc spring thickness much more than on any other dimensions. Standard DIN 2093 divides all disc springs into three groups in accordance with their thickness:

*Group 1* includes all disc springs with thickness less than 1.25 mm (0.0492 inch).

*Group 2* includes all disc springs with thickness between 1.25 mm and 6.0 mm (0.0492 inch and 0.2362 inch).

*Group 3* includes disc springs with thickness greater than 6.0 mm (0.2362 inch).

There are 87 standard disc spring items, which are manufactured in accordance with DIN 2093 specifications for dimensions and quality requirements. There are 30 standard disc spring items in *Group 1*. The smallest and the largest disc springs in this group are

8-4.2-0.2 and 40-20.4-1, respectively. *Group 2* has 45 standard disc spring items. The smallest and the largest disc springs are 22.5-11.2-1.25 and 200-102-5.5, respectively. *Group 3* includes 12 standard disc spring items. The smallest and the largest disc springs of this group are 125-64-8 and 250-127-14, respectively.

Summary of Disc Spring Sizes Specified in DIN 2093

Classification	OD		ID		Thickness	
	Min.	Max.	Min.	Max.	Min.	Max.
<i>Group 1</i>	6 mm (0.236 in)	40 mm (1.575 in)	3.2 mm (0.126 in)	20.4 mm (0.803 in)	0.2 mm (0.008 in)	1.2 mm (0.047 in)
<i>Group 2</i>	20 mm (0.787 in)	225 mm (8.858 in)	10.2 mm (0.402 in)	112 mm (4.409 in)	1.25 mm (0.049 in)	6 mm (0.236 in)
<i>Group 3</i>	125 mm (4.921 in)	250 mm (9.843 in)	61 mm (2.402 in)	127 mm (5.000 in)	6.5 mm (0.256 in)	16 mm (0.630 in)

The number of catalog items by disc spring dimensions depends on the manufacturer. Currently, the smallest disc spring is 6-3.2-0.3 and the largest is 250-127-16. One of the US disc spring manufacturers, Key Bellevilles, Inc. offers 190 catalog items. The greatest number of disc spring items can be found in Christian Bauer GmbH + Co. catalog. There are 291 disc spring catalog items in all three groups.

**Disc Spring Contact Surfaces.**—Disc springs are manufactured with and without contact (also called load-bearing) surfaces. Contact surfaces are small flats at points 1 and 3 in Fig. 2, adjacent to the corner radii of the spring. The width of the contact surfaces  $w$  depends on the outside diameter  $D$  of the spring, and its value is approximately  $w = D/150$ .

Fig. 2. Disc Spring with Contact Surfaces

Disc springs of *Group 1* and *Group 2*, that are contained in the DIN 2093 standard, do not have contact surfaces, although some *Group 2* disc springs not included in DIN 2093 are manufactured with contact surfaces. All disc springs of *Group 3* (standard and nonstandard) are manufactured with contact surfaces. Almost all disc springs with contact surfaces are manufactured with reduced thickness.

Disc springs without contact surfaces have a corner radii  $r$  whose value depends on the spring thickness  $t$ . One disc spring manufacturer recommends the following relationship:

$$r = t/6$$

**Disc Spring Materials.**—A wide variety of materials are available for disc springs, but selection of the material depends mainly on application. High-carbon steels are used only for *Group 1* disc springs. AISI 1070 and AISI 1095 carbon steels are used in the United States. Similar high-carbon steels such as DIN 1.1231 and DIN 1.1238 (Germany), and BS 060 A67 and BS 060 A78 (Great Britain) are used in other countries. The most common materials for *Groups 2* and *3* springs operating under normal conditions are

chromium-vanadium alloy steels such as AISI 6150 used in the United States. Similar alloys such as DIN 1.8159 and DIN 1.7701 (Germany) and BS 735 A50 (Great Britain) are used in foreign countries. Some disc spring manufacturers in the United States also use chromium alloy steel AISI 5160. The hardness of disc springs in *Groups* 2 and 3 should be 42 to 52 RC. The hardness of disc springs in *Group 1* tested by the Vickers method should be 412 to 544 HV.

If disc springs must withstand corrosion and high temperatures, stainless steels and heat-resistant alloys are used. Most commonly used stainless steels in the United States are AISI types 301, 316, and 631, which are similar to foreign material numbers DIN 1.4310, DIN 1.4401, and DIN 1.4568, respectively. The operating temperature range for 631 stainless steel is  $-330$  to  $660^{\circ}\text{F}$  ( $-200$  to  $350^{\circ}\text{C}$ ). Among heat-resistant alloys, Inconel 718 and Inconel X750 (similar to DIN 2.4668 and DIN 2.4669, respectively) are the most popular. Operating temperature range for Inconel 718 is  $-440$  to  $1290^{\circ}\text{F}$  ( $-260$  to  $700^{\circ}\text{C}$ ).

When disc springs are stacked in large numbers and their total weight becomes a major concern, titanium  $\alpha$ - $\beta$  alloys can be used to reduce weight. In such cases, Ti-6Al-4V alloy is used.

If nonmagnetic and corrosion resistant properties are required and material strength is not an issue, phosphor bronzes and beryllium-coppers are the most popular copper alloys for disc springs. Phosphor bronze C52100, which is similar to DIN material number 2.1030, is used at the ordinary temperature range. Beryllium-coppers C17000 and C17200, similar to material numbers DIN 2.1245 and DIN 2.1247 respectively, works well at very low temperatures.

Strength properties of disc spring materials are characterized by moduli of elasticity and Poisson's ratios. These are summarized in **Table 1**.

**Table 1. Strength Characteristics of Disc Spring Materials**

Material	Modulus of Elasticity		Poisson's Ratio
	10 <sup>6</sup> psi	N/mm <sup>2</sup>	
All Steels	28-31	193,000-213,700	0.30
Heat-resistant Alloys			0.28-0.29
$\alpha$ - $\beta$ Titanium Alloys (Ti-6Al-4V)	17	117,200	0.32
Phosphor Bronze (C52100)	16	110,300	0.35
Beryllium-copper (C17000)	17	117,200	0.30

**Stacking of Disc Springs.**—Individual disc springs can be arranged in series and parallel stacks. Disc springs in series stacking, **Fig. 3**, provide larger deflection  $S_{total}$  under the same load  $F$  as a single disc spring would generate. Disc springs in parallel stacking, **Fig. 4**, generate higher loads  $F_{total}$  with the same deflection  $s$  than a single disc spring would have.

$n$  = number of disc springs in stack

$s$  = deflection of single spring

$S_{total}$  = total deflection of stack of  $n$  springs

$F$  = load generated by a single spring

$F_{total}$  = total load generated by springs in stack

$L_0$  = length of unloaded spring stack

**Series:** For  $n$  disc springs arranged in series, **Fig. 3**, the following equations are applied:

$$F_{total} = F$$

$$S_{total} = s \times n$$

$$L_0 = H \times n = (t + h) \times n \quad (1)$$

Fig. 3. Disc Springs in Series Stacking  
 $L_{1,2}$  Indices Indicate Length of Spring Stack under Minimum and Maximum Load.

*Parallel:* Parallel stacking generates a force that is directly proportional to the number of springs arranged in parallel. Two springs in parallel will double the force, three springs in parallel will triple the force, and so on. However, it is a common practice to use two springs in parallel in order to keep the frictional forces between the springs as low as possible. Otherwise, the actual spring force cannot be accurately determined due to deviation from its theoretical value.

For  $n$  disc springs arranged in parallel as in Fig. 4, the following equations are applied:

$$\begin{aligned}
 F_{total} &= F \times n \\
 S_{total} &= s \\
 L_0 &= H + t(n - 1) = (h + t) + tn - t = h + tn
 \end{aligned}
 \tag{2}$$

Fig. 4. Disc Springs in Parallel Stacking

*Parallel-Series:* When both higher force and greater deflection are required, disc springs must be arranged in a combined parallel-series stacking as illustrated in Fig. 5.

Fig. 5. Disc Springs in Parallel-Series Stacking

Normally, two springs in parallel are nested in series stacking. Two springs in parallel, called a pair, double the force, and the number of pairs,  $n_p$ , determines the total deflection,  $S_{total}$ .

For  $n_p$  disc spring pairs arranged in series, the following equations are applied:

$$\begin{aligned} F_{total} &= 2 \times F \\ S_{total} &= s \times n_p \\ L_0 &= H \times n_p = (2t + h) \times n_p \end{aligned} \quad (3)$$

### Disc Spring Forces and Stresses

Several methods of calculating forces and stresses for given disc spring configurations exist, some very complicated, others of limited accuracy. The theory which is widely used today for force and stress calculations was developed more than 65 years ago by Almen and Laszlo.

The theory is based on the following assumptions: cross sections are rectangular without radii over the entire range of spring deflection; no stresses occur in the radial direction; disc springs are always under elastic deformation during deflection; and due to small cone angles of unloaded disc springs (between  $3.5^\circ$  and  $8.6^\circ$ ), mathematical simplifications are applied.

The theory provides accurate results for disc springs with the following ratios: outside-to-inside diameter,  $D/d = 1.3$  to  $2.5$ ; and cone height-to-thickness,  $h/t$  is up to  $1.5$ .

**Force Generated by Disc Springs Without Contact Surfaces.**—Disc springs in *Group 1* and most of disc springs in *Group 2* are manufactured without contact (load-bearing) surfaces, but have corner radii.

A single disc spring force applied to points 1 and 3 in Fig. 6 can be found from Equation (4) in which corner radii are not considered:

$$F = \frac{4 \cdot E \cdot s}{(1 - \mu^2) \cdot K_1 \cdot D^2} \left[ \left( h - \frac{s}{2} \right) \cdot (h - s) \cdot t + t^3 \right] \quad (4)$$

where  $F$  = disc spring force;  $E$  = modulus of elasticity of spring material;  $\mu$  = Poisson's ratio of spring material;  $K_1$  = constant depending on outside-to-inside diameter ratio;  $D$  = disc spring nominal outside diameter;  $h$  = cone (dish) height;  $s$  = disc spring deflection; and,  $t$  = disc spring thickness.

Fig. 6. Schematic of Applied Forces

It has been found that the theoretical forces calculated using Equation (4) are lower than the actual (measured) spring forces, as illustrated in Fig. 7. The difference between theoretical (trace 1) and measured force values (trace 3) was significantly reduced (trace 2) when the actual outside diameter of the spring in loaded condition was used in the calculations.

Fig. 7. Force-Deflection Relationships (80-36-3.6 Disc Springs)  
 1 - Theoretical Force Calculated by Equation (4)  
 2 - Theoretical Force Calculated by Equation (10)  
 3 - Measured Force

The actual outside diameter  $D_a$  of a disc spring contact circle is smaller than the nominal outside diameter  $D$  due to cone angle  $\alpha$  and corner radius  $r$ , as shown in Fig. 8. Diameter  $D_a$  cannot be measured, but can be calculated by Equation (9) developed by Dr. Isacov.

Fig. 8. Conventional Shape of Disc Spring

From Fig. 8,

$$\frac{D_a}{2} = \frac{D}{2} - (a + b) \tag{5}$$

where  $a = t \sin \alpha$  and  $b = r \cos \alpha$ . Substitution of  $a$  and  $b$  values into Equation (5) gives:

$$\frac{D_a}{2} = \frac{D}{2} - (t \sin \alpha + r \cos \alpha) \tag{6}$$

The cone angle  $\alpha$  is found from:

$$\tan \alpha = \frac{h}{\frac{D}{2} - \frac{d}{2}} = \frac{2h}{D-d} \quad \alpha = \text{atan} \left( \frac{2h}{D-d} \right) \tag{7}$$

Substituting  $\alpha$  from Equation (7) and  $r = \frac{t}{6}$  into Equation (6) gives:

$$\frac{D_a}{2} = \frac{D}{2} - t \left\{ \sin \left[ \text{atan} \left( \frac{2h}{D-d} \right) \right] + \frac{1}{6} \cos \left[ \text{atan} \left( \frac{2h}{D-d} \right) \right] \right\} \tag{8}$$

Finally,

$$D_a = D - 2t \left\{ \sin \left[ \text{atan} \left( \frac{2h}{D-d} \right) \right] + \frac{1}{6} \cos \left[ \text{atan} \left( \frac{2h}{D-d} \right) \right] \right\} \tag{9}$$

Substituting  $D_a$  from Equation (9) for  $D$  in Equation (4) yields Equation (10), that provides better accuracy for calculating disc spring forces.

$$F = \frac{4 \cdot E \cdot s}{(1 - \mu^2) K_1 \cdot D_a^2} \left[ \left( h - \frac{s}{2} \right) \cdot (h - s) \cdot t + t^3 \right] \tag{10}$$

The constant  $K_1$  depends on disc spring outside diameter  $D$ , inside diameter  $d$ , and their ratio  $\delta = \frac{D}{d}$ :

$$K_1 = \frac{\left( \frac{\delta - 1}{\delta} \right)^2}{\pi \left( \frac{\delta + 1}{\delta - 1} - \frac{2}{\ln \delta} \right)} \tag{11}$$

Table 2 compares the spring force of a series of disc springs deflected by 75 percent of their cone height, i.e.,  $s = 0.75h$ , as determined from manufacturers catalogs calculated in accordance with Equation (4), calculated forces by use of Equation (10), and measured forces.

**Table 2. Comparison Between Calculated and Measured Disc Spring Forces**

Disc Spring Catalog Item	Schnorr Handbook for Disc Springs	Christian Bauer Disc Spring Handbook	Key Bellevilles Disc Spring Catalog	Spring Force Calculated by Equation (10)	Measured Disc Spring Force
50-22.4-2.5 S = 1.05 mm	8510 N 1913 lbf	8510 N 1913 lbf	8616 N 1937 lbf	9020 N 2028 lbf	9563 N 2150 lbf
60-30.5-2.5 S = 1.35 mm	8340 N 1875 lbf	8342 N 1875 lbf	8465 N 1903 lbf	8794 N 1977 lbf	8896 N 2000 lbf
60-30.5-3 S = 1.275 mm	13200 N 2967 lbf	13270 N 2983 lbf	13416 N 3016 lbf	14052 N 3159 lbf	13985 N 3144 lbf
70-35.5-3 S = 1.575 mm	12300 N 2765 lbf	12320 N 2770 lbf	12397 N 2787 lbf	12971 N 2916 lbf	13287 N 2987 lbf
70-35.5-3.5 S = 1.35 mm		16180 N 3637 lbf		17170 N 3860 lbf	17304 N 3890 lbf

Comparison made at 75 percent deflection, in newtons (N) and pounds (lbf)

The difference between disc spring forces calculated by Equation (10) and the measured forces varies from -5.7 percent (maximum) to +0.5 percent (minimum). Disc spring forces calculated by Equation (4) and shown in manufacturers catalogs are less than measured forces by -11 percent (maximum) to -6 percent (minimum).

**Force Generated by Disc Spring with Contact Surfaces.**—Some of disc springs in Group 2 and all disc springs in Group 3 are manufactured with small contact (load-bearing) surfaces or flats in addition to the corner radii. These flats provide better contact between disc springs, but, at the same time, they reduce the springs outside diameter and generate higher spring force because in Equation (4) force  $F$  is inversely proportional to the square of outside diameter  $D^2$ . To compensate for the undesired force increase, the disc spring thickness is reduced from  $t$  to  $t'$ . Thickness reduction factors  $t'/t$  are approximately 0.94 for disc spring series A and B, and approximately 0.96 for series C springs. With such reduction factors, the disc spring force at 75 percent deflection is the same as for equivalent disc spring without contact surfaces. Equation (12), which is similar to Equation (10), has an additional constant  $K_4$  that correlates the increase in spring force due to contact surfaces. If disc springs do not have contact surfaces, then  $K_4^2 = K_4 = 1$ .

$$F = \frac{4 \cdot E \cdot K_4^2 \cdot s}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \left[ K_4^2 \cdot \left( h' - \frac{s}{2} \right) \cdot (h' - s) \cdot (t' + t)^3 \right] \quad (12)$$

where  $t'$  = reduced thickness of a disc spring

$h'$  = cone height adjusted to reduced thickness:  $h' = H - t'$  ( $h' > h$ )

$K_4$  = constant applied to disc springs with contact surfaces.

$K_4^2$  can be calculated as follows:

$$K_4^2 = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad (13)$$

where  $a = t'(H - 4t' + 3t)(5H - 8t' + 3t)$ ;  $b = 32(t')^3$ ; and,  $c = -t[5(H - t)^2 + 32t^2]$ .

**Disc Spring Functional Stresses.**—Disc springs are designed for both static and dynamic load applications. In static load applications, disc springs may be under constant or fluctuating load conditions that change up to 5,000 or 10,000 cycles over long time intervals. Dynamic loads occur when disc springs are under continuously changing deflection between pre-load (approximately 15 to 20 percent of the cone height) and the maximum deflection values over short time intervals. Both static and dynamic loads cause compressive and tensile stresses. The position of critical stress points on a disc spring cross section are shown in Fig. 9.

Fig. 9. Critical Stress Points  
s is Deflection of Spring by Force  $F$ ;  $h - s$  is a Cone Height of Loaded Disc Spring.

Compressive stresses are acting at points 0 and 1, that are located on the top surface of the disc spring. Point 0 is located on the cross-sectional midpoint diameter, and point 1 is located on the top inside diameter. Tensile stresses are acting at points 2 and 3, which are located on the bottom surface of the disc spring. Point 2 is on the bottom inside diameter, and point 3 is on the bottom outside diameter. The following equations are used to

calculate stresses. The minus sign “-” indicates that compressive stresses are acting in a direction opposite to the tensile stresses.

$$\text{Point 0: } \sigma_0 = -\frac{3}{\pi} \cdot \frac{4E \cdot t \cdot s \cdot K_4}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (14)$$

$$\text{Point 1: } \sigma_1 = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot K_2 \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (15)$$

$$\text{Point 2: } \sigma_2 = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (16)$$

$$\text{Point 3: } \sigma_3 = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) \right] + K_3 \cdot t}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} \quad (17)$$

$K_2$  and  $K_3$  are disc spring dimensional constants, defined as follows:

$$K_2 = \frac{6 \left( \frac{\delta - 1}{\ln \delta} - 1 \right)}{\pi \cdot \ln \delta} \quad (18) \qquad K_3 = \frac{3 \cdot (\delta - 1)}{\pi \cdot \ln \delta} \quad (19)$$

where  $\delta = D/d$  is the outside-to-inside diameter ratio.

In static application, if disc springs are fully flattened (100 percent deflection), compressive stress at point 0 should not exceed the tensile strength of disc spring materials. For most spring steels, the permissible value is  $\sigma_0 \leq 1600 \text{ N/mm}^2$  or 232,000 psi.

In dynamic applications, certain limitations on tensile stress values are recommended to obtain controlled fatigue life of disc springs utilized in various stacking. Maximum tensile stresses at points 2 and 3 depend on the *Group* number of the disc springs. Stresses  $\sigma_2$  and  $\sigma_3$  should not exceed the following values:

	Group 1	Group 2	Group 3
Maximum allowable tensile stresses at points 2 and 3	1300 N/mm <sup>2</sup> (188,000 psi)	1250 N/mm <sup>2</sup> (181,000 psi)	1200 N/mm <sup>2</sup> (174,000 psi)

**Fatigue Life of Disc Springs.**—Fatigue life is measured in terms of the maximum number of cycles that dynamically loaded disc springs can sustain prior to failure. Dynamically loaded disc springs are divided into two groups: disc springs with unlimited fatigue life, which exceeds  $2 \times 10^6$  cycles without failure, and disc springs with limited fatigue life between  $10^4$  cycles and less than  $2 \times 10^6$  cycles.

Typically, fatigue life is estimated from three diagrams, each representing one of the three Groups of disc springs (Fig. 10, Fig. 11, and Fig. 12). Fatigue life is found at the intersection of the vertical line representing minimum tensile stress  $\sigma_{\min}$  with the horizontal line, which represents maximum tensile stress  $\sigma_{\max}$ . The point of intersection of these two lines defines fatigue life expressed in number of cycles  $N$  that can be sustained prior to failure.

*Example:* For *Group 2* springs in Fig. 11, the intersection point of the  $\sigma_{\min} = 500 \text{ N/mm}^2$  line with the  $\sigma_{\max} = 1200 \text{ N/mm}^2$  line, is located on the  $N = 10^5$  cycles line. The estimated fatigue life is  $10^5$  cycles.

Fig. 10. Group 1 Diagram for Estimating Fatigue Life of Disc Springs ( $0.2 \leq t < 1.25$  mm)

Fig. 11. Group 2 Diagram for Estimating Fatigue Life of Disc Springs ( $1.25 \leq t \leq 6$  mm)

Fig. 12. Group 3 Diagram for Estimating Fatigue Life of Disc Springs ( $6 < t \leq 16$  mm)

When the intersection points of the minimum and maximum stress lines fall inside the areas of each cycle line, only the approximate fatigue life can be estimated by extrapolating the distance from the point of intersection to the nearest cycle line. The extrapolation cannot provide accurate values of fatigue life, because the distance between the cycle lines is expressed in logarithmic scale, and the distance between tensile strength values is expressed in linear scale (Figs. 10, 11, and 12), therefore linear-to-logarithmic scales ratio is not applicable.

When intersection points of minimum and maximum stress lines fall outside the cycle lines area, especially outside the  $N = 10^5$  cycles line, the fatigue life cannot be estimated.

Thus, the use of the fatigue life diagrams should be limited to such cases when the minimum and maximum tensile stress lines intersect exactly with each of the cycle lines.

To calculate fatigue life of disc springs without the diagrams, the following equations developed by the author can be used.

$$\text{Disc Springs in Group 1} \quad N = 10^{10.29085532 - 0.00542096(\sigma_{\max} - 0.5\sigma_{\min})} \quad (20)$$

$$\text{Disc Springs in Group 2} \quad N = 10^{10.10734911 - 0.00537616(\sigma_{\max} - 0.5\sigma_{\min})} \quad (21)$$

$$\text{Disc Springs in Group 3} \quad N = 10^{13.23985664 - 0.01084192(\sigma_{\max} - 0.5\sigma_{\min})} \quad (22)$$

As can be seen from Equations (20), (21), and (22), the maximum and minimum tensile stress range affects the fatigue life of disc springs. Since tensile stresses at Points 2 and 3 have different values, see Equations (16) and (17), it is necessary to determine at which critical point the minimum and maximum stresses should be used for calculating fatigue life. The general method is based on the diagram, Fig. 9 from which Point 2 or Point 3 can be found in relationship with disc spring outside-to-inside diameters ratio  $D/d$  and disc spring cone height-to-thickness ratio  $h/r$ . This method requires intermediate calculations of  $D/d$  and  $h/r$  ratios and is applicable only to disc springs without contact surfaces. The method is not valid for Group 3 disc springs or for disc springs in Group 2 that have contact surfaces and reduced thickness.

A simple and accurate method, that is valid for all disc springs, is based on the following statements:

if  $(\sigma_{2\max} - 0.5\sigma_{2\min}) > (\sigma_{3\max} - 0.5\sigma_{3\min})$ , then Point 2 is used, otherwise

if  $(\sigma_{3\max} - 0.5\sigma_{3\min}) > (\sigma_{2\max} - 0.5\sigma_{2\min})$ , then Point 3 is used

The maximum and minimum tensile stress range for disc springs in Groups 1, 2, and 3 is found from the following equations.

For disc springs in Group 1:

$$\sigma_{\max} - 0.5\sigma_{\min} = \frac{10.29085532 - \log N}{0.00542096} \quad (23)$$

For disc springs in Group 2:

$$\sigma_{\max} - 0.5\sigma_{\min} = \frac{10.10734911 - \log N}{0.00537616} \quad (24)$$

For disc springs in Group 3:

$$\sigma_{\max} - 0.5\sigma_{\min} = \frac{13.23985664 - \log N}{0.01084192} \quad (25)$$

Thus, Equations (23), (24), and (25) can be used to design any spring stack that provides required fatigue life. The following example illustrates how a maximum-minimum stress range is calculated in relationship with fatigue life of a given disc spring stack.

*Example:* A dynamically loaded stack, which utilizes disc springs in *Group 2*, must have the fatigue life of  $5 \times 10^5$  cycles. The maximum allowable tensile stress at Points 2 or 3 is  $1250 \text{ N/mm}^2$ . Find the minimum tensile stress value to sustain  $N = 5 \times 10^5$  cycles.

*Solution:* Substitution of  $\sigma_{\max} = 1250$  and  $N = 5 \times 10^5$  in *Equation (24)* gives:

$$1250 - 0.5\sigma_{\min} = \frac{10.10734911 - \log(5 \times 10^5)}{0.00537616} = \frac{10.10734911 - 5.69897}{0.00537616} = 820$$

from which  $\sigma_{\min} = \frac{1250 - 820}{0.5} = 860 \text{ N/mm}^2$  (124,700 psi)

**Recommended Dimensional Characteristics of Disc Springs.**—Dimensions of disc springs play a very important role in their performance. It is imperative to check selected disc springs for dimensional ratios, that should fall within the following ranges:

- 1) Diameters ratio,  $\delta = D_d/D_f = 1.7$  to  $2.5$ .
- 2) Cone height-to-thickness ratio,  $h_f/t = 0.4$  to  $1.3$ .
- 3) Outside diameter-to-thickness ratio,  $D_f/t = 18$  to  $40$ .

Small values of  $\delta$  correspond with small values of the other two ratios. The  $h_f/t$  ratio determines the shape of force-deflection characteristic graphs, that may be nearly linear or strongly curved. If  $h_f/t = 0.4$  the graph is almost linear during deflection of a disc spring up to its flat position. If  $h_f/t = 1.6$  the graph is strongly curved and its maximum point is at 75 percent deflection. Disc spring deflection from 75 to 100 percent slightly reduces spring force. Within the  $h_f/t = 0.4 - 1.3$  range, disc spring forces increase with the increase in deflection and reach maximum values at 100 percent deflection. In a stack of disc springs with a ratio  $h_f/t > 1.3$  deflection of individual springs may be unequal, and only one disc spring should be used if possible.

#### Example Applications of Disc Springs

*Example 1, Disc Springs in Group 2 (no contact surfaces):* A mechanical device that works under dynamic loads must sustain a minimum of 1,000,000 cycles. The applied load varies from its minimum to maximum value every 30 seconds. The maximum load is approximately 20,000N (4,500 lbf). A 40-mm diameter guide rod is a receptacle for the disc springs. The rod is located inside a hollow cylinder. Deflection of the disc springs under minimum load should not exceed 5.5 mm (0.217 inch) including a 20 percent preload deflection. Under maximum load, the deflection is limited to 8 mm (0.315 inch) maximum. Available space for the disc spring stack inside the cylinder is 35 to 40 mm (1.38 to 1.57 inch) in length and 80 to 85 mm (3.15 to 3.54 inch) in diameter.

Select the disc spring catalog item, determine the number of springs in the stack, the spring forces, the stresses at minimum and maximum deflection, and actual disc spring fatigue life.

*Solution:* 1) Disc spring standard inside diameter is 41 mm (1.61 inch) to fit the guide rod. The outside standard diameter is 80 mm (3.15 in) to fit the cylinder inside diameter. Disc springs with such diameters are available in various thickness: 2.25, 3.0, 4.0, and 5.0 mm (0.089, 0.118, 0.157, and 0.197 inch). The 2.25- and 3.0-mm thick springs do not fit the applied loads since the maximum force values for disc springs with such thickness are 7,200N and 13,400N (1,600 lbf and 3,000 lbf) respectively. A 5.0-mm thick disc spring should not be used because its  $D_f$  ratio,  $80/5 = 16$ , is less than 18 and is considered as unfavorable. Disc spring selection is narrowed to an 80-41-4 catalog item.

- 2) Checking 80 - 41 - 4 disc spring for dimensional ratios:

$$\delta = D_d/D_f = 80/41 = 1.95 \quad h_f/t = 22/4 = 0.55 \quad D_f/t = 80/4 = 20$$

Because the dimensional ratios are favorable, the 80-41-4 disc springs are selected.

3) The number of springs in the stack is found from Equation (1):

$$n = L_0 / (t + h) = 40 / (4 + 2.2) = \frac{40}{6.2} = 6.45.$$

Rounding  $n$  to the nearest integer gives  $n = 6$ . The actual length of unloaded spring stack is  $L_0 = 6.2 \times 6 = 37.2$  mm (1.465 inch) and it satisfies the  $L_0 < 40$  mm condition.

4) Calculating the cone angle  $\alpha$  from Equation (7) and actual outside diameter  $D_a$  from Equation (9) gives:

$$\alpha = \text{atan} \left( \frac{2 \times 2.2}{80 - 41} \right) = \text{atan} (0.11282) = 6.4^\circ$$

$$D_a = 80 - 2 \times 4 \left( \sin [\text{atan} (0.11282)] + \frac{1}{6} \cos [\text{atan} (0.11282)] \right)$$

$$D_a = 77.78 \text{ mm} (3.062 \text{ in})$$

5) Calculating constant  $K_1$  from Equation (11):

$$\delta = \frac{D}{d} = 1.95122$$

$$K_1 = \frac{\left( \frac{1.95122 - 1}{1.95122} \right)^2}{\pi \cdot \left[ \frac{1.95122 + 1}{1.95122 - 1} - \frac{2}{\ln(1.95122)} \right]} = 0.6841$$

6) Calculating minimum and maximum forces,  $F_{min}$  and  $F_{max}$  from Equation (10):

Based on the design requirements, the disc spring stack is deflecting by 5.5 mm (0.217 in) under minimum load, and each individual disc spring is deflecting by  $5.5 / 6 \cong 0.92$  mm (0.036 in). A single disc spring deflection  $s_{min} = 0.9$  mm (0.035 in) is used to calculate  $F_{min}$ . Under maximum load, the disc spring stack is permitted maximum deflection of 8 mm (0.315 in), and each individual disc spring deflects by  $8 / 6 \cong 1.33$  mm (0.0524 in). A disc spring deflection  $s_{max} = 1.32$  mm (0.052 in) will be used to calculate  $F_{max}$ . If disc springs are made of AISI 6150 alloy steel, then modulus of elasticity  $E = 206,000$  N/mm<sup>2</sup> ( $30 \times 10^6$  psi) and Poisson's ratio  $\mu = 0.3$ .

$$F_{min} = \frac{4 \cdot 206000}{(1 - 0.3^2)(0.6841)(77.78)^2} \left[ \left( 2.2 - \frac{0.9}{2} \right) \cdot (2.2 - 0.9) \cdot 4 + 4^3 \right] 0.9$$

$$F_{min} = 14390N (3235 \text{ lbf})$$

$$F_{max} = \frac{4 \cdot 206000}{(1 - 0.3^2)(0.6841)(77.78)^2} \left[ \left( 2.2 - \frac{1.32}{2} \right) \cdot (2.2 - 1.32) \cdot 4 + 4^3 \right] 1.32$$

$$F_{max} = 20050N (4510 \text{ lbf})$$

7) Calculating constant  $K_2$ , Equation (18):

$$\delta = \frac{D}{d} = \frac{80}{41} = 1.95122$$

$$K_2 = \frac{6 \left( \frac{\delta - 1}{\ln \delta} - 1 \right)}{\pi \cdot \ln \delta} = \frac{6 \left( \frac{1.95122 - 1}{\ln(1.95122)} - 1 \right)}{\pi \cdot \ln(1.95122)} = 1.2086$$

8) Calculating constant  $K_3$  (Equation (19)):

$$K_3 = \frac{3 \cdot (\delta - 1)}{\pi \cdot \ln \delta} = \frac{3 \cdot (1.95122 - 1)}{\pi \cdot \ln(1.95122)} = 1.3589$$

9) Compressive stress  $\sigma_0$  at point 0 due to maximum deflection, Equation (14):

$$\sigma_0 = -\frac{3}{\pi} \cdot \frac{4E \cdot t \cdot s \cdot K_4}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} = -\frac{3}{\pi} \cdot \frac{4 \cdot 206000 \cdot 4 \cdot 1.32 \cdot 1}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2}$$

$$\sigma_0 = 1103 \text{ N/mm}^2 = 160000 \text{ psi}$$

Because the compressive stress at point 0 does not exceed 1600 N/mm<sup>2</sup>, its current value satisfies the design requirement.

10) Tensile stress  $\sigma_2$  at point 2 due to minimum deflection  $s = 0.9$  mm, Equation (16):

$$\sigma_{2min} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 0.9 \left[ 1.3589 \cdot 4 - 1.2086 \cdot 1 \cdot \left( 2.2 - \frac{0.9}{2} \right) \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2} = 654 \text{ N/mm}^2$$

11) Tensile stress  $\sigma_2$  at point 2 due to maximum deflection  $s = 1.32$  mm, Equation (16):

$$\sigma_{2max} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 1.32 \cdot \left[ 1.3589 \cdot 4 - 1.2086 \cdot 1 \cdot \left( 2.2 - \frac{1.32}{2} \right) \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2} = 1032 \text{ N/mm}^2$$

Thus,  $\sigma_{2min} = 654 \text{ N/mm}^2$  (94,850 psi) and  $\sigma_{2max} = 1032 \text{ N/mm}^2$  (149,700 psi).

12) Tensile stress  $\sigma_3$  at point 3 due to minimum deflection  $s = 0.9$  mm, Equation (17):

$$\sigma_{3min} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 0.9 \cdot \left[ 1 \cdot (2 \cdot 1.3589 - 1.2086) \cdot \left( 2.2 - \frac{0.9}{2} \right) + 1.3589 \cdot 4 \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2 \cdot 1.95122} = 815 \text{ N/mm}^2$$

13) Tensile stress  $\sigma_3$  at point 3 due to maximum deflection  $s = 1.32$  mm, Equation (17):

$$\sigma_{3max} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 1.32 \cdot \left[ 1 \cdot (2 \cdot 1.3589 - 1.2086) \cdot \left( 2.2 - \frac{1.32}{2} \right) + 1.3589 \cdot 4 \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2 \cdot 1.95122} = 1149 \text{ N/mm}^2$$

Thus,  $\sigma_{3min} = 815 \text{ N/mm}^2$  (118,200 psi) and  $\sigma_{3max} = 1149 \text{ N/mm}^2$  (166,600 psi).

14) Functional tensile stress range at critical points 2 and 3.

Point 2:  $\sigma_{2max} - 0.5\sigma_{2min} = 1032 - 0.5 \times 654 = 705 \text{ N/mm}^2$

Point 3:  $\sigma_{3max} - 0.5\sigma_{3min} = 1149 - 0.5 \times 815 = 741.5 \text{ N/mm}^2$

Because  $\sigma_{3max} - 0.5\sigma_{3min} > \sigma_{2max} - 0.5\sigma_{2min}$ , the tensile stresses at point 3 are used for fatigue life calculations.

15) Fatigue life of selected disc springs, Equation (21):

$$N = 10^{[10.10734911 - 0.00537616(1149 - 0.5 \times 815)]} = 10^{10.10734911 - 3.98642264} = 10^{6.12092647}$$

$N = 1,321,000$  cycles. Thus, the calculated actual fatigue life exceeds required minimum number of cycles by 31 percent.

In conclusion, the six 80-41-4 disc springs arranged in series stacking, satisfy the requirements and will provide a 32 percent longer fatigue life than required by the design criteria.

*Example 2:* A company wishes to use *Group 3* disc springs with contact surfaces on couplings to absorb bumping impacts between railway cars.

Given:

$D = 200$  mm, disc spring outside diameter

$d = 102$  mm, disc spring inside diameter

$t = 14$  mm, spring standard thickness

$t' = 13.1$  mm, spring reduced thickness

$h = 4.2$  mm, cone height of unloaded spring

$n = 22$ , number of springs in series stacking

$S_i = 33.9$  mm, initial deflection of the pack

$S_a = 36.0$  mm, additional deflection of the pack

Find the fatigue life in cycles and determine if the selected springs are suitable for the application.

The calculations are performed in the following sequence:

1) Determine the minimum  $s_{min}$  and maximum  $s_{max}$  deflections of a single disc spring:

$$s_{max} = \frac{(S_i + S_a)}{n} = \frac{(33.9 + 36)}{22} = 3.18 \text{ mm}$$

$$s_{min} = \frac{S_i}{n} = \frac{33.9}{22} = 1.54 \text{ mm}$$

2) Use Equations (16) and (17) to calculate tensile stresses  $\sigma_2$  and  $\sigma_3$  at  $s_{min}$  and  $s_{max}$  deflections:

$$\sigma_{2min} = 674 \text{ N/mm}^2, \sigma_{2max} = 1513 \text{ N/mm}^2, \sigma_{3min} = 707 \text{ N/mm}^2, \sigma_{3max} = 1379 \text{ N/mm}^2$$

3) Determine critical stress points:

$$\sigma_{2max} - 0.5\sigma_{2min} = 1513 - 0.5 \times 674 = 1176 \text{ N/mm}^2$$

$$\sigma_{3max} - 0.5\sigma_{3min} = 1379 - 0.5 \times 707 = 1025.5 \text{ N/mm}^2$$

Because  $(\sigma_{2max} - 0.5\sigma_{2min}) > (\sigma_{3max} - 0.5\sigma_{3min})$ , then tensile stresses at point 2 are used to calculate fatigue life.

4) Fatigue life  $N$  is calculated using Equation (22):

$$N = 10^{[13.23985664 - (0.01084192 \times 1176)]} = 10^{0.49} = 3 \text{ cycles}$$

The selected disc springs at the above-mentioned minimum and maximum deflection values will not sustain any number of cycles. It is imperative to check the selected disc springs for dimensional ratios:

Outside-to-inside diameters ratio,  $200/102 = 1.96$ ; within recommended range.

Cone height-to-thickness ratio is  $4.2/13.1 = 0.3$ ; out of range, the minimum ratio is 0.4.

Outside diameter-to-thickness ratio is  $200/13.1 = 15$ ; out of range, the minimum ratio is 18. Thus, only one of the dimensional ratios satisfies the requirements for the best disc spring performance.

Notes: Values in parentheses are atomic weights of the most stable known isotopes. Melting points are at standard pressure except as noted.

## Heat and Combustion Related Properties

**Latent Heat.**—When a body changes from the solid to the liquid state or from the liquid to the gaseous state, a certain amount of heat is used to accomplish this change. This heat does not raise the temperature of the body and is called latent heat. When the body changes again from the gaseous to the liquid, or from the liquid to the solid state, it gives out this quantity of heat. The *latent heat of fusion* is the heat supplied to a solid body at the melting point; this heat is absorbed by the body although its temperature remains nearly stationary during the whole operation of melting. The *latent heat of evaporation* is the heat that must be supplied to a liquid at the boiling point to transform the liquid into a vapor. The latent heat is generally given in British thermal units per pound, or kilojoules per kilogram. The latent heat of evaporation of water is 966.6 Btu/pound, or 2248 kJ/kg. This means that it takes 966.6 Btu to evaporate 1 pound, or 2248 kJ to evaporate 1 kilogram, of water after it has been raised to the boiling point, 212°F or 100°C.

When a body changes from the solid to the gaseous state without passing through the liquid stage, as solid carbon dioxide does, the process is called *sublimation*.

Table 2. Latent Heat of Fusion

Substance	Btu per Pound	kJ/kg	Substance	Btu per Pound	kJ/kg	Substance	Btu per Pound	kJ/kg
Bismuth	22.75	52.92	Paraffine	63.27	147.17	Sulfur	16.86	39.22

			Oil of turpentine	315	157.2			

**Specific Heat.**—The specific heat of a substance is the ratio of the heat required to raise the temperature of a certain weight of the given substance 1°F to the heat required to raise the temperature of the same weight of water 1°F. As the specific heat is not constant at all temperatures, it is generally assumed that it is determined by raising the temperature from 62 to 63°F. For most substances, however, specific heat is practically constant for temperatures up to 212°F.

**In metric units, specific heat is defined as the ratio of the heat needed to raise the temperature of a mass by 1°C to the heat needed to raise the temperature of the same mass of water by 1°C. In the metric system, heat is measured in joules (J), mass is in grams (g), and measurements are usually taken at 15°C.**

Because specific heat is a dimensionless ratio, the values given in Table 5 and Table 6 that follow are valid in both the US system and the metric system.

**Table 5. Average Specific Heats of Various Substances**

Substance	Specific Heat	Substance	Specific Heat
Alcohol (absolute)	0.700	Lead	0.031

Carbonic oxide	0.245	0.176	Steam	0.480	0.346
Chlorine	0.121	...			

**Heat Loss from Uncovered Steam Pipes.**—The loss of heat from a bare steam or hot-water pipe varies with the temperature difference between the inside of the pipe and the surrounding air. The loss is 2.15 Btu per hour, per square foot of pipe surface, per degree F of temperature difference when the latter is 100 degrees; for a difference of 200 degrees, the loss is 2.66 Btu; for 300 degrees, 3.26 Btu; for 400 degrees, 4.03 Btu; for 500 degrees, 5.18 Btu. Thus, if the pipe area is 1.18 square feet per foot of length, and the temperature difference 300°F, the loss per hour per foot of length =  $1.18 \times 300 \times 3.26 = 1154$  Btu.

\* Alloy designations correspond to the Aluminum Association numbers for aluminum alloys and to the unified numbering system (UNS) for copper and stainless steel alloys. A220 and A536 are ASTM specified irons.

**Adjusting Lengths for Reference Temperature.**—The standard reference temperature for industrial length measurements is 20 degrees Celsius (68 degrees Fahrenheit). For other temperatures, corrections should be made in accordance with the difference in thermal expansion for the two parts, especially when the gage is made of a different material than the part to be inspected.

*Example:* An aluminum part is to be measured with a steel gage when the room temperature is 30 °C. The aluminum part has a coefficient of linear thermal expansion,  $\alpha_{part} = 24.7 \times 10^{-6}$  mm/mm-°C, and for the steel gage,  $\alpha_{Gage} = 10.8 \times 10^{-6}$  mm/mm-°C.

At the reference temperature, the specified length of the aluminum part is 20.021 mm. What is the length of the part at the measuring (room) temperature?

$\Delta L$ , the change in the measured length due to temperature, is given by:

$$\begin{aligned} \Delta L &= L(T_R - T_0)(\alpha_{part} - \alpha_{Gage}) \\ &= 20.021(30 - 20)(24.7 - 10.8) \times 10^{-6} \text{ mm} \\ &= 2782.919 \times 10^{-6} \approx 0.003 \text{ mm} \end{aligned}$$

where  $L$  = length of part at reference temperature;  $T_R$  = room temperature (temperature of part and gage) and  $T_0$  = reference temperature.

Thus, the temperature-corrected length at 30°C is  $L + \Delta L = 20.021 + 0.003 = 20.024$  mm.

**Length Change Due to Temperature.**—Table 14 gives changes in length for variations from the standard reference temperature of 68°F (20°C) for materials of known coefficients of expansion,  $\alpha$ . Coefficients of expansion are given in tables on pages 372, 373, 374, 386, 387, and elsewhere.

*Example:* In Table 14, for coefficients between those listed, add appropriate listed values. For example, a length change for a coefficient of 7 is the sum of values in the 5 and 2 columns. Fractional interpolation also is possible. Thus, in a steel bar with a coefficient of thermal expansion of  $6.3 \times 10^{-6} = 0.0000063$  in/in = 6.3  $\mu\text{in/in}$  of length/°F, the increase in length at 73°F is  $25 + 5 + 1.5 = 31.5$   $\mu\text{in/in}$  of length. For a steel with the same coefficient of expansion, the change in length, measured in degrees C, is expressed in microns (micrometers)/meter ( $\mu\text{m/m}$ ) of length.

Alternatively, and for temperatures beyond the scope of the table, the length difference due to a temperature change is equal to the coefficient of expansion multiplied by the change in temperature, i.e.,  $\Delta L = \alpha \Delta T$ . Thus, for the previous example,  $\Delta L = 6.3 \times (73 - 68) = 6.3 \times 5 = 31.5$   $\mu\text{in/in}$ .

**Change in Radius of Thin Circular Ring with Temperature.**—Consider a circular ring of initial radius  $r$ , that undergoes a temperature change  $\Delta T$ . Initially, the circumference of the ring is  $c = 2\pi r$ . If the coefficient of expansion of the ring material is  $\alpha$ , the change in circumference due to the temperature change is  $\Delta c = 2\pi r \alpha \Delta T$ .

The new circumference of the ring will be:  $c_n = c + \Delta c = 2\pi r + 2\pi r \alpha \Delta T = 2\pi r (1 + \alpha \Delta T)$ .

*Note:* An increase in temperature causes  $\Delta c$  to be positive, and a decrease in temperature causes  $\Delta c$  to be negative.

As the circumference increases, the radius of the circle also increases. If the new radius is  $R$ , the new circumference is  $2\pi R$ . For a given change in temperature,  $\Delta T$ , the change in radius of the ring is found as follows:

$$c_n = 2\pi R = 2\pi r(1 + \alpha \Delta T) \qquad R = r + r\alpha \Delta T \qquad \Delta r = R - r = r\alpha \Delta T$$

**Table 14. Differences in Length in Microinches/Inch (Microns/Meter) for Changes from the Standard Temperature of 68°F (20°C)**

### Properties of Mass and Weight

**Density.**—The density of any solid, fluid or gaseous substance is the mass of that substance per unit volume. If weight is used in the ordinary sense as being equivalent to mass, then density may be defined as the weight per unit volume. The density depends upon the unit in which the mass or weight is expressed, and upon the unit of volume used. In engineering and scientific work, density is generally expressed in grams per cubic centimeter, without naming the units, because the density will be equal to the specific gravity.

**Specific Gravity.**—Specific gravity is a number indicating how many times a volume of material is heavier than an equal volume of water. Density of water varies slightly at different temperatures. In exacting scientific studies, a reference temperature of 4°C (39.2°F) is often used, and the weight of 1 cubic meter of pure water at 4°C is 1000 kg. In engineering practice, the usual custom is to measure specific gravity at water temperature of 60 or 62°F (15.5 or 16.6°C); 1 cubic foot of pure water at 62°F weighs 62.355 pounds.

Given	Rule to find density	Given	Rule to find specific gravity
Specific Gravity (S.G.)	weight/cm <sup>3</sup> = S.G.	weight/cm <sup>3</sup>	S.G. = weight/cm <sup>3</sup>
	weight/m <sup>3</sup> = S.G. × 1000	weight/m <sup>3</sup>	S.G. = weight/m <sup>3</sup> ÷ 1000
	weight/in <sup>3</sup> = S.G. × 0.0361	weight/in <sup>3</sup>	S.G. = weight/in <sup>3</sup> ÷ 0.0361
	weight/ft <sup>3</sup> = S.G. ÷ 0.01604	weight/ft <sup>3</sup>	S.G. = weight/ft <sup>3</sup> × 0.01604

When specific gravity is known, the weight per cubic centimeter is equal to its specific gravity. The weight per cubic meter equals the specific gravity × 1000. The weight per cubic inch equals the specific gravity × 0.0361. The weight of a cubic foot equals the specific gravity divided by 0.01604.

When weight per cubic centimeter is known, the specific gravity is equal to the weight per cubic centimeter. If weight per cubic meter is known, the specific gravity equals this weight divided by 1000. If density is given in lb/in<sup>3</sup>, specific gravity may be determined by dividing the density by 0.0361. If weight per cubic foot is known, specific gravity equals this weight multiplied by 0.01604.

*Examples:* The specific gravity of cast iron is 7.2. The weight of 80 cm<sup>3</sup> of cast iron = 7.2 × 80 = 5.6 kg. The weight of 5 in<sup>3</sup> of cast iron = 7.2 × 0.0361 × 5 = 1.2996 pounds.

*Examples:* The weight of a cubic centimeter of gold is 19.31 grams. The specific gravity of gold = weight of a cubic centimeter of gold = 19.31. A cubic inch of gold weighs 0.697 pound. The specific gravity of gold = 0.697 ÷ 0.0361 = 19.31

**Table 15. Average Specific Gravity of Various Substances**

<sup>a</sup>The weight per cubic foot or cubic meter is calculated on the basis of the specific gravity except for those substances that occur in bulk, heaped, or loose form. In these instances, only the weights per cubic foot and cubic meter are given because the voids present in representative samples make the values of the specific gravities inaccurate.

#### Average Weights and Volumes of Solid Fuels

Material	lb/ft <sup>3</sup>	ft <sup>3</sup> /ton (2240 lb)	kg/m <sup>3</sup>	lb/bushel	m <sup>3</sup> /t
Anthracite coal	55–65	34–41	881–1041	67 (80 <sup>a</sup> )	0.96–1.14
Bituminous coal	50–55	41–45	801–881	78–86 (80 <sup>a</sup> )	1.14–1.25
Charcoal	18–18.5	121–124	288–296	22–23 (20 <sup>a</sup> )	3.37–3.47
Coke	28	80	449	35 (40 <sup>a</sup> )	2.23

<sup>a</sup>Legal commodities weight/bushel defined by statute in some states.

Note: t = metric ton = 1000 kg; ton = US ton of 2000 lbs; a gross or long ton = 2240 lbs.

**Specific Gravity of Gases.**—The specific gravity of gases is the number that indicates their weight in comparison with that of an equal volume of air. The specific gravity of air is 1, and the comparison is made at 32°F (0°C). Values are given in Table 16.

**Table 16. Specific Gravity of Gases At 32°F (0°C)**

Gas	Sp. Gr.	Gas	Sp. Gr.	Gas	Sp. Gr.
Air <sup>a</sup>	1.000	Ether vapor	2.586	Marsh gas	0.555
Acetylene	0.920	Ethylene	0.967	Nitrogen	0.971
Alcohol vapor	1.601	Hydrofluoric acid	2.370	Nitric oxide	1.039
Ammonia	0.592	Hydrochloric acid	1.261	Nitrous oxide	1.527
Carbon dioxide	1.520	Hydrogen	0.069	Oxygen	1.106
Carbon monoxide	0.967	Illuminating gas	0.400	Sulfur dioxide	2.250
Chlorine	2.423	Mercury vapor	6.940	Water vapor	0.623

<sup>a</sup>1 cubic foot of air at 32°F and atmospheric pressure weighs 0.0807 pound. 1 cubic meter of air at 0°C and atmospheric pressure weighs 1.29 kg.

**Specific Gravity of Liquids.**—The specific gravity of liquids is the number that indicates how much a certain volume of the liquid weighs compared with an equal volume of water, the same as with solid bodies. Specific gravity of various liquids is given in Table 17.

The density of liquid is often expressed in degrees on the hydrometer, an instrument for determining the density of liquids that is provided with graduations made to an arbitrary scale. The hydrometer consists of a glass tube with a bulb at one end containing air and arranged with a weight at the bottom so as to float in an upright position in the liquid, the density of which is to be measured. The depth to which the hydrometer sinks in the liquid is read off on the graduated scale. The most commonly used hydrometer is the Baumé, see Table 18. The value of the degrees of the Baumé scale differs according to whether the liquid is heavier or lighter than water. The specific gravity for liquids heavier than water equals  $145 \div (145 - \text{degrees Baumé})$ . For liquids lighter than water, the specific gravity equals  $140 \div (130 + \text{degrees Baumé})$ .

**Table 17. Specific Gravity of Liquids**

Liquid	Sp. Gr.	Liquid	Sp. Gr.	Liquid	Sp. Gr.	Liquid	Sp. Gr.
Acetic acid	1.06	Cotton-seed oil	0.93	Naphtha	0.76	Tar	1.00
Alcohol, commercial	0.83	Ether, sulfuric	0.72	Nitric acid	1.50	Turpentine oil	0.87
Alcohol, pure	0.79	Fluoric acid	1.50	Olive oil	0.92	Vinegar	1.08
Ammonia	0.89	Gasoline	0.70	Palm oil	0.97	Water	1.00
Benzene	0.69	Kerosene	0.80	Petroleum oil	0.82	Water, sea	1.03
Bromine	2.97	Linseed oil	0.94	Phosphoric acid	1.78	Whale oil	0.92
Carbolic acid	0.96	Mineral oil	0.92	Rape oil	0.92		
Carbon disulfide	1.26	Muriatic acid	1.20	Sulfuric acid	1.84		

**Table 18. Degrees on Baumé's Hydrometer Converted to Specific Gravity**

Deg. Baumé	Specific Gravity for Liquids		Deg. Baumé	Specific Gravity for Liquids		Deg. Baumé	Specific Gravity for Liquids

**How to Estimate the Weight of Natural Piles.**—To calculate the upper and lower limits of weight of a substance piled naturally on a plate, use the following:

Fig. 1a. Conical Pile

For a substance piled naturally on a circular plate, forming a cone of material,

$$W = MD^3 \quad (1)$$

where  $W$  = weight, lb (kg);  $D$  = diameter of plate in Fig. 1a, in feet (meters); and  $M$  = a materials factor, whose upper and lower limits are given in Table 19b.

Fig. 1b. Rectangular Pile

For a substance piled naturally on a rectangular plate,

$$W = MRA^3 \quad (2)$$

where  $W$  = weight, lb (kg);  $A$  and  $B$  = the length and width in feet (meters), respectively, of the rectangular plate in Fig. 1b, with  $B \leq A$ ;  $M$  = a materials factor, whose upper and lower limits are given in Table 19b; and  $R$  = is a factor given in Table 19a as a function of the ratio  $B/A$ .

*Example:* Find the upper and lower limits of the weight of dry ashes piled naturally on a plate 10 ft. in diameter.

Using Equation (1),  $M = 4.58$  from Table 19b, the lower limit  $W = 4.58 \times 10^3 = 4,580$  lb. For  $M = 5.89$ , the upper limit  $W = 5.89 \times 10^3 = 5,890$  lb.

*Example:* What weight of dry ashes rests on a rectangular plate 10 ft. by 5 ft.?

For  $B/A = 5/10 = 0.5$ ,  $R = 0.39789$  from Table 19a. Using Equation (2), for  $M = 4.58$ , the lower limit  $W = 4.58 \times 0.39789 \times 10^3 = 1,822$  lb. For  $M = 5.89$ , the upper limit  $W = 5.89 \times 0.39789 \times 10^3 = 2,344$  lb.

*Example:* What is the weight of a pile of cast iron chips resting on a rectangular plate 4 m by 2 m? For  $B/A = 2/4$ ,  $R = 0.39789$  from Table 19a. Using Equation (2), for  $M = 17.02$ , the lower limit  $W = 17.02 \times 0.39789 \times 4^3 = 433$  kg. For  $M = 26.18$ , the upper limit  $W = 26.18 \times 0.39789 \times 4^3 = 667$  kg.

Table 19a. Factor  $R$  as a Function of  $B/A$  ( $B \leq A$ )

Table 19b. Limits of Factor  $M$  for Various Materials

Material	Factor $M$	Material	Factor $M$	Material	Factor $M$
Almonds, whole	2.12-3.93	Coffee, ground	1.89-3.27	Peanuts, unshelled	1.13-3.14
Aluminum chips	0.92-1.96	Coke, pulverized	2.21	Peanuts, shelled	2.65-5.89
Aluminum silicate	3.7-6.41	Copper oxide, powdered	20.87	Peas, dry	2.75-3.05
Ammonium chloride	3.93-6.81	Cork, granulated	1.57-1.96	Potassium carbonate	3.85-6.68
Asbestos, shredded	2.62-3.27	Corn on cob	1.29-1.33	Potassium sulphate	5.5-6.28
Ashes, dry	4.58-5.89	Corn sugar	2.34-4.06	Pumice	5.24-5.89
Ashes, damp	6.24-7.80	Cottonseed, dry, de-linted	1.66-5.24	Rice, bran	1.51-2.75
Asphalt, crushed	3.4-5.89	Diatomaceous earth	0.83-1.83	Rubber, scrap, ground	2.11-4.58
Bakelite, powdered	3.93-5.24	Dicalcium phosphate	5.63	Salt, dry, coarse	3.02-3.38
Baking powder	3.1-5.37	Ebonite, crushed	4.91-9.16	Salt, dry, fine	5.29-10.47
Barium carbonate	9.42	Epsom salts	3.02-6.54	Saltpeper	6.05-10.47
Bauxite, mine run	5.9-6.69	Feldspar, ground	8.51-9.16	Salt rock, crushed	4.58
Beans, navy, dry	3.63	Fish scrap	5.24-6.54	Sand, very fine	7.36-9
Beets, sugar, shredded	0.47-0.55	Flour	5.61-10.43	Sawdust, dry	0.95-2.85
Bicarbonate of soda	3.10	Flue dust	2.65-3.40	Sesame seed	2.04-4.84
Borax	3.78-9.16	Fluorspar (Fluorite)	10.73-14.40	Shellac, powdered	2.34-4.06
Boric acid	4.16-7.20	Graphite, flake	3.02-5.24	Slag, furnace, granular	4.53-8.51
Bronze chips	3.93-6.54	Gravel	6.8-13.18	Soap powder	1.51-3.27
Buckwheat	2.8-3.17	Gypsum, calcined	6.04-6.59	Sodium nitrate	3.96-4.66
Calcium lactate	3.4-3.8	Hominy	2.8-6.54	Sodium sulphite	10.54
Calcium oxide (lime)	3.30	Hops, dry	4.58	Sodium sulphate	6.92
Carbon, ground	2.51	Kaolin clay	12.32-21.34	Soybeans	3.48-6.28
Casein	2.72-4.71	Lead silicate, granulated	25.26	Steel chips, crushed	7.56-19.63
Cashew nuts	4.19-4.84	Lead sulphate, pulverized	24.09	Sugar, refined	3.78-7.2
Cast iron chips	17.02-26.18	Lime, ground	7.85	Sulphur	4.5-6.95
Cement, Portland	6.8-13.09	Limestone, crushed	6.42-11.78	Talcum powder	4.37-5.9
Cinders, coal	3.02-5.24	Magnesium chloride	4.32	Tin oxide, ground	9.17
Clay, blended for tile	5.89	Malt, dry, ground	1.66-2.88	Tobacco stems	1.96-3.27
Coal, anthracite, chestnut	2.43	Manganese sulphate	5.29-9.16	Trisodium phosphate	4.53-7.85
Coal, bituminous, sized	2.64-4.48	Marble, crushed	6.8-12.44	Walnut shells, crushed	2.65-5.24
Coal, ground	2.90	Mica, ground	1.24-1.43	Wood chips, fir	2.49-2.88
Cocoa, powdered	3.93-4.58	Milk, whole, powdered	2.62	Zinc sulphate	8.85-11.12
Coconut, shredded	2.62-2.88	Oats	1.74-2.86	...	...
Coffee beans	2.42-5.89	Orange peel, dry	1.96	...	...

**Molecular Weight.**—The smallest mass of a chemical combination which can be conceived of as existing and yet preserving its chemical properties is known as a *molecule*. The molecular weight of a chemical compound is equal to the sum of the atomic weights of the atoms contained in the molecule, and is calculated from the atomic weights, when the symbol of the compound is known. See [Table 1](#) on page 368 for atomic weights. The atomic weight of silver is 107.88; of nitrogen, 14.01; and of oxygen, 16; hence, the molecular weight of silver-nitrate, the chemical formula of which is  $\text{AgNO}_3$  equals  $107.88 + 14.01 + (3 \times 16) = 169.89$ .

**Mole or Mol.**—This term is used as a designation of quantity in electro-chemistry to indicate the number of grams of a substance equal to its molecular weight. For example, one mol of silver-nitrate equals 169.89 grams, the molecular weight of silver-nitrate being 169.89.

**Air.**—Air is a mechanical mixture composed of 78 percent, by volume, of nitrogen, 21 percent of oxygen, and 1 percent of argon. The weight of pure air at 32 °F (0 °C), at an atmospheric pressure of 29.92 inches of mercury (760 mm mercury or 760 torr) or 14.70 pounds per square inch, is 0.08073 pound per cubic foot. The volume of a pound of air at the same temperature and pressure is 12.387 cubic feet. The weight of air, in pounds per cubic foot, at any other temperature or pressure may be determined by first multiplying the barometer reading (atmospheric pressure in inches of mercury) by 1.325 and then dividing the product by the absolute temperature in degrees F. The absolute zero from which all temperatures must be derived in dealing with the weight and volume of gases, is assumed to be minus 459.67 °F (273.15 °C). Hence, to obtain the absolute temperature, add to the temperature observed on a regular Fahrenheit thermometer the value 459.67.

**Alligation.**—Alligation or “the rule of mixtures” are names applied to several rules of arithmetical processes for determining the relation between proportions and prices of the ingredients of a mixture and the cost of the mixture per unit of weight or volume. For example, if an alloy is composed of several metals varying in price, the price per pound of the alloy can be found as in the following example: An alloy is composed of 50 pounds of copper at \$1.70 a pound, 10 pounds of tin at \$4.05 a pound, 20 pounds of zinc at \$0.99 a pound, and 5 pounds of lead at \$1.10 cents a pound. What is the cost of the alloy per pound, no account being taken of the cost of mixing it? Multiply the number of pounds of each of the ingredients by its price per pound, add these products together, and divide the sum by the total weight of all the ingredients. The quotient is the price per pound of the alloy.

*Example:* The foregoing example would be worked out numerically as follows:

Total cost of materials:  $50 \times 1.70 + 10 \times 4.05 + 20 \times 0.99 + 5 \times 1.10 = \$150.80$

Total weight of metal in alloy:  $50 + 10 + 20 + 5 = 85$  lbs.

Price per pound of alloy =  $150.80 \div 85 = \$1.77$ , approximately.

**Earth or Soil Weight.**—Loose earth has a weight of approximately  $75 \text{ lb/ft}^3$  ( $1200 \text{ kg/m}^3$ ) and rammed earth,  $100 \text{ lb/ft}^3$  ( $1600 \text{ kg/m}^3$ ).

**Composition of Earth Crust:** The solid crust of the earth, according to an estimate, is composed approximately of the following elements: oxygen 44 to 48.7 percent; silicon 22.8 to 36.2 percent; aluminum 6.1 to 9.9 percent; iron 2.4 to 9.9 percent; calcium 0.9 to 6.6 percent; magnesium 0.1 to 2.7 percent; sodium 2.4 to 2.5 percent; potassium 1.7 to 3.1 percent.

**Loads on Soils and Rocks:** The bearing capacities of soils and rocks is useful in structural engineering and also of value under certain conditions in connection with the installation of very heavy machinery requiring foundations. The ultimate resistance of various soils and rocks will be given in tons per square foot: natural earth that is solid and dry, 4 to 6 tons; thick beds of absolutely dry clay, 4 tons; thick beds of moderately dry clay, 2 tons; soft clay, 1 ton; gravel that is dry, coarse, and well packed, 6 to 8 tons; soft, friable rock and shales, 5 to 10 tons; sand that is compact, dry, and well cemented, 4 tons; natural sand in a clean dry condition, 2 to 4 tons; compact bedrock, northern red sandstone, 20 tons; compact bedrock, northern sound limestone, 25 tons; compact bedrock granite, 30 tons.

## PROPERTIES OF WOOD, CERAMICS, PLASTICS, METALS

### Properties of Wood

**Mechanical Properties of Wood.**—Wood is composed of cellulose, lignin, ash-forming minerals, and extractives formed into a cellular structure. (Extractives are substances that can be removed from wood by extraction with such solvents as water, alcohol, acetone, benzene, and ether.) Variations in the characteristics and volumes of the four components and differences in the cellular structure result in some woods being heavy and some light, some stiff and some flexible, and some hard and some soft. For a single species, the properties are relatively constant within limits; therefore, selection of wood by species alone may sometimes be adequate. However, to use wood most effectively in engineering applications, the effects of physical properties or specific characteristics must be considered.

The mechanical properties listed in the accompanying [Table 1](#) were obtained from tests on small pieces of wood termed “clear” and “straight grained” because they did not contain such characteristics as knots, cross grain, checks, and splits. However, these test pieces did contain such characteristics as growth rings that occur in consistent patterns within the piece. Since wood products may contain knots, cross grain, etc., these characteristics must be taken into account when assessing actual properties or when estimating actual performance. In addition, the methods of data collection and analysis have changed over the years during which the data in [Table 1](#) have been collected; therefore, the appropriateness of the data should be reviewed when used for critical applications such as stress grades of lumber.

Wood is an orthotropic material; that is, its mechanical properties are unique and independent in three mutually perpendicular directions—longitudinal, radial, and tangential. These directions are illustrated in the following figure.

**Modulus of Rupture:** The modulus of rupture in bending reflects the maximum load-carrying capacity of a member and is proportional to the maximum moment borne by the member. The modulus is an accepted criterion of strength, although it is not a true stress because the formula used to calculate it is valid only to the proportional limit.

**Work to Maximum Load in Bending:** The work to maximum load in bending represents the ability to absorb shock with some permanent deformation and more or less injury to a specimen; it is a measure of the combined strength and toughness of the wood under bending stress.

**Maximum Crushing Strength:** The maximum crushing strength is the maximum stress sustained by a compression parallel-to-grain specimen having a ratio of length to least diameter of less than 11.

**Compression Perpendicular to Grain:** Strength in compression perpendicular to grain is reported as the stress at the proportional limit because there is no clearly defined ultimate stress for this property.

**Shear Strength Parallel to Grain:** Shear strength is a measure of the ability to resist internal slipping of one part upon another along the grain. The values listed in the table are averages of the radial and tangential shears.

**Tensile Strength Perpendicular to Grain:** The tensile strength perpendicular to the grain is a measure of the resistance of wood to forces acting across the grain that tend to split the material. Averages of radial and tangential measurements are listed.

**Table 1. Mechanical Properties of Commercially Important US Grown Woods**

Use the first number in each column for GREEN wood; use the second number for DRY wood.	Static Bending				Maximum Crushing Strength (10 <sup>3</sup> psi)	Compression Strength Perpendicular to Grain (psi)	Shear Strength Parallel to Grain (psi)		Tensile Strength Perp. to Grain (psi)			
	Modulus of Rupture (10 <sup>3</sup> psi)	Work to Max Load (in-lb/in <sup>3</sup> )		Maximum Crushing Strength (10 <sup>3</sup> psi)			Compression Strength Perpendicular to Grain (psi)	Shear Strength Parallel to Grain (psi)	Tensile Strength Perp. to Grain (psi)	Tensile Strength Perp. to Grain (psi)

<sup>a</sup> Coast: grows west of the summit of the Cascade Mountains in OR and WA. Interior west: grows in CA and all counties in OR and WA east of but adjacent to the Cascade summit. Interior north: grows in remainder of OR and WA and ID, MT, and WY. Interior south: grows in UT, CO, AZ, and NM.

Results of tests on small, clear, straight-grained specimens. Data for dry specimens are from tests of seasoned material adjusted to a moisture content of 12%.

Source: US Department of Agriculture: *Wood Handbook*.

**Weight of Wood.**—The weight of seasoned wood per cord is approximately as follows, assuming about 70 cubic feet of *solid wood* per cord: beech, 3300 pounds; chestnut, 2600 pounds; elm, 2900 pounds; maple, 3100 pounds; poplar, 2200 pounds; white pine, 2200 pounds; red oak, 3300 pounds; white oak, 3500 pounds. For additional weights of green and dry woods, see [Table 2](#).

**Weight per Foot of Wood, Board Measure.**—The following is the weight in pounds of various kinds of woods, commercially known as dry timber, per foot board measure: white oak, 4.16; white pine, 1.98; Douglas fir, 2.65; short-leaf yellow pine, 2.65; red pine, 2.60; hemlock, 2.08; spruce, 2.08; cypress, 2.39; cedar, 1.93; chestnut, 3.43; Georgia yellow pine, 3.17; California spruce, 2.08. For other woods, divide the weight/ft<sup>3</sup> from [Table 2](#) by 12 to obtain the approximate weight per board foot.

**Effect of Pressure Treatment on Mechanical Properties of Wood.**—The strength of wood preserved with creosote, coal-tar, creosote-coal-tar mixtures, creosote-petroleum mixtures, or pentachlorophenol dissolved in petroleum oil is not reduced. However, waterborne salt preservatives contain chemicals, such as copper, arsenic, chromium, and ammonia, which have the potential of affecting mechanical properties

of treated wood and causing mechanical fasteners to corrode. Preservative salt-retention levels required for marine protection may reduce bending strength by 10 percent or more.

**Density of Wood.**—The following formula can be used to find the density of wood in lb/ft<sup>3</sup> as a function of its moisture content.

$$\rho = 62.4 \left( \frac{G}{1 + G \times 0.009 \times M} \right) \left( 1 + \frac{M}{100} \right)$$

where  $\rho$  is the density,  $G$  is the specific gravity of wood, and  $M$  is the moisture content expressed in percent.

**Machinability of Wood.**—The ease of working wood with hand tools generally varies directly with the specific gravity of the wood; the lower the specific gravity, the easier the wood is to cut with a sharp tool. A rough idea of the specific gravity of various woods can be obtained from the preceding table by dividing the weight of wood in lb/ft<sup>3</sup> by 62.355.

A wood species that is easy to cut does not necessarily develop a smooth surface when it is machined. Three major factors, other than specific gravity, influence the smoothness of the surface obtained by machining: interlocked and variable grain, hard deposits in the grain, and reaction wood. Interlocked and variable grain is a characteristic of many tropical and some domestic species; this type of grain structure causes difficulty in planing quarter sawn boards unless careful attention is paid to feed rates, cutting angles, and sharpness of the knives. Hard deposits of calcium carbonate, silica, and other minerals in the grain tend to dull cutting edges quickly, especially in wood that has been dried to the usual in service moisture content. Reaction wood results from growth under some physical stress, such as occurs in leaning trunks and crooked branches. Generally, reaction wood occurs as tension wood in hardwoods and as compression wood in softwoods. Tension wood is particularly troublesome, often resulting in fibrous and fuzzy surfaces, especially in woods of lower density. Reaction wood may also be responsible for pinching saw blades, resulting in burning and dulling of teeth.

The Table 3 rates the suitability of various domestic hardwoods for machining. The data for each species represent the percentage of pieces machined that successfully met

the listed quality requirement for the processes. For example, 62 percent of the black walnut pieces planed came out perfect, but only 34 percent of the pieces run on the shaper achieved good to excellent results.

**Table 3. Machinability and Related Properties of Various Domestic Hardwoods**

Type of Wood	Planing	Shaping	Turning	Boring	Mortising	Sanding
	Quality Required					
	Perfect	Good to Excellent	Fair to Excellent	Good to Excellent	Fair to Excellent	Good to Excellent

<sup>a</sup> To obtain specific gravity, divide density in lb/in<sup>3</sup> by 0.0361; for density in lb/ft<sup>3</sup>, multiply lb/in<sup>3</sup> by 1728; for kg/m<sup>3</sup>, multiply density in lb/in<sup>3</sup> by 27,679.9.

<sup>b</sup> To convert coefficient of expansion to 10<sup>-6</sup> in/in-°C, multiply table value by 1.8.

<sup>c</sup> Hardness value scales are: RM and RR for Rockwell M and R scales, respectively.

<sup>a</sup> For copper alloys, yield strength is determined by 0.5% extension under load or 0.2% offset method. A number in parentheses following a copper alloy indicates the UNS designation of that alloy (for example, Al Bronze C (954) identifies the alloy as UNS C95400).

<sup>b</sup> AC = air cooled to temperature indicated.

<sup>c</sup> Hardness value scales are: RB and RC for Rockwell B and C scales, respectively, and BHN for Brinell Hardness Numbers.

*Source:* Investment Casting Institute. Mechanical properties are average values of separately cast test bars and are for reference only. For items marked ... data are not available. Alloys identified by IC followed by an SAE designation number (IC 1010 steel, for example) are generally similar to the SAE material although properties and chemical composition may be different.

For allowable working stresses and recommended design stresses in bending related to severity of service, refer to Fig. 1 through Fig. 10 on pages 310 through 313, and for endurance limits for compression springs made from these materials refer to Fig. 11 on page 315 in the section on spring stresses.

**Effect of Temperature on Elasticity and Strength of Metals.**—Most ferrous metals have a maximum strength at approximately 400°F (204°C), whereas the strength of non-ferrous alloys is a maximum at about room temperature. The table below gives general data for variation in metal strength with temperature.

The modulus of elasticity of metals decreases regularly with increasing temperatures above room temperature until at some elevated temperature it falls off rapidly and reaches zero at the melting point.

## Influence of Temperature on the Strength of Metals

Material	210°F (99°C)	400°F (204°C)	570°F (299°C)	750°F (399°C)	930°F (499°C)	1100°F (593°C)	1300°F (704°C)	1475°F (802°C)

## STANDARD STEELS

## Properties, Compositions, and Applications

Steel is the generic term for a large family of iron-carbon alloys that are malleable, within some temperature range, immediately after solidification from the molten state. The principal raw materials used in steelmaking are iron ore, coal, and limestone. These materials are converted in a blast furnace into a product known as "pig iron," which contains considerable amounts of carbon, manganese, sulfur, phosphorus, and silicon. Pig iron is hard, brittle, and unsuitable for direct processing into wrought forms. Steelmaking is the process of refining pig iron as well as iron and steel scrap by removing undesirable elements from the melt and then adding desirable elements in predetermined amounts. A primary reaction in most steelmaking is the combination of carbon with oxygen to form a gas. If dissolved oxygen is not removed from the melt prior to or during pouring, the gaseous products continue to evolve during solidification. If the steel is strongly deoxidized by the addition of deoxidizing elements, no gas is evolved, and the steel is called "killed" because it lies quietly in the molds. Increasing degrees of gas evolution (decreased deoxidation) characterize steels called "semikilled," "capped," or "rimmed." The degree of deoxidation affects some of the properties of the steel. In addition to oxygen, liquid steel contains measurable amounts of dissolved hydrogen and nitrogen. For some critical steel applications, special deoxidation practices as well as vacuum treatments may be used to reduce and control dissolved gases.

By definition, steel is an iron-carbon alloy that contains less than 2 percent carbon and 1 percent manganese, which acts as a deoxidizer and facilitates hot-working. Silicon, phosphorus, and sulfur are also always present, if only in trace amounts. Other elements may be present, either as residuals that are not intentionally added but result from the raw materials or steelmaking practice, or as alloying elements added to effect changes in the properties of the steel.

Steels can be cast to shape, or the cast ingot or strand can be reheated and hot-worked by rolling, forging, extrusion, or other processes into a wrought mill shape. Wrought steels are the most widely used of engineering materials, offering a multitude of forms, finishes, strengths, and usable temperature ranges.

**Standard Steel Classification.**—Wrought steels may be classified into groups based on characteristics such as elemental composition and metallurgical structure; manufacturing, deoxidation, and finishing processes; product form; and so on. Chemical composition is commonly used as a basis for identifying and assigning standard designations to wrought steels. Although carbon is the principal hardening and strengthening element in steel, no single element controls the steel's characteristics. The combined effect of several elements influences microstructure, hardness, strength, response to heat treatment, formability, and corrosion resistance.

Standard steels can be divided by composition into three main groups: *plain carbon steels* (mild steels), which have no appreciable alloying element content; *low-alloy steels*, containing up to 8 percent alloying elements; and *high-alloy steels* with more than 8 percent alloys. The general term *alloy steel* also may be used for any grade to which are added any amount of alloying elements other than what is found in plain carbon steel, within specific ranges, to enhance certain attributes of steels. Thermal treatments and other processes also are used to develop specific properties.

**Carbon Steels (Mild Steels):** A steel qualifies as a carbon steel when its manganese content is limited to 1.65 percent (max), silicon to 0.60 percent (max), and copper to 0.60 percent (max). With the exception of deoxidizers and boron when specified, no other alloying elements are added intentionally, but they may be present as residuals. If any of these incidental elements are considered detrimental for special applications, maximum acceptable limits may be specified. Carbon steels are further divided into low-carbon (less than 0.2% carbon), medium-carbon (0.2% to 0.5%), and high-carbon (greater than 0.5%) categories. In contrast to most alloy steels, carbon steels are most often used without

a final heat treatment; however, they may be annealed, normalized, case hardened, or quenched and tempered to enhance fabrication or mechanical properties. Carbon steels may be killed, semikilled, capped, or rimmed, and, when necessary, the method of deoxidation may be specified.

*Low-Alloy Steels:* Low-alloy steels contain up to 8 percent of one or more alloying elements. Various alloy compositions are designed to enhance mechanical properties, fabricating characteristics, weathering performance, hardenability, or any other attribute of the steel.

*High-Alloy Steels:* These steels contain more than 8 percent of alloying elements, in combinations designed to achieve enhanced performance characteristics. Types of high-alloy steels include corrosion-resistant steels, heat-resistant steels, and wear-resistant steels. Stainless steels and some tool steels are important members of the high-alloy steels category.

*Stainless Steels:* These high-alloy steels owe much of their corrosion resistance to relatively large amounts of chromium. Other elements also may be added to increase corrosion resistance, but their usefulness in this respect is limited. Stainless steels generally contain at least 10 percent chromium, with or without other elements; however, it has been customary in the United States to include in this classification those steels that contain as little as 4 percent chromium. Together, these steels form a family known as *stainless and heat-resisting steels*, in which some members possess very high strength and oxidation resistance. Few, however, contain more than 30 percent chromium or less than 50 percent iron.

The most common stainless steels can be divided into groups based on their metallurgical structures: *austenitic*, *ferritic*, and *martensitic*. *Precipitation-hardening* stainless steels are classified as either semi-austenitic or martensitic. *Duplex stainless steels* contain approximately equal amounts of austenite and ferrite. In each group, the standard grades are defined by their compositional ranges, within which stainless steel will exhibit certain desired attributes. Variations in composition are made to obtain specific properties. For instance, added chromium, molybdenum, and nitrogen give *super duplex* grades enhanced corrosion resistance.

The *austenitic grades* are nonmagnetic in the annealed condition, although some may become slightly magnetic after cold-working. They can be hardened only by cold-working, and not by heat treatment, and combine outstanding corrosion and heat resistance with good mechanical properties over a wide temperature range. The austenitic grades are further classified into two subgroups: the chromium-nickel types and the less frequently used chromium-manganese-low-nickel types. The basic composition in the chromium-nickel group is widely known as 18-8 (Cr-Ni) and is the general-purpose austenitic grade. This grade is the basis for over 20 modifications that can be characterized as follows: the chromium-nickel ratio has been modified to change the forming characteristics; the carbon content has been decreased to prevent intergranular corrosion; the elements niobium or titanium have been added to stabilize the structure; or molybdenum has been added or the chromium and nickel contents have been increased to improve corrosion or oxidation resistance.

The standard *ferritic grades* are always magnetic and contain chromium but no nickel. They can be hardened to some extent by cold-working, but not by heat treatment, and they combine corrosion and heat resistance with moderate mechanical properties and decorative appeal. The ferritic grades generally are restricted to a narrower range of corrosive conditions than the austenitic grades. The basic ferritic grade contains 17 percent chromium. In this series, there are free-machining modifications and grades with increased chromium content to improve scaling resistance. Also in this ferritic group is a 12 percent chromium steel (the basic composition of the martensitic group) with other elements, such as aluminum or titanium, added to prevent hardening.

The standard *martensitic grades* are magnetic and can be hardened by quenching and tempering. They contain chromium and, with two exceptions, no nickel. The basic martensitic grade normally contains 12 percent chromium. There are more than 10 standard

compositions in the martensitic series; some are modified to improve machinability and others have small additions of nickel or other elements to improve the mechanical properties or their response to heat treatment. Still others have greatly increased carbon content, in the tool steel range, and are hardenable to the highest levels of all the stainless steels. The martensitic grades are excellent for service in mild environments, such as the atmosphere, freshwater, steam, and weak acids, but are not resistant to severely corrosive solutions.

**Numbering Systems for Metals and Alloys.**—Several different numbering systems have been developed for metals and alloys by various trade associations, professional engineering societies, standards organizations, and private industries for their own use. The numerical code used to identify the metal or alloy may or may not be related to a specification, which is a statement of the technical and commercial requirements that the product must meet. Numbering systems in use include those developed by the American Iron and Steel Institute (AISI), Society of Automotive Engineers (SAE), American Society for Testing and Materials (ASTM), American National Standards Institute (ANSI), Steel Founders Society of America, American Society of Mechanical Engineers (ASME), American Welding Society (AWS), Aluminum Association, Copper Development Association, US Department of Defense (Military Specifications), and the General Accounting Office (Federal Specifications).

The Unified Numbering System (UNS) was developed through a joint effort of the ASTM and the SAE to provide a means of correlating the different numbering systems for metals and alloys that have a commercial standing. This system avoids the confusion caused when more than one identification number is used to specify the same material, or when the same number is assigned to two entirely different materials. It is important to understand that a UNS number is not a specification; it is an identification number for metals and alloys for which detailed specifications are provided elsewhere. UNS numbers are shown in [Table 1](#); each number consists of a letter prefix followed by five digits. In some, the letter is suggestive of the family of metals identified by the series, such as A for aluminum and C for copper. Whenever possible, the numbers in the UNS groups contain numbering sequences taken directly from other systems to facilitate identification of the material; e.g., the corresponding UNS number for AISI 1020 steel is G10200. The UNS numbers corresponding to the commonly used AISI-SAE numbers that are used to identify plain carbon, alloy, and tool steels are given in [Table 2](#).

**Table 1. Unified Numbering System (UNS) for Metals and Alloys**

UNS Series	Metal
A00001 to A99999	Aluminum and aluminum alloys
C00001 to C99999	Copper and copper alloys
D00001 to D99999	Specified mechanical property steels
E00001 to E99999	Rare earth and rare earthlike metals and alloys
F00001 to F99999	Cast irons
G00001 to G99999	AISI and SAE carbon and alloy steels (except tool steels)
H00001 to H99999	AISI and SAE H-steels
J00001 to J99999	Cast steels (except tool steels)
K00001 to K99999	Miscellaneous steels and ferrous alloys
L00001 to L99999	Low-melting metals and alloys
M00001 to M99999	Miscellaneous nonferrous metals and alloys
N00001 to N99999	Nickel and nickel alloys
P00001 to P99999	Precious metals and alloys
R00001 to R99999	Reactive and refractory metals and alloys
S00001 to S99999	Heat and corrosion resistant (stainless) steels
T00001 to T99999	Tool steels, wrought and cast
W00001 to W99999	Welding filler metals
Z00001 to Z99999	Zinc and zinc alloys

**Identifying Metals.**—When it is necessary to sort materials, several rough methods may be used without elaborate chemical analysis. The most obvious of these is by using a magnet to pick out those materials that contain magnetic elements. To differentiate various levels of carbon and other elements in a steel bar, hold the bar in contact with a grinding wheel and observe the sparks. With high levels of carbon, for instance, sparks are produced that appear to split into several bright tracers. Patterns produced by several other elements, including small amounts of aluminum and titanium, for instance, can be identified with the aid of Data Sheet 13, issued by the American Society for Metals (ASM), Metals Park, OH.

**Standard Steel Numbering System.**—The most widely used systems for identifying wrought carbon, low-alloy, and stainless steels are based on chemical composition, and are those of the American Iron and Steel Institute (AISI) and the Society of Automotive Engineers (SAE). These systems are almost identical, but they are carefully coordinated. The standard steels so designated have been developed cooperatively by producers and users and have been found through long experience to cover most of the wrought ferrous metals used in automotive vehicles and related equipment. These designations, however, are not specifications, and should not be used for purchasing unless accompanied by supplementary information necessary to describe commercially the product desired. Engineering societies, associations, and institutes whose members make, specify, or purchase steel products publish standard specifications, many of which have become well known and respected. The most comprehensive and widely used specifications are those published by the American Society for Testing and Materials (ASTM). The US government and various companies also publish their own specification for steel products to serve their own special procurement needs. The Unified Numbering System (UNS) for metals and alloys is also used to designate steels (see pages 395 and 397).

The numerical designation system used by both AISI and SAE for wrought carbon, alloy, and stainless steels is summarized in Table 3. In Table 4 is given the compositions of the standard carbon steels; Table 5 lists the standard low-alloy steel compositions; and Table 6 includes the typical compositions of the standard stainless steels.

**Binary Alloy.**—An alloy containing two elements. When the term is used in regard to iron or steel, it refers to a material that has one alloying element in addition to iron. Since carbon is always present in steel, plain carbon steel is the typical binary iron alloy.

**Ternary Alloy.**—This is an alloy consisting of three elements. When the term refers to steel, it denotes a steel that contains two alloying elements in addition to iron; since carbon is always present, it is one of these elements. The third element may be nickel, chromium, manganese, tungsten, molybdenum, titanium, or any other element that is alloyed to give the steel some special property.

**Quarternary Alloy.**—A quarternary alloy is an alloy consisting of four elements. When applied to steel, such an alloy contains, in addition to iron, three alloying elements. Carbon is one of these, and the other two may be chromium and nickel, silicon and manganese, etc.

**Damascus Steel.**—A characteristic feature of Damascus steel is its surface patterns, which vary with the carbon content and are either in the form of wavy parallel stripes or mottled patterns. This steel represents an early development in steel making, as it was imported during the Middle Ages to Western Europe through Syria and Palestine, and is known also as Indian steel and bulat. The old Indian method of producing real damascene steel consists in using a pure ore and the best grade of charcoal. The Persian practice is to use soft iron bars and charcoal and plumbago (black lead or graphite) to supply the carbon; and a third method consists of a certain heat treatment which resembles a prolonged tempering. One investigator has concluded that the carbon, irregularly dispersed in the metal and forming two distinct combinations, is what causes the damask or characteristic pattern, and that the slower the cooling the larger the veins will be.

An imitation of Damascus steel can be obtained by etching the surface of the steel blade with acids, the parts which are not to be attacked by the acid being protected by a “resist.”

**Table 3. AISI and SAE System of Designating Carbon and Alloy Steels**

AISI-SAE Designation <sup>a</sup>		Type of Steel and Nominal Alloy Content (%)
		Carbon Steels
10xx		Plain Carbon (Mn 1.00% max.)
11xx		Resulfurized
12xx		Resulfurized and Rephosphorized
15xx		Plain Carbon (Max. Mn range 1.00 to 1.65%)
		Manganese Steels
13xx		Mn 1.75
		Nickel Steels
23xx		Ni 3.50
25xx		Ni 5.00
		Nickel-Chromium Steels
31xx		Ni 1.25; Cr 0.65 and 0.80
32xx		Ni 1.75; Cr 1.07
33xx		Ni 3.50; Cr 1.50 and 1.57
34xx		Ni 3.00; Cr 0.77
		Molybdenum Steels
40xx		Mo 0.20 and 0.25
44xx		Mo 0.40 and 0.52
		Chromium-Molybdenum Steels
41xx		Cr 0.50, 0.80, and 0.95; Mo 0.12, 0.20, 0.25, and 0.30
		Nickel-Chromium-Molybdenum Steels
43xx		Ni 1.82; Cr 0.50 and 0.80; Mo 0.25
43BVxx		Ni 1.82; Cr 0.50; Mo 0.12 and 0.35; V 0.03 min.
47xx		Ni 1.05; Cr 0.45; Mo 0.20 and 0.35
81xx		Ni 0.30; Cr 0.40; Mo 0.12
86xx		Ni 0.55; Cr 0.50; Mo 0.20
87xx		Ni 0.55; Cr 0.50; Mo 0.25
88xx		Ni 0.55; Cr 0.50; Mo 0.35
93xx		Ni 3.25; Cr 1.20; Mo 0.12
94xx		Ni 0.45; Cr 0.40; Mo 0.12
97xx		Ni 0.55; Cr 0.20; Mo 0.20
98xx		Ni 1.00; Cr 0.80; Mo 0.25
		Nickel-Molybdenum Steels
46xx		Ni 0.85 and 1.82; Mo 0.20 and 0.25
48xx		Ni 3.50; Mo 0.25
		Chromium Steels
50xx		Cr 0.27, 0.40, 0.50, and 0.65
51xx		Cr 0.80, 0.87, 0.92, 0.95, 1.00, and 1.05
50xxx		Cr 0.50; C 1.00 min.
51xxx		Cr 1.02; C 1.00 min.
52xxx		Cr 1.45; C 1.00 min.
		Chromium-Vanadium Steels
61xx		Cr 0.60, 0.80, and 0.95; V 0.10 and 0.15 min
		Tungsten-Chromium Steels
72xx		W 1.75; Cr 0.75
		Silicon-Manganese Steels
92xx		Si 1.40 and 2.00; Mn 0.65, 0.82, and 0.85; Cr 0.00 and 0.65
		High-Strength Low-Alloy Steels
9xx		Various SAE grades
xxBxx		B denotes boron steels
xxLxx		L denotes leaded steels
AISI	SAE	Stainless Steels
2xx	302xx	Chromium-Manganese-Nickel Steels
3xx	303xx	Chromium-Nickel Steels
4xx	514xx	Chromium Steels
5xx	515xx	Chromium Steels

<sup>a</sup> xx in the last two digits of the carbon and low-alloy designations (but not the stainless steels) indicates that the carbon content (in hundredths of a percent) is to be inserted.

<sup>a</sup>The following notes refer to boron, copper, lead, and silicon additions. Boron: Standard killed carbon steels, which are generally fine grain, may be produced with a boron treatment addition to improve hardenability. Such steels are produced to a range of 0.0005–0.003 percent B. These steels are identified by inserting the letter “B” between the second and third numerals of the AISI or SAE number, e.g., 10B46. Copper: When copper is required, 0.20 percent (min) is generally specified. Lead: Standard carbon steels can be produced with a lead range of 0.15–0.35 percent to improve machinability. Such steels are identified by inserting the letter “L” between the second and third numerals of the AISI or SAE number, e.g., 12L15 and 10L45. Silicon: It is not common practice to produce the 12XX series of resulfurized and rephosphorized steels to specified limits for silicon because of its adverse effect on machinability. When silicon ranges or limits are required for resulfurized or nonresulfurized steels, however, these values apply: a range of 0.08 percent Si for Si max up to 0.15 percent inclusive, a range of 0.10 percent Si for Si max over 0.15 to 0.20 percent inclusive, a range of 0.15 percent Si for Si max over 0.20 to 0.30 percent inclusive, and a range of 0.20 percent Si for Si max over 0.30 to 0.60 percent inclusive. Example: Si max is 0.25 percent, range is 0.10–0.25 percent.

<sup>b</sup>Values given are maximum percentages, except where a range of values is given.

<sup>c</sup>Standard grades for wire rods and wire only.

<sup>d</sup>0.15–0.35 percent Pb.

<sup>a</sup>Small quantities of certain elements are present that are not specified or required. These incidental elements may be present to the following maximum amounts: Cu, 0.35 percent; Ni, 0.25 percent; Cr, 0.20 percent; and Mo, 0.06 percent.

<sup>b</sup>Standard alloy steels can also be produced with a lead range of 0.15-0.35 percent. Such steels are identified by inserting the letter "L" between the second and third numerals of the AISI or SAE number, e.g., 41L40.

<sup>c</sup>Electric furnace steel.

<sup>d</sup>0.0005-0.003 percent B.

**Thermal Treatments of Steel.**—Steel’s versatility is due to its response to thermal treatment. Although most steel products are used in the as-rolled or un-heat-treated condition, thermal treatment greatly increases the number of properties that can be obtained because at certain “critical temperatures” iron changes from one type of crystal structure to another. This structural change, known as an allotropic transformation, is spontaneous and reversible and can be made to occur by simply changing the temperature of the metal.

In steel, the transformation in crystal structure occurs over a range of temperatures, bounded by lower and upper critical points. When heated, most carbon and low-alloy steels have a critical temperature range between 1300 and 1600°F (700 and 870°C). Steel above this temperature but below the melting range, has a crystalline structure known as austenite, in which the carbon and alloying elements are dissolved in a solid solution. Below this critical range, the crystal structure changes to a phase known as ferrite, which is capable of maintaining only a very small percentage of carbon in solid solution. The remaining carbon exists in the form of carbides, which are compounds of carbon and iron and certain of the other alloying elements. Depending primarily on cooling rate, the carbides may be present as thin plates alternating with the ferrite (pearlite); as spheroidal globular particles at ferrite grain boundaries or dispersed throughout the ferrite; or as a uniform distribution of extremely fine particles throughout a “ferritelike” phase, which has an acicular (needle-like) appearance, termed martensite. In some of the highly alloyed stainless steels, the addition of certain elements stabilizes the austenite structure so that it persists even at very low temperatures (austenitic grades). Other alloying elements can prevent the formation of austenite entirely up to the melting point (ferritic grades).

Fundamentally, all steel heat treatments are intended to either harden or soften the metal. They involve one or a series of operations in which the solid metal is heated and cooled under specified conditions to develop a required structure and properties. In general, there are five major forms of heat treatment for the standard steels that modify properties to suit either fabrication or end use.

*Quenching and Tempering:* The primary hardening treatment for steel, quenching and tempering, usually consists of three successive operations: heating the steel above the critical range and holding it at these temperatures for a sufficient time to approach a uniform solid solution (austenitizing); cooling the steel rapidly by quenching in oil, water,

brine, salt or air to form a hard, usually brittle, metastable structure known as untempered or white martensite; tempering the steel by reheating it to a temperature below the critical range in order to obtain the required combination of hardness, strength, ductility, toughness, and structural stability (tempered martensite).

Two well-known modifications of conventional quenching and tempering are “austempering” and “martempering.” They involve interrupted quenching techniques (two or more quenching media) that can be utilized for some steels to obtain desired structures and properties while minimizing distortion and cracking problems that may occur in conventional hardening.

*Normalizing:* The steel is heated to a temperature above the critical range, after which it is cooled in still air to produce a generally fine pearlite structure. The purpose is to promote uniformity of structure and properties after a hot-working operation such as forging or extrusion. Steels may be placed in service in the normalized condition, or they may be subjected to additional thermal treatment after subsequent machining or other operations.

*Annealing:* The steel is heated to a temperature above or within the critical range, then cooled at a predetermined slow rate (usually in a furnace) to produce a coarse pearlite structure. This treatment is used to soften the steel for improved machinability; to improve or restore ductility for subsequent forming operations; or to eliminate the residual stresses and microstructural effects of cold-working.

*Spheroidize Annealing:* This is a special form of annealing that requires prolonged heating at an appropriate temperature followed by slow cooling in order to produce globular carbides, a structure desirable for machining, cold forming, or cold drawing, or for the effect it will have on subsequent heat treatment.

*Stress Relieving:* This process reduces internal stresses caused by machining, cold-working, or welding. The steel is heated to a temperature below the critical range and held there long enough to equalize the temperature throughout the piece.

See the sections *HARDENING, TEMPERING, AND ANNEALING* on page 458 and *Heat Treating High-Speed Steels* on page 493 for more information about the heat treatment of steels.

**Applications.**—Many factors enter into the selection of a steel for a particular application. These factors include the mechanical and physical properties needed to satisfy the design requirements and service environment; the cost and availability of the material; the cost of processing (machining, heat treatment, welding, etc.); and the suitability of available processing equipment or the cost of any new equipment required.

These steel selection considerations require input from designers, metallurgists, manufacturing engineers, service engineers, and procurement specialists, and can be considered proper or optimum when the part is made from the lowest cost material consistent with satisfying engineering and service requirements. The factors in selection can vary widely among different organizations, so that several different steels may be used successfully for similar applications. The best choice of a steel for any application most often results from a balance or trade-offs among the various selection considerations.

The AISI/SAE designated “standard steels” provide a convenient way for engineers and metallurgists to state briefly but clearly the chemical composition and, in some instances, desired properties. These steels are widely recognized and used in the United States and in many other countries. There are, however, numerous nonstandard carbon, alloy, and stainless steel grades that are widely used for special applications.

The following sections and tables illustrate the general characteristics and typical applications of most of the standard carbon, alloy, and stainless steel grades.

*General Application of SAE Steels:* These applications are intended as a general guide only since the selection may depend on the exact character of the service, cost of material, machinability when machining is required, or other factors. When more than one steel is recommended for a given application, information on the characteristics of each steel listed will be found in the section *Carbon Steels* starting on page 407.

**Carbon Steels.**—*SAE Steels 1006, 1008, 1010, 1015:* These steels are the lowest carbon steels of the plain carbon type and are selected where cold formability is the primary requisite of the user. They are produced both as rimmed and killed steels. Rimmed steel is used for sheet, strip, rod, and wire where excellent surface finish or good drawing qualities are required, such as body and fender stock, hoods, lamps, oil pans, and other deep-drawn and -formed products. This steel is also used for cold-heading wire for tacks, and rivets and low carbon wire products. Killed steel (usually aluminum killed or special killed) is used for difficult stampings, or where nonaging properties are needed. Killed steels (usually silicon killed) should be used in preference to rimmed steel for forging or heat-treating applications.

These steels have relatively low tensile values and should not be selected where much strength is desired. Within the carbon range of the group, strength and hardness will rise with increases in carbon and/or with cold-work, but such increases in strength are at the sacrifice of ductility or the ability to withstand cold deformation. Where cold rolled strip is used, the proper temper designation should be specified to obtain the desired properties.

With less than 0.15 carbon, the steels are susceptible to serious grain growth, causing brittleness, which may occur as the result of a combination of critical strain (from cold-work) followed by heating to certain elevated temperatures. If cold-worked parts formed from these steels are to be later heated to temperatures in excess of 1100°F (590°C), the user should exercise care to avoid or reduce cold-working. When this condition develops, it can be overcome by heating the parts to a temperature well in excess of the upper critical point, or at least 1750°F (955°C).

Steels in this group, being nearly pure iron or ferritic in structure, do not machine freely and should be avoided for cut screws and operations requiring broaching or smooth finish on turning. The machinability of bar, rod, and wire products is improved by cold drawing. Steels in this group are readily welded.

*SAE 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1030:* Steels in this group, due to the carbon range covered, have increased strength and hardness, and reduced cold formability compared to the lowest carbon group. For heat-treating purposes, they are known as carburizing or case hardening grades. When uniform response to heat treatment is required, or for forgings, killed steel is preferred; for other uses, semi-killed or rimmed steel may be indicated, depending on the combination of properties desired. Rimmed steels can ordinarily be supplied up to 0.25 carbon.

Selection of one of these steels for carburizing applications depends on the nature of the part, the properties desired, and the processing practice preferred. Increases in carbon give greater core hardness with a given quench, or permit the use of thicker sections. Increases in manganese improve the hardenability of both the core and case; in carbon steels this is the only change in composition that will increase case hardenability. The higher manganese variants also machine much better. For carburizing applications, SAE 1016, 1018, and 1019 are widely used for thin sections or water-quenched parts. SAE 1022 and 1024 are used for heavier sections or where oil quenching is desired, and SAE 1024 is sometimes used for such parts as transmission and rear axle gears. SAE 1027 is used for parts given a light case to obtain satisfactory core properties without drastic quenching. SAE 1025 and 1030, although not usually regarded as carburizing types, are sometimes used in this manner for larger sections or where greater core hardness is needed.

For cold-formed or -headed parts, the lowest manganese grades (SAE 1017, 1020, and 1025) offer the best formability at their carbon level. SAE 1020 is used for fan blades and some frame members, and SAE 1020 and 1025 are widely used for low-strength bolts. The next higher manganese types (SAE 1018, 1021, and 1026) provide increased strength.

All steels listed may be readily welded or brazed by the common commercial methods. SAE 1020 is frequently used for welded tubing. These steels are used for numerous forged parts, the lower-carbon grades where high strength is not essential. Forgings from the lower-carbon steels usually machine better in the as-forged condition without annealing, or after normalizing.

*SAE 1030, 1033, 1034, 1035, 1036, 1038, 1039, 1040, 1041, 1042, 1043, 1045, 1046, 1049, 1050, 1052:* These steels, of the medium-carbon type, are selected for uses where higher mechanical properties are needed and are frequently further hardened and strengthened by heat treatment or by cold-work. These grades are ordinarily produced as killed steels.

Steels in this group are suitable for a wide variety of automotive-type applications. The particular carbon and manganese level selected is affected by a number of factors. Increases in the mechanical properties required in section thickness, or in depth of hardening, ordinarily indicate either higher carbon or manganese or both. The heat-treating practice preferred, particularly the quenching medium, has a great effect on the

steel selected. In general, any of the grades over 0.30 carbon may be selectively hardened by induction or flame methods.

The lower-carbon and manganese steels in this group find usage for certain types of cold-formed parts. SAE 1030 is used for shift and brake levers. SAE 1034 and 1035 are used in the form of wire and rod for cold upsetting such as bolts, and SAE 1038 for bolts and studs. The parts cold-formed from these steels are usually heat treated prior to use. Stampings are generally limited to flat parts or simple bends. The higher-carbon SAE 1038, 1040, and 1042 are frequently cold drawn to specified physical properties for use without heat treatment for some applications such as cylinder head studs.

Any of this group of steels may be used for forgings, the selection being governed by the section size and the physical properties desired after heat treatment. Thus, SAE 1030 and 1035 are used for shifter forks and many small forgings where moderate properties are desired, but the deeper-hardening SAE 1036 is used for more critical parts where a higher strength level and more uniformity are essential, such as some front suspension parts. Forgings such as connecting rods, steering arms, truck front axles, axle shafts, and tractor wheels are commonly made from the SAE 1038 to 1045 group. Larger forgings at similar strength levels need more carbon and perhaps more manganese. Examples are crankshafts made from SAE 1046 and 1052. These steels are also used for small forgings where high hardness after oil quenching is desired. Suitable heat treatment is necessary on forgings from this group to provide machinability. These steels are also widely used for parts machined from bar stock, the selection following an identical pattern to that described for forgings. They are used both with and without heat treatment, depending on the application and the level of properties needed. As a class, they are considered good for normal machining operations. It is also possible to weld these steels by most commercial methods, but precautions should be taken to avoid cracking from too rapid cooling.

*SAE 1055, 1060, 1062, 1064, 1065, 1066, 1070, 1074, 1078, 1080, 1085, 1086, 1090, 1095:* Steels in this group are of the high-carbon type, having more carbon than is required to achieve maximum as quenched hardness. They are used for applications where the higher carbon is needed to improve wear characteristics for cutting edges, to make springs, and for special purposes. Selection of a particular grade is affected by the nature of the part, its end use, and the manufacturing methods available.

In general, cold-forming methods are not practical on this group of steels, being limited to flat stampings and springs coiled from small-diameter wire. Practically all parts from these steels are heat treated before use, with some variations in heat-treating methods to obtain optimum properties for the particular use to which the steel is to be put.

Uses in the spring industry include SAE 1065 for pretempered wire and SAE 1066 for cushion springs of hard-drawn wire. SAE 1064 may be used for small washers and thin stamped parts, SAE 1074 for light flat springs formed from annealed stock, and SAE 1080 and 1085 for thicker flat springs. SAE 1085 is also used for heavier coil springs. Valve spring wire and music wire are special products.

Due to good wear properties when properly heat treated, the high-carbon steels find wide usage in the farm implement industry. SAE 1070 has been used for plow beams, SAE 1074 for plowshares, and SAE 1078 for such parts as rake teeth, scrapers, cultivator shovels, and plowshares. SAE 1085 has been used for scraper blades, disks, and for spring tooth harrows. SAE 1086 and 1090 find use as mower and binder sections, twine holders, and knottor disks.

*SAE 1111, 1112, 1113:* This class of steels is intended for those uses where easy machining is the primary requirement. They are characterized by a higher sulfur content than comparable carbon steels. This composition results in some sacrifice of cold-forming properties, weldability, and forging characteristics. In general, the uses are similar to those for carbon steels of similar carbon and manganese content.

These steels are commonly known as Bessemer screw stock and are considered the best machining steels available, machinability improving within the group as sulfur increases. They are used for a wide variety of machined parts. Although of excellent strength in the

cold-drawn condition, they have an unfavorable property of cold shortness and are not commonly used for vital parts. These steels may be cyanided or carburized, but when uniform response to heat treating is necessary, open-hearth steels are recommended.

*SAE 1109, 1114, 1115, 1116, 1117, 1118, 1119, 1120, 1126:* Steels in this group are used where a combination of good machinability and more uniform response to heat treatment is needed. The lower-carbon varieties are used for small parts that are to be cyanided or carbonitrided. SAE 1116, 1117, 1118, and 1119 carry more manganese for better hardenability, permitting oil quenching after case-hardening heat treatments in many instances. The higher-carbon SAE 1120 and 1126 provide more core hardness when this is needed.

*SAE 1132, 1137, 1138, 1140, 1141, 1144, 1145, 1146, 1151:* This group of steels has characteristics comparable to carbon steels of the same carbon level, except for changes due to higher sulfur as noted previously. They are widely used for parts where large amounts of machining are necessary, or where threads, splines, or other contours present special problems with tooling. SAE 1137, for example, is widely used for nuts and bolts and studs with machined threads. The higher-manganese SAE 1132, 1137, 1141, and 1144 offer greater hardenability, the higher-carbon types being suitable for oil quenching for many parts. All these steels may be selectively hardened by induction or flame heating if desired.

**Carburizing Grades of Alloy Steels.—*Properties of the Case:*** The properties of carburized and hardened cases (surface layers) depend on the carbon and alloy content, the structure of the case, and the degree and distribution of residual stresses. The carbon content of the case depends on the details of the carburizing process and the response of iron and the alloying elements present to carburization. The original carbon content of the steel has little or no effect on the carbon content produced in the case. The hardenability of the case, therefore, depends on the alloy content of the steel and the final carbon content produced by carburizing, but not on the initial carbon content of the steel.

With complete carbide solution, the effect of alloying elements on the hardenability of the case is about the same as the effect of these elements on the hardenability of the core. As an exception to this statement, any element that inhibits carburizing may reduce the hardenability of the case. Some elements that raise the hardenability of the core may tend to produce more retained austenite and consequently somewhat lower hardness in the case.

Alloy steels are frequently used for case hardening because the required surface hardness can be obtained by moderate speeds of quenching. Slower quenching may mean less distortion than would be encountered with water quenching. It is usually desirable to select a steel that will attain a minimum surface hardness of 58 or 60 RC (Rockwell C scale) after carburizing and oil quenching. Where section sizes are large, a high-hardenability alloy steel may be necessary, whereas for medium and light sections, low-hardenability steels will suffice.

In general, the case-hardening alloy steels may be divided into two classes as far as the hardenability of the case is concerned. Only the general type of steel (SAE 3300-4100, etc.) is discussed. The original carbon content of the steel has no effect on the carbon content of the case, so the last two digits in the specification numbers are not meaningful as far as the case is concerned.

a) High-Hardenability Case: SAE 2500, 3300, 4300, 4800, 9300

As these are high-alloy steels, both the case and the core have high hardenability. They are used particularly for carburized parts having thick sections, such as bevel drive pinions and heavy gears. Good case properties can be obtained by oil quenching. These steels are likely to have retained austenite in the case after carburizing and quenching; consequently, special precautions or treatments, such as refrigeration, may be required.

b) Medium-Hardenability Case: SAE 1300, 2300, 4000, 4100, 4600, 5100, 8600, 8700

Carburized cases of these steels have medium hardenability, which means that their hardenability is intermediate between that of plain carbon steel and the higher-alloy

carburizing steels discussed earlier. In general, these steels can be used for average-size case-hardened automotive parts, such as gears, pinions, piston pins, ball studs, universal joint crosses, crankshafts, etc. Satisfactory case hardness is usually produced by oil quenching.

**Core Properties:** The core properties of case-hardened steels depend on both carbon and alloy content of the steel. Each of the general types of alloy case-hardening steel is usually made with two or more carbon contents to permit different hardenability in the core.

The most desirable hardness for the core depends on the design and functioning of the individual part. In general, where high compressive loads are encountered, relatively high core hardness is beneficial in supporting the case. Low core hardnesses may be desirable where great toughness is essential.

The case-hardening steels may be divided into three general classes, depending on hardenability of the core.

a) Low-Hardenability Core: SAE 4017, 4023, 4024, 4027\*, 4028\*, 4608, 4615, 4617\*, 8615\*, 8617\*

b) Medium-Hardenability Core: SAE 1320, 2317, 2512, 2515\*, 3115, 3120, 4032, 4119, 4317, 4620, 4621, 4812, 4815\*, 5115, 5120, 8620, 8622, 8720, 9420

c) High-Hardenability Core: SAE 2517, 3310, 3316, 4320, 4817, 4820, 9310, 9315, 9317

**Heat Treatments:** In general, all the alloy carburizing steels are made with fine grain and most are suitable for direct quenching from the carburizing temperature. Several other types of heat treatment involving single and double quenching are also used for most of these steels. See [Table 4a](#) on page 487 and [Table 4b](#) on page 488.

**Directly Hardenable Grades of Alloy Steels.**—These steels may be considered in five groups on the basis of approximate mean carbon content of the SAE specification. In general, the last two figures of the specification agree with the mean carbon content. Consequently the heading *0.30–0.37 Mean Carbon Content of SAE Specification* includes steels such as SAE 1330, 3135, and 4137.

It is necessary to deviate from the above plan in the classification of the carbon molybdenum steels. Because of the low alloy content of carbon molybdenum steels, it is customary to specify a higher carbon content for any given application than would be specified for other alloy steels. For example, SAE 4063 is used for the same applications as SAE 4140, 4145, and 5150. Consequently, in the following discussion, the carbon molybdenum steels have been shown in the groups where they belong on the basis of applications rather than carbon content.

Mean Carbon Content of SAE Specification	Common Applications
(a) 0.30–0.37 percent	Heat-treated parts requiring moderate strength and great toughness.
(b) 0.40–0.42 percent	Heat-treated parts requiring higher strength and good toughness.
(c) 0.45–0.50 percent	Heat-treated parts requiring fairly high hardness and strength with moderate toughness.
(d) 0.50–0.62 percent	Springs and hand tools.
(e) 1.02 percent	Ball and roller bearings.

For the present discussion, steels of each carbon content are divided into two or three groups on the basis of hardenability. Transformation ranges and consequently heat-treating practices vary somewhat with different alloying elements even though the hardenability is not changed.

*0.30–0.37 Mean Carbon Content of SAE Specification:* These steels are frequently used for water-quenched parts of moderate section size and for oil-quenched parts of small section size. Typical applications of these steels are connecting rods, steering arms and steering knuckles, axle shafts, bolts, studs, screws, and other parts requiring strength

\* Borderline classifications might be considered in the next higher hardenability group.

and toughness where section size is small enough to permit the desired physical properties to be obtained with the customary heat treatment.

Steels falling in this classification may be subdivided into two groups on the basis of hardenability:

a) Low Hardenability: SAE 1330, 1335, 4037, 4042, 4130, 5130, 5132, 8630

b) Medium Hardenability: SAE 2330, 3130, 3135, 4137, 5135, 8632, 8635, 8637, 8735, 9437

*0.40–0.42 Mean Carbon Content of SAE Specification:* In general, these steels are used for medium and large parts requiring a high degree of strength and toughness. The choice of the proper steel depends on the section size and the mechanical properties that must be produced. The low and medium hardenability steels are used for average size automotive parts, such as steering knuckles, axle shafts, propeller shafts, etc. The high hardenability steels are used particularly for large axles and shafts for large aircraft parts.

These steels are usually considered as oil quenching steels, although some large parts made of the low and medium hardenability classifications may be quenched in water under properly controlled conditions.

These steels may be divided into three groups on the basis of hardenability:

a) Low Hardenability: SAE 1340, 4047, 5140, 9440

b) Medium Hardenability: SAE 2340, 3140, 3141, 4053, 4063, 4140, 4640, 8640, 8641, 8642, 8740, 8742, 9442

c) High Hardenability: SAE 4340, 9840

*0.45–0.50 Mean Carbon Content of SAE Specification:* These steels are used primarily for gears and other parts requiring fairly high hardness as well as strength and toughness. Such parts are usually oil-quenched and a minimum of 90 percent martensite in the as-quenched condition is desirable.

a) Low Hardenability: SAE 5045, 5046, 5145, 9747, 9763

b) Medium Hardenability: SAE 2345, 3145, 3150, 4145, 5147, 5150, 8645, 8647, 8650, 8745, 8747, 8750, 9445, 9845

c) High Hardenability: SAE 4150, 9850

*0.50–0.63 Mean Carbon Content of SAE Specification:* These steels are used primarily for springs and hand tools. The hardenability necessary depends on the thickness of the material and the quenching practice.

a) Medium hardenability: SAE 4068, 5150, 5152, 6150, 8650, 9254, 9255, 9260, 9261

b) High Hardenability: SAE 8653, 8655, 8660, 9262

*1.02 Mean Carbon Content of SAE Specification—SAE 50100, 51100, 52100:* These straight chromium electric furnace steels are used primarily for the races and balls or rollers of antifriction bearings. They are also used for other parts requiring high hardness and wear resistance. The compositions of the three steels are identical, except for a variation in chromium, with a corresponding variation in hardenability.

a) Low Hardenability: SAE 50100

b) Medium Hardenability: SAE 51100, 52100

*Resulfurized Steel:* Some of the alloy steels, SAE 4024, 4028, and 8641, are made resulfurized so as to give better machinability at a relatively high hardness. In general, increased sulfur results in decreased transverse ductility, notched impact toughness, and weldability.

**Characteristics and Typical Applications of Standard Stainless Steels.**—Typical applications of various stainless steel alloys are given in the following. The first number given is the AISI designation followed by the UNS number in parenthesis. (See also *Numbering Systems for Metals and Alloys* on page 395)

201 (S20100): High work-hardening rate; low-nickel equivalent of type 301. Flatware; automobile wheel covers, trim.

*202 (S20200)*: General-purpose low-nickel equivalent of type 302. Kitchen equipment; hub caps; milk handling.

*205 (S20500)*: Lower work-hardening rate than type 202; used for spinning and special drawing operations. Nonmagnetic and cryogenic parts.

*301 (S30100)*: High work-hardening rate; used for structural applications where high strength plus high ductility are required. Railroad cars; trailer bodies; aircraft structurals; fasteners; automobile wheel covers, trim; pole line hardware.

*302 (S30200)*: General-purpose austenitic stainless steel. Trim; food-handling equipment; aircraft cowlings; antennas; springs; cookware; building exteriors; tanks; hospital, household appliances; jewelry; oil refining equipment; signs.

*302B (S30215)*: More resistant to scale than type 302. Furnace parts; still liners; heating elements; annealing covers; burner sections.

*303 (S30300)*: Free-machining modification of type 302, for heavier cuts. Screw machine products; shafts; valves; bolts; bushings; nuts.

*303Se (S30323)*: Free-machining modification of type 302, for lighter cuts; used where hot-working or cold-heading may be involved. Aircraft fittings; bolts; nuts; rivets; screws; studs.

*304 (S30400)*: Low-carbon modification of type 302 for restriction of carbide precipitation during welding. Chemical and food processing equipment; brewing equipment; cryogenic vessels; gutters; downspouts; flashings.

*304L (S30403)*: Extra-low-carbon modification of type 304 for further restriction of carbide precipitation during welding. Coal hopper linings; tanks for liquid fertilizer and tomato paste.

*304Cu (S30430)*: Lower work-hardening rate than type 304. Severe cold-heading applications.

*304N (S30451)*: Higher nitrogen than type 304 to increase strength with minimum effect on ductility and corrosion resistance, more resistant to increased magnetic permeability. Type 304 applications requiring higher strength.

*305 (S30500)*: Low work-hardening rate; used for spin forming, severe drawing, cold heading, and forming. Coffee urn tops; mixing bowls; reflectors.

*308 (S30800)*: Higher-alloy steel having high corrosion and heat resistance. Welding filler metals to compensate for alloy loss in welding; industrial furnaces.

*309 (S30900)*: High-temperature strength and scale resistance. Aircraft heaters; heat-treating equipment; annealing covers; furnace parts; heat exchangers; heat-treating trays; oven linings; pump parts.

*309S (S30908)*: Low-carbon modification of type 309. Welded constructions; assemblies subject to moist corrosion conditions.

*310 (S31000)*: Higher elevated temperature strength and scale resistance than type 309. Heat exchangers; furnace parts; combustion chambers; welding filler metals; gas-turbine parts; incinerators; recuperators; rolls for roller hearth furnaces.

*310S (S31008)*: Low-carbon modification of type 310. Welded constructions; jet engine rings.

*314 (S31400)*: More resistant to scale than type 310. Severe cold-heading or -forming applications. Annealing and carburizing boxes; heat-treating fixtures; radiant tubes.

*316 (S31600)*: Higher corrosion resistance than types 302 and 304; high creep strength. Chemical and pulp handling equipment; photographic equipment; brandy vats; fertilizer parts; ketchup cooking kettles; yeast tubs.

*316L (S31603)*: Extra-low-carbon modification of type 316. Welded construction where intergranular carbide precipitation must be avoided. Type 316 applications requiring extensive welding.

*316F (S31620)*: Higher phosphorus and sulfur than type 316 to improve machining and nonseizing characteristics. Automatic screw machine parts.

*316N (S31651)*: Higher nitrogen than type 316 to increase strength with minimum effect on ductility and corrosion resistance. Type 316 applications requiring extra strength.

317 (S31700): Higher corrosion and creep resistance than type 316. Dyeing and ink manufacturing equipment.

317L (S31703): Extra-low-carbon modification of type 317 for restriction of carbide precipitation during welding. Welded assemblies.

321 (S32100): Stabilized for weldments under severe corrosive conditions and service from 800–1650°F (425–900°C). Aircraft exhaust manifolds; boiler shells; process equipment; expansion joints; cabin heaters; fire walls; flexible couplings; pressure vessels.

329 (S32900): Austenitic-ferritic type with general corrosion resistance similar to type 316 but with better resistance to stress-corrosion cracking; capable of age hardening. Valves; valve fittings; piping; pump parts.

330 (N08330): Good resistance to carburization and oxidation and to thermal shock. Heat-treating fixtures.

347 (S34700): Similar to type 321 with higher creep strength. Airplane exhaust stacks; welded tank cars for chemicals; jet engine parts.

348 (S34800): Similar to type 321; low retentivity. Tubes and pipes for radioactive systems; nuclear energy uses.

384 (S38400): Suitable for severe cold heading or cold forming; lower cold-work hardening rate than type 305. Bolts; rivets; screws; instrument parts.

403 (S40300): "Turbine quality" grade. Steam turbine blading and other highly stressed parts including jet engine rings.

405 (S40500): Nonhardenable grade for assemblies where air-hardening types such as 410 or 403 are objectionable. Annealing boxes; quenching racks; oxidation-resistant partitions.

409 (S40900): General-purpose construction stainless. Automotive exhaust systems; transformer and capacitor cases; dry fertilizer spreaders; tanks for agricultural sprays.

410 (S41000): General-purpose heat-treatable type. Machine parts; pump shafts; bolts; bushings; coal chutes; cutlery; hardware; jet engine parts; mining machinery; rifle barrels; screws; valves.

414 (41400): High hardenability steel. Springs; tempered rules; machine parts, bolts; mining machinery; scissors; ships' bells; spindles; valve seats.

416 (S41600): Free-machining modification of type 410, for heavier cuts. Aircraft fittings; bolts; nuts; fire extinguisher inserts; rivets; screws.

416Se (S41623): Free-machining modification of type 410, for lighter cuts. Machined parts requiring hot-working or cold-heading.

420 (S42000): Higher carbon modification of type 410. Cutlery; surgical instruments; valves; wear-resisting parts; glass molds; hand tools; vegetable choppers.

420F (S42020): Free-machining modification of type 420. Applications similar to those for type 420 requiring better machinability.

422 (S42200): High strength and toughness at service temperatures up to 1200°F (650°C). Steam turbine blades; fasteners.

429 (S42900): Improved weldability as compared to type 430. Nitric acid and nitrogen-fixation equipment.

430 (S43000): General-purpose nonhardenable chromium type. Decorative trim; nitric acid tanks; annealing baskets; combustion chambers; dishwashers; heaters; mufflers; range hoods; recuperators; restaurant equipment.

430F (S43020): Free-machining modification of type 430, for heavier cuts. Screw machine parts.

430FSe (S43023): Free-machining modification of type 430, for lighter cuts. Machined parts requiring light cold heading or forming.

431 (S43100): Special-purpose hardenable steel used where particularly high mechanical properties are required. Aircraft fittings; beater bars; paper machinery; bolts.

434 (S43400): Modification of type 430 designed to resist atmospheric corrosion in the presence of winter road conditioning and dust-laying compounds. Automotive trim and fasteners.

*436 (S43600)*: Similar to types 430 and 434. Used where low "roping" or "ridging" required. General corrosion and heat-resistant applications, such as automobile trim.

*440A (S44002)*: Hardenable to higher hardness than type 420 with good corrosion resistance. Cutlery; bearings; surgical tools.

*440B (S44003)*: Cutlery grade. Cutlery; valve parts; instrument bearings.

*440C (S44004)*: Yields highest hardnesses of hardenable stainless steels. Balls; bearings; races; nozzles; balls and seats for oil well pumps; valve parts.

*442 (S44200)*: High-chromium steel, principally for parts that must resist high service temperatures without scaling. Furnace parts; nozzles; combustion chambers.

*446 (S44600)*: High-resistance to corrosion and scaling at high temperatures, especially for intermittent service; often used in sulfur-bearing atmosphere. Annealing boxes; combustion chambers; glass molds; heaters; pyrometer tubes; recuperators; stirring rods; valves.

*501 (S50100)*: Heat resistance; good mechanical properties at moderately elevated temperatures. Heat exchangers; petroleum refining equipment.

*502 (S50200)*: More ductility and less strength than type 501. Heat exchangers; petroleum refining equipment; gaskets.

**Chromium-Nickel Austenitic Steels.**—(Not capable of heat treatment) *SAE 30201*: This steel is an austenitic chromium-nickel-manganese stainless steel usually required in flat products. In the annealed condition, it exhibits higher strength values than the corresponding chromium-nickel stainless steel (*SAE 30301*). It is nonmagnetic in the annealed condition, but may be magnetic when cold-worked. *SAE 30201* is used to obtain high strength by work-hardening and is well suited for corrosion-resistant structural members requiring high strength with low weight. It has excellent resistance to a wide variety of corrosive media, showing behavior comparable to stainless grade *SAE 30301*. It has high ductility and excellent forming properties. Owing to this steel's work-hardening rate and yield strength, tools for forming must be designed to allow for a higher springback or recovery rate. It is used for automotive trim, automotive wheel covers, railroad passenger car bodies and structural members, and truck trailer bodies.

*SAE 30202*: Like chromium-nickel stainless steel *SAE 30302*, this is a general-purpose stainless steel. It has excellent corrosion resistance and deep drawing qualities. It is nonhardenable by thermal treatments but may be cold-worked to high tensile strengths. In the annealed condition, it is nonmagnetic but slightly magnetic when cold-worked. Applications for this stainless steel are hub cap, railcar and truck trailer bodies, and spring wire.

*SAE 30301*: Capable of attaining high tensile strength and ductility by moderate or severe cold-working. It is used largely in the cold-rolled or cold-drawn condition in the form of sheet, strip, and wire. Its corrosion resistance is good but not equal to *SAE 30302*.

*SAE 30302*: The most widely used of the general-purpose austenitic chromium-nickel stainless steels. It is used for deep drawing largely in the annealed condition. It can be worked to high tensile strengths but with slightly lower ductility than *SAE 30301*.

*SAE 30303F*: A free-machining steel recommended for the manufacture of parts produced on automatic screw machines. Caution must be used in forging this steel.

*SAE 30304*: Similar to *SAE 30302* but somewhat superior in corrosion resistance and having superior welding properties for certain types of equipment.

*SAE 30305*: Similar to *SAE 30304* but capable of lower hardness. Has greater ductility with slower work-hardening tendency.

*SAE 30309*: A steel with high heat-resisting qualities which is resistant to oxidation at temperatures up to about 1800°F (980°C).

*SAE 30310*: This steel has the highest heat-resisting properties of the chromium nickel steels listed here and will resist oxidation at temperatures up to about 1900°F (1040°C).

*SAE 30316*: Recommended for use in parts where unusual resistance to chemical or salt water corrosion is necessary. It has superior creep strength at elevated temperatures.

*SAE 30317*: Similar to SAE 30316 but has the highest corrosion resistance of all these alloys in many environments.

*SAE 30321*: Recommended for use in the manufacture of welded structures where heat treatment after welding is not feasible. It is also recommended for use where temperatures up to 1600°F (870°C) are encountered in service.

*SAE 30325*: Used for such parts as heat control shafts.

*SAE 30347*: This steel is similar to SAE 30321. This niobium alloy is sometimes preferred to titanium because niobium is less likely to be lost in welding operations.

**Stainless Chromium Irons and Steels.**—*SAE 51409*: An 11 percent chromium alloy developed especially for automotive mufflers and tailpipes. Resistance to corrosion and oxidation is very similar to SAE 51410. It is nonhardenable and has good forming and welding characteristics. This alloy is recommended for mildly corrosive applications where surface appearance is not critical.

*SAE 51410*: A general-purpose stainless steel capable of heat treatment to show good physical properties. It is used for general stainless applications, both in the annealed and heat-treated condition, but is not as resistant to corrosion as SAE 51430 in either the annealed or heat-treated condition.

*SAE 51414*: A corrosion and heat-resisting nickel-bearing chromium steel with somewhat better corrosion resistance than SAE 51410. It will attain slightly higher mechanical properties when heat treated than SAE 51410. It is used in the form of tempered strip or wire, and in bars and forgings for heat-treated parts.

*SAE 51416F*: A free-machining grade for the manufacture of parts produced in automatic screw machines.

*SAE 51420*: This steel is heat-treatable to a relatively high hardness. It will harden to a maximum of approximately 500 BHN (Brinell Hardness Number). Maximum corrosion-resisting qualities exist only in the fully hardened condition. It is used for cutlery, hardened pump shafts, etc.

*SAE 51420F*: This is similar to SAE 51420 except for its free-machining properties.

*SAE 51430*: This high-chromium steel is not capable of heat treatment and is recommended for use in shallow parts requiring moderate draw. Corrosion and heat resistance are superior to SAE 51410.

*SAE 51430F*: This steel is similar to SAE 51430 except for its free-machining properties.

*SAE 51431*: This nickel-bearing chromium steel is designed for heat treatment to high mechanical properties. Its corrosion resistance is superior to other hardenable steels.

*SAE 51440A*: A hardenable chromium steel with greater quenched hardness than SAE 51420 and greater toughness than SAE 51440B and 51440C. Maximum corrosion resistance is obtained in the fully hardened and polished condition.

*SAE 51440B*: A hardenable chromium steel with greater quenched hardness than SAE 51440A. Maximum corrosion resistance is obtained in the fully hardened and polished condition. Capable of hardening to 50–60 RC (Rockwell C scale) depending on carbon content.

*SAE 51440C*: This steel has the greatest quenched hardness and wear resistance on heat treatment of any corrosion- or heat-resistant steel.

*SAE 51440F*: The same as SAE 51440C, except for its free-machining characteristics.

*SAE 51442*: A corrosion- and heat-resisting chromium steel with corrosion-resisting properties slightly better than SAE 51430 and with good scale resistance up to 1600°F (870°C).

*SAE 51446*: A corrosion- and heat-resisting steel with maximum amount of chromium consistent with commercial malleability. Used principally for parts that must resist high temperatures in service without scaling. Resists oxidation up to 2000°F (1095°C).

*SAE 51501*: Used for its heat and corrosion resistance and good mechanical properties at temperatures up to approximately 1000°F (540°C).

**High-Strength, Low-Alloy Steels.**—High-strength, low-alloy (HSLA) steel represents a specific group of steels in which enhanced mechanical properties and, sometimes, resistance to atmospheric corrosion are obtained by the addition of moderate amounts of one or more alloying elements other than carbon. Different types are available, some of which are carbon-manganese steels and others contain further alloy additions, governed by special requirements for weldability, formability, toughness, strength, and economics. These steels may be obtained in the form of sheet, strip, plates, structural shapes, bars, and bar size sections.

HSLA steels are especially characterized by their mechanical properties, obtained in the as-rolled condition. They are not intended for quenching and tempering. For certain applications, they are sometimes annealed, normalized, or stress relieved with some influence on mechanical properties.

Where these steels are used for fabrication by welding, care must be exercised in selection of grade and in the details of the welding process. Certain grades may be welded without preheat or postheat.

Because of their high strength-to-weight ratio, abrasion resistance, and, in certain compositions, improved atmospheric corrosion resistance, these steels are adapted particularly for use in mobile equipment and other structures where substantial weight savings are generally desirable. Typical applications are truck bodies, frames, structural members, scrapers, truck wheels, cranes, shovels, booms, chutes, and conveyors.

*Grade 942X:* A niobium- or vanadium-treated carbon-manganese high-strength steel similar to 945X and 945C except for somewhat improved welding and forming properties.

*Grade 945A:* A HSLA steel with excellent welding characteristics, both arc and resistance, and the best formability, weldability, and low-temperature notch toughness of the high-strength steels. It is generally used in sheets, strip, and light plate thicknesses.

*Grade 945C:* A carbon-manganese high-strength steel with satisfactory arc welding properties if adequate precautions are observed. It is similar to grade 950C, except that lower carbon and manganese improve arc welding characteristics, formability, and low-temperature notch toughness at some sacrifice in strength.

*Grade 945X:* A niobium- or vanadium-treated carbon-manganese high-strength steel similar to 945C, except for somewhat improved welding and forming properties.

*Grade 950A:* A HSLA steel with good weldability, both arc and resistance, with good low-temperature notch toughness, and good formability. It is generally used in sheet, strip, and light plate thicknesses.

*Grade 950B:* A HSLA steel with satisfactory arc welding properties and fairly good low-temperature notch toughness and formability.

*Grade 950C:* A carbon-manganese high-strength steel that can be arc welded with special precautions, but is unsuitable for resistance welding. The formability and toughness are fair.

*Grade 950D:* A HSLA steel with good weldability, both arc and resistance, and fairly good formability. Where low-temperature properties are important, the effect of phosphorus in conjunction with other elements present should be considered.

*Grade 950X:* A niobium- or vanadium-treated carbon-manganese high-strength steel similar to 950C, except for somewhat improved welding and forming properties.

*Grades 955X, 960X, 965X, 970X, 980X:* These are steels similar to 945X and 950X with higher strength obtained by increased amounts of strengthening elements, such as carbon or manganese, or by the addition of nitrogen up to about 0.015 percent. This increased strength involves reduced formability and usually decreased weldability. Toughness will vary considerably with composition and mill practice.

The formability, composition, and minimum mechanical properties of the HSLA steel grades are shown in [Table 7](#) through [Table 9](#) on page 418.

**Table 7. HSLA Steel Grades in Approximate Order of Increasing Excellence**

	Weldability	Formability	Toughness
 (Best)	980X	980X	980X
	970X	970X	970X
	965X	965X	965X
	960X	960X	960X

<sup>a</sup> Synonymous in other literature to the modulus of elasticity in torsion and the modulus of rigidity, *G*.

<sup>b</sup> Minimum specified value of the American Society for Testing and Materials. The specifications for the various materials are as follows: Cast iron, ASTM A48; structural steel for bridges and structures, ASTM A7; structural rivet steel, ASTM A141; high-strength structural rivet steel, ASTM A195.

<sup>c</sup> Range of minimum specified values of the ASTM (ASTM A47, A197, and A220).

<sup>d</sup> Range of minimum specified values of the ASTM (ASTM A339) and the Munitions Board Standards Agency (MIL-I-17166A and MIL-I-11466).

<sup>e</sup> Carburizing grades of steel.

<sup>f</sup> Nonhardenable nickel-chromium and chromium-nickel-manganese steel (austenitic).

<sup>g</sup> Hardenable chromium steel (martensitic).

<sup>h</sup> Nonhardenable chromium steel (ferritic).

## TOOL STEELS

## Overview

As the designation implies, tool steels serve primarily for making tools used in manufacturing and in the trades for the working and forming of metals, wood, plastics, and other industrial materials. Tools must withstand high specific loads, often concentrated at exposed areas, may have to operate at elevated or rapidly changing temperatures and in continual contact with abrasive types of work materials, and are often subjected to shocks, or may have to perform under other varieties of adverse conditions. Nevertheless, when employed under circumstances that are regarded as normal operating conditions, the tool should not suffer major damage, untimely wear resulting in the dulling of the edges, or be susceptible to detrimental metallurgical changes.

Tools for less demanding uses, such as ordinary handtools, including hammers, chisels, files, mining bits, etc., are often made of standard AISI steels that are not considered to belong to any of the tool steel categories.

The steel for most types of tools must be used in a heat-treated state, usually hardened and tempered, to provide properties needed for a particular application. Adaptability to heat treatment, with minimum harmful effects, dependably resulting in intended beneficial changes in material properties, is another requirement for tool steels.

To meet such varied requirements, steel types of different chemical composition, often produced by special metallurgical processes, have been developed. Due to the large number of tool steel types produced by the steel mills, which generally are made available with proprietary designations, it is rather difficult for the user to select those types that are most suitable for any specific application, unless the recommendations of a particular steel producer or producers are obtained.

Substantial clarification has resulted from the development of a classification system that is now widely accepted throughout the industry, on the part of both the producers and the users of tool steels. The tool steel classification system establishes seven basic categories of tool and die steels. These categories are associated with the predominant applicational characteristics of the tool steel types they comprise. A few of these categories are composed of several groups to distinguish between families of steel types that, while serving the same general purpose, differ with regard to one or more dominant characteristics. The classification categories are given in [Table 3](#).

To provide an easily applicable guide for the selection of tool steel types best suited for a particular application, the subsequent discussions and tables are based on the previously mentioned application-related categories. As an introduction to the detailed surveys, a concise discussion is presented of the principal tool steel characteristics that govern the suitability for varying service purposes and operational conditions. A brief review of the major steel alloying elements and of the effect of these constituents on the significant characteristics of tool steels is also given in the following sections.

**The Properties of Tool Steels.**—Tool steels must possess certain properties to a higher than ordinary degree to make them adaptable for uses that require the ability to sustain heavy loads and perform dependably even under adverse conditions. The extent and types of loads, operating conditions, and expected performance with regard to both duration and level of consistency are the principal considerations, in combination with aspects of cost, that govern selection of tool steels for specific applications.

Although it is not possible to define and apply exact parameters for measuring significant tool steel characteristics, certain properties can be determined that may assist in appraising suitability of various tool steels for specific uses. AISI standards define the chemical composition of tool steels, but the quality of ingredients (such as element purity and initial particle size) and processing of materials (manufacturing methods and heat-treatment parameters) can result in different properties. Material testing and controlled processes help ensure that desired properties are obtained.

Because tool steels are generally heat treated to make them adaptable to the intended use by enhancing the desirable properties, *the behavior of the steel during heat treatment* is of prime importance. The behavior of the steel comprises, in this respect, both the resistance to harmful effects and the attainment of the desirable properties. The following are considered the major properties related to heat treatment:

**Safety in Hardening:** This designation expresses the ability of the steel to withstand the harmful effects of exposure to very high heat and particularly to the sudden temperature changes during quenching, without harmful effects. One way of obtaining this property is by adding alloying elements to reduce the critical speed at which quenching must be carried out, thus permitting the use of milder quenching media, such as oil, salt, or just still air.

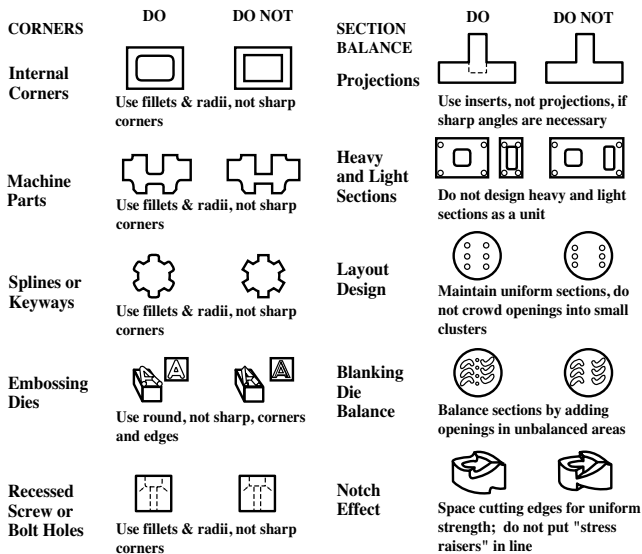

Fig. 1. Tool and Die Design Tips to Reduce Breakage in Heat Treatment  
Courtesy of Society of Automotive Engineers, Inc.

Parts made of tool steel suffer most commonly during heat treatment from the development of cracks. In addition to the composition of the steel and the applied heat-treating process, the configuration of the part can also affect the sensitivity to cracking. The preceding figure illustrates a few design characteristics related to cracking and warpage in heat treatment; the observation of these design tips, which call for generous filleting, avoidance of sharp angles, and major changes without transition in the cross-section, is particularly advisable when using tool steel types with a low index value for safety in hardening.

In current practice, the previously mentioned property of tool steels is rated in the order of decreasing safety (i.e., increasing sensitivity) as Highest, Very High, High, Medium, and Low safety, expressed in Table 6 through Table 11 by the letters A, B, C, D, and E.

**Distortions in Heat Treating:** In parts made from tool steels, distortions are often a consequence of inadequate design (See Fig. 1) or improper heat treatment (e.g., lack of stress relieving). However, certain types of tool steels display different degrees of

sensitivity to distortion. Steels that are less stable require safer design of the parts for which they are used, more careful heat treatment, including the proper support for long and slender parts, or thin sections, and possibly greater grinding allowance to permit subsequent correction of the distorted shape. Some parts made of a type of steel generally sensitive to distortions can be heat treated with very little damage when the requirements of the part call for a relatively shallow hardened layer over a soft core. However, for intricate shapes and large tools, steel types should be selected that possess superior nondeforming properties. The ratings used in [Table 6](#) through [Table 11](#) express the nondeforming properties (stability of shape in heat treatment) of the steel types and start with the lowest distortion (the best stability) designated as A; the greatest susceptibility to distortion is designated as E.

*Depth of Hardening:* Hardening depth is indicated by a relative rating based on how deep the phase transformation penetrates from the surface and thus produces a hardened layer. Because of the effect of the heat-treating process, and particularly of the applied quenching medium, on the depth of hardness, reference is made in [Table 6](#) through [Table 11](#) to the quench that results in the listed relative hardenability values. These values are designated by letters A, B, and C, expressing deep, medium, and shallow depth, respectively.

*Resistance to Decarburization:* Higher or lower sensitivity to losing a part of the carbon content of the surface exposed to heat depends on the chemistry of the steel. The sensitivity can be balanced partially by appropriate heat-treating equipment and processes. Also, the amount of material to be removed from the surface after heat treatment, usually by grinding, should be specified in such a manner as to avoid the retention of a decarburized layer on functional surfaces. The relative resistance of individual tool steel types to decarburization during heat treatment is rated in [Table 6](#) through [Table 11](#) from High to Low, expressed by the letters A, B, and C.

Tool steels must be workable with available means, without requiring highly specialized processes. The tools made from these steels must, of course, perform adequately, often under adverse environmental and burdensome operational conditions. The ability of individual types of tool steels to satisfy, to different degrees, such applicational requirements can be appraised based on significant properties, such as the following.

*Machinability:* Tools are precision products whose final shape and dimensions must be produced by machining, a process to which not all tool steel types lend themselves equally. The difference in machinability is particularly evident in tool steels that, depending on their chemical composition, may contain substantial amounts of metallic carbides, beneficial to increased wear resistance, yet detrimental to service life of tools with which the steel has to be worked. The microstructure of the steel type can also affect the ease of machining and, in some types, certain phase conditions, such as those due to low carbon content, may cause difficulties in achieving a fine surface finish. Machinability of certain types of tool steels may be improved by adding small amounts of sulfur or lead. Note that machinability ratings may be defined for a single cutting process not optimal for the material grades being considered.

Machinability affects the cost of making the tool, particularly for intricate tool shapes, and must be considered in selection of the steel to be used. The ratings in [Table 6](#) through [Table 11](#), starting with A for the greatest ease of machining to E for the lowest machinability, refer to working of the steel in an unhardened condition. Machinability is not necessarily identical with grindability, which expresses how well the steel is adapted to grinding after heat treating. The ease of grinding, however, may become an important consideration in tool steel selection, particularly for cutting tools and dies, which require regular sharpening involving extensive grinding. AVCO Bay State Abrasives Company compiled information on the relative grindability of frequently used types of tool steels. A simplified version of that information is presented in [Table 1](#), which assigns the listed tool steel types to one of the following grindability grades: High (A), Medium (B), Low (C), and Very Low (D), expressing decreasing ratios of volume of metal removed to wheel wear.

**Table 1. Relative Grindability of Selected Types of Frequently Used Tool Steels**

AISI Tool Steel Type	H41	H42	H43	Other H	D2	D3	D5	D7	A Types	O Types	L Types	F Types					
Relative Grindability Index	B	B	B	A	B	B	B	C	A	A	A	B					
High-Speed Tool Steel Type	M1	M2	M3 (1)	M3 (2)	M4	M7	M8	M10	M15	M36	M43	T1	T2	T3	T5	T6	T15
Relative Grindability Index	A	B	C	C	D	B	A	B	D	B	B	A	B	C	B	B	D

**Hot Hardness:** This property designates the steel's resistance to the softening effect of elevated temperature. This characteristic is related to the tempering temperature of the type of steel, which is controlled by various alloying elements, such as tungsten, molybdenum, vanadium, cobalt, and chromium. Hot hardness testing is typically performed using a Rockwell or Vickers hardness tester. Hardness is measured over time, with the samples at high temperature (often 2100°F or 1200°C).

Hot hardness is a necessary property of tools used for hot-work, like forging, casting, and hot extrusion. Hot hardness is also important in cutting tools operated at high-speed, which generate sufficient heat to raise their temperature well above the level where ordinary steels lose their hardness; hence the designation *high-speed steels*, which refers to a family of tool steels developed for use at high cutting speeds. Frequently it is the degree of the tool steel's resistance to softening at elevated temperature that governs important process data, such as the applicable cutting speed. In the ratings of [Table 6](#) through [Table 11](#), tool steel types having the highest hot hardness are marked with A. Subsequent letters express gradually decreasing capacity to endure elevated temperature without losing hardness.

**Wear Resistance:** The gradual erosion of the tool's operating surface, most conspicuously occurring at the exposed edges, is known as wear. Resistance to wear prolongs the useful life of the tool by delaying the degradation of its surface through abrasive contact with the work at regular operating temperatures; these temperatures vary according to the type of process. Wear resistance is observable experimentally and measurable by comparison based on a specific and unchanging set of test parameters. As a result, these ratings must be used with caution. Certain types of metallic carbides embedded into the steel matrix are considered to be the prime contributing factors to wear resistance, besides the hardness of the heat-treated steel material. The ratings of [Table 6](#) through [Table 11](#), starting with A for the best to E for poor, are based on conditions thought to be normal in operations for which various types of tool materials are primarily used.

**Toughness:** Toughness is amount of energy a material can absorb without fracture. For tool steels, this is the material's ability to withstand shocks, major impacts, and sudden loading and unloading. Steels used for making tools also must be able to absorb such forces with a minimum of elastic deformation and without permanent deformation that would interfere with proper functioning of the tool. Certain types of tool steels, particularly those with high carbon content and without beneficial alloying constituents, tend to be the most sensitive to shocks. They can be made functionally tougher when they are used in tools that permit a hardened case to be supported by a soft core. Also, tempering improves toughness, while generally reducing hardness.

In [Table 6](#) through [Table 11](#), an A rating is for steels with the highest toughness, while an E rating is for steels that are the most sensitive to shocks. These ratings apply to tools heat-treated to hardness values normally used for the particular type of tool steel. Such relative ratings often are used when comparing materials, but toughness also is a measurable property with units of energy. Results of standardized testing methods can be affected by material variations and may not represent performance in real-world applications.

**Common Tool Faults and Failures.**—The proper selection of the steel grade used for any particular type of tool is of great importance, but it should be recognized that many of the failures experienced in common practice originate from causes other than those related to the tool material.

To permit a better appraisal of the actual causes of failure and possible corrective action, a general, although not complete, list of common tool faults, resulting failures, and corrective actions is shown in Table 2a through Table 2d. In this list, the potential failure causes are grouped into four categories. The possibility of more than a single cause being responsible for the experienced failure should not be excluded.

*Note:* Examples of tool failures from causes such as those listed in Table 2a through Table 2d may be found in "The Tool Steel Trouble Shooter" handbook, published by Bethlehem Steel Corporation.

Finally, it must be remembered that the proper usage of tools is indispensable for obtaining satisfactory performance and tool life. Using the tools properly involves, for example, the avoidance of damage to the tool, overloading, excessive speeds and feeds, the application of adequate coolant when called for, a rigid setup, proper alignment, and firm tool and work holding.

**Table 2a. Common Tool Faults, Failures, and Cures**  
Improper Tool Design

Fault Description	Probable Failure	Possible Cure
Drastic section changes—widely different thicknesses of adjacent wall sections or protruding elements	In liquid quenching, the thin section will cool and then harden more rapidly than the adjacent thicker section, setting up stresses that may exceed the strength of the steel.	Make such parts of two pieces or use an air-hardening tool steel that avoids the harsh action of a liquid quench.
Sharp corners on shoulders or in square holes	Cracking can occur, particularly in liquid quenching, due to stress concentrations.	Apply fillets to the corners and/or use an air-hardening tool steel.
Sharp cornered keyways	Failure may arise during service and is usually considered to be caused by fatigue.	The use of round keyways should be preferred when the general configuration of the part makes it prone to failure due to square keyways.
Abrupt section changes in battering tools	Due to impact in service, pneumatic tools are particularly sensitive to stress concentrations that lead to fatigue failures.	Use taper transitions, which are better than even generous fillets.
Functional inadequacy of tool design—e.g., insufficient guidance for a punch	Excessive wear or breakage in service may occur.	Assure solid support, avoid unnecessary play, adapt travel length to operational conditions (e.g., punch to penetrate to four-fifths of thickness in hard work material).
Improper tool clearance, such as in blanking and punching tools	Deformed and burred parts may be produced, excessive tool wear or breakage can result.	Adapt clearances to material conditions and dimensions to reduce tool load and to obtain clean sheared surfaces.

**The Effect of Alloying Elements on Tool Steel Properties.**—*Carbon (C):* The presence of carbon, usually in excess of 0.60 percent for nonalloyed types, is essential for raising the hardenability of steels to the levels needed for tools. Raising the carbon content by different amounts up to a maximum of about 1.3 percent increases the hardness slightly and the wear resistance considerably. The amount of carbon in tool steels is designed to attain certain properties (such as in the water-hardening category where higher carbon content may be chosen to improve wear resistance, although to the detriment of toughness) or, in the alloyed types of tool steels, in conformance with the other constituents to produce well-balanced metallurgical and performance properties.

*Manganese (Mn):* In small amounts, to about 0.60 percent, manganese is added to reduce brittleness and to improve forgeability. Larger amounts of manganese improve hardenability, permitting oil quenching for nonalloyed carbon steels, thus reducing deformation, although, with regard to several other properties, manganese is not an equivalent replacement for the regular alloying elements.

*Silicon (Si):* In itself, silicon may not be considered an alloying element of tool steels, but it is needed as a deoxidizer and improves the hot-forming properties of the steel. In combination with certain alloying elements, the silicon content is sometimes raised to about 2 percent to increase the strength and toughness of steels used for tools that have to sustain shock loads.

**Table 2b. Common Tool Faults, Failures, and Cures**  
Faulty Condition or Inadequate Grade of Tool Steel

Fault Description	Probable Failure	Possible Cure
Improper tool steel grade selection	Typical failures: Chipping—insufficient toughness. Wear—poor abrasion resistance. Softening— inadequate “red hardness.”	Choose the tool steel grade by following recommendations and improve selection when needed, guided by property ratings.
Material defects—voids, streaks, tears, flakes, surface cooling cracks, etc.	When not recognized during material inspection, tools made of defective steel often prove to be useless.	Obtain tool steels from reliable sources and inspect tool material for detectable defects.
Decarburized surface layer (“bark”) in rolled tool steel bars	Cracking may originate from the decarburized layer or it will not harden (“soft skin”).	Provide allowance for stock to be removed from all surfaces of hot-rolled tool steel. Recommended amounts are listed in tool steel catalogs and vary according to section size, generally about 10 percent for smaller and 5 percent for larger diameters.
Brittleness caused by poor carbide distribution in high-alloy tool steels	Excessive brittleness can cause chipping or breakage during service.	Bars with large diameter (above about 4 inches or 10 cm) tend to be prone to nonuniform carbide distribution. Choose upset forged discs instead of large-diameter bars.
Unfavorable grain flow	Improper grain flow of the steel used for milling cutters and similar tools can cause teeth to break out.	Upset forged discs made with an upset ratio of about 2 to 1 (starting to upset thickness) display radial grain flow. Highly stressed tools, such as gear-shaper cutters, may require the cross forging of blanks.

**Tungsten (W):** Tungsten is one of the important alloying elements of tool steels, particularly because of two valuable properties: it improves “hot hardness,” that is, the resistance of the steel to the softening effect of elevated temperature, and it forms hard, abrasion-resistant carbides, thus improving the wear properties of tool steels.

**Vanadium (V):** Vanadium contributes to the refinement of the carbide structure and thus improves the forgeability of alloy tool steels. Vanadium has a very strong tendency to form a hard carbide, which improves both the hardness and the wear properties of tool steels. However, a large amount of vanadium carbide makes the grinding of the tool very difficult (causing low grindability).

**Molybdenum (Mo):** In small amounts, molybdenum improves certain metallurgical properties of alloy steels, such as deep hardening and toughness. It is used often in larger amounts in certain high-speed tool steels to replace tungsten, primarily for economic reasons, often with nearly equivalent results.

**Cobalt (Co):** As an alloying element of tool steels, cobalt increases hot hardness and is used in applications where that property is needed. Substantial addition of cobalt, however, raises the critical quenching temperature of the steel with a tendency to increase the decarburization of the surface, and reduces toughness.

**Chromium (Cr):** This element is added in amounts of several percent to high-alloy tool steels and up to 12 percent to types in which chromium is the major alloying element. Chromium improves hardenability and, together with high carbon, provides both wear resistance and toughness, a combination valuable in certain tool applications. However, high chromium raises the hardening temperature of the tool steel and thus can make it prone to hardening deformations. A high percentage of chromium also affects the grindability of the tool steel.

**Nickel (Ni):** Generally in combination with other alloying elements, particularly chromium, nickel is used to improve the toughness and, to some extent, the wear resistance of tool steels.

**Table 2c. Common Tool Faults, Failures, and Cures**  
Heat-Treatment Faults

Fault Description	Probable Failure	Possible Cure
Improper preparation for heat treatment. Certain tools may require stress relieving or annealing, and often preheating as well	Tools highly stressed during machining or forming, unless stress-relieved, may aggravate the thermal stresses of heat treatment, thus causing cracks. Excessive temperature gradients developed in nonpreheated tools with different section thicknesses can cause warpage.	Stress relieve, when needed, before hardening. Anneal prior to heavy machining or cold forming (e.g., hobbing). Preheat tools (a) having substantial section thickness variations or (b) requiring high quenching temperatures, as those made of high-speed tool steels.
Overheating during hardening; quenching from too high a temperature	Causes grain coarsening and a sensitivity to cracking that is more pronounced in tools with drastic section changes.	Overheated tools have a characteristic microstructure that aids recognition of the cause of failure and indicates the need for improved temperature control.
Low hardening temperature	The tool may not harden at all, or in its outer portion only, thereby setting up stresses that can lead to cracks.	Controlling both the temperature of the furnace and the time of holding the tool at quenching temperature will prevent this not too frequent deficiency.
Inadequate composition or condition of the quenching media	Water-hardening tool steels are particularly sensitive to inadequate quenching media, which can cause soft spots or even violent cracking.	For water-hardening tool steels, use water free of dissolved air and contaminants, also assure sufficient quantity and proper agitation of the quench.
Improper handling during and after quenching	Cracking, particularly of tools with sharp corners, during the heat treatment can result from holding the part too long in the quench or from incorrectly applied tempering.	Following the steel producer's specifications is a safe way to assure proper heat-treatment handling. In general, the tool should be left in the quench until it reaches a temperature of 150–200°F (66–93°C), and should then be transferred promptly into a warm tempering furnace.
Insufficient tempering	Omission of double tempering for steel types that require it may cause early failure by heat checking in hot-work steels or make the tool abnormally sensitive to grinding checks.	Double temper highly alloyed tool steel of the high-speed, hot-work, and high-chromium categories to remove stresses caused by martensite formed during the first tempering phase. Second temper also increases hardness of most high-speed steels.
Decarburization and carburization	Unless hardened in a neutral atmosphere the original carbon content of the tool surface may be changed: Reduced carbon (decarburization) causes a soft layer that wears rapidly. Increased carbon (carburization) when excessive may cause brittleness.	Heating in neutral atmosphere or well-maintained salt bath and controlling the furnace temperature and the time during which the tool is subjected to heating can usually keep the carbon imbalance within acceptable limits.

The addition of more than one element to a steel often produces what is called a synergistic effect. Thus, the combined effects of two or more alloy elements may be greater than the sum of the individual effects of each element.

**Classification of Tool Steels.**—Steels for tools must satisfy a number of different, often conflicting, requirements. The need for specific steel properties arising from widely varying applications has led to the development of many compositions of tool steels, each intended to meet a particular combination of applicational requirements. The diversity of tool steels, their number being continually expanded by the addition of new developments, makes it extremely difficult for the user to select the type best suited to his needs or to find equivalent alternatives for specific types available from particular sources.

As a cooperative industrial effort under the sponsorship of AISI and SAE, a tool classification system has been developed in which the commonly used tool steels are grouped into seven major categories. These categories, several of which contain more than a single group, are listed in Table 3 with the letter symbols used for their identification. The individual types of tool steels within each category are identified by suffix numbers following the letter symbols.

**Table 2d. Common Tool Faults, Failures, and Cures**  
Grinding Damages

Fault Description	Probable Failure	Possible Cure
Grinding Damages		
Excessive stock removal rate causing heating of the part surface beyond the applied tempering temperature	Scorched tool surface displaying temper colors varying from yellow to purple, depending on the degree of heat, causes softening of the ground surface. When coolant is used, a local rehardening can take place, often resulting in cracks.	Prevention: by reducing speed and feed, or using coarser, softer, more openstructured grinding wheel, with ample coolant. Correction: eliminate the discolored layer by subsequent light stock removal. Not always a cure, because the effects of abusive grinding may not be corrected.
Improper grinding wheel specifications: grain too fine or bond too hard	Intense localized heating during grinding may set up surface stresses causing grinding cracks. These cracks are either parallel but at right angles to the direction of grinding or, when more advanced, form a network. May need cold etch or magnetic particle testing to become recognizable.	Prevention: by correcting the grinding wheel specifications. Correction: in shallow (0.002–0.004-inch, or 0.05–0.1 mm) cracks, by removing the damaged layer, when permitted by the design of the tool, using very light grinding passes.
Incorrectly dressed or loaded grinding wheel	Heating of the work surface can cause scorching or cracking. Incorrect dressing can also cause a poor finish of the ground work surface.	Dress wheel with sharper diamond and faster diamond advance to produce coarser wheel surface. Alternate dressing methods, like crush-dressing, can improve wheel surface conditions. Dress wheel regularly to avoid loading or glazing of the wheel surface.
Inadequate coolant, with regard to composition, amount, distribution, and cleanliness	Introducing into the tool surface heat that is not adequately dissipated or absorbed by the coolant can cause softening or even the development of cracks.	Improve coolant supply and quality, or reduce stock removal rate to reduce generation of heat in grinding.
Damage caused by abusive abrasive cutoff	The intensive heat developed during this process can cause a hardening of the steel surface, or may even result in cracks.	Reduce rate of advance; adopt wheel specifications better suited for the job. Use ample coolant or, when harmful effect not eliminated, replace abrasive cutoff by some cooler-acting stock separation method (e.g., sawing or lathe cutoff) unless damaged surface is being removed by subsequent machining.

**Table 3. Classification of Tool Steels**

Category Designation	Letter Symbol	Group Designation	Application Type
High-speed tool steels	M	Molybdenum types	Cutting Tools
	M50 - M52	Intermediate types	
	T	Tungsten types	
Hot-work tool steels	H1 - H19	Chromium types	Hot-work
	H20 - H39	Tungsten types	
	H40 - H59	Molybdenum types	
Cold-work tool steels	D	High-carbon, high-chromium types	Cold-work
	A	Medium-alloy, air-hardening types	
	O	Oil-hardening types	
Shock-resistant tool steels	S	—	Cold-work; hot-work (some grades)
Low-carbon tool and mold steels	P	—	Cold-work
Special-purpose tool steels	L	Low-alloy types	Cold-work
	F	Carbon-tungsten types	
Water-hardening tool steels	W	-	Cold-work

The following detailed discussion of tool steels will be in agreement with these categories, showing for each type the percentages of the major alloying elements. However, these values are for identification only; elements in tool steels of different producers in the mean analysis of the individual types may deviate from the listed percentages.

<sup>a</sup>C = carbon; Mn = manganese; Si = silicon; Cr = chromium; V = vanadium; W = tungsten; Mo = molybdenum; Co = cobalt.

<sup>b</sup>Carbon tool steels are usually available in four grades or qualities: *Special (Grade 1)*—The highest quality water-hardening carbon tool steel, controlled for hardenability, chemistry held to closest limits, and subject to rigid tests to ensure maximum uniformity in performance; *Extra (Grade 2)*—A high-quality water-hardening carbon tool steel, controlled for hardenability, subject to tests to ensure good service; *Standard (Grade 3)*—A good-quality water-hardening carbon tool steel, not controlled for hardenability, recommended for application where some latitude with respect to uniformity is permissible; *Commercial (Grade 4)*—A commercial-quality water-hardening carbon tool steel, not controlled for hardenability, not subject to special tests. On *special* and *extra* grades, limits on manganese, silicon, and chromium are not generally required if Shepherd hardenability limits are specified. For *standard* and *commercial* grades, limits are 0.35 max. each for Mn and Si; 0.15 max. Cr for standard; 0.20 max. Cr for commercial.

<sup>c</sup>Toughness decreases somewhat when increasing depth of hardening.

<sup>d</sup>Optional element. Steels have found satisfactory application either with or without the element present. In silicon-manganese steel listed under Shock-Resisting, if chromium, vanadium, and molybdenum are not present, then hardenability will be affected.

<sup>e</sup>This steel may have 0.50 percent nickel as an optional element. The steel has been found to give satisfactory application either with or without the element present.

<sup>f</sup>Approximate nickel content of this steel is 1.50 percent.

<sup>g</sup>Poor when water-quenched, fair when oil-quenched.

<sup>h</sup>Poor when water-quenched, good when oil-quenched.

**The Selection of Tool Steels for Particular Applications.**—Although the advice of the specialized steel producer is often sought as a reliable source of information, the engineer is still faced with the task of selecting the tool steel. It must be realized that frequently the designation of the tool or of the process will not define the particular tool steel type best suited for the job. For that reason, tool steel selection tables naming a single type for each listed application cannot take into consideration such often conflicting work factors as ease of tool fabrication and maintenance (resharpening), productivity, product quality, and tooling cost. For certain high-speed cutting applications, alternate, advanced materials, such as carbides and ceramics, may be preferable.

When data related to past experience with tool steels for identical or similar applications are not available, a tool steel selection procedure may be followed, based on information in this Handbook section as follows:

Identify the AISI category that contains the type of steel sought by consulting the Quick Reference Guide, [Table 5](#), starting on page 441. Within the defined category:

a) find from the listed applications of the most frequently used types of tool steels the particular type that corresponds to the job on hand; or

b) evaluate from the table of property ratings the best compromise between any conflicting properties (e.g., compromising on wear resistance to obtain better toughness).

For those willing to refine even further the first choice or to improve on it when there is not entirely satisfactory experience in one or more meaningful respects, the identifying analyses of the different types of tool steels within each general category may provide additional guidance. In this procedure, the general discussion of the effects of different alloying elements on the properties of tool steels, in a previous section, will probably be found useful.

The following two examples illustrate the procedure for refining an original choice with the purpose of adopting a tool steel grade best suited to a particular set of conditions:

*Example 1, Workpiece—Trimming Dies:* For the manufacture of a type of trimming die, the first choice was grade A2 because, for the planned medium rate of production, the lower material cost was considered an advantage.

A subsequent rise in the production rate indicated the use of a higher-alloy tool steel, such as D2, whose increased abrasion resistance would permit longer runs between regrinds.

A still further increase in the abrasion-resistant properties was then sought, which led to the use of D7, the high carbon and high chromium content of which provided excellent edge retainment, although at the cost of greatly reduced grindability. Finally, it became a matter of economic appraisal, whether the somewhat shorter tool regrind intervals (for D2) or the more expensive tool sharpening (for D7) constituted the lesser burden.

*Example 2, Workpiece—Circular form cutter made of high-speed tool steel for use on multiple-spindle automatic turning machines:* The first choice from [Table 5](#) may be the classical tungsten-base high-speed tool steel T1, because of its good performance and ease of heat treatment, or its alternate in the molybdenum high-speed tool steel category, the type M2.

In practice, neither of these grades provided a tool that could hold its edge and profile over the economical tool change time because of the abrasive properties of the work material and the high cutting speeds applied in the cycle. An overrating of the problem resulted in reaching for the top of the scale, making the tool from T15, a high-alloy high-speed tool steel (high vanadium and high cobalt).

Although the performance of the tools made of T15 was excellent, the cost of this steel type was rather high, and the grinding of the tool, both for making it and in regularly needed resharpening, proved to be very time-consuming and expensive. Therefore, an intermediate tool steel type was tried, the M3 that provided added abrasion resistance (due to increased carbon and vanadium content), and was less expensive and much easier to grind than the T15.

**Table 5. Quick Reference Guide for Tool Steel Selection**

Application Areas	Tool Steel Categories and AISI Letter Symbol						
	High-Speed Tool Steels, M and T	Hot-Work Tool Steels, H	Cold-Work Tool Steels, D, A, and O	Shock-Resisting Tool Steels, S	Mold Steels, P	Special-Purpose Tool Steels, L and F	Water-Hardening Tool Steels, W
Examples of Typical Applications							
Cutting Tools Single-point types (lathe, planer, boring) Milling cutters Drills Reamers Taps Threading dies Form cutters	General-purpose production tools: M2, T1 For increased abrasion resistance: M3, M4, and M10 Heavy-duty work calling for high hot hardness: T5, T15 Heavy-duty work calling for high abrasion resistance: M42, M44		Tools with keen edges (knives, razors) Tools for operations where no high-speed is involved, yet stability in heat treatment and substantial abrasion resistance are needed	Pipe cutter wheels			Uses that do not require hot hardness or high abrasion resistance. Examples with carbon content of applicable group: Taps (1.05 / 1.10% C) Reamers (1.10 / 1.15% C) Twist drills (1.20 / 1.25% C) Files (1.35 / 1.40% C)
Hot Forging Tools and Dies Dies and inserts Forging machine plungers and pierces	For combining hot hardness with high abrasion resistance: M2, T1	Dies for presses and hammers: H20, H21 For severe conditions over extended service periods: H22 to H26, also H43	Hot trimming dies: D2	Hot trimming dies Blacksmith tools Hot swaging dies			Smith's tools (1.65 / 0.70% C) Hot chisels (0.70 / 0.75% C) Drop forging dies (0.90 / 1.00% C) Applications limited to short-run production
Hot Extrusion Tools and Dies Extrusion dies and mandrels Dummy blocks Valve extrusion tools	Brass extrusion dies: T1	Extrusion dies and dummy blocks: H20 to H26 For tools that are exposed to less heat: H10 to H19		Compression molding: S1			

**Table 5. (Continued) Quick Reference Guide for Tool Steel Selection**

Application Areas	Tool Steel Categories and AISI Letter Symbol						
	High-Speed Tool Steels, M and T	Hot-Work Tool Steels, H	Cold-Work Tool Steels, D, A, and O	Shock-Resisting Tool Steels, S	Mold Steels, P	Special-Purpose Tool Steels, L and F	Water-Hardening Tool Steels, W
Examples of Typical Applications							
Cold-Forming Dies Bending, forming, drawing, and deep drawing dies and punches	Burnishing tools: M1, T1	Cold heading; die-casting dies: H13	Drawing dies: O1 Coining tools: O1, D2 Forming and bending dies: A2 Thread rolling dies: D2	Hobbing and short-run applications: S1, S7 Rivet sets and rivet busters		Blanking, forming, and trimmer dies when toughness has precedence over abrasion resistance: L6	Cold-heading dies: W1 or W2 (C $\cong$ 1.00%) Bending dies: W1 (C $\cong$ 1.00%)
Shearing Tools Dies for piercing, punching, and trimming Shear blades	Special dies for cold- and hot-work: T1 For work requiring high abrasion resistance: M2, M3	For shearing knives: H11, H12 For severe hot shearing applications: M21, M25	Dies for medium runs: A2, A6 also O1 and O4 Dies for long runs: D2, D3 Trimming dies (also for hot trimming): A2	Cold and hot shear blades Hot punching and piercing tools Boilermaker's tools		Knives for work requiring high toughness: L6	Trimming dies (0.90/0.95% C) Cold blanking and punching dies (1.00% C)
Die-Casting Dies and Plastics Molds		For zinc and lead: H11 For aluminum: H13 For brass: H21	A2 and A6  O1		Plastics molds: P2 to P4, and P20		
Structural Parts for Severe Service Conditions	Roller bearings for high-temperature environment: T1 Lathe centers: M2 and T1	For aircraft components (landing gear, arrester hooks, rocket cases): H11	Lathe centers: D2, D3 Arbors: O1 Bushings: A4 Gages: D2	Pawls Clutch parts		Spindles, clutch parts (where high toughness is needed): L6	Spring steel (1.10/1.15% C)
Battering Tools for Hand and Power Tool Use				Pneumatic chisels for cold-work: S5 For higher performance: S7			For intermittent use: W1 (0.80% C)

### High-Speed Tool Steels

The primary application of high-speed steels is for tools used for the working of metals at high cutting speeds. Cutting metal at high speed generates heat, the penetration of the cutting tool edge into the work material requires great hardness and strength, and the continued frictional contact of the tool with both the parent material and the detached chips can only be sustained by an abrasion-resistant tool edge.

Accordingly, the dominant properties of high-speed steel are a) resistance to the softening effect of elevated temperature; b) great hardness penetrating to substantial depth from the surface; and c) excellent abrasion resistance.

High-speed tool steels are listed in the AISI specifications in two groups: molybdenum types and tungsten types, these designations expressing the dominant alloying element of the respective group.

**Molybdenum-Type High-Speed Tool Steels.**—Unlike the traditional tungsten-base high-speed steels, the tool steels listed in this category are considered to have molybdenum as the principal alloying constituent, this element also being used in the designation of the group. Other significant elements like tungsten and cobalt might be present in equal, or even greater, amounts in several types listed in this category. The available range of types also includes high-speed tool steels with higher than usual carbon and vanadium content. Amounts of these alloying elements have been increased to obtain better abrasion resistance although such a change in composition may adversely affect the machinability and grindability of the steel. The series in whose AISI identification numbers the number 4 is the first digit was developed to attain exceptionally high hardness in heat treatment that, for these types, usually requires triple tempering rather than the double tempering generally applied for high-speed tool steels.

*Frequently Used Molybdenum Types: AISI M1:* This alloy was developed as a substitute for the classical T1 to save on the alloying element tungsten by replacing most of it with molybdenum. In most uses, this steel is an acceptable substitute, although it requires greater care or more advanced equipment for its heat treatment than the tungsten-alloyed type it replaces. The steel is often selected for cutting tools like drills, taps, milling cutters, reamers, lathe tools used for lighter cuts, and for shearing dies.

*AISI M2:* Similar to M1, yet with substantial tungsten content replacing a part of the molybdenum. This is one of the general-purpose high-speed tool steels, combining the economic advantages of the molybdenum-type steels with greater ease of hardening, excellent wear resistance, and improved toughness. It is a preferred steel type for the manufacture of general-purpose lathe tools; of most categories of multiple-edge cutting tools, like milling cutters, taps, dies, reamers, and for form tools in lathe operations.

*AISI M3:* A high-speed tool steel with increased vanadium content for improved wear resistance, yet still below the level where vanadium would interfere with the ease of grinding. This steel is preferred for cutting tools requiring improved wear resistance, like broaches, form tools, milling cutters, chasers, and reamers.

*AISI M7:* The chemical composition of this type is similar to that of M1, except for the higher carbon and vanadium content that raises the cutting efficiency without materially reducing the toughness. Because of sensitivity to decarburization, heat treatment in a salt bath or a controlled atmosphere is advisable. Used for blanking and trimming dies, shear blades, lathe tools, and thread rolling dies.

*AISI M10:* Although the relatively high vanadium content assures excellent wear and cutting properties, the only slightly increased carbon does not cause brittleness to an extent that is harmful in many applications. Form cutters and single-point lathe tools, broaches, planer tools, punches, blanking dies, and shear blades are examples of typical uses.

**AISI M42:** In applications where high hardness both at regular and at elevated temperatures is needed, this type of high-speed steel with high cobalt content can provide excellent service. Typical applications are tool bits, form tools, shaving tools, fly cutters, roll turning tools, and thread rolling dies. Important uses are found for M42, and for other types of the "M40" group, in the working of "difficult-to-machine" alloys.

**Tungsten-Type High-Speed Tool Steels.**—For several decades following their introduction, the tungsten-base high-speed steels were the only types available for cutting operations involving the generation of substantial heat and are still preferred by users who do not have the kind of advanced heat-treating equipment that efficient hardening of the molybdenum-type high-speed tool steels requires. Most tungsten high-speed steels display excellent resistance to decarburization and can be brought to good hardness by simple heat treatment. However, even with tungsten-type high-speed steels, heat treatment using modern methods and furnaces can appreciably improve the metallurgical qualities of the hardened material and the performance of the cutting tools made from these steels.

**Frequently Used Tungsten Types: AISI T1:** Also mentioned as the 18-4-1 type with reference to the nominal percentage of its principal alloying elements (W-Cr-V), it is considered to be the classical type of high-speed tool steel. The chemical composition of T1 was developed in the early 1900s, and has changed very little since. T1 is still considered to be perhaps the best general-purpose high-speed tool steel because of the comparative ease of its machining and heat treatment. It combines a high degree of cutting ability with relative toughness. T1 steel is used for all types of multiple-edge cutting tools like drills, reamers, milling cutters, threading taps and dies, light- and medium-duty lathe tools, and is also used for punches, dies, and machine knives, as well as for structural parts that are subjected to elevated temperatures, like lathe centers and certain types of antifriction bearings.

**AISI T2:** Similar to T1 except for somewhat higher carbon content and twice the vanadium contained in the former grade. Its handling ease, both in machining and heat treating, is comparable to that of T1, although it should be held at the quenching temperature slightly

longer, particularly when the heating is carried out in a controlled-atmosphere furnace. The applications are similar to those of T1. However, because of its increased wear resistance, T2 is preferred for tools required for finer cuts and where the form or size retention of the tool is particularly important, such as for form and finishing tools.

**AISI T5:** The essential characteristic of this type of high-speed steel, its superior red hardness, stems from its substantial cobalt content that, combined with the relatively high amount of vanadium, provides this steel with excellent wear resistance. In heat treatment, the tendency for decarburization must be considered, and heating in a controlled, slightly reducing atmosphere is recommended. This type of high-speed tool steel is mainly used for single-point tools and inserts; it is well adapted for working at high speeds and feeds, for cutting hard materials and those that produce discontinuous chips, also for nonferrous metals and, for all kinds of tools needed for hogging (removing great bulks of material).

**AISI T15:** The performance qualities of this high-alloy tool steel surpass most of those found in other grades of high-speed tool steels. The high vanadium content, supported by uncommonly high carbon, assures superior cutting ability and wear resistance. The addition of high cobalt increases the "hot hardness," and therefore tools made of T15 can sustain cutting speeds in excess of those commonly applicable to tools made of steel. The machining and heat treatment of T15 does not cause extraordinary problems, although for best results, heating to high temperature is often applied in its heat treatment, and double or even triple tempering is recommended. On the other hand, T15 is rather difficult to grind because of the presence of large amounts of very hard metallic carbides; therefore, it is considered to have a very low "grindability" index. The main uses are in the field of high-speed cutting and the working of hard metallic materials, T15 being often considered to represent in its application a transition from the regular high-speed tool steels to cemented carbides. Lathe tool bits, form cutters, and solid and inserted blade milling cutters are examples of uses of this steel type for cutting tools; excellent results may also be obtained with such tools as cold-work dies, punches, blanking, and forming dies, etc. The low toughness rating of the T15 steel excludes its application for operations that involve shock or sudden variations in load.

### Hot-Work Tool Steels

A family of special tool steels has been developed for tools that in their regular service are in contact with hot metals over a shorter or longer period of time, with or without cooling being applied, and are known as hot-work steels. The essential property of these steels is their ability to sustain elevated temperature without seriously affecting the usefulness of the tools made from them. Depending on the purpose of the tools for which they were developed, the particular types of hot-work tool steels have different dominant properties and are assigned to one of three groups, based primarily on their principal alloying elements.

**Hot-Work Tool Steels, Chromium Types.**—As referred to in the group designation, the chromium content is considered the characteristic element of these tool steels. Their predominant properties are high hardenability, excellent toughness, and great ductility, even at the cost of wear resistance. Some members of this family are made with the addition of tungsten, and in one type, cobalt as well. These alloying elements improve the resistance to the softening effect of elevated temperatures, but reduce ductility.

**Frequently Used Chromium Types:** **AISI H11:** This hot-work tool steel of the Chromium-molybdenum-vanadium type has excellent ductility, can be machined easily, and retains its strength at temperatures up to 1000°F (538°C).

These properties, combined with relatively good abrasion and shock resistance, account for the varied fields of application of H11, which include the following typical uses:

a) structural applications where high strength is needed at elevated operating temperatures, as for gas turbine engine components; and b) hot-work tools, particularly of the kind whose service involves shocks and drastic cooling of the tool, such as in extrusion tools, pierce and draw punches, bolt header dies, etc.

*AISI H12:* The properties of this type of steel are comparable to those of H11, with increased abrasion resistance and hot hardness resulting from the addition of tungsten, yet in an amount that does not affect the good toughness of this steel type. The applications based on these properties are hot-work tools that often have to withstand severe impact, such as various punches, bolt header dies, trimmer dies, and hot shear blades. H12 is also used to make aluminum extrusion dies and die-casting dies.

*AISI H13:* This type of tool steel differs from the preceding ones particularly in properties related to the addition of about 1 percent vanadium, which contributes to increased hot hardness, abrasion resistance, and reduced sensitivity to heat checking. Such properties are needed in die casting, particularly of aluminum, where the tools are subjected to drastic heating and cooling at high operating temperatures. Besides die-casting dies, H13 is also widely used for extrusion dies, trimmer dies, hot gripper and header dies, and hot shear blades.

*AISI H19:* This high-alloyed hot-work tool steel containing chromium, tungsten, cobalt, and vanadium has excellent resistance to abrasion and shocks at elevated temperatures. It is particularly well adapted to severe hot-work uses where the tool, to retain its size and shape, must withstand wear and the washing-out effect of molten work material. Typical applications include brass extrusion dies and dummy blocks, inserts for forging and valve extrusion dies, press forging dies, and hot punches.

**Hot-Work Tool Steels, Tungsten Types.**—A substantial amount of tungsten and very low-carbon content characterize the hot-work tool steels of this group. These tool steels have been developed for applications where the tool is in contact with the hot-work material over extended periods of time; therefore, the resistance of the steel to the softening effect of elevated temperatures is of prime importance, even to the extent of accepting a lower degree of toughness.

*Frequently Used Tungsten Types: AISI H21:* This medium-tungsten alloyed hot-work tool steel has substantially increased abrasion resistance over the chromium-alloyed types yet possesses a degree of toughness that represents a transition between the chromium and the higher-alloyed tungsten-steel types. The principal applications are for tools subjected to continued abrasion yet to only a limited amount of shock loads, like tools for the extrusion of brass, both dies and dummy blocks, pierces for forging machines, inserts for forging tools, and hot nut tools. Another typical application is dies for the hot extrusion of automobile valves.

*AISI H24:* The comparatively high tungsten content (about 14 percent) of this steel results in good hardness, great compression strength, and excellent abrasion resistance, but makes it sensitive to shock loads. By taking these properties into account, the principal applications include extrusion dies for brass in long-run operations, hot-forming and gripper dies with shallow impressions, punches that are subjected to great wear yet only to moderate shocks, and hot shear blades.

*AISI H20:* The composition of this high-alloyed tungsten-type hot-work steel resembles the tungsten-type high-speed steel AISI T1, except for the somewhat lower carbon content for improved toughness. The high amount of tungsten provides the maximum resistance to the softening effect of elevated temperature and assures excellent wear-resistant properties, including withstanding the washing-out effect of certain processes. However, this steel is less resistant to thermal shocks than the chromium hot-work steels. Typical applications comprise extrusion dies for long production runs, extrusion mandrels operated without cooling, hot piercing punches, hot forging dies and inserts. It is also used as special structural steel for springs operating at elevated temperatures.

**Hot-Work Tool Steels, Molybdenum Types.**—These steels are closely related to certain types of molybdenum high-speed steels and possess excellent resistance to the softening effect of elevated temperature, but their ductility is rather low. These steel types are generally available on special orders only.

*Frequently Used Molybdenum Types: AISI H43:* The principal constituents of this hot-work steel, chromium, molybdenum, and vanadium, provide excellent abrasion- and wear-resistant properties at elevated temperatures. H43 has a good resistance to the development of heat checks and a toughness adequate for many different purposes. Applications include tools and operations that tend to cause surface wear in high-temperature work, like hot headers, punch and die inserts, hot heading and hot nut dies, as well as different kinds of punches operating at high temperature in service involving considerable wear.

### Cold-Work Tool Steels

Tool steels of the cold-working category are primarily intended for die work, although their use is by no means restricted to that general field. Cold-work tool steels are extensively used for tools whose regular service does not involve elevated temperatures. They are available in chemical compositions adjusted to the varying requirements of a wide range of different applications. According to their predominant properties, characterized either by the chemical composition or by the quenching medium in heat treatment, the cold-work tool steels are assigned to three different groups, as discussed below.

**Cold-Work Tool Steels, High-Carbon, High-Chromium Types.**—The chemical composition of tool steels of this family is characterized by the very high chromium content, to the order of 12 to 13 percent, and the uncommonly high carbon content, in the range of about 1.50 to 2.30 percent. Additional alloying elements that are present in different amounts in some of the steel types of this group are vanadium, molybdenum, and cobalt, each of which contributes desirable properties.

The predominant properties of the whole group are: 1) excellent dimensional stability in heat treatment, where, with one exception, air quench is used; 2) great wear resistance, particularly in the types with the highest carbon content; and 3) rather good machinability.

*Frequently Used High-Carbon, High-Chromium Types: AISI D2:* An air-hardening die steel with high-carbon, high-chromium content having several desirable tool steel properties, such as abrasion resistance, high hardness, and nondeforming characteristics. The carbon content of this type, although relatively high, is not particularly detrimental to its machining. The ease of working can be further improved by selecting the same basic type with the addition of sulfur. Several steel producers supply the sulfurized version of D2, in which the uniformly distributed sulfide particles substantially improve the machinability and the resulting surface finish. The applications comprise primarily cold-working press tools for shearing (blanking and stamping dies, punches, shear blades), for forming (bending, seaming), and for thread rolling dies, solid gages, and wear-resistant structural parts. Dies for hot trimming of forgings are also made of D2, which is then heated treated to a lower hardness for the purpose of increasing toughness.

*AISI D3:* The high carbon content of this high-chromium tool steel type results in excellent resistance to wear and abrasion and provides superior compressive strength as long as the pressure is applied gradually without exerting sudden shocks. In hardening, an oil quench is used without affecting the excellent nondeforming properties of this type. Its deep-hardening properties make it particularly suitable for tools that require repeated regrinding during their service life, such as different types of dies and punches. The more important applications comprise blanking, stamping, and trimming dies and punches for long production runs; forming, bending and drawing tools; and structural elements like plug and ring gages, and lathe centers, in applications where high wear resistance is important.

**Cold-Work Tool Steels, Oil-Hardening Types.**—With a relatively low percentage of alloying elements, yet with a substantial amount of manganese, these less expensive types

of tool steels attain good depth of hardness in an oil quench, although at the cost of reduced resistance to deformation. Their good machinability supports general-purpose applications, yet, because of relatively low wear resistance, they are mostly selected for comparatively short-run work.

*Frequently Used Oil-Hardening Types: AISI O1:* A low-alloy tool steel that is hardened in oil and exhibits only a low tendency to shrinking or warping. It is used for cutting tools, the operation of which does not generate high heat, such as taps and threading dies, reamers, and broaches, and for press tools like blanking, trimming, and forming dies in short- or medium-run operations.

*AISI O2:* Manganese is the dominant alloying element in this type of oil-hardening tool steel that has good nondeforming properties, can be machined easily, and performs satisfactorily in low-volume production. The low hardening temperature results in good safety in hardening, both with regard to form stability and freedom from cracking. The combination of handling ease, including free-machining properties, with good wear resistance, makes this type of tool steel adaptable to a wide range of common applications, such as cutting tools for low- and medium-speed operations; forming tools including thread rolling dies; structural parts, such as bushings and fixed gages; and for plastics molds.

*AISI O6:* This oil-hardening type of tool steel belongs to a group often designated as graphitic because of the presence of small particles of graphitic carbon that are uniformly dispersed throughout the steel. Usually, about one-third of the total carbon is present as free graphite in nodular form, which contributes to the uncommon ease of machining. In the service of parts made of this type of steel, the free graphite acts like a lubricant, reducing wear and galling. The ease of hardening is also excellent, requiring only a comparatively low quenching temperature. Deep hardness penetration is produced and the oil quench causes very little dimensional change. The principal applications of the O6 tool steel are in the field of structural parts, like arbors, bushings, bodies for inserted tool cutters, and shanks for cutting tools, jigs, and machine parts, and fixed gages like plugs, rings, and snap gages. It is also used for blanking, forming, and trimming dies and punches, in applications where the stability of the tool material is more important than high wear resistance.

**Cold-Work Tool Steels, Medium-Alloy, Air-Hardening Types.**—The desirable nondeforming properties of the high-chromium types are approached by the members of this family, with substantially lower alloy content that, nonetheless, is sufficient to permit hardening by air quenching. The machinability is good, and the comparatively low wear resistance is balanced by relatively high toughness, a property that, in certain applications, may be considered of prime importance.

*Frequently Used Medium-Alloy, Air-Hardening Types: AISI A2:* The lower chromium content, about 5 percent, makes this air-hardening tool steel less expensive than the high-chromium types, without affecting its nondeforming properties. The somewhat reduced wear resistance is balanced by greater toughness, making this type suitable for press work where the process calls for tough tool materials. The machinability is improved by the addition of about 0.12 percent sulfur, offered as a variety of the basic composition by several steel producers. The prime uses of this tool steel type are punches for blanking and forming, cold and hot trimming dies (the latter heat treated to a lower hardness), thread rolling dies, and plastics molds.

*AISI A6:* The composition of this type of tool steel makes it adaptable to air hardening from a relatively low temperature, comparable to that of oil-hardening types, yet offers improved stability in heat treating. Its reduced tendency to heat-treatment distortions makes this tool steel type well adapted for die work, forming tools, and gages, which do not require the highest degree of wear resistance.

### Shock-Resisting, Mold, and Special-Purpose Tool Steels

There are fields of tool application in which specific properties of the tool steels have dominant significance, determining to a great extent the performance and the service life of tools made of these materials. To meet these requirements, special types of tool steels have been developed. These individual types grew into families with members that, while similar in their major characteristics, provide related properties to different degrees. Originally developed for a specific use, the resulting particular properties of some of these tool steels made them desirable for other uses as well. In the tool steel classification system, they are shown in three groups, as discussed below.

**Shock-Resisting Tool Steels.**—These steels are made with low-carbon content for increased toughness, even at the expense of wear resistance, which is generally low. Each member of this group also contains alloying elements, different in composition and amount, selected to provide properties particularly adjusted to specific applications. Such varying properties are the degree of toughness (generally high in all members), hot hardness, abrasion resistance, and machinability.

*Properties and Applications of Frequently Used Shock-Resisting Types:* **AISI S1:** This Chromium-tungsten alloyed tool steel combines, in its hardened state, great toughness with high hardness and strength. Although it has a low-carbon content for reasons of good toughness, the carbon-forming alloys contribute to deep hardenability and abrasion resistance. When high wear resistance is also required, this property can be improved by carburizing the surface of the tool while still retaining its shock-resistant characteristics. Primary uses are for battering tools, including hand and pneumatic chisels. The chemical composition, particularly the silicon and tungsten content, also provides good hot hardness up to operating temperatures of about 1050°F (566°C), making this tool steel type adaptable for such hot-work tool applications involving shock loads as headers, pierces, forming tools, drop forge die inserts, and heavy shear blades.

**AISI S2:** This steel type serves primarily for hand chisels and pneumatic tools, but it also has limited applications for hot-work. Although its wear-resistance properties are only moderate, S2 is sometimes used for forming and thread rolling applications, when the resistance to rupturing is more important than extended service life. For hot-work applications, this steel requires heat treatment in a neutral atmosphere to avoid either carburization or decarburization of the surface. Such conditions make this tool steel type particularly susceptible to failure in hot-work uses.

**AISI S5:** This composition is essentially a silicon-manganese-type tool steel with small additions of chromium, molybdenum, and vanadium for the purpose of improved deep hardening and refinement of the grain structure. The most important properties of this steel are its high elastic limit and good ductility, resulting in excellent shock-resisting characteristics, when used at atmospheric temperatures. Its recommended quenching medium is oil, although a water quench may also be applied as long as the design of the tools avoids sharp corners or drastic sectional changes. Typical applications include pneumatic tools in severe service, like chipping chisels as well as shear blades, heavy-duty punches, and bending rolls. Occasionally, this steel is also used for structural applications, like shanks for carbide tools and machine parts subject to shocks.

**Mold Steels.**—These materials differ from all other types of tool steels by their very low-carbon content, generally requiring carburizing to obtain a hard operating surface. A special property of most steel types in this group is adaptability to shaping by impression (hobbing) instead of by conventional machining. They also have high resistance to decarburization in heat treatment and dimensional stability, characteristics that obviate the need for grinding following heat treatment. Molding dies for plastics materials require an excellent surface finish, even to the degree of high luster; the generally high-chromium content of these types of tool steels greatly aids in meeting this requirement.

<sup>a</sup> Contains also about 1.20 percent Al. Solution treated in hardening.

<sup>b</sup> Quenched in oil.

<sup>c</sup> After carburizing.

<sup>d</sup> Carburized case.

<sup>e</sup> Core hardenability.

<sup>f</sup> Sometimes brine is used.

*Properties and Applications of Frequently Used Mold Steel Types: AISI P3 and P4:* Essentially, both types of tool steels were developed for the same special purpose, that is, the making of plastics molds. The application conditions of plastics molds require high core strength, good wear resistance at elevated temperature, and excellent surface finish. Both types are carburizing steels that possess good dimensional stability. Hobbing is the process of sinking a cavity by pressing a punch that is the inverse replica of the cavity into the tool material, and is the process by which many plastics mold cavities are produced. Good "hobbability" is an important requirement of tool steels used for this purpose. The different chemistry of these two types of mold steels is responsible for the high core hardness of P4, which makes it better suited for applications requiring high strength at elevated temperature.

*AISI P6:* This nickel-chromium-type plastics mold steel has exceptional core strength and develops a deep carburized case. Due to the high nickel-chromium content, the cavities of molds made of this steel type are produced by machining rather than by hobbing. An outstanding characteristic of this steel type is the high luster that is produced by polishing of the hard case surface.

*AISI P20:* This general-type mold steel is adaptable to both through hardening and carburized case hardening. In through hardening, an oil quench is used and a relatively lower, yet deeply penetrating, hardness is obtained, such as is needed for zinc die-casting dies and injection molds for plastics. After the direct quenching and tempering, carburizing produces a very hard case and comparatively high core hardness. When thus heat treated, this steel is particularly well adapted for making compression, transfer, and plunger-type plastics molds.

**Special-Purpose Tool Steels.**—These steels include several low-alloy types of tool steels that were developed to provide transitional types between the more commonly used basic types of tool steels, and thereby contribute to the balancing of certain conflicting properties, such as wear resistance and toughness. They offer intermediate depth of hardening and are less expensive than the higher-alloyed types of tool steels.

*Properties and Applications of Frequently Used Special-Purpose Types: AISI L6:* This material is a low-alloy-type special-purpose tool steel. Comparatively safe hardening and fair nondeforming properties, combined with the service advantage of good toughness in comparison to most other oil-hardening types, explain the acceptance of this steel with a rather special chemical composition. L6 is used for tools whose toughness requirements prevail over abrasion-resistant properties, such as forming rolls and forming and trimmer dies in applications where combinations of moderate shock- and wear-resistant properties are sought. The areas of use also include structural parts, like clutch members, pawls, and knuckle pins, that must withstand shock loads and still display good wear properties.

*AISI F2:* This carbon-tungsten type is one of the most abrasion-resistant of all water-hardening tool steels. However, it is sensitive to thermal changes, such as those involved in heat treatment, and it is also susceptible to distortions. Consequently, its use is limited to tools of simple shape in order to avoid cracking in hardening. The shallow hardening characteristics of F2 result in a tough core and are desirable properties for certain tool types that, at the same time, require excellent wear-resistant properties.

**Water-Hardening Tool Steels.**—Steel types in this category are made without, or with only a minimum amount of, alloying elements, and their heat treatment needs the harsh quenching action of water or brine, hence the general designation of the category.

Water-hardening steels are usually available with different percentages of carbon, to provide properties required for different applications; the classification system lists a carbon range of 0.60 to 1.40 percent. In practice, however, the steel mills produce these steels in a few varieties of differing carbon content, often giving proprietary designations to each particular group. Typical carbon content limits of frequently used water-hardening tool steels are 0.70–0.90, 0.90–1.10, 1.05–1.20, and 1.20–1.30 percent. The appropriate group should be chosen according to the intended use, as indicated in the steel selection

guide for this category, keeping in mind that whereas higher carbon content results in deeper hardness penetration, it also reduces toughness.

The general system distinguishes the following four grades, listed in the order of decreasing quality: 1) special; 2) extra; 3) standard; and 4) commercial.

The differences between these grades, which are not offered by all steel mills, are defined in principle only. The distinguishing characteristics are purity and consistency resulting from different degrees of process refinement and inspection steps applied in making the steel. Higher qualities are selected for assuring dependable uniformity and performance of the tools made from the steel.

The groups with higher carbon content are more sensitive to heat-treatment defects and are generally used for the more demanding applications, so the better grades are usually chosen for the high-carbon types and the lower grades for applications where steels with lower carbon content only are needed.

Water-hardening tool steels, although the least expensive and quite acceptable in many types of applications, have several drawbacks. Some limiting properties are the tendency to deformation in heat treatment due to harsh effects of the applied quenching medium, the sensitivity to heat during the use of the tools made of these steels, the only fair degree of toughness, and the shallow penetration of hardness. However, this last-mentioned property may prove a desirable characteristic in certain applications, such as cold-heading dies, because the relatively shallow hard case is supported by the tough, although softer, core.

The AISI designation for water-hardening tool steels is W, followed by a numeral indicating the type, primarily defined by the chemical composition, as shown in Table 11.

**Table 11. Water-Hardening Tool Steels—Identifying Chemical Composition and Heat-Treatment Data**

*Water-Hardening Type W1 (Plain Carbon) Tool Steels, Recommended Applications:*

*Group I (C 0.70 to 0.90%):* This group is relatively tough and therefore preferred for tools that are subjected to shocks or abusive treatment. Used for such applications as hand tools, chisels, screwdriver blades, cold punches, and nail sets, and fixture elements, vise jaws, anvil faces, and chuck jaws.

*Group II (C 0.90 to 1.10%):* This group combines greater hardness with fair toughness, resulting in improved cutting capacity and moderate ability to sustain shock loads. Used for such applications as hand tools, knives, center punches, pneumatic chisels, cutting

tools, reamers, hand taps, and threading dies, wood augers; die parts, drawing and heading dies, shear knives, cutting and forming dies; and fixture elements, drill bushings, lathe centers, collets, and fixed gages.

*Group III (C 1.05 to 1.20%):* The higher carbon content of this group increases the depth of hardness penetrations, yet reduces toughness, thus the resistance to shock loads. Preferred for applications where wear resistance and cutting ability are the prime considerations. Used for such applications as hand tools, woodworking chisels, paper knives, cutting tools (for low-speed applications), milling cutters, reamers, planer tools, thread chasers, center drills, die parts, cold blanking, coining, bending dies.

*Group IV (C 1.20 to 1.30%):* The high carbon content of this group produces a hard case of considerable depth with improved wear resistance yet sensitivity to shock and concentrated stresses. Selected for applications where the capacity to withstand abrasive wear is needed and where the retention of a keen edge or the original shape of the tool is important. Used for such applications as cutting tools for finishing work, like cutters and reamers, and for cutting chilled cast iron and forming tools, for ferrous and nonferrous metals, and burnishing tools.

By adding small amounts of alloying elements to W-steel types 2 and 5, certain characteristics that are desirable for specific applications are improved. The vanadium in type 2 contributes to retaining a greater degree of fine-grain structure after heat treating. Chromium in type 5 improves the deep-hardening characteristics of the steel, a property needed for large sections, and assists in maintaining the keen cutting edge that is desirable in cutting tools like broaches, reamers, threading taps, and dies.

### Mill Production Forms of Tool Steels

Tool steels are produced in many different forms, but not all those listed in the following are always readily available; certain forms and shapes are made for special orders only.

*Hot-Finished Bars and Cold-Finished Bars:* These bars are the most commonly produced forms of tool steels. Bars can be furnished in many different cross sections, the round shape being the most common. Sizes can vary over a wide range, with a more limited number of standard stock sizes. Various conditions may also be available; however, technological limitations prevent all conditions applying to every size, shape, or type of steel. Tool steel bars may be supplied in one of the following conditions and surface finishes:

*Conditions:* Hot-rolled or forged (natural); hot-rolled or forged and annealed; hot-rolled or forged and heat treated; cold- or hot-drawn (as drawn); and cold- or hot-drawn and annealed.

*Finishes:* Hot-rolled finish (scale not removed); pickled or blast-cleaned; cold-drawn; turned or machined; rough ground; centerless ground or precision flat ground; and polished (rounds only).

Other forms in which tool steels are supplied are the following:

*Rolled or Forged Special Shapes:* These shapes are usually produced on special orders only, for the purpose of reducing material loss and machining time in the large-volume manufacture of certain frequently used types of tools.

*Forgings:* All types of tool steels may be supplied in the form of forgings that are usually specified for special shapes and for dimensions that are beyond the range covered by bars.

*Wires:* Tool steel wires are produced either by hot or cold drawing and are specified when special shapes, controlled dimensional accuracy, improved surface finish, or special mechanical properties are required. Round wire is commonly produced within an approximate size range of 0.015 to 0.500 inch (0.38 to 12.7 mm), and these dimensions also indicate the limits within which other shapes of tool steel wires, like oval, square, or rectangular, may be produced.

*Drill Rods:* Rods are produced in round, rectangular, square, hexagonal, and octagonal shapes, usually with tight dimensional tolerances to eliminate subsequent machining, thereby offering manufacturing economies for the users.

*Hot-Rolled Plates and Sheets, and Cold-Rolled Strips:* Such forms of tool steel are generally specified for the high-volume production of specific tool types.

*Tool Bits:* These pieces are semifinished tools and are used by clamping in a tool holder or shank in a manner permitting ready replacement. Tool bits are commonly made of high-speed types of tool steels, mostly in square, but also in round, rectangular, and other shapes. Tool bits are made of hot-rolled bars and are commonly, yet not exclusively, supplied in hardened and ground form, ready for use after the appropriate cutting edges are ground, usually in the user's plant.

*Hollow Bars:* These bars are generally produced by trepanning, boring, or drilling of solid round rods and are used for making tools or structural parts of annular shapes, like rolls, ring gages, bushings, etc.

**Tolerances of Dimensions.**—Such tolerances have been developed and published by the American Iron and Steel Institute (AISI) as a compilation of available industry experience that, however, does not exclude the establishment of closer tolerances, particularly for hot-rolled products manufactured in large quantities. The tolerances differ for various categories of production processes (e.g., forged, hot-rolled, cold-drawn, centerless ground) and of general shapes.

**Allowances for Machining.**—These allowances provide freedom from soft spots and defects of the tool surface, thereby preventing failures in heat treatment or in service. After a layer of specific thickness, known as the allowance, has been removed, the bar or other form of tool steel material should have a surface without decarburization and other surface defects, such as scale marks or seams. The accepted industry-wide machining allowance values for tool steels in different conditions, shapes, and size ranges are spelled out in AISI specifications and are generally also listed in the tool steel catalogs of the producer companies.

**Decarburization Limits.**—Heating of steel for production operation causes the oxidation of the exposed surfaces, resulting in the loss of carbon. That condition, called decarburization, penetrates to a certain depth from the surface, depending on the applied process, the shape and the dimensions of the product. Values of tolerance for decarburization must be considered one of the factors for defining the machining allowances, which must also compensate for expected variations of size and shape, the dimensional effects of heat treatment, and so forth. Decarburization can be present not only in hot-rolled and forged, but also in rough turned and cold-drawn conditions.

**Advances in Tool Steel-Making Technology.**—Significant advances in processes for tool steel production have been made that offer more homogeneous materials of greater density and higher purity for applications where such extremely high quality is required. Two of these methods of tool steel production are of particular interest.

*Vacuum-melted tool steels:* These steels are produced by the consumable electrode method, which involves remelting of the steel originally produced by conventional processes. Inside a vacuum-tight shell that has been evacuated, the electrode cast of tool steel of the desired chemical analysis is lowered into a water-cooled copper mold where it strikes a low-voltage, high-amperage arc causing the electrode to be consumed by gradual melting. The undesirable gases and volatiles are drawn off by the vacuum, and the inclusions float on the surface of the pool, accumulating on the top of the produced ingot, to be removed later by cropping. In the field of tool steels, the consumable-electrode vacuum-melting (CVM) process is applied primarily to the production of special grades of hot-work and high-speed tool steels.

*High-speed tool steels produced by powder metallurgy:* The steel produced by conventional methods is reduced to a fine powder by a gas atomization process. The powder is compacted by a hot isostatic method with pressures in the range of 15,000 to 17,000 psi (103 to 117 MPa). The compacted billets are hot-rolled to the final bar size, yielding a tool-steel material which has 100 percent theoretical density. High-speed tool steels produced by the PM method offer a tool material providing increased tool wear life and high impact strength, of particular advantage in interrupted cuts.

**HARDENING, TEMPERING, AND ANNEALING****Heat Treatment of Standard Steels**

**Heat Treating Definitions.**—This glossary of heat-treating terms has been adopted by the American Foundry Society (AFS, formerly American Foundrymen's Association), ASM International (formerly American Society for Metals), American Society for Testing and Materials (ASTM), and the Society of Automotive Engineers (SAE). Since it is not intended to be a specification but is strictly a set of definitions, temperatures have purposely been omitted.

**Aging:** Describes a time-temperature-dependent change in the properties of certain alloys. Except for strain aging and age softening, it is the result of precipitation from a solid solution of one or more compounds whose solubility decreases with decreasing temperature. For each alloy susceptible to aging, there is a unique range of time-temperature combinations to which it will respond.

**Annealing:** A term denoting a treatment, consisting of heating to and holding at a suitable temperature followed by cooling at a suitable rate, used primarily to soften but also to simultaneously produce desired changes in other properties or in microstructure. The purpose of such changes may be, but is not confined to, improvement of machinability, facilitation of cold-working, improvement of mechanical or electrical properties, or increase in stability of dimensions. The time-temperature cycles used vary widely both in maximum temperature attained and in cooling rate employed, depending on the composition of the material, its condition, and the results desired. When applicable, the following more specific process names should be used: Black Annealing, Blue Annealing, Box Annealing, Bright Annealing, Cycle Annealing, Flame Annealing, Full Annealing, Graphitizing, Intermediate Annealing, Isothermal Annealing, Process Annealing, Quench Annealing, and Spheroidizing. When the term is used without qualification, full annealing is implied. When applied only for the relief of stress, the process is properly called stress relieving.

**Black Annealing:** Box annealing or pot annealing, used mainly for sheet, strip, or wire.

**Blue Annealing:** Heating hot-rolled sheet in an open furnace to a temperature within the transformation range and then cooling in air to soften the metal. The formation of a bluish oxide on the surface is incidental.

**Box Annealing:** Annealing in a sealed container under conditions that minimize oxidation. In box annealing, the charge is usually heated slowly to a temperature below the transformation range, but sometimes above or within it, and is then cooled slowly; this process is also called "close annealing" or "pot annealing."

**Bright Annealing:** Annealing in a protective medium to prevent discoloration of the bright surface.

**Cycle Annealing:** An annealing process employing a predetermined and closely controlled time-temperature cycle to produce specific properties or microstructure.

**Flame Annealing:** Annealing in which the heat is applied directly by a flame.

**Full Annealing:** Austenitizing and then cooling at a rate such that the hardness of the product approaches a minimum.

**Graphitizing:** Annealing in such a way that some or all of the carbon is precipitated as graphite.

**Intermediate Annealing:** Annealing at one or more stages during manufacture and before final thermal treatment.

**Isothermal Annealing:** Austenitizing and then cooling to and holding at a temperature at which austenite transforms to a relatively soft ferrite-carbide aggregate.

**Process Annealing:** An imprecise term used to denote various treatments that improve workability. For the term to be meaningful, the condition of the material and the time-temperature cycle used must be stated.

**Quench Annealing:** Annealing an austenitic alloy by *Solution Heat Treatment*.

**Spheroidizing:** Heating and cooling in a cycle designed to produce a spheroidal or globular form of carbide.

**Austempering:** Quenching from a temperature above the transformation range, in a medium having a rate of heat abstraction high enough to prevent the formation of high-temperature transformation products, and then holding the alloy, until transformation is complete, at a temperature below that of pearlite formation and above that of martensite formation.

**Austenitizing:** Forming austenite by heating into the transformation range (partial austenitizing) or above the transformation range (complete austenitizing). When used without qualification, the term implies complete austenitizing.

**Baking:** Heating to a low temperature in order to remove entrained gases.

**Bluing:** A treatment of the surface of iron-base alloys, usually in the form of sheet or strip, on which, by the action of air or steam at a suitable temperature, a thin blue oxide film is formed on the initially scale-free surface, as a means of improving appearance and resistance to corrosion. This term is also used to denote a heat treatment of springs after fabrication, to reduce the internal stress created by coiling and forming.

**Carbon Potential:** A measure of the ability of an environment containing active carbon to alter or maintain, under prescribed conditions, the carbon content of the steel exposed to it. In any particular environment, the carbon level attained will depend on such factors as temperature, time, and steel composition.

**Carbon Restoration:** Replacing the carbon lost in the surface layer from previous processing by carburizing this layer to substantially restore the original carbon level.

**Carbonitriding:** A case-hardening process in which a suitable ferrous material is heated above the lower transformation temperature in a gaseous atmosphere of such composition as to cause simultaneous absorption of carbon and nitrogen by the surface and, by diffusion, create a concentration gradient. The process is completed by cooling at a rate that produces the desired properties in the workpiece.

**Carburizing:** A process in which carbon is introduced into a solid iron-base alloy by heating above the transformation temperature range while in contact with a carbonaceous material that may be a solid, liquid, or gas. Carburizing is frequently followed by quenching to produce a hardened case.

**Case:** 1) The surface layer of an iron-base alloy that has been suitably altered in composition and can be made substantially harder than the interior or core by a process of case hardening; and 2) the hardened surface layer of a piece of steel that is large enough to have a distinctly softer core or center.

**Cementation:** The process of introducing elements into the outer layer of metal objects by means of high-temperature diffusion.

**Cold Treatment:** Exposing to suitable subzero temperatures for the purpose of obtaining desired conditions or properties, such as dimensional or microstructural stability. When the treatment involves the transformation of retained austenite, it is usually followed by a tempering treatment.

**Conditioning Heat Treatment:** A preliminary heat treatment used to prepare a material for a desired reaction to a subsequent heat treatment. For the term to be meaningful, the treatment used must be specified.

**Controlled Cooling:** A term used to describe a process by which a steel object is cooled from an elevated temperature, usually from the final hot-forming operation in a predetermined manner of cooling to avoid hardening, cracking, or internal damage.

**Core:** 1) The interior portion of an iron-base alloy that after case hardening is substantially softer than the surface layer or case; and 2) the relatively soft central portion of certain hardened tool steels.

**Critical Range or Critical Temperature Range:** Synonymous with *Transformation Range*, which is preferred.

**Cyaniding:** A process of case hardening an iron-base alloy by the simultaneous absorption of carbon and nitrogen by heating in a cyanide salt. Cyaniding is usually followed by quenching to produce a hard case.

*Decarburization:* The loss of carbon from the surface of an iron-base alloy as the result of heating in a medium that reacts with the carbon.

*Drawing:* Drawing, or drawing the temper, is synonymous with *Tempering*, which is preferable.

*Eutectic Alloy:* The alloy composition that freezes at constant temperature similar to a pure metal. The lowest melting (or freezing) combination of two or more metals. The alloy structure (homogeneous) of two or more solid phases formed from the liquid eutectically.

*Hardenability:* In a ferrous alloy, the property that determines the depth and distribution of hardness induced by quenching.

*Hardening:* Any process of increasing hardness of metal by suitable treatment, usually involving heating and cooling. See also *Aging*.

*Hardening, Case:* A process of surface hardening involving a change in the composition of the outer layer of an iron-base alloy followed by appropriate thermal treatment. Typical case-hardening processes are *Carburizing*, *Cyaniding*, *Carbonitriding*, and *Nitriding*.

*Hardening, Flame:* A process of heating the surface layer of an iron-base alloy above the transformation temperature range by means of a high-temperature flame, followed by quenching.

*Hardening, Precipitation:* A process of hardening an alloy in which a constituent precipitates from a supersaturated solid solution. See also *Aging*.

*Hardening, Secondary:* An increase in hardness following the normal softening that occurs during the tempering of certain alloy steels.

*Heating, Differential:* A heating process by which the temperature is made to vary throughout the object being heated so that, on cooling, different portions may have such different physical properties as may be desired.

*Heating, Induction:* A process of local heating by electrical induction.

*Heat Treatment:* A combination of heating and cooling operations applied to a metal or alloy in the solid state to obtain desired conditions or properties. Heating for the sole purpose of hot-working is excluded from the meaning of this definition.

*Heat Treatment, Solution:* A treatment in which an alloy is heated to a suitable temperature and held at this temperature for a sufficient length of time to allow a desired constituent to enter into solid solution, followed by rapid cooling to hold the constituent in solution. The material is then in a supersaturated, unstable state, and may subsequently exhibit *Age Hardening*.

*Homogenizing:* A high-temperature heat-treatment process intended to eliminate or to decrease chemical segregation by diffusion.

*Isothermal Transformation:* A change in phase at constant temperature.

*Malleablizing:* A process of annealing white cast iron in which the combined carbon is wholly or in part transformed to graphitic or free carbon and, in some cases, part of the carbon is removed completely. See *Temper Carbon*.

*Maraging:* A precipitation hardening treatment applied to a special group of iron-base alloys to precipitate one or more intermetallic compounds in a matrix of essentially carbon-free martensite.

*Martempering:* A hardening procedure in which an austenitized ferrous workpiece is quenched into an appropriate medium whose temperature is maintained substantially at the  $M_s$  of the workpiece, held in the medium until its temperature is uniform throughout but not long enough to permit bainite to form, and then cooled in air. The treatment is followed by tempering.

*Nitriding:* A process of case hardening in which an iron-base alloy of special composition is heated in an atmosphere of ammonia or in contact with nitrogenous material. Surface hardening is produced by the absorption of nitrogen without quenching.

*Normalizing:* A process in which an iron-base alloy is heated to a temperature above the transformation range and subsequently cooled in still air at room temperature.

*Overheated:* A metal is said to have been overheated if, after exposure to an unduly high temperature, it develops an undesirably coarse grain structure but is not permanently damaged. The structure damaged by overheating can be corrected by suitable heat treatment or by mechanical work or by a combination of the two. In this respect it differs from a Burnt structure.

*Patenting:* A process of heat treatment applied to medium- or high-carbon steel in wire making prior to the wire drawing or between drafts. It consists in heating to a temperature above the transformation range, followed by cooling to a temperature below that range in air or in a bath of molten lead or salt maintained at a temperature appropriate to the carbon content of the steel and the properties required of the finished product.

*Preheating:* Heating to an appropriate temperature immediately prior to austenitizing when hardening high-hardenability constructional steels, many of the tool steels, and heavy sections.

*Quenching:* Rapid cooling. When applicable, the following more specific terms should be used: Direct Quenching, Fog Quenching, Hot Quenching, Interrupted Quenching, Selective Quenching, Slack Quenching, Spray Quenching, and Time Quenching.

*Direct Quenching:* Quenching carburized parts directly from the carburizing operation.

*Fog Quenching:* Quenching in a mist.

*Hot Quenching:* An imprecise term used to cover a variety of quenching procedures in which a quenching medium is maintained at a prescribed temperature above 160°F (71°C).

*Interrupted Quenching:* A quenching procedure in which the workpiece is removed from the first quench at a temperature substantially higher than that of the quenchant and is then subjected to a second quenching system having a different cooling rate than the first.

*Selective Quenching:* Quenching only certain portions of a workpiece.

*Slack Quenching:* The incomplete hardening of steel due to quenching from the austenitizing temperature at a rate slower than the critical cooling rate for the particular steel, resulting in the formation of one or more transformation products in addition to martensite.

*Spray Quenching:* Quenching in a spray of liquid.

*Time Quenching:* Interrupted quenching in which the duration of holding in the quenching medium is controlled.

*Soaking:* Prolonged heating of a metal at a selected temperature.

*Stabilizing Treatment:* A treatment applied to stabilize the dimensions of a workpiece or the structure of a material such as 1) before finishing to final dimensions, heating a workpiece to or somewhat beyond its operating temperature and then cooling to room temperature a sufficient number of times to ensure stability of dimensions in service; 2) transforming retained austenite in those materials that retain substantial amounts when quench hardened (see cold treatment); and 3) heating a solution-treated austenitic stainless steel that contains controlled amounts of titanium or niobium plus tantalum to a temperature below the solution heat-treating temperature to cause precipitation of finely divided, uniformly distributed carbides of those elements, thereby substantially reducing the amount of carbon available for the formation of chromium carbides in the grain boundaries on subsequent exposure to temperatures in the sensitizing range.

*Stress Relieving:* A process to reduce internal residual stresses in a metal object by heating the object to a suitable temperature and holding for a proper time at that temperature. This treatment may be applied to relieve stresses induced by casting, quenching, normalizing, machining, cold-working, or welding.

*Temper Carbon:* The free or graphitic carbon that comes out of solution usually in the form of rounded nodules in the structure during *Graphitizing* or *Malleablizing*.

*Tempering:* Heating a quench-hardened or normalized ferrous alloy to a temperature below the transformation range to produce desired changes in properties.

*Double Tempering:* A treatment in which quench-hardened steel is given two complete tempering cycles at substantially the same temperature for the purpose of ensuring completion of the tempering reaction and promoting stability of the resulting microstructure.

**Snap Temper:** A precautionary interim stress-relieving treatment applied to high hardenability steels immediately after quenching to prevent cracking because of delay in tempering them at the prescribed higher temperature.

**Temper Brittleness:** Brittleness that results when certain steels are held within, or are cooled slowly through, a certain range of temperatures below the transformation range. The brittleness is revealed by notched-bar impact tests at or below room temperature.

**Transformation Ranges or Transformation Temperature Ranges:** Those ranges of temperature within which austenite forms during heating and transforms during cooling. The two ranges are distinct, sometimes overlapping but never coinciding. The limiting temperatures of the ranges depend on the composition of the alloy and on the rate of change of temperature, particularly during cooling.

**Transformation Temperature:** The temperature at which a change in phase occurs. The term is sometimes used to denote the limiting temperature of a transformation range. The following symbols are used for iron and steels:

- $A_{cm}$  = In hypereutectoid steel, the temperature at which the solution of cementite in austenite is completed during heating
- $A_1$  = The temperature at which austenite begins to form during heating
- $A_3$  = The temperature at which transformation of ferrite to austenite is completed during heating
- $A_4$  = The temperature at which austenite transforms to delta ferrite during heating
- $Ae_1, Ae_3, Ae_{cm}, Ae_4$  = The temperatures of phase changes at equilibrium
- $A_{cm}$  = In hypereutectoid steel, the temperature at which precipitation of cementite starts during cooling
- $Ar_1$  = The temperature at which transformation of austenite to ferrite or to ferrite plus cementite is completed during cooling
- $Ar_3$  = The temperature at which austenite begins to transform to ferrite during cooling
- $Ar_4$  = The temperature at which delta ferrite transforms to austenite during cooling
- $M_s$  = The temperature at which transformation of austenite to martensite starts during cooling
- $M_f$  = The temperature, during cooling, at which transformation of austenite to martensite is substantially completed

All these changes, except the formation of martensite, occur at lower temperatures during cooling than during heating, and depend on the rate of change of temperature.

**Hardness and Hardenability.**—Hardenability is the property of steel that determines the *depth* and *distribution of hardness* induced by quenching from the austenitizing temperature. Hardenability should not be confused with hardness as such or with maximum hardness. Hardness is a measure of the ability of a metal to resist penetration as determined by any one of a number of standard tests (Brinell, Rockwell, Vickers, etc). The maximum attainable hardness of any steel depends solely on carbon content and is not significantly affected by alloy content. Maximum hardness is realized only when the cooling rate in quenching is rapid enough to ensure full transformation to martensite.

The as-quenched surface hardness of a steel part is dependent on carbon content and cooling rate, but the *depth* to which a certain hardness level is maintained with given quenching conditions is a function of its hardenability. Hardenability is largely determined by the percentage of alloying elements in the steel; however, austenite grain size, time and temperature during austenitizing, and prior microstructure also significantly affect the hardness depth. The hardenability required for a particular part depends on size, design, and service stresses. For highly stressed parts, the best combination of strength and toughness is obtained by through hardening to a martensitic structure followed by adequate tempering. There are applications, however, where through hardening is not

necessary or even desirable. For parts that are stressed principally at or near the surface, or in which wear resistance or resistance to shock loading is anticipated, a shallow hardening steel with a moderately soft core may be appropriate.

For through hardening of thin sections, carbon steels may be adequate; but as section size increases, alloy steels of increasing hardenability are required. The usual practice is to select the most economical grade that can meet the desired properties consistently. It is not good practice to utilize a higher alloy grade than necessary, because excessive use of alloying elements adds little to the properties and can sometimes induce susceptibility to quenching cracks.

*Quenching Media:* The choice of quenching media is often a critical factor in the selection of steel of the proper hardenability for a particular application. Quenching severity can be varied by selection of quenching medium, agitation control, and additives that improve the cooling capability of the quenchant. Increasing the quenching severity permits the use of less expensive steels of lower hardenability; however, consideration must also be given to the amount of distortion that can be tolerated and the susceptibility to quench cracking. In general, the more severe the quenchant and the less symmetrical the part being quenched, the greater are the size and shape changes that result from quenching and the greater is the risk of quench cracking. Consequently, although water quenching is less costly than oil quenching and water-quenched steels are less expensive than those requiring oil quenching, it is important to know that the parts being hardened can withstand the resulting distortion and the possibility of cracking.

Oil, salt, and synthetic water-polymer quenchants are also used, but they often require steels of higher alloy content and hardenability. A general rule for the selection of steel and quenchant for a particular part is that the steel should have a hardenability not exceeding that required by the severity of the quenchant selected. The carbon content of the steel should also not exceed that required to meet specified hardness and strength, because quench cracking susceptibility increases with carbon content.

The choice of quenching media is important in hardening, but another factor is agitation of the quenching bath. The more rapidly the bath is agitated, the more rapidly heat is removed from the steel and the more effective is the quench.

*Hardenability Test Methods:* The most commonly used method for determining hardenability is the end-quench test developed by Jominy and Boegehold, and described in detail in both SAE J406 and ASTM A255. In this test a normalized 1-inch-round (25.4 mm), approximately 4-inch-long (102 mm) specimen of the steel to be evaluated is heated uniformly to its austenitizing temperature. The specimen is then removed from the furnace, placed in a jig, and immediately end quenched by a jet of room-temperature water. The water is played on the end face of the specimen, without touching the sides, until the entire specimen has cooled. Longitudinal flat surfaces are ground on opposite sides of the piece, and Rockwell C scale hardness readings are taken at  $\frac{1}{16}$ -inch (1.6 mm) intervals from the quenched end. The resulting data are plotted on graph paper with the hardness values as ordinates ( $y$ -axis) and distances from the quenched end as abscissas ( $x$ -axis). Representative data have been accumulated for a variety of standard steel grades and are published by SAE and AISI as "H-bands." These data show graphically and in tabular form the high and low limits applicable to each grade. The suffix H following the standard AISI/SAE numerical designation indicates that the steel has been produced to specific hardenability limits.

Experiments have confirmed that the cooling rate at a given point along the Jominy bar corresponds closely to the cooling rate at various locations in round bars of various sizes. In general, when end-quench curves for different steels coincide approximately, similar treatments will produce similar properties in sections of the same size. On occasion it is necessary to predict the end-quench hardenability of a steel not available for testing, and reasonably accurate means of calculating hardness for any Jominy location on a section of steel of known analysis and grain size have been developed.

**Tempering:** As-quenched steels are in a highly stressed condition and are seldom used without tempering. Tempering imparts plasticity or toughness to the steel and is inevitably accompanied by a loss in hardness and strength. The loss in strength, however, is only incidental to the very important increase in toughness, which is due to the relief of residual stresses induced during quenching and to precipitation, coalescence, and spheroidization of iron and alloy carbides resulting in a microstructure of greater plasticity.

Alloying slows the tempering rate, so that alloy steel requires a higher tempering temperature to obtain a given hardness than carbon steel of the same carbon content. The higher tempering temperature for a given hardness permits a greater relaxation of residual stress and thereby improves the steel's mechanical properties. Tempering is done in furnaces or in oil or salt baths at temperatures varying from 300 to 1200°F (149 to 649°C). With most grades of alloy steel, the range between 500 and 700°F (260 to 371°C) is avoided because of a phenomenon known as "blue brittleness," which reduces impact properties. Tempering the martensitic stainless steels in the range of 800–1100°F (427 to 593°C) is not recommended because of the low and erratic impact properties and reduced corrosion resistance that result. Maximum toughness is achieved at higher temperatures. It is important to temper parts as soon as possible after quenching because any delay greatly increases the risk of cracking resulting from the high-stress condition in the as-quenched part.

**Surface Hardening Treatment (Case Hardening).**—Many applications require high hardness or strength primarily at the surface, and complex service stresses frequently require not only a hard, wear-resistant surface, but also core strength and toughness to withstand impact stress.

To achieve these different properties, two general processes are used: 1) The chemical composition of the surface is altered, prior to or after quenching and tempering; the processes used include carburizing, nitriding, cyaniding, and carbonitriding; and 2) Only the surface layer is hardened by the heating and quenching process; the most common processes used for surface hardening are flame hardening and induction hardening.

**Carburizing:** Carbon is diffused into the part's surface to a controlled depth by heating the part in a carbonaceous medium. The resulting depth of carburization, commonly referred to as case depth, depends on the carbon potential of the medium used and the time and temperature of the carburizing treatment. The steels most suitable for carburizing to enhance toughness are those with sufficiently low carbon contents, usually below 0.3 percent. Carburizing temperatures range from 1550 to 1750°F (843 to 954°C), with the temperature and time at temperature adjusted to obtain various case depths. Steel selection, hardenability, and type of quench are determined by section size, desired core hardness, and service requirements.

Three types of carburizing are most often used: 1) *Liquid carburizing* involves heating the steel in molten barium cyanide or sodium cyanide. The case absorbs some nitrogen in addition to carbon, thus enhancing surface hardness; 2) *Gas carburizing* involves heating the steel in a gas of controlled carbon content. When used, the carbon level in the case can be closely controlled; and 3) *Pack carburizing*, which involves sealing both the steel and solid carbonaceous material in a gas-tight container, then heating this combination.

With any of these methods, the part may be either quenched after the carburizing cycle without reheating or air cooled followed by reheating to the austenitizing temperature prior to quenching. The case depth may be varied to suit the conditions of loading in service. However, service characteristics frequently require that only selective areas of a part have to be case hardened. Covering the areas not to be cased, with copper plating or a layer of commercial paste, allows the carbon to penetrate only the exposed areas. Another method involves carburizing the entire part, then removing the case in selected areas by machining, prior to quench hardening.

**Nitriding:** The steel part is heated to a temperature of 900–1150°F (482 to 621°C) in an atmosphere of ammonia gas and dissociated ammonia for an extended period of time

that depends on the case depth desired. A thin, very hard case results from the formation of nitrides. Strong nitride-forming elements (chromium and molybdenum) are required to be present in the steel, and often special nonstandard grades containing aluminum (a strong nitride former) are used. The major advantage of this process is that parts can be quenched and tempered, then machined, prior to nitriding, because only a little distortion occurs during nitriding.

**Cyaniding:** This process involves heating the part in a bath of sodium cyanide to a temperature slightly above the transformation range, followed by quenching, to obtain a thin case of high hardness.

**Carbonitriding:** This process is similar to cyaniding except that the absorption of carbon and nitrogen is accomplished by heating the part in a gaseous atmosphere containing hydrocarbons and ammonia. Temperatures of 1425–1625°F (774 to 885°C) are used for parts to be quenched, and lower temperatures, 1200–1450°F (649 to 788°C), may be used where a liquid quench is not required.

**Flame Hardening:** This process involves rapid heating with a direct high-temperature gas flame, such that the surface layer of the part is heated above the transformation range, followed by cooling at a rate that causes the desired hardening. Steels for flame hardening are usually in the range of 0.30–0.60 percent carbon, with hardenability appropriate for the case depth desired and the quenchant used. The quenchant is usually sprayed on the surface a short distance behind the heating flame. Immediate tempering is required and may be done in a conventional furnace or by a flame-tempering process, depending on part size and costs.

**Induction Hardening:** This process is similar in many respects to flame hardening except that the heating is caused by a high-frequency electric current sent through a coil or inductor surrounding the part. The depth of heating depends on the frequency, the rate of heat conduction from the surface, and the length of the heating cycle. Quenching is usually accomplished with a water spray introduced at the proper time through jets in or near the inductor block or coil. In some instances, however, parts are oil-quenched by immersing them in a bath of oil after they reach the hardening temperature.

**Structure of Fully Annealed Carbon Steel.**—In carbon steel that has been fully annealed, there are normally present, apart from such impurities as phosphorus and sulfur, two constituents: the element iron in a form metallurgically known as *ferrite* and the chemical compound iron carbide in the form metallurgically known as *cementite*. This latter constituent consists of 6.67 percent carbon and 93.33 percent iron. A certain proportion of these two constituents will be present as a mechanical mixture. This mechanical mixture, the amount of which depends on the carbon content of the steel, consists of alternate bands or layers of ferrite and cementite. Under the microscope, the matrix frequently has the appearance of mother-of-pearl and hence has been named *pearlite*. Pearlite contains about 0.85 percent carbon and 99.15 percent iron, neglecting impurities. A fully annealed steel containing 0.85 percent carbon would consist entirely of pearlite. Such a steel is known as *eutectoid* steel and has a laminated structure characteristic of a eutectic alloy. Steel that has less than 0.85 percent carbon (*hypoeutectoid* steel) has an excess of ferrite above that required to mix with the cementite present to form pearlite; hence, both ferrite and pearlite are present in the fully annealed state. Steel having a carbon content greater than 0.85 percent (*hypereutectoid* steel) has an excess of cementite over that required to mix with the ferrite to form pearlite; hence, both cementite and pearlite are present in the fully annealed state. The structural constitution of carbon steel in terms of ferrite, cementite, pearlite and austenite for different carbon contents and at different temperatures is shown by the accompanying figure, *Phase Diagram of Carbon Steel*.

**Effect of Heating Fully Annealed Carbon Steel.**—When carbon steel in the fully annealed state is heated above the lower critical point, which is some temperature in the range of 1335 to 1355°F (724 to 735°C) depending on the carbon content, the alternate

bands or layers of ferrite and cementite that make up the pearlite begin to merge into each other. This process continues until the pearlite is thoroughly "dissolved," forming what is known as *austenite*. If the temperature of the steel continues to rise and there is present, in addition to the pearlite, any excess ferrite or cementite, this also will begin to dissolve into the austenite until finally only austenite will be present. The temperature at which the excess ferrite or cementite is completely dissolved in the austenite is called the *upper critical point*. This temperature varies with the carbon content of the steel much more widely than the lower critical point (see Fig. 1).

Fig. 1. Phase Diagram of Carbon Steel

**Effect of Slow Cooling on Carbon Steel.**—If carbon steel that has been heated to the point where it consists entirely of austenite is slowly cooled, the process of transformation that took place during the heating will be reversed, but the upper and lower critical points will occur at somewhat lower temperatures than they do on heating. Assuming that the steel was originally fully annealed, its structure on returning to atmospheric temperature after slow cooling will be the same as before in terms of the proportions of ferrite or cementite and pearlite present. The austenite will have entirely disappeared.

**Effect of Rapid Cooling or Quenching on Carbon Steel.**—Observations have shown that as the rate at which carbon steel is cooled from an austenitic state is increased, the temperature at which the austenite begins to change into pearlite drops more and more below the slow cooling transformation temperature of about 1300°F (704°C). For example, a 0.80 percent carbon steel that is cooled at such a rate that the temperature drops 500°F (278°C drop) in one second will show transformation of austenite beginning at 930°F (500°C). As the cooling rate is increased, the laminations of the pearlite formed by the transformation of the austenite become finer and finer up to the point where they cannot be detected under a high-power microscope, while the steel itself increases in hardness and tensile strength. As the rate of cooling is still further increased, this transformation temperature suddenly drops to around 500°F (260°C) or lower, depending on the carbon content of the steel. The cooling rate at which this sudden drop in transformation

temperature takes place is called the *critical cooling rate*. When a piece of carbon steel is quenched at this rate or faster, a new structure is formed. The austenite is transformed into *martensite*, which is characterized by an angular needle-like structure and a very high hardness.

If carbon steel is subjected to a severe quench or to extremely rapid cooling, a small percentage of the austenite, instead of being transformed into martensite during the quenching operation, may be retained. Over a period of time, however, this remaining austenite tends to be gradually transformed into martensite even though the steel is not subjected to further heating or cooling. Martensite has a lower density than austenite, and such a change, or "aging" as it is called, often results in an appreciable increase in volume or "growth" and the setting up of new internal stresses in the steel.

**Steel Heat Treating Furnaces.**—Various types of furnaces heated by gas, oil, or electricity are used for the heat treatment of steel. These furnaces include the oven or box type in various modifications for "in-and-out" or for continuous loading and unloading; the retort type; the pit type; the pot type; and the salt-bath electrode type.

*Oven or Box Furnaces:* This type of furnace has a box or oven-shaped heating chamber. The "in-and-out" oven furnaces are loaded by hand or by a track-mounted car that, when rolled into the furnace, forms the bottom of the heating chamber. The car type is used where heavy or bulky pieces must be handled. Some oven-type furnaces are provided with a full muffle or a semimuffle, which is an enclosed refractory chamber into which the parts to be heated are placed. The full-muffle, being fully enclosed, prevents any flames or burning gases from coming in contact with the work and permits a special atmosphere to be used to protect or condition the work. The semimuffle, which is open at the top, protects the work from direct impingement of the flame although it does not shut off the work from the hot gases. In the direct-heat-type oven furnace, the work is open to the flame. In the electric oven furnace, a retort is provided when gas atmospheres are to be employed to confine the gas and prevent it from attacking the heating elements. Where muffles are used, they must be replaced periodically, and a greater amount of fuel is required than in a direct-heat type of oven furnace.

For continuous loading and unloading, there are several types of furnaces, such as rotary hearth car; roller-, furnace belt-, walking-beam, or pusher-conveyor; and a continuous-kiln-type through which track-mounted cars are run. In the continuous type of furnace, the work may pass through several zones that are maintained at different temperatures for preheating, heating, soaking, and cooling.

*Retort Furnace:* This is a vertical type of furnace provided with a cylindrical metal retort into which the parts to be heat treated are suspended either individually, if large enough, or in a container of some sort. The use of a retort permits special gas atmospheres to be employed for carburizing, nitriding, etc.

*Pit-Type Furnace:* This is a vertical furnace arranged for the loading of parts in a metal basket. The parts within the basket are heated by convection, and when the basket is lowered into place, it fits into the furnace chamber in such a way as to provide a dead-air space to prevent direct heating.

*Pot-Type Furnace:* This furnace is used for the immersion method of heat treating small parts. A cast-alloy pot is employed to hold a bath of molten lead or salt in which the parts are placed for heating.

*Salt Bath Electrode Furnace:* In this type of electric furnace, heating is accomplished by means of electrodes suspended directly in the salt bath. The patented grouping and design of electrodes provide an electromagnet action that results in an automatic stirring action. This stirring tends to produce an even temperature throughout the bath.

**Vacuum Furnace:** Vacuum heat treatment is a relatively new development in metallurgical processing, with a vacuum substituting for the more commonly used protective gas atmospheres. The most commonly used furnace is the "cold wall" type, consisting of a water-cooled vessel that is maintained near ambient temperature during operation. During quenching, the chamber is backfilled up to or above atmospheric pressure with an inert gas, which is circulated by an internal fan. When even faster cooling rates are needed, furnaces are available with capability for liquid quenching, performed in an isolated chamber.

**Fluidized-Bed Furnace:** Fluidized-bed techniques are not new; however, new furnace designs have extended the technology into the temperature ranges required for most common heat treatments. In fluidization, a bed of dry, finely divided particles, typically aluminum oxide, is made to behave like a liquid by feeding gas upward through the bed. An important characteristic of the bed is high-efficiency heat transfer. Applications include continuous or batch-type units for all general heat treatments.

**Physical Properties of Heat Treated Steels.**—Steels that have been "fully hardened" to the same hardness when quenched will have about the same tensile and yield strengths regardless of composition and alloying elements. When the hardness of such a steel is known, it is also possible to predict its reduction of area and tempering temperature. The accompanying figures illustrating these relationships have been prepared by the Society of Automotive Engineers.

Fig. 2 gives the range of Brinell Hardness Numbers (BHN) that could be expected for any particular tensile strength, or it may be used to determine the range of tensile strengths that would correspond to any particular hardness. Fig. 3 shows the relationship between the tensile strength, hardness, and the yield point. The solid line is the normal-expectancy curve. The dotted-line curves give the range of the variation of scatter of the plotted data. Fig. 4 shows the relationship that exists between the tensile strength (or hardness) and the reduction of area. The curve to the left represents the alloy steels and that on the right the carbon steels. Both are normal-expectancy curves and the extremities of the perpendicular lines that intersect them represent the variations from the normal-expectancy curves that may be caused by quality differences and by the magnitude of parasitic stresses induced by quenching. Fig. 5 shows the relationship between the hardness (or approximately equivalent tensile strength) and the tempering temperature. Three curves are given, one for fully hardened steels with a carbon content between 0.40 and 0.55 percent, one for fully hardened steels with a carbon content between 0.30 and 0.40 percent, and one for steels that are not fully hardened.

From Fig. 2, it can be seen that for a tensile strength of, say, 200,000 pounds per square inch (1379 MPa), the Brinell Hardness Number could range between 375 and 425. By taking 400 as the mean hardness value and using Fig. 5, it can be seen that the tempering temperature of fully hardened steels of 0.40 to 0.55 percent carbon content would be 990°F (532°C) and that of fully hardened steels of 0.30 to 0.40 percent carbon would be 870°F (466°C). This chart also shows that the tempering temperature for a steel not fully hardened would approach 520°F (271°C). A yield point of  $0.9 \times 200,000$ , or 180,000 pounds per square inch (1241 MPa) is indicated (Fig. 3) for the fully hardened steel with a tensile strength of 200,000 pounds per square inch. Most alloy steels of 200,000 pounds per square inch tensile strength would probably have a reduction in area of close to 44 percent (Fig. 4), but some would have values in the range of 35 to 53 percent. Carbon steels of the same tensile strength would probably have a reduction in area of close to 24 percent but could possibly range from 17 to 31 percent.

Fig. 3 and Fig. 4 represent steel in the quenched and tempered condition, and Fig. 2 represents steel in the hardened and tempered, as-rolled, annealed, and normalized conditions. These charts give a good general indication of mechanical properties; however, more exact information when required should be obtained from tests on samples of the individual heats of steel under consideration.

Fig. 5.

### Hardening

**Basic Steps in Hardening.**—The operation of hardening steel consists fundamentally of two steps. The first step is to heat the steel to some temperature above its transformation point (usually at least 100°F or 56°C above) so that it becomes entirely austenitic in structure. The second step is to quench the steel at some rate faster than the critical rate (which depends on the carbon content, the amounts of alloying elements present other than carbon, and the grain size of the austenite) to produce a martensitic structure. The hardness of a martensitic steel depends on its carbon content and ranges from about 460 BHN at

0.20 percent carbon to about 710 BHN above 0.50 carbon. In comparison, ferrite has a hardness of about 90 BHN, pearlite about 240 BHN, and cementite around 550 BHN.

**Critical Points of Decalescence and Recalescence.**—The critical or transformation point at which pearlite is transformed into austenite as it is being heated is also called the *decalescence point*. If the temperature of the steel was observed as it passed through the decalescence point, it would be noted that it would continue to absorb heat without appreciably rising in temperature, although the immediate surroundings were hotter than the steel. Similarly, the critical or transformation point at which austenite is transformed back into pearlite on cooling is called the *recalescence point*. When this point is reached, the steel will give out heat so that its temperature, instead of continuing to fall, will momentarily increase.

The recalescence point is lower than the decalescence point by anywhere from 85 to 215°F (47 to 119°C lower), and the lower of these points does not manifest itself unless the higher one has first been fully passed. These critical points have a direct relation to the hardening of steel. Unless a temperature sufficient to reach the decalescence point is obtained, so that the pearlite is changed into austenite, no hardening action can take place; and unless the steel is cooled suddenly before it reaches the recalescence point, thus preventing the changing back again from austenite to pearlite, no hardening can take place. The critical points vary for different kinds of steel and must be determined by tests. The variation in the critical points makes it necessary to heat different steels to different temperatures when hardening.

**Hardening Temperatures.**—The maximum temperature to which a steel is heated before quenching to harden it is called the hardening temperature. Hardening temperatures vary for different steels and different classes of service, although, in general, it may be said that the hardening temperature for any given steel is above the lower critical point of that steel.

Just how far above this point the hardening temperature lies for any particular steel depends on three factors: 1) the chemical composition of the steel; 2) the amount of excess ferrite (if the steel has less than 0.85 percent carbon content) or the amount of excess cementite (if the steel has more than 0.85 percent carbon content) that is to be dissolved in the austenite; and 3) the maximum grain size permitted, if desired.

The general range of full-hardening temperatures for carbon steels is shown in Fig. 5. This range is merely indicative of general practice and is not intended to represent absolute hardening temperature limits. It can be seen that for steels of less than 0.85 percent carbon content, the hardening range is above the upper critical point—that is, above the temperature at which all the excess ferrite has been dissolved in the austenite. On the other hand, for steels of more than 0.85 percent carbon content, the hardening range lies somewhat below the upper critical point. This indicates that in this hardening range, some of the excess cementite still remains undissolved in the austenite. If steel of more than 0.85 percent carbon content were heated above the upper critical point and then quenched, the resulting grain size would be excessively large.

At one time, it was considered desirable to heat steel only to the minimum temperature at which it would fully harden, one of the reasons being to avoid grain growth that takes place at higher temperature. It is now realized that no such rule as this can be applied generally since there are factors other than hardness that must be taken into consideration. For example, in many cases, toughness can be impaired by too low a temperature just as much as by too high a temperature. It is true, however, that excessive hardening temperatures result in warpage, distortion, increased scale, and decarburization.

**Hardening Temperatures for Carbon Tool Steels.**—The best hardening temperatures for any given tool steel are dependent on the type of tool and the intended class of service. Wherever possible, the specific recommendations of the tool steel manufacturer should be followed. General recommendations for hardening temperatures of carbon tool steels based on carbon content are as follows: For steel of 0.65 to 0.80 percent carbon content, 1450 to 1550°F (788 to 843°C); for steel of 0.80 to 0.95 percent carbon content, 1410 to

1460°F (766 to 793°C); for steel of 0.95 to 1.10 percent carbon content, 1390 to 1430°F (754 to 777°C); and for steels of 1.10 percent and over carbon content, 1380 to 1420°F (749 to 771°C). For a given hardening temperature range, the higher temperatures tend to produce deeper hardness penetration and increased compressional strength, whereas the lower temperatures tend to result in shallower hardness penetration but increased resistance to splitting or bursting stresses.

**Determining Hardening Temperatures.**—A hardening temperature can be specified directly, or it may be specified indirectly as a certain temperature rise above the lower critical point of the steel. Where the temperature is specified directly, a pyrometer of the type that indicates the furnace temperature or a pyrometer of the type that indicates the work temperature may be employed. If the pyrometer shows furnace temperature, care must be taken to allow sufficient time for the work to reach the furnace temperature after the pyrometer indicates that the required hardening temperature has been attained. If the pyrometer indicates work temperature, then, where the workpiece is large, time must be allowed for the interior of the work to reach the temperature of the surface, which is the temperature indicated by the pyrometer.

Where the hardening temperature is specified as a given temperature rise above the critical point of the steel, a pyrometer that indicates the temperature of the work should be used. The critical point, as well as the given temperature rise, can be more accurately determined with this type of pyrometer. As the work is heated, its temperature, as indicated by the pyrometer, rises steadily until the lower critical or decalcence point of the steel is reached. At this point, the temperature of the work ceases to rise and the pyrometer indicating or recording pointer remains stationary or fluctuates slightly. After a certain elapsed period, depending on the heat input rate, the internal changes in structure of the steel that take place at the lower critical point are completed and the temperature of the work again begins to rise. A small fluctuation in temperature may occur in the interval during which structural changes are taking place, so for uniform practice, the critical point may be considered as the temperature at which the pointer first becomes stationary.

**Heating Steel in Liquid Baths.**—The liquid bath commonly used for heating steel tools preparatory to hardening are molten lead, sodium cyanide, barium chloride, a mixture of barium and potassium chloride, and other metallic salts. The molten substance is retained in a crucible or pot, and the heat required may be obtained from gas, oil, or electricity. The principal advantages of heating baths are as follows: No part of the work can be heated to a temperature above that of the bath; the temperature can be easily maintained at whatever degree has proved, in practice, to give the best results; the submerged steel can be heated uniformly; and the finished surfaces are protected against oxidation.

**Salt Baths.**—Molten baths of various salt mixtures or compounds are used extensively for heat-treating operations, such as hardening and tempering; they are also utilized for annealing ferrous and nonferrous metals. Commercial salt-bath mixtures are available that meet a wide range of temperature and other metallurgical requirements. For example, there are neutral baths for heating tool and die steels without carburizing the surfaces; baths for carburizing the surfaces of low-carbon steel parts; baths adapted for the usual tempering temperatures of, say, 300 to 1100°F (approx. 150 to 595°C); and baths that may be heated to temperatures up to approximately 2400°F (1315°C) for hardening high-speed steels. Salt baths are also adapted for local or selective hardening, the type of bath being selected to suit the requirements. For example, a neutral bath may be used for annealing the ends of tubing or other parts, or an activated cyanide bath for carburizing the ends of shafts or other parts. Surfaces that are not to be carburized are protected by copper plating. When the work is immersed, the unplated surfaces are subjected to the carburizing action.

Baths may consist of a mixture of sodium, potassium, barium, and calcium chlorides or nitrates of sodium, potassium, barium, and calcium in varying proportions, to which sodium carbonate and sodium cyanide are sometimes added to prevent decarburization. Various proportions of these salts provide baths of different properties. Potassium

cyanide is seldom used, as sodium cyanide costs less. The specific gravity of a salt bath is not as high as that of a lead bath; consequently, the work may be suspended in a salt bath and does not have to be held below the surface as in a lead bath.

**The Lead Bath.**—The lead bath is extensively used but is not adapted to the high temperatures required for hardening high-speed steel, as it begins to vaporize at about 1190°F (645°C). As the temperature increases, the lead volatilizes and gives off poisonous vapors; hence, lead furnaces should be equipped with hoods to carry away the fumes. Lead baths are generally used for temperatures below 1500 or 1600°F (815 or 870°C). They are often employed for heating small pieces that must be hardened in quantities. It is important to use pure lead that is free from sulfur. The work should be preheated before plunging it into the molten lead.

**Defects in Hardening.**—Uneven heating is the cause of most defects in hardening. Cracks of a circular form, from the corners or edges of a tool, indicate uneven heating in hardening. Cracks of a vertical nature and dark-colored fissures indicate that the steel has been burned and should be put on the scrap heap. Tools that have hard and soft places have been either unevenly heated, unevenly cooled, or “soaked,” a term used to indicate prolonged heating. A tool not thoroughly moved about in the hardening fluid will show hard and soft places, and have a tendency to crack. Tools that are hardened by dropping them to the bottom of the tank sometimes have soft places, owing to contact with the floor or sides.

**Scale on Hardened Steel.**—The formation of scale on the surface of hardened steel is due to the contact of oxygen with the heated steel; hence, to prevent scale, the heated steel must not be exposed to the action of the air. When using an open heating furnace, the flame should be so regulated that it is not visible in the heating chamber. The heated steel should be exposed to the air as little as possible when transferred from the furnace to the quenching bath. An old method of preventing scale and retaining a fine finish on dies used in jewelry manufacture, small taps, etc., is as follows: Fill the die impression with powdered boracic acid and place near the fire until the acid melts; then add a little more acid to ensure all the surfaces are covered. The die is then hardened in the usual way. If the boracic acid does not come off entirely in the quenching bath, immerse the work in boiling water. Dies hardened by this method are said to be as durable as those heated without the acid.

**Hardening or Quenching Baths.**—The purpose of a quenching bath is to remove heat from the steel being hardened at a rate that is faster than the critical cooling rate. Generally speaking, the more rapid the rate of heat extraction above the cooling rate, the higher will be the resulting hardness. To obtain the different rates of cooling required by different classes of work, baths of various kinds are used. These include plain or fresh water, brine, caustic soda solutions, oils of various classes, oil-water emulsions, baths of molten salt or lead for high-speed steels, and air cooling for some high-speed steel tools when a slow rate of cooling is required. To minimize distortion and cracking where such tendencies are present, without sacrificing depth-of-hardness penetration, a quenching medium should be selected that will cool rapidly at the higher temperatures and more slowly at the lower temperatures, that is below 750°F (400°C). Oil quenches in general meet this requirement.

*Oil Quenching Baths:* Oil is used very extensively as a quenching medium, as it results in a good proportion of hardness, toughness, and freedom from warp when used with standard steels. Oil baths are used extensively for alloy steels. Various kinds of oils are employed, such as prepared mineral oils and vegetable, animal, and fish oils, either singly or in combination. Prepared mineral quenching oils are widely used because they have good quenching characteristics, are chemically stable, do not have an objectionable odor, and are relatively inexpensive. Special compounded oils of the soluble type are used in many plants instead of such oils as fish oil, linseed oil, cottonseed oil, etc. The soluble properties enable the oil to form an emulsion with water.

Oil cools steel at a slower rate than water, but the rate is fast enough for alloy steel. Oils have different cooling rates, however, and this rate may vary through the initial and final stages of the quenching operation. Faster cooling in the initial stage and slower cooling

at lower temperatures are preferable because there is less danger of cracking the steel. The temperature of quenching oil baths should range ordinarily between 90 and 130°F (32 and 55°C). A fairly constant temperature may be maintained either by circulating the oil through cooling coils or by using a tank provided with a cold-water jacket.

A good quenching oil should possess a flash and fire point sufficiently high to be safe under the conditions used. 350°F (175°C) should be about the minimum point. The specific heat of the oil regulates the hardness and toughness of the quenched steel; and the greater the specific heat, the higher will be the hardness produced. Specific heats of quenching oils vary from 0.20 to 0.75, the specific heats of fish, animal, and vegetable oils usually being from 0.2 to 0.4, and of soluble and mineral oils from 0.5 to 0.7. The efficient temperature range for quenching oil is from 90 to 140°F (32 to 60°C).

**Quenching in Water.**—Many carbon tool steels are hardened by immersing them in a bath of fresh water, but water is not an ideal quenching medium. Contact between the water and work and the cooling of the hot steel are impaired by the formation of gas bubbles or an insulating vapor film, especially in holes, cavities, or pockets. The results are uneven cooling and sometimes excessive strains, which may cause the tool to crack; in fact, there is greater danger of cracking in a fresh-water bath than in one containing salt water or brine.

In order to secure more even cooling and reduce the danger of cracking, either rock salt (8 or 9 percent) or caustic soda (3 to 5 percent) may be added to the bath to eliminate or prevent the formation of a vapor film or gas pockets, thus promoting rapid early cooling. Brine is commonly used and  $\frac{3}{4}$  pound of rock salt per gallon (90 gm per liter) of water is equivalent to about 8 percent of salt. Brine is not inherently a more severe or drastic quenching medium than plain water, although it may seem to be because the brine makes better contact with the heated steel, and cooling is more effective. In still-bath quenching, a slow up-and-down movement of the tool is preferable to a violent swishing around.

The temperature of water-base quenching baths should preferably be kept around 70°F (21°C), but up to 90 or 100°F (32 to 38°C) is a safe range. The temperature of the hardening bath has a great deal to do with the hardness obtained. The higher the temperature of the quenching water, the more nearly does its effect approach that of oil; and if boiling water is used for quenching, it will have an effect even more gentle than that of oil — in fact, it would leave the steel nearly soft. Parts of irregular shape are sometimes quenched in a water bath that has been warmed somewhat to prevent sudden cooling and cracking.

When water is used, it should be “soft” because unsatisfactory results will be obtained with “hard” water. Any contamination of water-base quenching liquids by soap tends to decrease their rate of cooling. A water bath having 1 or 2 inches (2.5 to 5 cm) of oil on the top is sometimes employed to advantage for quenching tools made of high-carbon steel, as the oil through which the work first passes reduces the sudden quenching action of the water.

The bath should be amply large to dissipate the heat rapidly, and the temperature should be kept about constant so that successive pieces will be cooled at the same rate. Irregularly shaped parts should be immersed so that the heaviest or thickest section enters the bath first. After immersion, the part to be hardened should be agitated in the bath; the agitation reduces the tendency of the formation of a vapor coating on certain surfaces, and a more uniform rate of cooling is obtained. The work should never be dropped to the bottom of the bath until quite cool.

*Flush or Local Quenching by Pressure-Spraying:* When dies for cold heading, drawing, extruding, etc., or other tools, require a hard working surface and a relatively soft but tough body, the quenching may be done by spraying water under pressure against the interior or other surfaces to be hardened. Special spraying fixtures are used to hold the tool and apply the spray where the hardening is required. The pressure spray prevents the formation of gas pockets previously referred to in connection with the fresh-water quenching bath; hence, fresh water is effective for flush quenching and there is no advantage in using brine.

**Quenching in Molten Salt Bath.**—A molten salt bath may be used in preference to oil for quenching high-speed steel. The object in using a liquid salt bath for quenching (instead of an oil bath) is to obtain maximum hardness with minimum cooling stresses and distortion that might result in cracking expensive tools, especially if there are irregular sections. The temperature of the quenching bath may be around 1100 or 1200°F (595 to 650°C). Quenching is followed by cooling to room temperature and then the tool is tempered or drawn in a bath having a temperature range of 950 to 1100°F (510 to 593°C). In many cases, the tempering temperature is about 1050°F (566°C).

**Tanks for Quenching Baths.**—The main point to be considered in a quenching bath is to keep it at a uniform temperature so that successive pieces quenched will be subjected to the same heat treatment. The next consideration is to keep the bath agitated so that it will not be of different temperatures in different places; if thoroughly agitated and kept in motion, as is the case with the bath shown in Fig. 6, it is not even necessary to keep the pieces in motion in the bath, as steam will not be likely to form around the pieces quenched. Experience has proved that if a piece is held still in a thoroughly agitated bath, it will come out much straighter than if it has been moved around in an unagitated bath, an important consideration, especially when hardening long pieces. It is, besides, no easy matter to keep heavy and long pieces in motion unless by mechanical means.

Fig. 6 illustrates a water or brine tank for quenching baths. Water is forced by a pump or other means through the supply pipe into the intermediate space between the outer and inner tank. From the intermediate space, it is forced into the inner tank through holes as indicated. The water returns to the storage tank by overflowing from the inner tank into the outer one and then through the overflow pipe as indicated. Fig. 8 illustrates another water or brine tank of a more common type. In this case, the water or brine is pumped from the storage tank and continuously returned to it. If the storage tank contains a large volume of water, there is no need for a special means for cooling. Otherwise, arrangements must be made for cooling the water after it has passed through the tank. The bath is agitated by the force with which the water is pumped into it. The holes at A are drilled at an angle, so as to throw the water toward the center of the tank. Fig. 7 shows an oil-quenching tank in which water is circulated in an outer surrounding tank to keep the oil bath cool. Air is forced into the oil bath to keep it agitated. Fig. 9 shows the ordinary type of quenching tank cooled by water forced through a coil of pipe. This arrangement can be used for oil, water, or brine. Fig. 10 shows a similar type of quenching tank, but with two coils of pipe. Water flows through one of these and steam through the other. By these means, it is possible to keep the bath at a constant temperature.

Fig. 6.

Fig. 7.

**Interrupted Quenching.**—*Austempering, martempering, and isothermal quenching* are three methods of interrupted quenching that have been developed to obtain greater toughness and ductility for given hardnesses and to avoid the difficulties of quench cracks, internal stresses, and warpage, frequently experienced when the conventional method of quenching steel directly and rapidly from above the transformation point to atmospheric temperature is employed. In each of these three methods, quenching is begun when the work has reached some temperature above the transformation point and is conducted at a rate faster than the critical rate. The rapid cooling of the steel is interrupted, however, at some temperature above that at which martensite begins to form. The three methods differ in the temperature range at which interruption of the rapid quench takes place, the length of time that the steel is held at this temperature, and whether the subsequent cooling to atmospheric temperature is rapid or slow, and is or is not preceded by a tempering operation.

One of the reasons for maintaining the steel at a constant temperature for a definite period of time is to permit the inside sections of the piece to reach the same temperature as the outer sections so that when transformation of the structure does take place, it will occur at about the same rate and period of time throughout the piece. In order to maintain the constant temperature required in interrupted quenching, a quenching arrangement for absorbing and dissipating a large quantity of heat without increase in temperature is needed. Molten salt baths equipped for water spray or air cooling around the exterior of the bath container have been used for this purpose.

*Austempering:* This is a heat-treating process in which steels are quenched in a bath maintained at some constant temperature in the range of 350 to 800°F (177 to 427°C), depending on the analysis of the steel and the characteristics to be obtained. On immersion in the quenching bath, the steel is cooled more rapidly than the critical quenching rate. When the temperature of the steel reaches that of the bath, however, the quenching action is interrupted. If the steel is now held at this temperature for a predetermined length of time, say, from 10 to 60 minutes, the austenitic structure of the steel is gradually changed into a new structure, called *bainite*. The structure of bainite is acicular (needlelike) and resembles that of tempered martensite such as is usually obtained by quenching in the usual manner to atmospheric temperature and tempering at 400°F (204°C) or higher.

Hardnesses ranging up to 60 RC (Rockwell C scale), depending on the carbon and alloy content of the steel, are obtainable and compare favorably with those obtained for

the respective steels by a conventional quench and tempering to above 400°F (204°C). Much greater toughness and ductility are obtained in an austempered piece, however, as compared with a similar piece quenched and tempered in the usual manner.

Two factors are important in austempering. First, the steel must be quenched rapidly enough to the specified subtransformation temperature to avoid any formation of pearlite, and, second, it must be held at this temperature until the transformation from austenite to bainite is completed. Time and temperature transformation curves (called S-curves because of their shape) have been developed for different steels, and these curves provide important data governing the conduct of austempering as well as the other interrupted quenching methods.

Austempering has been applied chiefly to steels having 0.60 percent or more carbon content with or without additional low-alloy content, and to pieces of small diameter or section, usually under 1 inch (2.5 cm), but varying with the composition of the steel. Case-hardened parts may also be austempered.

**Martempering:** In this process the steel is first rapidly quenched from some temperature above the transformation point down to some temperature (usually about 400°F or 204°C) just above that at which martensite begins to form. It is then held at this temperature for a length of time sufficient to equalize the temperature throughout the part, after which it is removed and cooled in air. As the temperature of the steel drops below the transformation point, martensite begins to form in a matrix of austenite at a fairly uniform rate throughout the piece. The soft austenite acts as a cushion to absorb some of the stresses which develop as the martensite is formed. The difficulties presented by quench cracks, internal stresses, and dimensional changes are largely avoided; thus a structure of high hardness can be obtained. If greater toughness and ductility are required, conventional tempering may follow. In general, heavier sections can be hardened more easily by the martempering process than by the austempering process. The martempering process is especially suited to the higher-alloyed steels.

**Isothermal Quenching:** This process resembles austempering in that the steel is first rapidly quenched from above the transformation point down to a temperature that is above that at which martensite begins to form and is held at this temperature until the austenite is completely transformed into bainite. The constant temperature to which the piece is quenched and then maintained is usually 450°F (232°C) or above. The process differs from austempering in that, after transformation to a bainite structure has been completed, the steel is immersed in another bath and is brought up to some higher temperature, depending on the characteristics desired. It is maintained at that temperature for a definite period of time, followed by cooling in air. Thus, tempering to obtain the desired toughness or ductility takes place immediately after the structure of the steel has changed to bainite and before it is cooled to atmospheric temperature.

**Laser and Electron-Beam Surface Hardening.**—Industrial lasers and electron-beam equipment are now available for surface hardening of steels, a process referred to as *laser peening*. The laser and electron beams can generate intense energy fluxes and steep temperature profiles in the workpiece so that external quench media are not needed. This self-quenching is due to a cold interior with sufficient mass acting as a large heat sink to rapidly cool the hot surface by conducting heat to the interior of a part. The laser beam is a beam of light and does not require a vacuum for operation. The electron beam is a stream of electrons, and processing usually takes place in a vacuum chamber or envelope. Both processes may normally be applied to finished machined or ground surfaces because little distortion results.

### Tempering

The object of *tempering* or *drawing* is to reduce the brittleness in hardened steel and to remove the internal strains caused by the sudden cooling in the quenching bath. The tempering process consists in heating the steel by various means to a certain temperature and then cooling it. When steel is in a fully hardened condition, its structure consists

largely of *martensite*. On reheating to a temperature of about 300 to 750°F (150 to 400°C), a softer and tougher structure known as *troostite* is formed. If the steel is reheated to a temperature of 750 to 1290°F (400 to 700°C), a structure known as *sorbite* is formed that has somewhat less strength than troostite but much greater ductility.

**Tempering Temperatures.**—If steel is heated in an oxidizing atmosphere, a film of oxide forms on the surface that changes color as the temperature increases. These oxide colors (see Table 1) have been used extensively in the past as a means of gaging the correct amount of temper; but, since these colors are affected to some extent by the composition of the metal, the method is not dependable.

**Table 1. Temperatures as Indicated by the Color of Plain Carbon Steel**

Degrees		Color of Steel	Degrees		Color of Steel
Fahrenheit	Centigrade		Fahrenheit	Centigrade	
430	221.1	Very pale yellow	510	265.6	Spotted red-brown
440	226.7	Light yellow	520	271.1	Brown-purple
450	232.2	Pale straw-yellow	530	276.7	Light purple
460	237.8	Straw-yellow	540	282.2	Full purple
470	243.3	Deep straw-yellow	550	287.8	Dark purple
480	248.9	Dark yellow	560	293.3	Full blue
490	254.4	Yellow-brown	570	298.9	Dark blue
500	260.0	Brown-yellow	640	337.8	Light blue

The availability of reliable pyrometers in combination with tempering baths of oil, salt, or lead makes it possible to heat the work uniformly and to a given temperature within close limits.

Suggested temperatures for tempering various tools are given in Table 2.

**Table 2. Tempering Temperatures for Various Plain Carbon Steel Tools**

Degrees F	Degrees C	Class of Tool
495 to 500	257 to 260	Taps, ½ inch (1.27 cm) or over, for use on automatic screw machines
495 to 500	257 to 260	Nut taps, ½ inch (1.27 cm) and under
515 to 520	268 to 271	Taps, ¼ inch (0.635 cm) and under, for use on automatic screw machines
525 to 530	274 to 277	Thread dies to cut thread close to shoulder
500 to 510	260 to 266	Thread dies for general work
495	257	Thread dies for tool steel or steel tube
525 to 540	274 to 282	Dies for bolt threader threading to shoulder
460 to 470	238 to 243	Thread rolling dies
430 to 435	221 to 224	Hollow mills (solid type) for roughing on automatic screw machines
485	252	Knurls
450	232	Twist drills for hard service
450	232	Centering tools for automatic screw machines
430	221	Forming tools for automatic screw machines
430 to 435	221 to 224	Cut-off tools for automatic screw machines
440 to 450	227 to 232	Profile cutters for milling machines
430	221	Formed milling cutters
435 to 440	224 to 227	Milling cutters
430 to 440	221 to 227	Reamers
460	238	Counterbores and countersinks
480	249	Cutters for tube- or pipe-cutting machines
460 to 520	238 to 271	Snaps for pneumatic hammers — harden full length, temper to 460°F (238°C), then bring point to 520°F (271°C)

**Tempering in Oil.**—Oil baths are extensively used for tempering tools (especially in quantity), the work being immersed in oil heated to the required temperature, as indicated by a thermometer. It is important that the oil have a uniform temperature throughout and that the work be immersed long enough to acquire this temperature. Cold steel should not be plunged into a bath heated for tempering, owing to the danger of cracking. The steel should either be preheated to about 300°F (150°C) before placing it in the bath or the bath should be at a comparatively low temperature before the steel is immersed, and then reheated to the required degree. A temperature of from 650 to 700°F (343 to 371°C) can be obtained with heavy tempering oils; for higher temperatures, either a bath of nitrate salts or a lead bath may be used.

In tempering, the best method is to immerse the pieces to be tempered before starting to heat the oil so that they are heated with the oil. After the tempered pieces are taken out of the oil bath, they should be immediately dipped in a tank of caustic soda and, after that, in a tank of hot water. This will remove all oil that might adhere to the tools. The following tempering oil has given satisfactory results: mineral oil, 94 percent; saponifiable oil, 6 percent; specific gravity, 0.920; flash point, 550°F (288°C); fire test, 625°F (329°C).

**Tempering in Salt Baths.**—Molten salt baths may be used for tempering or drawing operations. Nitrate baths are particularly adapted for the usual drawing temperature range of, say, 300 to 1100°F (150 to 595°C). Tempering in an oil bath usually is limited to temperatures of 500 to 600°F (260 to 315°C), and some heat-treating specialists recommend the use of a salt bath for temperatures above 350 or 400°F (175 or 205°C), as it is considered more efficient and economical. Tempering in a bath (salt or oil) has several advantages, such as ease in controlling the temperature range and maintenance of a uniform temperature. The work is also heated much more rapidly in a molten bath. A gas- or oil-fired muffle or semimuffle furnace may be used for tempering, but a salt bath or oil bath is preferable. A salt bath is recommended for tempering high-speed steel, although furnaces may also be used. The bath or furnace temperature should be increased gradually, say, from 300 to 400°F (150 to 205°C) up to the tempering temperature, which may range from 1050 to 1150°F (565 to 620°C) for high-speed steel.

**Tempering in a Lead Bath.**—The lead bath is commonly used for heating steel in connection with tempering, as well as for hardening. The bath is first heated to the temperature at which the steel should be tempered; the preheated work is then placed in the bath long enough to acquire this temperature, after which it is removed and cooled. As the melting temperature of pure lead is about 620°F (327°C), tin is commonly added to lower the temperature sufficiently for tempering. Reductions in temperature can be obtained by varying the proportions of lead and tin, as shown in Table 3.

**Table 3. Temperatures of Lead Bath Alloys**

Parts Lead	Parts Tin	Melting Temperature		Parts Lead	Parts Tin	Melting Temperature		Parts Lead	Parts Tin	Melting Temperature	
		Deg. F	Deg. C			Deg. F	Deg. C			Deg. F	Deg. C
200	8	560	293	39	8	510	266	19	8	460	238
100	8	550	288	33	8	500	260	17	8	450	232
75	8	540	282	28	8	490	254	16	8	440	227
60	8	530	277	24	8	480	249	15	8	430	221
48	8	520	271	21	8	470	243	14	8	420	216

**To Prevent Lead from Sticking to Steel.**—To prevent hot lead from sticking to parts heated in it, mix common whiting (calcium carbonate) with wood alcohol and paint the part that is to be heated. Water can be used instead of alcohol, but, in that case, the paint must be thoroughly dry, as otherwise the moisture will cause the lead to “fly.” Another method is to make a thick paste according to the following formula: pulverized charred leather, 1 pound; fine wheat flour, 1½ pounds; fine table salt, 2 pounds. Coat the tool with

this paste and heat slowly until dry, then proceed to harden. Still another method is to heat the work to a blue color, or about 600°F (316°C), and then dip it in a strong solution of salt water prior to heating in the lead bath. The lead is sometimes removed from parts having fine projections or teeth, by using a stiff brush just before immersing in the cooling bath. Removal of lead is necessary to prevent the formation of soft spots.

**Tempering in Sand.**—The sand bath is used for tempering certain classes of work. One method is to deposit the sand on an iron plate or in a shallow box that has burners beneath it. With this method of tempering, tools such as boiler punches, etc., can be given a varying temper by placing them endwise in the sand. As the temperature of the sand bath is higher toward the bottom, a tool can be so placed that the color of the lower end will become a deep dark blue when the middle portion is a very dark straw, and the working end or top a light straw color, the hardness gradually increasing from the bottom up.

**Double Tempering.**—In tempering high-speed steel tools, it is common practice to repeat the tempering operation or “double temper” the steel. Double tempering is done by heating the steel to tempering temperature, say 1050°F (566°C), and holding it at that temperature for 2 hours. It is then cooled to room temperature, reheated to the same temperature for another two-hour period, and again cooled to room temperature. After the first tempering operation, some untempered martensite remains in the steel. This martensite is not only tempered by a second tempering operation but is relieved of internal stresses, thus improving the steel for service conditions. The hardening temperature for the higher-alloy steels may affect the hardness after tempering. For example, molybdenum high-speed steel heated to 2100°F (1149°C) had a 61 RC (Rockwell C scale) after tempering, whereas a temperature of 2250°F (1232°C) resulted in hardness of 64.5 RC after tempering.

### Annealing, Spheroidizing, and Normalizing

Annealing of steel is a heat-treating process in which the steel is heated to some elevated temperature, usually in or near the critical range, is held at this temperature for some period of time, and is then cooled, usually at a slow rate. Spheroidizing and normalizing may be considered as special cases of annealing.

The *full annealing* of carbon steel consists in heating it slightly above the *upper* critical point for hypoeutectoid steels (steels of less than 0.85 percent carbon content) and slightly above the *lower* critical point for hypereutectoid steels (steels of more than 0.85 percent carbon content), holding it at this temperature until it is uniformly heated and then slowly cooling it to 1000°F (538°C) or below. The resulting structure is layerlike, or lamellar, in character due to the pearlite that is formed during the slow cooling.

Annealing is employed 1) to soften steel for machining, cutting, stamping, etc., or for some particular service; 2) to alter ductility, toughness, electrical or magnetic characteristics or other physical properties; 3) to refine the crystal structure; 4) to produce grain re-orientation; and 5) to relieve stresses and hardness resulting from cold-working.

The *spheroidizing* of steel, according to the American Society of Metals, is “any process of heating and cooling that produces a rounded or globular form of carbide.” High-carbon steels are spheroidized to improve their machinability especially in continuous cutting operations, such as are performed by lathes and screw machines. In low-carbon steels, spheroidizing may be employed to meet certain strength requirements before subsequent heat treatment. Spheroidizing also tends to increase resistance to abrasion.

The *normalizing* of steel consists in heating it to some temperature above that used for annealing, usually about 100°F (56°C) above the upper critical range, and then cooling it in still air at room temperature. Normalizing is intended to put the steel into a uniform, unstressed condition of proper grain size and refinement so that it will properly respond to further heat treatments. It is particularly important in the case of forgings that are to be later heat treated. Normalizing may or may not (depending on the composition) leave steel in a sufficiently soft state for machining with available tools. Annealing for machinability

is often preceded by normalizing, and the combined treatment—frequently called a *double anneal*—produces a better result than a simple anneal.

**Annealing Practice.**—For carbon steels, the following annealing temperatures are recommended by the American Society for Testing and Materials:

Percent Carbon	Annealing Temperature	
	°F	°C
less than 0.12%	1600 to 1700	871 to 927
0.12 to 0.29%	1550 to 1600	843 to 871
0.30 to 0.49%	1500 to 1550	816 to 843
0.50 to 1.00%	1450 to 1500	788 to 816

Slightly lower temperatures are satisfactory for steels having more than 0.75 percent manganese content. Heating should be uniform to avoid the formation of additional stresses. In the case of large workpieces, the heating should be slow enough so that the temperature of the interior does not lag too far behind that of the surface.

It has been found that in annealing steel, the higher the temperature to which it is heated to produce an austenitic structure, the greater the tendency of the structure to become lamellar (pearlitic) in cooling. On the other hand, the closer the austenitizing temperature to the critical temperature, the greater is the tendency of the annealed steel to become spheroidal.

*Rate of Cooling:* After the steel is heated to some temperature within the annealing range, it should be cooled slowly enough to permit the development of the desired softness and ductility. In general, the slower the cooling rate, the greater the resulting softness and ductility. Steel of a high-carbon content should be cooled more slowly than steel of a low-carbon content; and the higher the alloy content, the slower is the cooling rate usually required. Where extreme softness and ductility are not required, the steel may be cooled in the annealing furnace to some temperature well below the critical point, say, to about 1000°F (538°C) and then removed and cooled in air.

**Annealing by Constant-Temperature Transformation.**—It has been found that steel that has been heated above the critical point so that it has an austenitic structure can be transformed into a lamellar (pearlitic) or a spheroidal structure by holding it for a definite period of time at some constant subcritical temperature. In other words, it is feasible to anneal steel by means of a constant-temperature transformation as well as by the conventional continuous cooling method. When the constant-temperature transformation method is employed, the steel, after being heated to some temperature above the critical and held at this temperature until it is austenitized, is cooled as rapidly as feasible to some relatively high subcritical transformation temperature. This temperature selection is governed by the desired microstructure and hardness required, and is taken from a transformation time and temperature curve (often called a TTT curve). As drawn for a particular steel, such a curve shows the length of time required to transform that steel from an austenitic state at various subcritical temperatures. After being held at the selected sub-critical temperature for the required length of time, the steel is cooled to room temperature — again, as rapidly as feasible. This rapid cooling down to the selected transformation temperature and then down to room temperature has a negligible effect on the structure of the steel and often produces a considerable time saving over the conventional slow cooling method of annealing.

The softest condition in steel can be developed by heating it to a temperature usually less than 100°F (56°C) above the lower critical point and then cooling it to some temperature, usually less than 100 degrees (56°C), below the critical point, where it is held until the transformation is completed. Certain steels require a very lengthy period of time for transformation of the austenite when held at a constant temperature within this range. For such steels, a practical procedure is to allow most of the transformation to take place in this temperature range where a soft product is formed and then to finish the transformation at a lower temperature where the time for the completion of the transformation is short.

**Spheroidizing Practice.**—A common method of spheroidizing steel consists in heating it to or slightly below the lower critical point, holding it at this temperature for a period of time, and then cooling it slowly to about 1000°F (538°C) or below. The length of time for which the steel is held at the spheroidizing temperature largely governs the degree of spheroidization. High-carbon steel may be spheroidized by subjecting it to a temperature that alternately rises and falls between a point within and a point without the critical range. Tool steel may be spheroidized by heating to a temperature slightly above the critical range and then, after being held at this temperature for a period of time, cooling without removal from the furnace.

**Normalizing Practice.**—When using the lower-carbon steels, simple normalizing is often sufficient to place the steel in its best condition for machining and will lessen distortion in carburizing or hardening. In the medium- and higher-carbon steels, combined normalizing and annealing constitutes the best practice. For unimportant parts, the normalizing may be omitted entirely or annealing may be practiced only when the steel is otherwise difficult to machine. Both processes are recommended in the following heat treatments (for SAE steels) as representing the best metallurgical practice. The temperatures recommended for normalizing and annealing have been made indefinite in many instances because of the many different types of furnaces used in various plants and the difference in results desired.

### Case Hardening

In order to harden low-carbon steel, it is necessary to increase the carbon content of the surface of the steel so that a thin outer “case” can be hardened by heating the steel to the hardening temperature and then quenching it. The process, therefore, involves two separate operations. The first is the *carburizing* operation for impregnating the outer surface with sufficient carbon, and the second operation is that of heat treating the carburized parts so as to obtain a hard outer case and, at the same time, give the “core” the required physical properties. The term “case hardening” is ordinarily used to indicate the complete process of carburizing and hardening.

**Carburization.**—Carburization is the result of heating iron or steel to a temperature below its melting point in the presence of a solid, liquid, or gaseous material that decomposes so as to liberate carbon when heated to the temperature used. In this way, it is possible to obtain, by the gradual penetration, diffusion, or absorption of the carbon by the steel, a “zone” or “case” of higher-carbon content at the outer surfaces than that of the original object. When a carburized object is rapidly cooled or quenched in water, oil, brine, etc., from the proper temperature, this case becomes hard, leaving the inside of the piece soft but of great toughness.

**Use of Carbonaceous Mixtures.**—When carburizing materials of the solid class are used, the case-hardening process consists in packing steel articles in metal boxes or pots, with a carbonaceous compound surrounding the steel objects. The boxes or pots are sealed and placed in a carburizing oven or furnace maintained usually at a temperature of from about 1650 to 1700°F (899 to 927°C) for a length of time depending on the extent of the carburizing action desired. The carbon from the carburizing compound will then be absorbed by the steel on the surfaces desired, and the low-carbon steel is converted into high-carbon steel at these portions. The internal sections and the insulated parts of the object retain practically their original low-carbon content. The result is a steel of a dual structure, a high-carbon and a low-carbon steel in the same piece. The carburized steel may now be heat treated by heating and quenching, in much the same way as high-carbon steel is hardened, in order to develop the properties of hardness and toughness; but, as the steel is, in reality, two steels in one, one high-carbon and one low-carbon, the correct heat treatment after carburizing includes two distinct processes, one suitable for the high-carbon portion or the “case,” as it is generally called, and one suitable for the low-carbon portion or core. The method of heat treatment varies according to the kind of steel used.

Usually, an initial heating and slow cooling is followed by reheating to 1400–1450°F (760 to 788°C), quenching in oil or water, and a final tempering. More definite information is given in the following section on SAE steels.

**Carburizers:** There are many commercial carburizers on the market in which the materials used as the generator may be hard and soft wood charcoal, animal charcoal, coke, coal, beans and nuts, bone and leather, or various combinations of these. The energizers may be barium, cyanogen, and ammonium compounds, various salts, soda ash, or lime and oil hydrocarbons.

**Pack-Hardening.**—When cutting tools, gages, and other parts made from high-carbon steels are heated for hardening while packed in some carbonaceous material in order to protect delicate edges, corners, or finished surfaces, the process is usually known as pack-hardening. Thus, the purpose is to protect the work, prevent scale formation, ensure uniform heating, and minimize the danger of cracking and warpage. The work is packed, as in carburizing, and in the same type of receptacle. Common hardwood charcoal often is used, especially if it has had an initial heating to eliminate shrinkage and discharge its more impure gases. The lowest temperature required for hardening should be employed for pack-hardening—usually 1400 to 1450°F (760 to 788°C) for carbon steels. Pack-hardening has also been applied to high-speed steels, but modern developments in heat-treating salts have made it possible to harden high-speed steel without decarburization, injury to sharp edges, or marring the finished surfaces. See *Salt Baths* on page 471.

**Cyanide Hardening.**—When low-carbon steel requires a very hard outer surface but does not need high shock-resisting qualities, the cyanide-hardening process may be employed to produce what is known as superficial hardness. This superficial hardening is the result of carburizing a very thin outer skin (which may be only a few thousandths inch thick) by immersing the steel in a bath containing sodium cyanide. The temperatures usually vary from 1450 to 1650°F (788 to 899°C), and the percentage of sodium cyanide in the bath extends over a wide range, depending on the steel used and properties required.

**Nitriding Process.**—Nitriding is a process for surface hardening certain alloy steels by heating the steel in an atmosphere of nitrogen (ammonia gas) at approximately 950°F (510°C). The steel is then cooled slowly. Finish machined surfaces hardened by nitriding are subject to minimum distortion. The physical properties, such as toughness, high impact strength, etc., can be imparted to the core by previous heat treatments and are unaffected by drawing temperatures up to 950°F (510°C). The “Nitalloy” steels suitable for this process may be readily machined in the heat-treated as well as in the annealed state, and they forge as easily as alloy steels of the same carbon content. Certain heat treatments must be applied prior to nitriding, the first being annealing to relieve rolling, forging, or machining strains. Parts or sections not requiring heat treating should be machined or ground to the exact dimensions required. Close tolerances must be maintained in finish machining, but allowances for growth due to adsorption of nitrogen should be made, and this usually amounts to about 0.0005 inch (0.0127 mm) for a case depth of 0.02 inch (0.508 mm). Parts requiring heat treatment for definite physical properties are forged or cut from annealed stock, heat treated for the desired physical properties, rough machined, normalized, and finish machined. If quenched and drawn parts are normalized afterwards, the drawing and normalizing temperatures should be alike. The normalizing temperature may be below but should never be above the drawing temperature.

**Ion Nitriding.**—Ion nitriding, also referred to as glow discharge nitriding, is a process for case hardening of steel parts, such as tool spindles, cutting tools, extrusion equipment, forging dies, gears, and crankshafts. An electrical potential ionizes low-pressure nitrogen gas, and the ions produced are accelerated to and impinge on the workpiece, heating it to the appropriate temperature for diffusion to take place. Therefore, there is no requirement for a supplemental heat source. The inward diffusion of the nitrogen ions forms the iron

and alloy nitrides in the case. White layer formation, familiar in conventional gas nitriding, is readily controlled by this process.

**Liquid Carburizing.**—Activated liquid salt baths are now used extensively for carburizing. Sodium cyanide and other salt baths are used. The salt bath is heated by electrodes immersed in it, the bath itself acting as the conductor and resistor. One or more groups of electrodes, with two or more electrodes per group, may be used. The heating is accompanied by a stirring action to ensure uniform temperature and carburizing activity throughout the bath. The temperature may be controlled by a thermocouple immersed in the bath and connecting with a pyrometer designed to provide automatic regulation. The advantages of liquid baths include rapid action, uniform carburization, minimum distortion, and elimination of the packing and unpacking required when carbonaceous mixtures are used. In selective carburizing, the portions of the work that are not to be carburized are copperplated, and the entire piece is then immersed in an activated cyanide bath. The copper inhibits any carburizing action on the plated parts, and this method offers a practical solution for selectively carburizing any portion of a steel part.

**Gas Carburizing.**—When carburizing gases are used, the mixture varies with the type of case and quality of product desired. The gaseous hydrocarbons most widely used are methane (natural gas), propane, and butane. These carbon-bearing gases are mixed with air, with manufactured gases of several types, with flue gas, or with other specially prepared "diluent" gases. It is necessary to maintain a continuous fresh stream of carburizing gases to the carburizing retort or muffle as well as to continuously remove the spent gases from the muffle in order to obtain the correct mixture of gases inside the muffle. A slight pressure is maintained on the muffle to exclude unwanted gases.

The horizontal rotary type of gas carburizing furnace has a retort or muffle that revolves slowly. This type of furnace is adapted to small parts, such as ball and roller bearings, chain links, small axles, bolts, etc. With this type of furnace, very large pieces, such as gears, for example, may be injured by successive shocks due to tumbling within the rotor.

The vertical pit type of gas carburizer has a stationary workholder that is placed vertically in a pit. The work, instead of circulating in the gases as with the rotary type, is stationary, and the gases circulate around it. This type is applicable to long, large shafts or other parts or shapes that cannot be rolled in a rotary type of furnace.

There are three types of continuous gas furnaces that may be designated as

- 1) direct quench and manually operated
- 2) direct quench and mechanically operated
- 3) cooling-zone type

Where production does not warrant using a large continuous-type furnace, a horizontal muffle furnace of the batch type may be used, especially if the quantities of work are varied and the production not continuous.

**Vacuum Carburizing.**—Vacuum carburizing is a high-temperature gas carburizing process that is performed at pressures below atmospheric. The furnace atmosphere usually consists solely of an enriching gas, such as natural gas, pure methane, or propane; nitrogen is sometimes used as a carrier gas. Vacuum carburizing offers several advantages, such as combining of processing operations and reduced total processing time.

**Carburizing Steels.**—A low-carbon steel containing, say, from 0.10 to 0.20 percent of carbon is suitable for carburized case hardening. In addition to straight-carbon steels, the low-carbon alloy steels are employed. The alloys add to case-hardened parts the same advantageous properties they give to other classes of steel. Various steels suitable for case hardening will be found in the section on SAE steels.

**To Clean Work after Case Hardening.**—To clean work, especially if knurled, or if dirt is likely to stick into crevices after case hardening, wash it in caustic soda (1 part soda to 10 parts water). In making the solution, the soda should be put into hot water gradually, and

the mixture stirred until the soda is thoroughly dissolved. A still more effective method of cleaning is to dip the work into a mixture of 1 part sulfuric acid and 2 parts water. Leave the pieces in this mixture about 3 minutes; then wash them immediately in a soda solution.

**Flame Hardening.**—This method of hardening is especially applicable to selective hardening of large steel forgings or castings that must be finish-machined prior to heat-treatment or, because of size or shape, cannot be heat treated by using a furnace or bath. An oxyacetylene torch is used to quickly heat the surface to be hardened, which is then quenched to secure a hardened layer that may vary in depth from a mere skin to  $\frac{1}{4}$  inch (6.35 mm) and with hardness ranging from 400 to 700 BHN (Brinell Hardness Number). A multiflame torchhead may be equipped with quenching holes or a spray nozzle behind the flame. This is not a carburizing or a case-hardening process as the torch is only a heating medium. Most authorities recommend tempering or drawing of the hardened surface at temperatures between 200 and 350°F (93 and 177°C). This treatment may be performed in a standard furnace, in an oil bath, or with a gas flame. It should follow the hardening process as closely as possible. Medium-carbon and many low-alloy steels are suitable for flame hardening. Plain carbon steels ranging from 0.35 to 0.60 percent carbon will give hardnesses of from 400 to 700 BHN. Steels in the 0.40 to 0.45 percent carbon range are preferred, as they have excellent core properties and produce hardnesses of from 400 to 500 BHN without checking or cracking. Higher-carbon steels will give greater hardnesses, but extreme care must be taken to prevent cracking. Careful control of the quenching operation is required.

*Spinning Method of Flame Hardening:* This method is employed on circular objects that can be rotated or spun past a stationary flame. It may be subdivided according to the speed of rotation, where the part is rotated slowly in front of a stationary flame and the quench is applied immediately after the flame. This method is used on large circular pieces, such as track wheels and bearing surfaces. There will be a narrow band of material with lower hardness between adjacent torches if more than one path of the flame is required to harden the surface. There will also be an area of lower hardness where the flame is extinguished. A second method is applicable to small rollers or pinions. The work is spun at a speed of 50 to 150 rpm in front of the flame until the entire piece has reached the proper temperature; then it is quenched as a unit by a cooling spray or by ejecting it into a cooling bath.

*The Progressive Method:* In this method the torch travels along the face of the work and the work remains stationary. It is used to harden lathe ways, gear teeth, and track rails.

*The Stationary or Spot-hardening Method:* When this method is employed, the work and torch are both stationary. When the spot to be hardened reaches the quenching temperature, the flame is removed and the quench applied.

*The Combination Method:* This approach is a combination of the spinning and progressive methods, and is used for long bearing surfaces. The work rotates slowly past the torch as the torch travels longitudinally across the face of the work at the rate of the torch width per revolution of the work.

Equipment for the stationary method of flame hardening consists merely of an acetylene torch, an oxyacetylene supply, and a suitable means of quenching; but when the other methods are employed, work-handling tools are essential and specially designed torches are desirable. A lathe is ideally suited for the spinning or combination hardening method, whereas a planer is easily adapted for progressive hardening. Production jobs, such as the hardening of gears, require specially designed machines. These machines reduce handling and hardening time, as well as assuring consistent results.

**Induction Hardening.**—The hardening of steel by means of induction heating and subsequent quenching in either liquid or air is particularly applicable to parts that require localized hardening or controlled depth of hardening and to irregularly shaped parts, such as cams that require uniform surface hardening around their contour.

Advantages offered by induction hardening are: 1) a short heating cycle that may range from a fraction of a second to several seconds; heat energy can be induced in a piece of steel at the rate of 100 to 250 Btu/in<sup>2</sup>/min (165 to 410 J/mm<sup>2</sup>/min) by induction heating, as

compared with a rate of 3 Btu/in<sup>2</sup>/min (5 J/mm<sup>2</sup>/min) for the same material at room temperature when placed in a furnace with a wall temperature of 2000°F (1093°C); 2) absence of tendency to produce oxidation or decarburization; 3) exact control of depth and area of hardening; 4) close regulation of degree of hardness obtained by automatic timing of heating and quenching cycles; 5) minimum warpage or distortion; and 6) possibility of substituting carbon steels for higher-cost alloy steels.

To the designer, the principal advantage of induction hardening lies in its application to localized zones. Thus, specific areas in a given part can be heat treated separately to the respective hardnesses required. Parts can be designed so that the stresses at any given point in the finished piece can be relieved by local heating. Parts can be designed in which welded or brazed assemblies are built up prior to heat treating with only internal surfaces or projections requiring hardening.

**Types of Induction Heating Equipment.**—Induction heating is secured by placing the metal part inside or close to an “applicator” coil of one or more turns through which alternating current is passed. The coil, formed to suit the general class of work to be heated, is usually made of copper tubing through which water is passed to prevent overheating of the coil itself. The workpiece is either held in a fixed position or rotated slowly within or close to the applicator coil. Where the length of work is too great to permit heating in a fixed position, progressive heating may be employed. Thus, a rod or tube of steel may be fed through an applicator coil of one or more turns so that the heating zone travels progressively along the entire length of the workpiece.

The frequency of the alternating current used and the type of generator employed to supply this current to the applicator coil depend on the character of the work to be done.

There are three types of commercial equipment used to produce high-frequency current for induction heating: 1) motor generator sets that deliver current at frequencies of approximately 1000, 2000, 3000, and 10,000 cycles; 2) spark gap oscillator units that produce frequencies ranging from 80,000 to 300,000 cycles; and 3) vacuum tube oscillator sets, which produce currents at frequencies ranging from 350,000 to 15,000,000 cycles or more.

**Depth of Heat Penetration.**—Generally speaking, the higher the frequency used, the shallower the depth of heat penetration. For heating clear through, for deep hardening, and for large workpieces, low power concentrations and low frequencies are usually used. For very shallow and closely controlled depths of heating, as in surface hardening and localized heat treating of small workpieces, currents at high frequencies are used.

For example, a  $\frac{1}{2}$ -inch (12.7 mm) round bar of hardenable steel will be heated through its entire structure quite rapidly by an induced current of 2000 cycles. After quenching, the bar would show through hardness with a decrease in hardness from surface to center. The same piece of steel could be readily heated and surface hardened to a depth of 0.100 inch (2.5 mm) with current at 9600 cycles, and to an even shallower depth with current at 100,000 cycles. A  $\frac{1}{4}$ -inch (6.35 mm) bar, however, would not reach a sufficiently high temperature at 2000 cycles to permit hardening, but at 9600 cycles through hardening would be accomplished. Current at over 100,000 cycles would be needed for surface hardening such a bar.

**Types of Steel for Induction Hardening.**—Most of the standard types of steels can be hardened by induction heating, providing the carbon content is sufficient to produce the desired degree of hardness by quenching. Thus, low-carbon steels with a carburized case, medium- and high-carbon steels (both plain and alloy), and cast iron with a portion of the carbon in combined form, may be used for this purpose. Induction heating of alloy steels should be limited primarily to the shallow-hardening type, that is, those of low alloy content; otherwise the severe quench usually required may result in a highly stressed surface with consequent reduced load-carrying capacity and danger of cracking.

**Through Hardening, Annealing, and Normalizing by Induction.**—For through hardening, annealing, and normalizing by induction, low power concentrations are desirable to prevent too great a temperature differential between the surface and the interior of the work. A satisfactory rate of heating is obtained when the total power input to the work is slightly greater than the radiation losses at the desired temperature. If possible, as low a frequency should be used as is consistent with good electrical coupling. A number of applicator coils may be connected in a series so that several workpieces can be heated simultaneously, thus reducing the power input to each. Widening the spacing between work and applicator coil also will reduce the amount of power delivered to the work.

**Induction Surface Hardening.**—As indicated on page 485 in “*Depth of Heat Penetration*,” currents at much higher frequencies are required in induction surface hardening than in through hardening by induction. In general, the smaller the workpiece, the thinner the section; or the shallower the depth to be hardened, the higher the frequency required. High power concentrations are also needed to make possible a short heating period so that an undue amount of heat will not be conducted to adjacent or interior areas, where a change in hardness is not desired. Generators of large capacity and applicator coils of but a few turns, or even a single turn, provide the necessary concentration of power in the localized area to be hardened.

Induction heating of internal surfaces, such as the interior of a hollow cylindrical part or the inside of a hole, can be accomplished readily with applicator coils shaped to match the cross section of the opening, which may be round, square, elliptical or some other form. If the internal surface is of short length, a multiturn applicator coil extending along its entire length may be employed. Where the power available is insufficient to heat the entire internal surface at once, progressive heating is used. For this purpose, an applicator coil of few turns — often but a single turn — is employed, and either coil or work is moved so that the heated zone passes progressively from one end of the hole or opening to the other. For bores of small diameter, a hairpin-shaped applicator, extending the entire length of the hole, may be used and the work rotated about the axis of the hole to ensure even heating.

**Quenching After Induction Heating.**—After induction heating, quenching may be by immersion in a liquid bath (usually oil), by liquid spray (usually water), or by self-quenching. The term “self-quenching” is used when there is no quenching medium and hardening of the heated section is due chiefly to rapid absorption of heat by the mass of cool metal adjacent to it. Quenching by immersion offers the advantage of even cooling and is particularly satisfactory for through heated parts. Spray quenching may be arranged so that the quenching ring and applicator coil are in the same or adjacent units, permitting the quenching cycle to follow the heating cycle immediately without removal of the work from the holding fixture. Automatic timing to a fraction of a second may also be employed for both heating and quenching with this arrangement to secure the exact degree of hardness desired. Self-quenching is applicable only in thin-surface hardening where the mass of adjacent cool metal in the part is great enough to conduct the heat rapidly out of the surface layer being hardened. It has been recommended that for adequate self-quenching, the mass of the unheated section should be at least ten times that of the heated shell. It has been found difficult to use the self-quenching technique to produce hardened shells of much more than about 0.060 inch (1.52 mm) thickness. Close to this limit, self-quenching can only be accomplished with the easily hardenable steels. By using a combination of self-quench and liquid quench, however, it is possible to produce hardened shells on work too thin to self-quench completely. In general, self-quenching is confined chiefly to relatively small parts and simple shapes.

**Induction Hardening of Gear Teeth.**—Several advantages are claimed for the induction hardening of gear teeth. One advantage is that the gear teeth can be completely machined, including shaving, when in the soft-annealed or normalized condition, and then hardened, because when induction heating is used, distortion is held to a minimum. Another advantage claimed is that bushings and inserts can be assembled in the gears

before hardening. A wide latitude in choice of built-up webs and easily machined hubs is afforded because the hardness of neither web nor hub is affected by the induction-hardening operation although slight dimensional changes may occur in certain designs. Regular carbon steels can be used in place of alloy steels for a wide variety of gears, and steel with a higher carbon content can frequently be substituted for a carburizing steel so that the carburizing operation can be eliminated. Another time-saving benefit is elimination of cleaning after hardening.

In heating spur gear teeth by induction, the gear is usually placed inside a circular unit that combines the applicator coil and quenching ring. An automatic timing device controls both the heating and quenching cycles. During the heating cycle, the gear is rotated at 25 to 35 rpm to ensure uniform heating.

In hardening bevel gears, the applicator coil is wound to conform to the face angle of the gear. In some spiral-bevel gears, there is a tendency to obtain more heat on one side of the tooth than on the other. In some sizes of spiral-bevel gears, this tendency can be overcome by applying slightly more heat to ensure hardening of the concave side. In some forms of spiral-bevel gears, it has been the practice to carburize that part of the gear surface which is to be hardened after the teeth have been rough-cut. Carburizing is followed by the finish-cutting operation, after which the teeth can be induction heated, using a long enough period to heat the entire tooth. When the gear is quenched, only the carburized surface will become hardened.

<sup>a</sup> Symbols: A = water or brine; B = water or oil; C = cool slowly; D = air or oil; E = oil; F = water, brine, or oil.

<sup>b</sup> Even where tempering temperatures are shown, tempering is not mandatory in many applications. Tempering is usually employed for partial stress relief and improved resistance to grinding cracks.

<sup>c</sup> Activated or cyanide baths.

<sup>d</sup> May be given refining heat as in other processes.

<sup>e</sup> Carbonitriding atmospheres.

<sup>f</sup> Normalizing temperatures at least 50°F (28°C) above the carburizing temperature are sometimes recommended where minimum heat-treatment distortion is of vital importance.

<sup>a</sup> Normalizing temperatures should be not less than 50°F (28°C) higher than the carburizing temperature. Follow by air cooling.

<sup>b</sup> For cycle annealing, heat to normalizing temperature; hold for uniformity; cool rapidly to 1000-1250°F (538-677°C); hold 1 to 3 hours; then air or furnace cool to obtain a structure suitable for machining and finishing.

<sup>c</sup> Symbols: C = cool slowly; E = oil.

<sup>d</sup> Tempering treatment is optional and is generally employed for partial stress relief and improved resistance to cracking from grinding operations.

<sup>e</sup> For use when case hardness only is paramount.

<sup>f</sup> For use when higher core hardness is desired.

<sup>g</sup> Treatment is for fine-grained steels only, when a second reheat is often unnecessary.

<sup>h</sup> Treatment is for activated or cyanide baths. Parts may be given refining heats as indicated for other heat-treating processes.

<sup>i</sup> After normalizing, reheat to temperatures of 1000-1200°F (538-649°C) and hold approximately 4 hours.

**Metallography.**—The science or study of the microstructure of metal is known by most metallurgists as “metallography” or sometimes “crystallography”. The examination of metals and metal alloys by the aid of the microscope is one of the most effective methods of studying their properties and is also a valuable means of controlling the quality of manufactured metallic articles and of testing the finished product. In preparing the specimen, a flat surface is first formed by filing or grinding and then given a high polish, which is later etched in order to clearly reveal the internal structure under the microscope. This process clearly shows an experienced observer the effect of variation in composition, heat treatment, etc., and in many cases it has proved a correct means of determining certain properties of industrial products that a chemical analysis has failed to reveal.

### Heat Treating High-Speed Steels

**Cobaltcrom Steel.**—A tungstenless alloy steel or high-speed steel that contains approximately 1.5 percent carbon, 12.5 percent chromium, and 3.5 percent cobalt. Tools such as dies and milling cutters made from cobaltcrom steel can be cast to shape in suitable molds, the cutter teeth being formed so that it is necessary only to grind them.

Before the blanks can be machined, they must be annealed; this operation is performed by pack annealing at the temperature of 1800°F (982°C), for a period of from 3 to 6 hours, according to the size of the castings being annealed. The following directions are given for the hardening of blanking and trimming dies, milling cutters, and similar tools made from cobaltcrom steel: Heat slowly in a hardening furnace to about 1830°F (999°C), and hold at this temperature until the tools are thoroughly soaked. Reduce the temperature about 50°F (28°C), withdraw the tools from the furnace, and allow them to cool in the atmosphere. As soon as the red color disappears from the cooling tool, place it in quenching oil until cold. The slight drop of 50°F (28°C) in temperature while the tool is still in the hardening furnace is highly important to obtain proper results. The steel will be injured if the tool is heated above 1860°F (1016°C). In cooling milling cutters or other rotary tools, it is suggested that they be suspended on a wire to ensure a uniform rate of cooling.

Tools that are to be subjected to shocks or vibration, such as pneumatic rivet sets, shear blades, etc., should be heated slowly to 1650°F (899°C), after which the temperature should be reduced to about 1610°F (877°C), at which point the tool should be removed from the furnace and permitted to cool in the atmosphere. No appreciable scaling occurs in the hardening of cobaltcrom steel tools.

**Preheating Tungsten High-Speed Steel.**—Tungsten high-speed steel must be hardened at a very high temperature; consequently, tools made from such steel are seldom hardened without at least one preheating stage to avoid internal strain. This requirement applies especially to milling cutters, taps, and other tools having thin teeth and thick bodies and to forming tools of irregular shape and section. The tools should be heated slowly and carefully to a temperature somewhat below the critical point of the steel, usually in the range of 1500 to 1600°F (816 to 871°C). Limiting the preheating temperature prevents the operation from being unduly sensitive, and the tool may be safely left in the furnace until it reaches a uniform temperature throughout its length and cross section.

A single stage of preheating is customary for tools of simple form that are not more than from 1 to 1½ inches (25 to 38 mm) in thickness. For large, intricate tools, two stages of preheating are frequently used. The first brings the tool up to a temperature of about 1100 to 1200°F (593 to 649°C), and the second raises its temperature to 1550 to 1600°F (843 to 649°C). A preheating time of 5 minutes for each ¼ inch (6.4 mm) in tool thickness has been recommended for a furnace temperature of 1600°F (871°C). This is where a single stage of preheating is used and the furnace capacity should be sufficient to maintain practically constant temperature when the tools are changed. To prevent undue chilling, it is common practice to insert a single tool or a small lot in the hardening furnace whenever a tool or lot is removed rather than to insert a full charge of cold metal at one time.

Preheating is usually done in a simple type of oven furnace heated by gas, electricity, or oil. Atmospheric control is seldom used, although for 18-4-1 steel a slightly reducing atmosphere (2 to 6 percent carbon monoxide) has been found to produce the least amount of scale and will result in a better surface after final hardening.

**Hardening of Tungsten High-Speed Steel.**—All tungsten high-speed steels must be heated to a temperature close to their fusion point to develop their maximum efficiency as metal-cutting tools. Hardening temperatures ranging from 2200 to 2500°F (1204 to 1371°C) may be needed. The effects of changes in the hardening temperature on the cutting efficiency of several of the more common high-speed steels are shown in [Table 1](#). The figures given are ratios, the value 1.00 for each steel being assigned to the highest observed cutting speed for that steel. The figures for different steels, therefore, cannot

be directly compared with each other, except to note changes in the point of maximum cutting efficiency.

**Table 1. Relation of Hardening Temperature to Cutting Efficiency**

Hardening Temperature		Typical Analyses of High-Speed Steels			
Deg. F	Deg. C	18-4-1	14-4-2	18-4-1 Cobalt	14-4-2 Cobalt
2200	1204	0.86	0.83	0.84	0.85
2250	1232	0.88	0.88	0.86	0.88
2300	1260	0.90	0.93	0.90	0.91
2350	1288	0.95	0.98	0.94	0.94
2400	1316	0.99	0.98	0.98	0.98
2450	1343	1.00	...	0.99	1.00
2500	1371	0.98	...	1.00	0.97

The figures in the table refer to tools heated in an oven-type furnace in which a neutral atmosphere is maintained. The available data indicate that a steel reaches its best cutting qualities at a temperature approximately 50°F (28°C) lower than the figures in the table if it is hardened in a bath-type furnace. It is, however, desirable to use a hardening temperature approximately 50°F (28°C) lower than that giving maximum cutting qualities to avoid the possibility of overheating the tool.

*Length of Time for Heating:* The cutting efficiency of a tool is affected by the time that it is kept at the hardening temperature, almost as much as by the hardening temperature itself. It has been common practice to heat a tool for hardening until a "sweat" appears on its surface. This sweat is presumably a melting of the oxide film on the surface of a tool heated in an oxidizing atmosphere. It does not appear when the tool is heated in an inert atmosphere. This method of determining the proper heating time is at best an approximation and indicates only the temperature on the outside of the tool rather than the condition of the interior. As such, it cannot be relied upon to give consistent results.

The only safe method is to heat the tool for a definite predetermined time, based on the size and the thickness of metal that the heat must penetrate to reach the interior. The values given in **Table 2** are based on a series of experiments to determine the relative cutting efficiency of a group of tools hardened in an identical manner except for variations in the time the tools were kept at the hardening temperature. The time given is based on that required to harden throughout a tool resting on a conducting hearth; the tool receives heat freely from three sides, on its large top surface and its smaller side surfaces. (The table does not apply to a disk lying flat on the hearth.) For a tool having a projecting cutting edge, such as a tap, the thickness or depth of the projecting portion on which the cutting edge is formed should be used when referring to the table.

**Table 2. Length of Heating Time for Through Hardening**

High-Speed Steel Tool Thickness		Time in Furnace at High Heat, Minutes	High-Speed Steel Tool Thickness		Time in Furnace at High Heat, Minutes	High-Speed Steel Tool Thickness		Time in Furnace at High Heat, Minutes
Inch	Centimeter		Inch	Centimeter		Inch	Centimeter	
¼	0.635	2	1½	3.81	7	5	12.7	18
½	1.27	3	2	5.08	8	6	15.24	20
¾	1.905	4	3	7.62	12	8	20.32	25
1	2.54	5	4	10.16	15	10	25.4	30

The time periods given in **Table 2** are based on complete penetration of the hardening effect. For very thick tools, the practical procedure is to harden to a depth sufficient to produce an adequate cutting edge, leaving the interior of the tool relatively soft.

Where atmosphere control is not provided, it often will be found impracticable to use both the temperature for maximum cutting efficiency, given in Table 1, and the heating time, given in Table 2, because abnormal scaling, grain growth, and surface decarburization of the tool will result. The principal value of an accurate control of the furnace atmosphere appears to lie in the fact that its use makes possible the particular heat treatment that produces the best structure in the tool without destruction of the tool surface or grain.

**Quenching Tungsten High-Speed Steel.**—High-speed steel is usually quenched in oil. The oil bath offers a convenient quench; it calls for no unusual care in handling and brings about a uniform and satisfactory rate of cooling, which does not vary appreciably with the temperature of the oil. Some authorities believe it desirable to withdraw the tool from the oil bath for a few seconds after it has reached a dull red. It is also believed desirable to move the tool around in the quenching oil, particularly immediately after being placed in it, to prevent the formation of a gas film on the tool. Such a film is usually a poor conductor of heat and slows the rate of cooling.

*Salt Bath:* Quenching in a lead or salt bath at from 1000 to 1200°F (538 to 649°C) has the advantage that cooling of the tool from hardening to room temperature is accomplished in two stages, thus reducing the possibility of setting up internal strains that may tend to crack the tool. The quenching temperature is sufficiently below the lower critical point for a tool so quenched to be allowed to cool to room temperature in still air. This type of quench is particularly advantageous for tools of complicated section that would easily develop hardening cracks. The salt quench has the advantage that the tool sinks and requires only a support, whereas the same tool will float in the lead bath and must be held under the surface. It is believed that the lead quench gives a somewhat higher matrix hardness, and is of advantage for tools that tend to fail by nose abrasion. Tools treated as described are brittle unless given a regular tempering treatment, because the 1000°F (538°C) quenching temperature is not a substitute for later tempering at the same temperature, after the tool has cooled to room temperature.

*Air Cooling:* Many high-speed steel tools are quenched in air, either in a stream of dry compressed air or in still air. Small sections harden satisfactorily in still air, but heavier sections should be subjected to air under pressure. One advantage of air cooling is that the tool can be kept straight and free from distortion, although it is likely that there will be more scale on a tool thus quenched than when oil, lead, or salt is used. Cooling between steel plates may help to keep thin flat tools straight and flat.

**Straightening Tools when Quenching.**—The final straightness required in a tool must be considered when it is quenched. When several similar tools are to be hardened, a jig can be used to advantage for holding the tools while quenching. When long slender tools are quenched without holders, they frequently warp and must be straightened later. The best time for this straightening is during the first few minutes after the tools have been quenched, as the steel is then quite pliable and may be straightened without difficulty. The straightening must be done at once, as the tools become hard in a few minutes.

**Anneal Before Rehardening.**—Tools that are too soft after hardening must be annealed before rehardening. A quick anneal, such as previously described, is all that is required to put such a tool into the proper condition for rehardening. This treatment is absolutely essential. For milling cutters and forming tools of irregular section, a full anneal should be used.

**Tempering or Drawing Tungsten High-Speed Steel.**—The tempering or drawing temperature for high-speed steel tools usually varies from 900 to 1200°F (482 to 649°C). This temperature is higher for turning and planing tools than for such tools as milling cutters, forming tools, etc. If the temperature is below 800°F (427°C), the tool is likely to be too brittle. The general idea is to temper tools at the highest temperature likely to occur in service. Because this temperature ordinarily is unknown, the general practice is to temper at whatever temperature experience with that particular steel and tool has proved to be the best. The furnace used for tempering usually is kept at a temperature of from 1000 to

1100°F (538 to 593°C) for ordinary high-speed steels and from 1200 to 1300°F (649 to 704°C) for steels of the cobalt type. These furnace temperatures apply to tools of the class used on lathes and planers. Such tools, in service, frequently heat to the point of visible redness. Milling cutters, forming tools, or any other tools for lighter duty may be tempered as low as 850 or 900°F (454 to 482°C). When the tool has reached the temperature of the furnace, it should be held at this temperature for from one to several hours until it has been heated evenly throughout. It should then be allowed to cool gradually in the air and in a place that is dry and free from air drafts. In tempering, the tool should not be quenched because quenching tends to produce strains that may result later in cracks.

**Annealing Tungsten High-Speed Steel.**—The following method of annealing high-speed steel has been used extensively. Use an iron box or pipe of sufficient size to allow at least  $\frac{1}{2}$  inch (12.7 mm) of packing between the pieces of steel to be annealed and the sides of the box or pipe. It is not necessary that each piece of steel be kept separate from every other piece, but only that the steel be prevented from touching the sides of the annealing pipe or box. Pack carefully with powdered charcoal, fine dry lime, or mica (preferably charcoal), and cover with an airtight cap or lute with fire clay; heat slowly to 1600 to 1650°F (871 to 899°C) and keep at this heat from 2 to 8 hours, depending on the size of the pieces to be annealed. A piece measuring  $2 \times 1 \times 8$  inches ( $5 \times 2.5 \times 20.3$  cm) requires about 3 hours. Cool as slowly as possible, and do not expose to the air until cold because cooling in air is likely to cause partial hardening. A good method is to allow the box or pipe to remain in the furnace until cold.

**Hardening Molybdenum High-Speed Steels.**—Table 3 gives the compositions of several molybdenum high-speed steels that are widely used for general commercial tool applications. The general method of hardening molybdenum high-speed steels resembles that used for 18-4-1 tungsten high-speed steel except that the hardening temperatures are lower and more precautions must be taken to avoid decarburization, especially on tools made from Type I or Type II steels, when the surface is not ground after hardening. Either salt baths or atmosphere-controlled furnaces are recommended for hardening molybdenum high-speed steels.

**Table 3. Compositions of Molybdenum High-Speed Steels**

Element	Molybdenum-Tungsten		Molybdenum-Vanadium	Tungsten-Molybdenum
	Type Ia (Percent)	Type Ib <sup>a</sup> (Percent)	Type II (Percent)	Type III (Percent)
Carbon	0.70-0.85	0.76-0.82	0.70-0.90	0.75-0.90
Tungsten	1.25-2.00	1.60-2.30	...	5.00-6.00
Chromium	3.00-5.00	3.70-4.20	3.00-5.00	3.50-5.00
Vanadium	0.90-1.50	1.05-1.35	1.50-2.25	1.25-1.75
Molybdenum	8.00-9.50	8.00-9.00	7.50-9.50	3.50-5.50
Cobalt	See footnote	4.50-5.50	See footnote	See footnote

<sup>a</sup> Cobalt may be used in any of these steels in varying amounts up to 9 percent, and the vanadium content may be as high as 2.25 percent. When cobalt is used in Type III steel, the vanadium content may be as high as 2.25 percent. When cobalt is used in Type III steel, this steel becomes susceptible to decarburization. As an illustration of the use of cobalt, Type Ib steel is included. This is steel T10 in the US Navy Specification 46S37, dated November 1, 1939.

The usual method is to preheat uniformly in a separate furnace to 1250 to 1550°F (677 to 843°C), then transfer to a high-heat furnace maintained within the hardening temperature range given in Table 4. Single-point cutting tools, in general, should be hardened at the upper end of the temperature range indicated by Table 4. Slight grain coarsening is not objectionable in such tools when they are properly supported in service and are not subjected to chattering; however, when these tools are used for intermittent cuts, it is better

to use the middle of the temperature range. All other cutting tools, such as drills, countersinks, taps, milling cutters, reamers, broaches, and form tools, should be hardened in the middle of the range shown. For certain tools, such as slender taps, cold punches, and blanking and trimming dies, where greater toughness to resist shocks is required, the lower end of the hardening temperature range should be used.

**Table 4. Heat Treatment of Molybdenum High-Speed Steels**

Heat-Treating Operation	Molybdenum-Tungsten		Molybdenum-Vanadium		Tungsten-Molybdenum	
	Types Ia and Ib <sup>a</sup> Temp.		Type II Temp.		Type III Temp.	
	Deg. F	Deg. C	Deg. F	Deg. C	Deg. F	Deg. C
Forging	1850-2000	1010-1093	1850-2000	1010-1093	1900-2050	1038-1121
Not below	1600	871	1600	871	1600	871
Annealing	1450-1550	788-843	1450-1550	788-843	1450-1550	788-843
Strain relief	1150-1350	621-732	1150-1350	621-732	1150-1350	621-732
Preheating	1250-1500	677-816	1250-1500	677-816	1250-1550	677-843
Hardening <sup>b</sup>	2150-2250 <sup>a</sup>	1177-1232 <sup>a</sup>	2150-2250	1177-1232	2175-2275	1191-1246
Salt	2150-2225	1177-1218	2150-2225	1177-1218	2150-2250	1177-1232
Tempering	950-1100	510-593	950-1100	510-593	950-1100	510-593

<sup>a</sup> For similar working conditions, Type Ib steel requires slightly higher hardening heat than Type Ia.  
<sup>b</sup> The higher side of the hardening range should be used for large sections, and the lower side for small sections.

Molybdenum high-speed steels can be pack-hardened following the same practice as is used for tungsten high-speed steels but keeping on the lower side of the hardening range (approximately 1850°F or 1010°C). Special surface treatments such as nitriding by immersion in molten cyanide that are used for tungsten high-speed steels are also applicable to molybdenum high-speed tools.

When heated in an open fire or in furnaces without atmosphere control, these steels do not sweat like 18-4-1 steels; consequently, determining the proper time in the high-heat chamber is a matter of experience. This time approximates that used with 18-4-1 steels, although it may be slightly longer when the lower part of the hardening range is used. Much can be learned by preliminary hardening of test pieces and checking on the hardness fracture and structure. It is difficult to give the exact heating time because it is affected by temperature, type of furnace, size and shape, and furnace atmosphere. Rate of heat transfer is most rapid in salt baths and slowest in controlled-atmosphere furnaces with high carbon monoxide content.

**Quenching and Tempering of Molybdenum High-Speed Tools.**—Quenching may be done in oil, air, or molten bath. To reduce the possibility of breakage and undue distortion of intricately shaped tools, it is advisable to quench in a molten bath at approximately 1100°F (593°C). The tool also may be quenched in oil and removed while still red, or at approximately 1100°F (593°C). The tool is then cooled in air to room temperature and tempered immediately to avoid cracking.

When straightening is necessary, it should be done after quenching and before cooling to room temperature prior to tempering.

To temper, the tools should be reheated slowly and uniformly to 950 to 1100°F (510 to 593°C). For general work, 1050°F (566°C) is most common. The tools should be held at this temperature at least 1 hour. Two hours is a safer minimum, and 4 hours is maximum. The time and temperature depend on the hardness and toughness required. Where tools are subjected to more or less shock, multiple temperings are suggested.

**Protective Coatings for Molybdenum Steels.**—To protect the surface from oxidation during heat treatment, borax may be sprinkled lightly over the steel when the latter is heated in a furnace to a low temperature, 1200 to 1400°F (649 to 760°C). Small tools may be rolled in a box of borax before heating. Another method more suitable for finished tools is to apply the borax or boric acid in the form of a supersaturated water solution. The tools

are then immersed in the solution at 180 to 212°F (82 to 100°C), or the solution may be applied with a brush or spray. Pieces so treated are heated as usual and carefully handled to ensure good adherence of the coating. When properly applied, special protective coatings or paints have been found to be extremely useful. These materials do not fuse or run at the temperatures used and therefore do not affect the furnace hearth. When applying these coatings, it is necessary to have a surface free from scale or grease to ensure good adherence. Coatings may be sprayed or brushed on, and usually one thin coat is sufficient. Heavy coats tend to pit the surface of the tool and are difficult to remove. Tools covered with these coatings should be allowed to dry before they are charged into the preheat furnace. After hardening and tempering, the coating can be easily removed by light blasting with sand or steel shot. When tools are lightly ground, these coatings come off immediately. Protection may also be obtained by wrapping pieces in stainless steel foil.

**Nitriding High-Speed Steel Tools.**—Nitriding is applied to high-speed steel for the purpose of increasing tool life by producing a very hard skin or case, the thickness of which ordinarily is from 0.001 to 0.002 inch (0.025 to 0.05 mm). Nitriding is done after the tool has been fully heat treated and finish-ground. (The process differs entirely from that which is applied to surface harden certain alloy steels by heating in an atmosphere of nitrogen or ammonia gas.) The temperature of the high-speed steel nitriding bath, which is a mixture of sodium and potassium cyanides, is equal to or slightly lower than the tempering temperature. For ordinary tools, this temperature usually varies from about 1025 to 1050°F (552 to 566°C); but, if the tools are exceptionally fragile, the range may be reduced to 950 or 1000°F (510 to 538°C). Accurate temperature control is essential to prevent exceeding the final tempering temperature. The nitriding time may vary from 10 or 15 minutes to 30 minutes or longer, and should be determined by experiment. The shorter periods are applied to tools for iron or steel, or any shock-resisting tools, and the longer periods are for tools used in machining nonferrous metals and plastics. This nitriding process is applied to tools, such as hobs, reamers, taps, box tools, form tools, and milling cutters. Nitriding may increase tool life 50 to 200 percent, or more, but it should always be preceded by correct heat treatment.

*Nitriding Bath Mixtures and Temperatures:* A mixture of 60 percent sodium cyanide and 40 percent potassium cyanide is commonly used for nitriding. This mixture has a melting point of 925°F (496°C), which is gradually reduced to 800°F (427°C) as the cyanate content of the bath increases. A more economical mixture of 70 percent sodium cyanide and 30 percent potassium cyanide may be used if the bath temperature is only 1050°F (566°C). Nitriding bath temperatures should not exceed 1100°F (593°C) because higher temperatures accelerate the formation of carbonate at the expense of the essential cyanide. A third mixture used for nitriding consists of 55 percent sodium cyanide, 25 percent potassium chloride, and 20 percent sodium carbonate. This mixture melts at 930°F (499°C).

**Equipment for Hardening High-Speed Steel.**—Equipment for hardening high-speed steel consists of a hardening furnace capable of maintaining a temperature of 2350 to 2450°F (1288 to 1343°C); a preheating furnace capable of maintaining a temperature of 1700 to 1800°F (927 to 982°C) and of sufficient size to hold a number of pieces of the work; a tempering (drawing) furnace capable of maintaining a temperature of 1000 to 1200°F (538 to 649°C) as a general rule; and a water-cooled tank of quenching oil.

High-speed steels usually are heated for hardening either in some type of electric furnace or in a gas-fired furnace of the muffle type. The small furnaces used for high-speed steel seldom are oil-fired. It is desirable to use automatic temperature control and, where an oven-type of furnace is employed, a controlled atmosphere is advisable because of the variations in cutting qualities caused by hardening under uncontrolled conditions. Some furnaces of both electric and fuel-fired types are equipped with a salt bath suitable for high-speed steel hardening temperatures. Salt baths have the advantage of providing protection against the atmosphere during the heating period. A type of salt developed for commercial use is water-soluble so that all deposits from the hardening bath may be

removed by immersion in water after quenching in oil or salt, or after air cooling. One type of electric furnace heats the salt bath internally by electrodes immersed in it. The same type of furnace is also applied to various heat-treating operations, such as cyanide hardening, liquid carburizing, tempering, and annealing.

An open-forge fire has many disadvantages, especially in hardening cutters or other tools that cannot be ground all over after hardening. The air blast decarburizes the steel, and lack of temperature control makes it impossible to obtain uniform results. Electric and gas furnaces provide continuous uniform heat, and the temperature may be regulated accurately, especially when pyrometers are used. In shops equipped with only one furnace for carbon steel and one for high-speed steel, the tempering can be done in the furnace used for hardening carbon steel after the preheating is finished and the steel has been removed for hardening.

**Heating High-Speed Steel for Forging.**—Care should be taken not to heat high-speed steel for forging too abruptly. In winter, the steel may be extremely cold when brought into the forge shop. If the steel is put directly into the hot forge fire, it is likely to develop cracks that will show up later in the finished tool. The steel, therefore, should be warmed gradually before heating for forging.

### Subzero Treatment of Steel

Subzero treatment consists of subjecting the steel, after hardening and either before or after tempering, to a subzero temperature that usually ranges from  $-100$  to  $-120^{\circ}\text{F}$  ( $-73$  to  $-84^{\circ}\text{C}$ ), and for a period of time varying with the size or volume of the tool, gage, or other part. Commercial equipment is available for obtaining these low temperatures.

The subzero treatment is employed by most gage manufacturers to stabilize precision gages and prevent subsequent changes in size or form. Subzero treatment is also applied to some high-speed steel cutting tools. The object here is to increase the durability or life of the tools; however, up to the present time, the results of tests by metallurgists and tool engineers often differ considerably and in some instances are contradictory. Methods of procedure also vary, especially with regard to the order and number of operations in the complete heat-treating and cooling cycle.

**Changes Resulting From Subzero Treatment.**—When steel is at the hardening temperature it contains a solid solution of carbon and iron known as *austenite*. When the steel is hardened by sudden cooling, most of the austenite, which is relatively soft, tough, and ductile even at room temperatures, is transformed into martensite, a hard and strong constituent. If all the austenite were changed to martensite upon reaching room temperature, this process would be an ideal hardening operation, but many steels retain some austenite. In general, the higher the carbon and alloy contents and the higher the hardening temperature, the greater the tendency to retain austenite. When steel is cooled to subzero temperatures, the stability of the retained austenite is reduced so that it is more readily transformed. To obtain more complete transformation, the subzero treatment may be repeated. The ultimate transformation of austenite to martensite may take place in carbon steel without the aid of subzero treatment, but this natural transformation might require 6 months or longer, whereas by refrigeration this change occurs in a few hours.

The thorough, uniform heating that is always recommended in heat-treating operations should be accompanied by thorough, uniform cooling when the subzero treatment is applied. To ensure uniform cooling, the subzero cooling period should be increased for the larger tools and it may range from 2 to 6 hours. The tool or other part is sometimes surrounded by one or more layers of heavy wrapping for insulating material to delay the cooling somewhat and ensure uniformity. After the cooling cycle is started, it should continue without interruption.

Subzero treatment may sometimes cause cracking. Normally, the austenite in steel provides a cushioning effect that may prevent cracking or breakage resulting from treatments

involving temperature and dimensional changes; but if this cushioning effect is removed, particularly at very low temperatures as in subzero treatments, there may be danger of cracking, especially with tools having large or irregular sections and sharp corners offering relatively low resistance to stresses. This effect is one reason why subzero treatments may differ in regard to the cooling and tempering cycle.

**Stabilizing Dimensions of Gages or Precision Parts by Subzero Cooling.**—Transformation of austenite into martensite is accompanied by an increase in volume; consequently, the transformation of austenite, that may occur naturally over a period of months or years, tends to change the dimensions and form of steel parts, and such changes may be serious in the case of precision gages, close-fitting machine parts, etc. To prevent such changes, the subzero treatment has proved effective. Gage blocks, for example, may be stabilized by hardening followed by repeated cycles of chilling and tempering, to transform a large percentage of the austenite into martensite.

*Order of Operations for Stabilizing Precision Gages:* If precision gages and sine-bars are heat treated in the ordinary manner and then finished without some stabilizing treatment, dimensional changes and warpage are liable to occur. Subzero cooling provides a practical and fairly rapid method of obtaining the necessary stabilization by transforming the austenite into martensite. In stabilization treatments of this kind, tempering is the final operation. One series of treatments that has been recommended after hardening and rough-grinding is as follows:

a) Cool to  $-120^{\circ}\text{F}$  ( $-84^{\circ}\text{C}$ ). This cooling period may require from 1 to 6 hours, depending on the size and form of the gage.

b) Place gage in boiling water for 2 hours (oil or salt bath may also be used).

Note: Steps *Item a)* and *Item b)* may be repeated from two to six times, depending on the size and form of the gage. These repeated cycles will eventually transform practically all the austenite into martensite. Two or three cooling and drawing operations usually are sufficient for such work as thread gages and gage blocks.

c) Follow with regular tempering or drawing operation and finish gage by lapping.

*Series of Stabilizing Treatments for Chromium Steel:* The following series of treatments has proved successful in stabilizing precision gage blocks made from SAE 52100 chromium steel.

a) Preheat to  $600^{\circ}\text{F}$  ( $316^{\circ}\text{C}$ ), then heat to  $1575^{\circ}\text{F}$  ( $857^{\circ}\text{C}$ ) for a period of four minutes.

b) Quench in oil at  $85^{\circ}\text{F}$  ( $29^{\circ}\text{C}$ ). Uniform quenching is essential.

c) Temper at  $275^{\circ}\text{F}$  ( $135^{\circ}\text{C}$ ) for one hour.

d) Cool in tempering furnace to room temperature.

e) Continue cooling in atmosphere of industrial refrigerator for 6 hours with temperature of atmosphere at  $-120^{\circ}\text{F}$  ( $-84^{\circ}\text{C}$ ).

f) Allow gage blocks to return to room temperature and again temper.

Note: The complete treatment consists of six subzero cooling periods, each followed by a tempering operation. The transformation to martensite is believed to be complete even after the fifth cooling period. The hardness is about 66 RC (Rockwell C scale). Transformation is checked by magnetic tests based upon the magnetism of martensite and the nonmagnetic qualities of austenite.

**Stabilizing Dimensions of Close-Fitting Machine Parts.**—Subzero treatment will always cause an increase in size. Machine parts subjected to repeated and perhaps drastic changes in temperature, as in aircraft, may eventually cause trouble due to growth or warpage as the austenite gradually changes to martensite. In some instances, the sizes of close-fitting moving parts have increased sufficiently to cause seizure. Such treatment, for example, may be applied to precision bearings made from SAE 52100 or alloy carburizing steels for stabilizing or aging them. *Time* aging of 52100 steels after hardening has been found to cause

changes as large as 0.0025 inch (0.064 mm) in medium size sections. A practical remedy is to apply the subzero treatment before the final grinding or other machining operation.

**Subzero Treatment of Carburized Parts to Improve Physical Properties.**—The subzero treatment has been applied to carburized machine parts. For example, the amount of retained austenite in carburized gears may be sufficient to reduce the life of the gears. In one component, the Rockwell hardness was increased from 55 to 65 RC without loss of impact resistance qualities; in fact, impact and fatigue resistance may be increased in some examples.

**Application of Subzero Treatments to High-Speed Steel.**—The subzero treatment has been applied to such tools as milling cutters, hobs, taps, broaches, and drills. It is applicable to different classes of high-speed steels, such as the 18-4-1 tungsten, 18-4-14 cobalt, and the molybdenum high-speed steels. This *cold* treatment is applied preferably in conjunction with the heat treatment, both being combined in a continuous cycle of operations. The general procedure is either to harden the steel, cool it to a subzero temperature, and then temper; or, especially if there is more than one tempering operation, the first tempering may *precede* subzero cooling. The cooling and tempering cycle may be repeated two or more times. The number and order of the operations, or the complete cycle, may be varied to suit the class of work and to minimize the danger of cracking, particularly if the tool has large or irregular sections, sharp corners or edges, or a high cobalt content. A subzero treatment of some kind with a final tempering operation for stress relief is intended to increase strength and toughness without much loss in hardness; consequently, if there is greater strength at a given hardness, tools subjected to subzero treatment can operate with a higher degree of hardness than those heat treated in the ordinary manner, or, if preferred, greater toughness can be obtained by tempering to the original degree of hardness.

**Order of Cooling and Tempering Periods for High-Speed Steel.**—The order or cycle for the cooling and tempering periods has not been standardized. The methods that follow have been applied to high-speed steel tools. They are given as examples of procedure and are subject to possible changes due to subsequent developments. The usual ranges of preheating and hardening temperatures are given, but, for a particular steel, the recommended temperatures should be obtained from the manufacturer.

1) *Double Subzero Treatment:* (For rugged simple tool forms without irregular sections, sharp corners or edges where cracks might develop during the subzero treatment).

- a) Preheat between 1400 and 1600°F (760 and 871°C). Double preheating is preferable, the first preheating ranging from 700 to 1000°F (371 to 538°C).
- b) Heat to the hardening temperature. *Note:* Tests indicate that the effect of subzero treatment on high-speed steel may be influenced decidedly by the hardening temperature. If this temperature is near the lower part of the range, the results are unsatisfactory. Effective temperatures for ordinary high-speed steels appear to range from 2300 to 2350°F (1260 to 1288°C).
- c) Quench in oil, salt, lead, or air, down to a workpiece temperature of 150–200°F (66–93°C). *Note:* One method is to quench in oil; a second method is to quench in oil to about 200–225°F (93–107°C) and then air cool; a third method is to quench in salt bath at 1050–1100°F (566–593°C) and then air cool.
- d) Cool in refrigerating unit to temperature of –100 to –120°F (–73 to –84°C) *right after quenching*. *Note:* Tests have shown that a delay of one hour has a detrimental effect, and in 10 hours the efficiency of the subzero treatment is reduced 50 percent. This is because the austenite becomes more and more stabilized when the subzero treatment is delayed; consequently, the austenite is more difficult to transform into martensite.) The refrigerating period usually varies from 2 to 6 hours, depending on the size of the tool. Remove the tool from the refrigerating unit and allow it to return to room temperature.
- e) Temper to required hardness for a period of 2½ to 3 hours. The tempering temperature usually varies from a minimum of 1000 to 1100°F (538 to 593°C) for ordinary high-speed steels. Tests indicate that if this first tempering is less

than  $2\frac{1}{2}$  hours at 1050°F (566°C), there will not be sufficient precipitation of carbides at the tempering temperature to allow complete transformation of the retained austenite on cooling, whereas more than 3 hours causes some loss in room temperature hardness, hot hardness, strength, and toughness.

- f) Repeat subzero treatment, step **Item d**).
- g) Repeat the tempering operation, **Item e**). *Note:* The time for the second tempering operation is sometimes reduced to about  $\frac{1}{2}$  the time required for the first tempering.

2) *Single Subzero Treatment:* This treatment is the same as procedure **Item 1**) except that a second subzero cooling is omitted; hence, the cycle consists of hardening, subzero cooling, and double tempering. Procedure **Item 3**), which follows, also has one subzero cooling period in the cycle, but this follows the first tempering operation.

3) *Tempering Followed by Subzero Treatment:* This treatment is for tools having irregular sections, sharp corners, or edges where cracks might develop if the hardening operation were followed immediately by subzero cooling.

- a) Preheat and heat for hardening.
- b) Preheat and heat for hardening.
- c) Quench as described under procedure **Item 1**).
- d) Temper to required hardness.
- e) Cool to subzero temperature  $-100$  to  $-120^\circ\text{F}$  ( $-73$  to  $-84^\circ\text{C}$ ) and then allow the tool to return to room temperature.
- f) Repeat tempering operation.

### Testing the Hardness of Metals

**Brinell Hardness Test.**—The Brinell test for determining the hardness of metallic materials consists in applying a known load to the surface of the material to be tested through a hardened steel ball of known diameter. The diameter of the resulting permanent impression in the metal is measured and the Brinell Hardness Number (BHN)\* is then calculated from the following formula in which  $D$  = diameter of ball in millimeters,  $d$  = measured diameter at the rim of the impression in millimeters, and  $P$  = applied load in kilograms.

$$\text{BHN} = \frac{\text{load on indenting tool in kilograms}}{\text{surface area of indentation in sq. mm.}} = \frac{P}{\frac{\pi D}{2}(D - \sqrt{D^2 - d^2})}$$

If the steel ball were not deformed under the applied load and if the impression were truly spherical, then the preceding formula would be a general one, and any combination of applied load and size of ball could be used. The impression, however, is not quite a spherical surface because there must always be some deformation of the steel ball and some recovery of form of the metal in the impression. Hence, for a standard Brinell Hardness test, the size and characteristics of the ball and the magnitude of the applied load must be standardized. In the standard test, a ball 10 millimeters in diameter and a load of 3000, 1500, or 500 kilograms is used. It is desirable, although not mandatory, that the test load be of such magnitude that the diameter of the impression be in the range of 2.50 to 4.75 millimeters. The following test loads and approximate Brinell Hardness Numbers for this range of impression diameters are: 3000 kg, 160 to 600 BHN; 1500 kg, 80 to 300 BHN; 500 kg, 26 to 100 BHN. In making a Brinell Hardness test, the load should be applied steadily and without a jerk for at least 15 seconds for iron and steel, and at least 30 seconds in testing other metals. A minimum period of 2 minutes, for example, has been recommended for magnesium and magnesium alloys. (For the softer metals, loads of 250, 125, or 100 kg are sometimes used.)

According to the American Society for Testing and Materials Standard E10-66, a steel ball may be used on material having a BHN not over 450, a Hultgren ball on material not over 500, or a carbide ball on material not over 630. The Brinell Hardness test is not recommended for material having a BHN over 630.

\* Brinell Hardness Numbers also may be identified with the letters HB, HBS for hardness measured with a steel indenter, and HBW for hardness measured with a carbide indenter.

**Rockwell Hardness Test.**—The Rockwell hardness tester is essentially a machine that measures hardness by determining the depth of penetration of a penetrator into the specimen under certain fixed test conditions. The penetrator may be either a steel ball or a diamond spheroconical penetrator. The hardness number is related to the depth of indentation, and the number is higher the harder the material. A minor load of 10 kg is first applied, causing an initial penetration; the dial is set at zero on the black-figure scale, and the major load is applied. This major load is customarily 60 or 100 kg when a steel ball is used as a penetrator, but other loads may be used when necessary. The ball penetrator is  $\frac{1}{16}$  inch in diameter normally, but other penetrators of larger diameter, such as  $\frac{1}{8}$  inch, may be employed for soft metals. When a diamond spheroconical penetrator is employed, the load usually is 150 kg. Experience decides the best combination of load and penetrator for use. After the major load is applied and removed, according to standard procedure, the reading is taken while the minor load is still applied.

**The Rockwell Hardness Scales.**—The various Rockwell scales and their applications are shown in the following table. The type of penetrator and load used with each are shown in Table 5 and Table 6, which give comparative hardness values for different hardness scales.

Scale	Testing Application
A	For tungsten carbide and other extremely hard materials. Also for thin, hard sheets.
B	For materials of medium hardness such as low- and medium-carbon steels in the annealed condition.
C	For materials harder than 100 RB on the Rockwell B scale.
D	Where a somewhat lighter load is desired than on the Rockwell C scale, as on case-hardened pieces.
E	For very soft materials such as bearing metals.
F	Same as the Rockwell E scale but using a $\frac{1}{16}$ -inch ball.
G	For metals harder than tested on the Rockwell B scale.
H & K	For softer metals.
15-N; 30-N; 45-N	Where a shallow impression or a small area is desired. For hardened steel and hard alloys.
15-T; 30-T; 45-T	Where a shallow impression or a small area is desired for materials softer than hardened steel.

**Shore's Scleroscope.**—The scleroscope is an instrument that measures the hardness of the work in terms of elasticity. A diamond-tipped hammer is allowed to drop from a known height on the metal to be tested. As this hammer strikes the metal, it rebounds, and the harder the metal, the greater the rebound. The extreme height of the rebound is recorded, and an average of a number of readings taken on a single piece will give a good indication of the hardness of the work. The surface smoothness of the work affects the reading of the instrument. The readings are also affected by the contour and mass of the work and the depth of the case, and, in carburized work, the soft core of light-depth carburizing, pack-hardening, or cyanide hardening, absorbing the force of the hammer fall and decreasing the rebound. The hammer weighs about 40 grains, the height of the rebound of hardened steel is in the neighborhood of 100 on the scale, or about  $6\frac{1}{4}$  inches (158.8 mm), and the total fall is about 10 inches or 255 millimeters.

**Vickers Hardness Test.**—The Vickers test is similar in principle to the Brinell Hardness test. The standard Vickers penetrator is a square-based diamond pyramid having an included point angle of 136 degrees. The numerical value of the hardness number equals the applied load in kilograms divided by the area of the pyramidal impression. A smooth, firmly supported, flat surface is required. The load, which is usually applied for 30 seconds, may be 5, 10, 20, 30, 50, or 120 kilograms. The 50-kilogram load is the most usual. The hardness number is based upon the diagonal length of the square impression. The Vickers test is considered to be very accurate and may be applied to thin sheets as well as to larger sections with proper load regulation.

**Knoop Hardness Numbers.**—The Knoop hardness test is applicable to extremely thin metal, plated surfaces, exceptionally hard and brittle materials, very shallow carburized or nitrided surfaces, or whenever the applied load must be kept below 3600 grams. The Knoop indenter is a diamond ground to an elongated pyramidal form and it produces an indentation having long and short diagonals with a ratio of approximately 7 to 1. The longitudinal angle of the indenter is 172 degrees, 30 minutes, and the transverse angle 130 degrees. The Tukon Tester in which the Knoop indenter is used is fully automatic under electronic control. The Knoop hardness number equals the load in kilograms divided by the projected area of indentation in square millimeters. The indentation number corresponding to the long diagonal and for a given load may be determined from a table computed for a theoretically perfect indenter. The load, which may be varied from 25 to 3600 grams, is applied for a definite period and always normal to the surface tested. Lapped plane surfaces free from scratches are required.

**Monotron Hardness Indicator.**—With this instrument, a diamond-ball impressor point  $\frac{3}{4}$  mm in diameter is forced into the material to a depth of  $\frac{9}{5000}$  inch; the pressure required to produce this constant impression indicates the hardness. One of two dials shows the pressure in kilograms and pounds, and the other shows the depth of the impression in millimeters and inches. Readings in Brinell Hardness Numbers may be obtained by means of a scale designated as *M-1*.

**Keep's Test.**—With this apparatus, a standard steel drill makes a definite number of revolutions while it is pressed with standard force against the specimen to be tested. The hardness is automatically recorded on a diagram on which a dead soft material gives a horizontal line, and a material as hard as the drill itself gives a vertical line, intermediate hardness being represented by the corresponding angle between 0 and 90 degrees.

**Comparison of Hardness Scales.**—Table 5, Table 6, and Table 7 show comparisons of various hardness scales. All such tables are based on the assumption that the metal tested is homogeneous to a depth several times that of the indentation. To the extent that the metal being tested is not homogeneous, errors are introduced because different loads and different shapes of penetrators meet the resistance of metal of varying hardness, depending on the depth of indentation. Another source of error is introduced in comparing the hardness of different materials as measured on different hardness scales. This error arises from the fact that in any hardness test, metal that is severely cold-worked actually supports the penetrator, and different metals, different alloys, and different analyses of the same type of alloy have different cold-working properties. In spite of the possible inaccuracies introduced by such factors, it is of considerable value to be able to compare hardness values in a general way.

The data shown in Table 5 are based on extensive tests on carbon and alloy steels mostly in the heat-treated condition but have been found to be reliable on constructional alloy steels and tool steels in the as-forged, annealed, normalized, quenched, and tempered conditions, providing they are homogeneous. These hardness comparisons are not as accurate for special alloys such as high manganese steel, 18-8 stainless steel and other austenitic steels, nickel-base alloys, constructional alloy steels, and nickel-base alloys in the cold-worked condition.

The data shown in Table 6 are for hardness measurements of unhardened steel, steel of soft temper, gray and malleable cast iron, and most nonferrous metals. Again these hardness comparisons are not as accurate for annealed metals of high Rockwell B hardness, such as austenitic stainless steel, nickel and high nickel alloys, and cold-worked metals of low Rockwell B scale hardness, such as aluminum and the softer alloys.

Table 7 is intended to provide a general numerical comparison of the various Rockwell hardness scales; however, it should not be used for conversion between the various scales.

Note: The values in this table shown in **boldface** type correspond to those shown in American Society for Testing and Materials Specification E140-67.

Values in ( ) are beyond the normal range and are given for information only.

**Turner's Sclerometer.**—In making this test, a weighted diamond point is drawn once forward and once backward over the smooth surface of the material to be tested. The hardness number is the weight in grams required to produce a standard scratch.

**Mohs's Hardness Scale.**—Hardness, in general, is determined by what is known as Mohs's scale, a standard for hardness that is applied mainly to nonmetallic elements and minerals. In this hardness scale, there are ten degrees or steps, each designated by a mineral, the difference in hardness of the different steps being determined by the fact that any member in the series will scratch any of the preceding members. This scale is as follows:

1) talc; 2) gypsum; 3) calcite; 4) fluorspar; 5) apatite; 6) orthoclase; 7) quartz; 8) topaz; 9) sapphire or corundum; and 10) diamond.

These minerals, arbitrarily selected as standards, are successively harder, from talc, the softest of all minerals, to diamond, the hardest. This scale, which is now universally used for nonmetallic minerals, is not applied to metals.

**Relation Between Hardness and Tensile Strength.**—The approximate relationship between hardness and tensile strength is shown by the following formula:

Tensile strength =  $BHN \times 515$  (for Brinell Hardness Numbers up to 175).

Tensile strength =  $BHN \times 490$  (for Brinell Hardness Numbers larger than 175).

The above formulas give the tensile strength in pounds per square inch for steels. These approximate relationships between hardness and tensile strength do not apply to nonferrous metals, with the possible exception of certain aluminum alloys.

**Durometer Tests.**—The durometer is a portable hardness tester for measuring hardness of rubber, plastics, and some soft metals. The instrument is designed to apply pressure to the specimen and the hardness is read from a scale while the pressure is maintained. Various scales can be used by changing the indenter and the load applied.

Source: George Dorian of GPDorian Co. Note: This chart is for the general comparison of Rockwell scales only.

## NONFERROUS ALLOYS

## Strength Data for Nonferrous Metals

The ultimate tensile, shear, and yield strengths and moduli of elasticity of many nonferrous metals are given in Table 1. Values for the most part are given in ranges rather than as single values because of differences in composition, forms, sizes, and shapes for the aluminum alloys, and differences in heat treatments undergone for the other nonferrous metals. The values in the table are meant to serve as a guide, not as specifications. More specific data should be obtained from the supplier.

Table 1. Strength Data for Nonferrous Metals

Material	Ultimate Strength				Yield Strength (0.2% offset)		Modulus of Elasticity			
	in Tension		in Shear		kpsi	MPa	in Tension, $E$		in Shear, $G$	
	kpsi	MPa	kpsi	MPa			10 <sup>6</sup> psi	10 <sup>3</sup> MPa	10 <sup>6</sup> psi	10 <sup>3</sup> MPa

### Coppers and Copper Alloys

Pure copper is a reddish, highly malleable metal, and was one of the first to be found and utilized. Copper and its alloys are widely used because of their excellent electrical and thermal conductivities, outstanding resistance to corrosion, ease of fabrication, and broad ranges of obtainable strengths and special properties. Almost 400 commercial copper and copper-alloy compositions are available from mills as wrought products (rod, plate, sheet, strip, tube, pipe, extrusions, foil, forgings, and wire) and from foundries as castings.

Copper alloys are grouped into several general categories according to composition:

- coppers and high-copper alloys
- brasses
- bronzes
- copper nickels
- copper-nickel-zinc alloys (nickel silvers)
- lead coppers
- special alloys

The designation system originally developed by the US copper and brass industry for identifying copper alloys used a three-digit number preceded by the letters CA. These designations have now been made part of the Unified Numbering System (UNS) simply by expanding the numbers to five digits preceded by the letter C. Because the old numbers are embedded in the new UNS numbers, no confusion results. UNS C10000 to C79999 are assigned to wrought compositions, and UNS C80000 to C99999 are assigned to castings. The designation system is not a specification but a method for identifying the composition of mill and foundry products. The precise technical and quality assurance requirements to be satisfied are defined in relevant standard specifications issued by the federal government, the military, and the ASTM.

**Table 1. Classification of Coppers and Copper Alloys**

Family	Principal Alloying Element	UNS Numbers <sup>a</sup>
Coppers, high-copper alloys		C1xxxx
Brasses	Zn	C2xxxx, C3xxxx, C4xxxx, C66400 to C69800
Phosphor bronzes	Sn	C5xxxx
Aluminum bronzes	Al	C60600 to C64200
Silicon bronzes	Si	C64700 to C66100
Copper nickels, nickel silvers	Ni	C7xxxx

<sup>a</sup>Wrought alloys.

**Cast Coppers and Copper Alloys.**—Generally, casting permits greater latitude in the use of alloying elements than in the fabrication of wrought products, which requires either hot or cold-working. The cast compositions of coppers and high-copper alloys have a designated minimum copper content and may include other elements to impart special properties. The cast brasses are comprised of copper-zinc-tin alloys (red, semired, and yellow brasses); manganese bronze alloys (high-strength yellow brasses); leaded manganese bronze alloys (leaded high-strength yellow brasses); and copper-zinc-silicon alloys (silicon brasses and bronzes).

The cast bronze alloys have four main families: copper-tin alloys (tin bronzes); copper-tin-lead alloys (leaded and high-leaded tin bronzes); copper-tin-nickel alloys (nickel-tin bronzes); and copper-aluminum alloys (aluminum bronzes).

The cast copper-nickel alloys contain nickel as the principal alloying element. The leaded coppers are cast alloys containing 20 percent or more lead.

Table 2 lists the properties and applications of common cast copper alloys.

**Table 2. Properties and Applications of Cast Coppers and Copper Alloys**

UNS Designation	Nominal Composition (%)	Typical Mechanical Properties, as Cast or Heat-Treated <sup>a</sup>				Typical Applications
		Tensile Strength (ksi)	Yield Strength (ksi)	Elongation in 2 in. (%)	Machinability Rating <sup>b</sup>	
<b>Copper Alloys</b>						
C80100	99.95 Cu + Ag min, 0.05 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation-resistant applications.
C80300	99.95 Cu + Ag min, 0.034 Ag min, 0.05 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation-resistant applications.
C80500	99.75 Cu + Ag min, 0.034 Ag min, 0.02 B max, 0.23 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation-resistant applications.
C80700	99.75 Cu + Ag min, 0.02 B max, 0.23 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation-resistant applications.
C80900	99.70 Cu + Ag min, 0.034 Ag min, 0.30 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation-resistant applications.
C81100	99.70 Cu + Ag min, 0.30 others max	25	9	40	10	Electrical and thermal conductors; corrosion and oxidation resistant applications.
<b>High-Copper Alloys</b>						
C81300	98.5 Cu min, 0.06 Be, 0.80 Co, 0.40 others max	(53)	(36)	(11)	20	Higher hardness electrical and thermal conductors.
C81400	98.5 Cu min, 0.06 Be, 0.80 Cr, 0.40 others max	(53)	(36)	(11)	20	Higher hardness electrical and thermal conductors.
C81500	98.0 Cu min, 1.0 Cr, 0.50 others max	(51)	(40)	(17)	20	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-81100 are required.
C81700	94.2 Cu min, 1.0 Ag, 0.4 Be, 0.9 Co, 0.9 Ni	(92)	(68)	(8)	30	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-81100 are required. Also used in place of C81500 where electrical and/or thermal conductivities can be sacrificed for hardness and strength.
C81800	95.6 Cu min, 1.0 Ag, 0.4 Be, 1.6 Co	50 (102)	25 (75)	20 (8)	20	Resistance-welding electrodes, dies.
C82000	96.8 Cu, 0.6 Be, 2.6 Co	50 (100)	20 (75)	20 (8)	20	Current-carrying parts, contact and switch blades, bushings and bearings, and soldering iron and resistance-welding tips.
C82100	97.7 Cu, 0.5 Be, 0.9 Co, 0.9 Ni	(92)	(68)	(8)	30	Electrical and/or thermal conductors used as structural members where strength and hardness greater than that of C80100-81100 are required. Also used in place of C81500 where electrical and/or thermal conductivities can be sacrificed for hardness and strength.
C82200	96.5 Cu min, 0.6 Be, 1.5 Ni	57 (95)	30 (75)	20 (8)	20	Clutch rings, brake drums, seam-welder electrodes, projection welding dies, spot-welding tips, beam-welder shapes, bushings, water-cooled holders.
C82400	96.4 Cu min, 1.70 Be, 0.25 Co	72 (150)	37 (140)	20 (1)	20	Safety tools, molds for plastic parts, cams, bushings, bearings, valves, pump parts, gears.
C82500	97.2 Cu, 2.0 Be, 0.5 Co, 0.25 Si	80 (160)	45	20 (1)	20	Safety tools, molds for plastic parts, cams, bushings, bearings, valves, pump parts.
C82600	95.2 Cu min, 2.3 Be, 0.5 Co, 0.25 Si	82 (165)	47 (155)	20 (1)	20	Bearings and molds for plastic parts.
C82700	96.3 Cu, 2.45 Be, 1.25 Ni	(155)	(130)	(0)	20	Bearings and molds for plastic parts.
C82800	96.6 Cu, 2.6 Be, 0.5 Co, 0.25 Si	97 (165)	55 (145)	20 (1)	10	Molds for plastic parts, cams, bushings, bearings, valves, pump parts, sleeves.

**Table 2. (Continued) Properties and Applications of Cast Coppers and Copper Alloys**

UNS Designation	Nominal Composition (%)	Typical Mechanical Properties, as Cast or Heat-Treated <sup>a</sup>				Typical Applications
		Tensile Strength (ksi)	Yield Strength (ksi)	Elongation in 2 in. (%)	Machinability Rating <sup>b</sup>	
<b>Red Brasses and Leaded Red Brasses</b>						
C83300	93 Cu, 1.5 Sn, 1.5 Pb, 4 Zn	32	10	35	35	Terminal ends for electrical cables.
C83400	90 Cu, 10 Zn	35	10	30	60	Moderate strength, moderate conductivity castings; rotating bands.
C83600	85 Cu, 5 Sn, 5 Pb, 5 Zn	37	17	30	84	Valves, flanges, pipe fittings, plumbing goods, pump castings, water pump impellers and housings, ornamental fixtures, small gears.
C83800	83 Cu, 4 Sn, 6 Pb, 7 Zn	35	16	25	90	Low-pressure valves and fittings, plumbing supplies and fittings, general hardware, air-gas-water fittings, pump components, railroad catenary fittings.
<b>Semired Brasses and Leaded Semired Brasses</b>						
C84200	80 Cu, 5 Sn, 2.5 Pb, 12.5 Zn	35	14	27	80	Pipe fittings, elbows, T's, couplings, bushings, locknuts, plugs, unions.
C84400	81 Cu, 3 Sn, 7 Pb, 9 Zn	34	15	26	90	General hardware, ornamental castings, plumbing supplies and fixtures, low-pressure valves and fittings.
C84500	78 Cu, 3 Sn, 7 Pb, 12 Zn	35	14	28	90	Plumbing fixtures, cocks, faucets, stops, waste, air and gas fittings, low-pressure valve fittings.
C84800	76 Cu, 3 Sn, 6 Pb, 15 Zn	36	14	30	90	Plumbing fixtures, cocks, faucets, stops, waste, air, and gas, general hardware, and low-pressure valve fittings.
<b>Yellow Brasses and Leaded Yellow Brasses</b>						
C85200	72 Cu, 1 Sn, 3 Pb, 24 Zn	38	13	35	80	Plumbing fittings and fixtures, ferrules, valves, hardware, ornamental brass, chandeliers, and irons.
C85400	67 Cu, 1 Sn, 3 Pb, 29 Zn	34	12	35	80	General-purpose yellow casting alloy not subject to high internal pressure. Furniture hardware, ornamental castings, radiator fittings, ship trimmings, battery clamps, valves, and fittings.
C85500	61 Cu, 0.8 Al, bal Zn	60	23	40	80	Ornamental castings.
C85700	63 Cu, 1 Sn, 1 Pb, 34.7 Zn, 0.3 Al	50	18	40	80	Bushings, hardware fittings, ornamental castings.
C85800	58 Cu, 1 Sn, 1 Pb, 40 Zn	55	30	15	80	General-purpose die-casting alloy having moderate strength.
<b>Manganese and Leaded Manganese Bronze Alloys</b>						
C86100	67 Cu, 21 Zn, 3 Fe, 5 Al, 4 Mn	95	50	20	30	Marine castings, gears, gun mounts, bushings and bearings, marine racing propellers.
C86200	64 Cu, 26 Zn, 3 Fe, 4 Al, 3 Mn	95	48	20	30	Marine castings, gears, gun mounts, bushings and bearings.
C86300	63 Cu, 25 Zn, 3 Fe, 6 Al, 3 Mn	115	83	15	8	Extra-heavy duty, high-strength alloy. Large valve stems, gears, cams, slow-speed heavy-load bearings, screwdown nuts, hydraulic cylinder parts.
C86400	59 Cu, 1 Pb, 40 Zn	65	25	20	65	Free-machining manganese bronze. Valve stems, marine fittings, lever arms, brackets, light-duty gears.
C86500	58 Cu, 0.5 Sn, 39.5 Zn, 1 Fe, 1 Al	71	28	30	26	Machinery parts requiring strength and toughness, lever arms, valve stems, gears.
C86700	58 Cu, 1 Pb, 41 Zn	85	42	20	55	High strength, free-machining manganese bronze. Valve stems.
C86800	55 Cu, 37 Zn, 3 Ni, 2 Fe, 3 Mn	82	38	22	30	Marine fittings, marine propellers.
<b>Silicon Bronzes and Silicon Brasses</b>						
C87200	89 Cu min, 4 Si	55	25	30	40	Bearings, bells, impellers, pump and valve components, marine fittings, corrosion-resistant castings.
C87400	83 Cu, 14 Zn, 3 Si	55	24	30	50	Bearings, gears, impellers, rocker arms, valve stems, clamps.

**Table 2. (Continued) Properties and Applications of Cast Coppers and Copper Alloys**

UNS Designation	Nominal Composition (%)	Typical Mechanical Properties, as Cast or Heat-Treated <sup>a</sup>				Typical Applications
		Tensile Strength (ksi)	Yield Strength (ksi)	Elongation in 2 in. (%)	Machinability Rating <sup>b</sup>	
C87500	82 Cu, 14 Zn, 4 Si	67	30	21	50	Bearings, gears, impellers, rocker arms, valve stems, small boat propellers.
C87600	90 Cu, 5.5 Zn, 4.5 Si	66	32	20	40	Valve stems.
C87800	82 Cu, 14 Zn, 4 Si	85	50	25	40	High-strength, thin-wall die castings; brush holders, lever arms, brackets, clamps, hexagonal nuts.
C87900	65 Cu, 34 Zn, 1 Si	70	35	25	80	General-purpose die-casting alloy having moderate strength.
Tin Bronzes						
C90200	93 Cu, 7 Sn	38	16	30	20	Bearings and bushings.
C90300	88 Cu, 8 Sn, 4 Zn	45	21	30	30	Bearings, bushings, pump impellers, piston rings, valve components, seal rings, steam fittings, gears.
C90500	88 Cu, 10 Sn, 2 Zn	45	22	25	30	Bearings, bushings, pump impellers, piston rings, valve components, steam fittings, gears.
C90700	89 Cu, 11 Sn	44 (55)	22 (30)	20 (16)	20	Gears, bearings, bushings.
C90900	87 Cu, 13 Sn	40	20	15	20	Bearings and bushings.
C91000	85 Cu, 14 Sn, 1 Zn	32	25	2	20	Piston rings and bearings.
C91100	84 Cu, 16 Sn	35	25	2	10	Piston rings, bearings, bushings, bridge plates.
C91300	81 Cu, 19 Sn	35	30	0.5	10	Piston rings, bearings, bushings, bridge plates, bells.
C91600	88 Cu, 10.5 Sn, 1.5 Ni	44 (60)	22 (32)	16 (16)	20	Gears.
C91700	86.5 Cu, 12 Sn, 1.5 Ni	44 (60)	22 (32)	16 (16)	20	Gears.
Leaded Tin Bronzes						
C92200	88 Cu, 6 Sn, 1.5 Pb, 4.5 Zn	40	20	30	42	Valves, fittings, and pressure-containing parts for use up to 550°F.
C92300	87 Cu, 8 Sn, 4 Zn	40	20	25	42	Valves, pipe fittings, and high-pressure steam castings. Superior machinability to C90300.
C92500	87 Cu, 11 Sn, 1 Pb, 1 Ni	44	20	20	30	Gears, automotive synchronizer rings.
C92600	87 Cu, 10 Sn, 1 Pb, 2 Zn	44	20	30	40	Bearings, bushings, pump impellers, piston rings, valve components, steam fittings, and gears. Superior machinability to C90500.
C92700	88 Cu, 10 Sn, 2 Pb	42	21	20	45	Bearings, bushings, pump impellers, piston rings, and gears. Superior machinability to C90500.
C92800	79 Cu, 16 Sn, 5 Pb	40	30	1	70	Piston rings.
C92900	82 Cu min, 9 Sn min, 2 Pb min, 2.8 Ni min	47 (47)	26 (26)	20 (20)	40	Gears, wear plates, guides, cams, parts requiring machinability superior to that of C91600 or 91700.
High-Leaded Tin Bronzes						
C93200	83 Cu, 6.3 Sn min, 7 Pb, 3 Zn	35	18	20	70	General-utility bearings and bushings.
C93400	84 Cu, 8 Sn, 8 Pb	32	16	20	70	Bearings and bushings.
C93500	85 Cu, 5 Sn, 9 Pb	32	16	20	70	Small bearings and bushings, bronze backing for babbit-lined automotive bearings.
C93700	80 Cu, 10 Sn, 10 Pb	35	18	20	80	Bearings for high speed and heavy pressures, pumps, impellers, corrosion-resistant applications, pressure-tight castings.
C93800	78 Cu, 7 Sn, 15 Pb	30	16	18	80	Bearings for general service and moderate pressure, pump impellers, and bodies for use in acid mine water.
C93900	79 Cu, 6 Sn, 15 Pb	32	22	7	80	Continuous castings only. Bearings for general service, pump bodies, and impellers for mine waters.
C94300	70 Cu, 5 Sn, 25 Pb	27	13	15	80	High-speed bearings for light loads.
C94400	81 Cu, 8 Sn, 11 Pb, 0.35 P	32	16	18	80	General-utility alloy for bushings and bearings.
C94500	73 Cu, 7 Sn, 20 Pb	25	12	12	80	Locomotive wearing parts; high-low, low-speed bearings.

**Table 2. (Continued) Properties and Applications of Cast Coppers and Copper Alloys**

UNS Designation	Nominal Composition (%)	Typical Mechanical Properties, as Cast or Heat-Treated <sup>a</sup>				Typical Applications
		Tensile Strength (ksi)	Yield Strength (ksi)	Elongation in 2 in. (%)	Machinability Rating <sup>b</sup>	
<b>Nickel-Tin Bronzes</b>						
C94700	88 Cu, 5 Sn, 2 Zn, 5 Ni	50 (85)	23 (60)	35 (10)	30 (20)	Valve stems and bodies, bearings, wear guides, shift forks, feeding mechanisms, circuit breaker parts, gears, piston cylinders, nozzles.
C94800	87 Cu, 5 Sn, 5 Ni	45 (60)	23 (30)	35 (8)	50 (40)	Structural castings, gear components, motion-translation devices, machinery parts, bearings.
<b>Aluminum Bronzes</b>						
C95200	88 Cu, 3 Fe, 9 Al	80	27	35	50	Acid-resisting pumps, bearings, gears, valve seats, guides, plungers, pump rods, bushings.
C95300	89 Cu, 1 Fe, 10 Al	75 (85)	27 (42)	25 (15)	55	Pickling baskets, nuts, gears, steel-mill slippers, marine equipment, welding jaws.
C95400	85 Cu, 4 Fe, 11 Al	85 (105)	35 (54)	18 (8)	60	Bearings, gears, worms, bushings, valve seats and guides, pickling hooks.
C95500	81 Cu, 4 Ni, 4 Fe, 11 Al	100 (120)	44 (68)	12 (10)	50	Valve guides and seats in aircraft engines, corrosion-resistant parts, bushings, gears, worms, pickling hooks and baskets, agitators.
C95600	91 Cu, 7 Al, 2 Si	75	34	18	60	Cable connectors, terminals, valve stems, marine hardware, gears, worms, pole-line hardware.
C95700	75 Cu, 2 Ni, 3 Fe, 8 Al, 12 Mn	95	45	26	50	Propellers, impellers, stator clamp segments, safety tools, welding rods, valves, pump casings.
C95800	81 Cu, 5 Ni, 4 Fe, 9 Al, 1 Mn	95	38	25	50	Propeller hubs, blades, and other parts in contact with salt water.
<b>Copper-Nickels</b>						
C96200	88.6 Cu, 10 Ni, 1.4 Fe	45 min	25 min	20 min	10	Components of items being used for seawater corrosion resistance.
C96300	79.3 Cu, 20 Ni, 0.7 Fe	75 min	55 min	10 min	15	Centrifugally cast tailshaft sleeves.
C96400	69.1 Cu, 30 Ni, 0.9 Fe	68	37	28	20	Valves, pump bodies, flanges, elbows used for seawater corrosion resistance.
C96600	68.5 Cu, 30 Ni, 1 Fe, 0.5 Be	(110)	(70)	(7)	20	High-strength structural parts for seawater corrosion resistance.
<b>Nickel Silvers</b>						
C97300	56 Cu, 2 Sn, 10 Pb, 12 Ni, 20 Zn	35	17	20	70	Hardware fittings, valves and valve trim, statuary, ornamental castings.
C97400	59 Cu, 3 Sn, 5 Pb, 17 Ni, 16 Zn	38	17	20	60	Valves, hardware, fittings, ornamental castings.
C97600	64 Cu, 4 Sn, 4 Pb, 20 Ni, 8 Zn	45	24	20	70	Marine castings, sanitary fittings, ornamental hardware, valves, pumps.
C97800	66 Cu, 5 Sn, 2 Pb, 25 Ni, 2 Zn	55	30	15	60	Ornamental and sanitary castings, valves and valve seats, musical instrument components.
<b>Special Alloys</b>						
C99300	71.8 Cu, 15 Ni, 0.7 Fe, 11 Al, 1.5 Co	95	55	2	20	Glass-making molds, plate glass rolls, marine hardware.
C99400	90.4 Cu, 2.2 Ni, 2.0 Fe, 1.2 Al, 1.2 Si, 3.0 Zn	66 (79)	34 (54)	25	50	Valve stems, marine and other uses requiring resistance to dezincification and dealuminification, propeller wheels, electrical parts, mining equipment gears.
C99500	87.9 Cu, 4.5 Ni, 4.0 Fe, 1.2 Al, 1.2 Si, 1.2 Zn	70 min	40 min	12 min	50	Same as C99400, but where higher yield strength is required.
C99700	56.5 Cu, Al, 1.5 Pb, 12 Mn, 5 Ni, 24 Zn	55	25	25	80	
C99750	58 Cu, 1 Al, 1 Pb, 20 Mn, 20 Zn	65 (75)	32 (40)	30 (20)		

<sup>a</sup> Values in parentheses are for heat-treated condition.

<sup>b</sup> Free cutting brass = 100.

**Wrought Coppers and Copper Alloys.**—Wrought copper alloys can be utilized in the annealed, cold-worked, stress-relieved, or hardened-by-heat-treatment conditions, depending on composition and end use. The “temper designation” for copper alloys is defined in ASTM Standard Recommended Practice B601, which is applicable to all product forms.

Wrought coppers and high-copper alloys, like cast alloys, have a designated minimum copper content and may include other elements to impart special properties. Wrought brasses have zinc as the principal alloying element and may have other designated elements. They comprise the copper-zinc alloys; copper-zinc-lead alloys (leaded brasses); and copper-zinc-tin alloys (tin brasses).

Four main groups comprise the wrought bronzes: copper-tin-phosphorus alloys (phosphor bronze); copper-tin-lead-phosphorus alloys (leaded phosphor bronze); copper-aluminum alloys (aluminum bronzes); and copper-silicon alloys (silicon bronze).

Wrought copper-nickel alloys, like the cast alloys, have nickel as the principal alloying element. The wrought copper-nickel-zinc alloys are known as “nickel silvers” because of their color.

Table 3 lists the nominal composition, properties, and applications of common wrought copper alloys.

**Table 3. Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C10100 Oxygen-free electronic	99.99 Cu	32-66	10-53	55	20	Excellent hot and cold workability; good forgeability. Fabricated by blanking, coining, coppersmithing, drawing and upsetting, hot forging and pressing, spinning, swaging, stamping. Uses: busbars, bus conductors, waveguides, hollow conductors, lead-in wires and anodes for vacuum tubes, vacuum seals, transistor components, glass to metal seals, coaxial cables and tubes, klystrons, microwave tubes, rectifiers.
C10200 Oxygen-free copper	99.95 Cu	32-66	10-53	55	20	Fabricating characteristics same as C10100. Uses: busbars, waveguides.
C10300 Oxygen-free, extra-low phosphorus	99.95 Cu, 0.003 P	32-55	10-50	50	20	Fabricating characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring good conductivity and welding or brazing properties.
C10400, C10500, C10700 Oxygen-free, silver-bearing	99.95 Cu	32-66	10-53	55	20	Fabricating characteristics same as C10100. Uses: auto gaskets, radiators, busbars, conductivity wire, contacts, radio parts, winding, switches, terminals, commutator segments; chemical process equipment, printing rolls, clad metals, printed-circuit foil.
C10800 Oxygen-free, low phosphorus	99.95 Cu, 0.009 P	32-55	10-50	50	20	Fabricating characteristics same as C10100. Uses: refrigerators, air conditioners, gas and heater lines, oil burner tubes, plumbing pipe and tube, brewery tubes, condenser and heat-exchanger tubes, dairy and distiller tubes, pulp and paper lines, tanks; air, gasoline, and hydraulic lines.
C11000 Electrolytic tough pitch copper	99.90 Cu, 0.04 O	32-66	10-53	55	20	Fabricating characteristics same as C10100. Uses: downspouts, gutters, roofing, gaskets, auto radiators, busbars, nails, printing rolls, rivets, radio parts.
C11000 Electrolytic tough pitch, anneal-resistant	99.90 Cu, 0.04 O, 0.01 Cd	66			20	Fabricated by drawing and stranding, stamping. Uses: electrical power transmission where resistance to softening under overloads is desired.
C11300, C11400, C11500, C11600 Silver-bearing tough pitch copper	99.90 Cu, 0.04 O, Ag	32-66	10-53	55	20	Fabricating characteristics same as C10100. Uses: gaskets, radiators, busbars, windings, switches, chemical process equipment, clad metals, printed-circuit foil.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C12000, C12100 Phosphorus deoxidized, low residual phosphorus	99.9 Cu	32-57	10-53	55	20	Fabricating characteristics same as C10100. Uses: busbars, electrical conductors, tubular bus, and applications requiring welding or brazing.
C12200, C12210 Phosphorus deoxidized copper, high residual phosphorus	99.90 Cu, 0.02 P	32-55	10-53	55	20	Fabricating characteristics same as C10100. Uses: gas and heater lines; oil burner tubing; plumbing pipe and tubing; condenser, evaporator, heat exchanger, dairy, and distiller tubing; steam and water lines; air, gasoline, and hydraulic lines.
C12500, C12700, C12800, C12900, C13000 Fire-refined tough pitch with silver	99.88 Cu	32-66	10-53	55	20	Fabricating characteristics same as C10100. Uses: same as C11000, electrolytic tough pitch copper.
C14200 Phosphorus deoxidized, arsenical	99.68 Cu, 0.3 As, 0.02 P	32-55	10-50	45	20	Fabricating characteristics same as C10100. Uses: staybolts, heat-exchanger and condenser tubes.
C14300, C14310 Cadmium copper, deoxidized	99.9 Cu, 0.1 Cd	32-58	11-56	42	20	Fabricating characteristics same as C10100. Uses: anneal-resistant electrical applications requiring thermal softening and embrittlement resistance, lead frames, contacts, terminals, solder-coated and solder-fabricated parts, furnace-brazed assemblies and welded components, cable wrap.
C14500, C14510, C14520 Tellurium bearing	99.5 Cu, 0.50 Te, 0.008 P	32-56	10-51	50	85	Fabricating characteristics same as C10100. Uses: Forgings and screw-machine products, and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these; electrical connectors, motor and switch parts, plumbing fittings, soldering coppers, welding torch tips, transistor bases, and furnace-brazed articles.
C14700, C14710, C14720 Sulfur bearing	99.6 Cu, 0.40 S	32-57	10-55	52	85	Fabricating characteristics same as C10100. Uses: screw-machine products and parts requiring high conductivity, extensive machining, corrosion resistance, copper color, or a combination of these; electrical connectors, motor and switch components, plumbing fittings, cold-headed and machined parts, cold forgings, furnace-brazed articles, screws, soldering coppers, rivets and welding torch tips.
C15000 Zirconium copper	99.8 Cu, 0.15 Zr	29-76	6-72	54	20	Fabricating characteristics same as C10100. Uses: switches, high-temperature circuit breakers, commutators, stud bases for power transmitters, rectifiers, soldering welding tips.
C15500	99.75 Cu, 0.06 P, 0.11 Mg, Ag	40-80	18-72	40	20	Fabricating characteristics same as C10100. Uses: high-conductivity light-duty springs, electrical contacts, fittings, clamps, connectors, diaphragms, electronic components, resistance-welding electrodes.
C15715	99.6 Cu, 0.13 Al <sub>2</sub> O <sub>3</sub>	52-88	44-84	27	20	Excellent cold workability. Fabricated by extrusion, drawing, rolling, heading, swaging, machining, blanking, roll threading. Uses: integrated-circuit lead frames, diode leads; vacuum, microwave, and x-ray tube components; electrical components; brush springs; commutators, electric generator and motor components.
C15720	99.5 Cu, 0.18 Al <sub>2</sub> O <sub>3</sub>	64-98	54-96	25		Excellent cold workability. Fabricated by extrusion, drawing, rolling, heading, swaging, machining, blanking. Uses: relay and switch springs, lead frames, contact supports, heat sinks, circuit breaker parts, rotor bars, resistance-welding electrodes and wheels, connectors, soldering gun tips.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Ratings	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C15760	98.8 Cu, 0.58 Al <sub>2</sub> O <sub>3</sub>	70-90	65-87	22		Excellent cold workability. Fabricated by extrusion and drawing. Uses: resistance-welding electrodes, soldering gun tips, MIG welding contact tips, continuous-casting molds.
C16200, C16210 Cadmium copper	99.0 Cu, 1.0 Cd	35-100	7-69	57	20	Excellent cold workability; good hot formability. Uses: trolley wires, heating pads, electric-blanket elements, spring contacts, railbands, high-strength transmission lines, connectors, cable wrap, switch-gear components, and waveguide cavities.
C16500	98.6 Cu, 0.8 Cd, 0.6 Sn	40-95	14-71	53	20	Fabricating characteristics same as C16200. Uses: electrical springs and contacts, trolley wire, clips, flat cable, resistance-welding electrodes.
C17000 Beryllium copper	98.3 Cu, 1.7 Be, 0.20 Co	70-190	32-170	45	20	Fabricating characteristics same as C16200. Commonly fabricated by blanking, forming and bending, turning, drilling, tapping. Uses: bellows, Bourdon tubing, diaphragms, fuse clips, fasteners, lock-washers, springs, switch parts, roll pins, valves, welding equipment.
C17200 Beryllium copper	98.1 Cu, 1.9 Be, 0.20 Co	68-212	25-195	48	20	Similar to C17000, particularly for its nonsparking characteristics.
C17300 Beryllium copper	98.1 Cu, 1.9 Be, 0.40 Pb	68-212	25-195	48	50	Combines superior machinability with good fabricating characteristics of C17200.
C17500, C17510 Beryllium copper	96.9 Cu, 2.5 Co, 0.6 Be	45-115	25-110	28		Fabricating characteristics same as C16200. Uses: fuse clips, fasteners, springs, switch and relay parts, electrical conductors, welding equipment.
C18200, C18400, C18500 Chromium copper	99.2 Cu	34-86	14-77	40	20	Excellent cold workability, good hot workability. Uses: resistance-welding electrodes, seam-welding wheels, switch gear, electrode-holder jaws, cable connectors, current-carrying arms and shafts, circuit-breaker parts, molds, spot-welding tips, flash-welding electrodes, electrical and thermal conductors requiring strength, switch contacts.
C18700 Leaded copper	99.0 Cu, 1.0 Pb	32-55	10-50	45	85	Good cold workability; poor hot formability. Uses: connectors, motor and switch parts, screw-machine parts requiring high conductivity.
C18900	98.7 Cu, 0.8 Sn, 0.3 Si, 0.20 Mn	38-95	9-52	48	20	Fabricating characteristics same as C10100. Uses: welding rod and wire for inert gas tungsten arc and metal arc welding, and oxyacetylene welding of copper.
C19000 Copper-nickel-phosphorus alloy	98.6 Cu, 1.1 Ni, 0.3 P	38-115	20-81	50	30	Fabricating characteristics same as C10100. Uses: springs, clips, electrical connectors, power tube and electron tube components, high-strength electrical conductors, bolts, nails, screws, cotter pins, and parts requiring some combination of high strength, high electrical or thermal conductivity, high resistance to fatigue and creep, and good workability.
C19100 Copper-nickel-phosphorus-tellurium alloy	98.2 Cu, 1.1 Ni, 0.5 Te, 0.2 P	36-104	10-92	27	75	Good hot and cold workability. Uses: forgings and screw-machine parts requiring high strength, hardenability, extensive machining, corrosion resistance, copper color, good conductivity, or a combination of these; bolts, bushings, electrical connectors, gears, marine hardware, nuts, pinions, tie rods, tumbuckle barrels, welding torch tips.
C19200	99 Cu, 1.0 Fe, 0.03 P	37-77	11-74	40	20	Excellent hot and cold workability. Uses: automotive hydraulic brake lines, flexible hose, electrical terminals, fuse clips, gaskets, gift hollow ware, applications requiring resistance to softening and stress corrosion, air-conditioning and heat-exchanger tubing.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C19400	97.4 Cu, 2.4 Fe, 0.13 Zn, 0.04 P	45-76	24-73	32	20	Excellent hot and cold workability. Uses: circuit-breaker components, contact springs, electrical clamps, electrical springs, electrical terminals, flexible hose, fuse clips, gaskets, gift hollow ware, plug contacts, rivets, and welded condenser tubes.
C19500	97.0 Cu, 1.5 Fe, 0.6 Sn, 0.10 P, 0.80 Co	80-97	65-95	15	20	Excellent hot and cold workability. Uses: electrical springs, sockets, terminals, connectors, clips, and other current-carrying parts requiring strength.
C21000 Gilding, 95%	95.0 Cu, 5.0 Zn	34-64	10-58	45	20	Excellent cold workability, good hot workability for blanking, coining, drawing, piercing and punching, shearing, spinning, squeezing and swaging, stamping. Uses: coins, medals, bullet jackets, fuse caps, primers, plaques, jewelry base for gold plate.
C22000 Commercial bronze, 90%	90.0 Cu, 10.0 Zn	37-72	10-62	50	20	Fabricating characteristics same as C21000, plus heading and upsetting, roll threading and knurling, hot forging and pressing. Uses: etching bronze, grillwork, screen cloth, weatherstripping, lipstick cases, compacts, marine hardware, screws, rivets.
C22600 Jewelry bronze, 87.5%	87.5 Cu, 12.5 Zn	39-97	11-62	46	30	Fabricating characteristics same as C21000, plus heading and up-setting, roll threading and knurling. Uses: angles, channels, chain, fasteners, costume jewelry, lipstick cases, powder compacts, base for gold plate.
C23000 Red brass, 85%	85.0 Cu, 15.0 Zn	39-105	10-63	55	30	Excellent cold workability; good hot formability. Uses: weather-stripping, conduit, sockets, fasteners, fire extinguishers, condenser and heat-exchanger tubing, plumbing pipe, radiator cores.
C24000 Low brass, 80%	80.0 Cu, 20.0 Zn	42-125	12-65	55	30	Excellent cold workability. Fabricating characteristics same as C23000. Uses: battery caps, bellows, musical instruments, clock dials, pump lines, flexible hose.
C26000, C26100, C26130, C26200 Cartridge brass, 70%	70.0 Cu, 30.0 Zn	44-130	11-65	66		Excellent cold workability. Uses: radiator cores and tanks, flashlight shells, lamp fixtures, fasteners, screws, springs, grillwork, stencils, plumbing accessories, plumbing brass goods, locks, hinges, ammunition components, plumbing accessories, pins, rivets.
C26800, C27000 Yellow brass	65.0 Cu, 35.0 Zn	46-128	14-62	65	30	Excellent cold workability. Fabricating characteristics same as C23000. Uses: same as C26000 except not used for ammunition.
C28000 Muntz metal, 60%	60.0 Cu, 40.0 Zn	54-74	21-55	52	40	Excellent hot formability and forgeability for blanking, forming and bending, hot forging and pressing, hot heading and upsetting, shearing. Uses: architectural, large nuts and bolts, brazing rod, condenser plates, heat-exchanger and condenser tubing, hot forgings.
C31400 Leaded commercial bronze	89.0 Cu, 1.9 Pb, 0.1 Zn	37-60	12-55	45	80	Excellent machinability. Uses: screws, machine parts, pickling crates.
C31600 Leaded commercial bronze, nickel-bearing	89.0 Cu, 1.9 Pb, 1.0 Ni, 8.1 Zn	37-67	12-59	45	80	Good cold workability; poor hot formability. Uses: electrical connectors, fasteners, hardware, nuts, screws, screw-machine parts.
C33000 Low-leaded brass tube	66.0 Cu, 0.5 Pb, 33.5 Zn	47-75	15-60	60	60	Combines good machinability and excellent cold workability. Fabricated by forming and bending, machining, piercing and punching. Uses: pump and power cylinders and liners, ammunition primers, plumbing accessories.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Ratings	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C33200 High-leaded brass tube	66.0 Cu, 2.0 Pb, 32.0 Zn	47-75	15-60	50	80	Excellent machinability. Fabricated by piercing, punching, and machining. Uses: general-purpose screw-machine parts.
C33500 Low-leaded brass	63.5 Cu, 0.5 Pb, 36 Zn	46-74	14-60	65	60	Similar to C33200. Commonly fabricated by blanking, drawing, machining, piercing and punching, stamping. Uses: butts, hinges, watch backs.
C34000 Medium-leaded brass	63.5 Cu, 1.0 Pb, 35.5 Zn	47-88	15-60	60	70	Similar to C33200. Fabricated by blanking, heading and upsetting, machining, piercing and punching, roll threading and knurling, stamping. Uses: butts, gears, nuts, rivets, screws, dials, engravings, instrument plates.
C34200 High-leaded brass	63.5 Cu, 2.0 Pb, 34.5 Zn	49-85	17-62	52	90	Combines excellent machinability with moderate cold workability. Uses: clock plates and nuts, clock and watch backs, gears, wheels and channel plate.
C35000 Medium-leaded brass	62.5 Cu, 1.1 Pb, 36.4 Zn	45-95	13-70	66	70	Fair cold workability; poor hot formability. Uses: bearing cages, book dies, clock plates, gears, hinges, hose couplings, keys, lock parts, lock tumblers, meter parts, nuts, sink strainers, strike plates, templates, type characters, washers, wear plates.
C35300 High-leaded brass	61.5 Cu, 2.8 Pb, 36.5 Zn	49-85	17-62	52	90	Similar to C34200.
C35600 Extra-high-leaded brass	61.5 Cu, 2.5 Pb, 36 Zn	47-97	17-87	60	100	Excellent machinability. Fabricated by blanking, machining, piercing and punching, stamping. Uses: clock plates and nuts, clock and watch backs, gears, wheels, and channel plate.
C36000 Free-cutting brass	61.5 Cu, 3.1 Pb, 35.4 Zn	49-68	18-45	53	100	Excellent machinability. Fabricated by machining, roll threading, and knurling. Uses: gears, pinions, automatic high-speed screw-machine parts.
C36500 to C36800 Leaded Muntz metal	59.5 Cu, 0.5 Pb, 40.0 Zn	54 (As hot rolled)	20	45	60	Combines good machinability with excellent hot formability. Uses: condenser-tube plates.
C37000 Free-cutting Muntz metal	60.0 Cu, 1.0 Pb, 39.0 Zn	54-80	20-60	40	70	Fabricating characteristics similar to C36500 to 36800. Uses: automatic screw-machine parts.
C37700 Forging brass	59.5 Cu, 2.0 Pb, 38.0 Zn	52 (As ex- truded)	20	45	80	Excellent hot workability. Fabricated by heading and upsetting, hot forging and pressing, hot heading and upsetting, machining. Uses: forgings and pressings of all kinds.
C38500 Architectural bronze	57.0 Cu, 3.0 Pb, 40.0 Zn	60 (As ex- truded)	20	30	90	Excellent machinability and hot workability. Fabricated by hot forging and pressing, forming, bending, and machining. Uses: architectural extrusions, store fronts, thresholds, trim, butts, hinges, lock bodies, and forgings.
C40500	95 Cu, 1 Sn, 4 Zn	39-78	12-70	49	20	Excellent cold workability. Fabricated by blanking, forming, and drawing. Uses: meter clips, terminals, fuse clips, contact and relay springs, washers.
C40800	95 Cu, 2 Sn, 3 Zn	42-79	13-75	43	20	Excellent cold workability. Fabricated by blanking, stamping, and shearing. Uses: electrical connectors.
C41100	91 Cu, 0.5 Sn, 8.5 Zn	39-106	11-72	43	20	Excellent cold workability, good hot formability. Fabricated by blanking, forming and bending, drawing, piercing and punching, shearing, spinning, and stamping. Uses: bushings, bearing sleeves, thrust washers, flexible metal hose.
C41300	90.0 Cu, 1.0 Sn, 9.0 Zn	41-105	12-82	45	20	Excellent cold workability; good hot formability. Uses: plater bar for jewelry products, flat springs for electrical switchgear.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C41500	91 Cu, 1.8 Sn, 7.2 Zn	46-81	17-75	44	30	Excellent cold workability. Fabricated by blanking, drawing, bending, forming, shearing, and stamping. Uses: spring applications for electrical switches.
C42200	87.5 Cu, 1.1 Sn, 11.4 Zn	43-88	15-75	46	30	Excellent cold workability; good hot formability. Fabricated by blanking, piercing, forming, and drawing. Uses: sash chains, fuse clips, terminals, spring washers, contact springs, electrical connectors.
C42500	88.5 Cu, 2.0 Sn, 9.5 Zn	45-92	18-76	49	30	Excellent cold workability. Fabricated by blanking, piercing, forming, and drawing. Uses: electrical switches, springs, terminals, connectors, fuse clips, pen clips, weather stripping.
C43000	87.0 Cu, 2.2 Sn, 10.8 Zn	46-94	18-73	55	30	Excellent cold workability; good hot formability. Fabricated by blanking, coining, drawing, forming, bending, heading, and upsetting. Uses: same as C42500.
C43400	85.0 Cu, 0.7 Sn, 14.3 Zn	45-90	15-75	49	30	Excellent cold workability. Fabricated by blanking, drawing, bonding, forming, stamping, and shearing. Uses: electrical switch parts, blades, relay springs, contacts.
C43500	81.0 Cu, 0.9 Sn, 18.1 Zn	46-80	16-68	46	30	Excellent cold workability for fabrication by forming and bending. Uses: Bourdon tubing and musical instruments.
C44300, C44400, C44500 Inhibited admiralty	71.0 Cu, 28.0 Zn, 1.0 Sn	48-55	18-22	65	30	Excellent cold workability for forming and bending. Uses: condenser, evaporator and heat-exchanger tubing, condenser tubing plates, distiller tubing, ferrules.
C46400 to C46700 Naval brass	60.0 Cu, 39.2 Zn, 0.8 Sn	55-88	25-66	50	30	Excellent hot workability and hot forgeability. Fabricated by blanking, drawing, bending, heading and upsetting, hot forging, pressing. Uses: aircraft turnbuckle barrels, balls, bolts, marine hardware, nuts, propeller shafts, rivets, valve stems, condenser plates, welding rod.
C48200 Naval brass, medium-leaded	60.5 Cu, 0.7 Pb, 0.8 Sn, 38.0 Zn	56-75	25-53	43	50	Good hot workability for hot forging, pressing, and machining operations. Uses: marine hardware, screw-machine products, valve stems.
C48500 Leaded naval brass	60.0 Cu, 1.8 Pb, 37.5 Zn, 0.7 Sn	57-75	25-53	40	70	Combines good hot forgeability and machinability. Fabricated by hot forging and pressing, machining. Uses: marine hardware, screw-machine parts, valve stems.
C50500 Phosphor bronze, 1.25% E	98.7 Cu, 1.3 Sn, trace P	40-79	14-50	48	20	Excellent cold workability; good hot formability. Fabricated by blanking, bending, heading and upsetting, shearing and swaging. Uses: electrical contacts, flexible hose, pole-line hardware.
C51000 Phosphor bronze, 5% A	94.8 Cu, 5.0 Sn, trace P	47-140	19-80	64	20	Excellent cold workability. Fabricated by blanking, drawing, bending, heading and upsetting, roll threading and knurling, shearing, stamping. Uses: bellows, Bourdon tubing, clutch discs, cotter pins, diaphragms, fasteners, lock washers, wire brushes, chemical hardware, textile machinery, welding rod.
C51100	95.6 Cu, 4.2 Sn, 0.2 P	46-103	50-80	48	20	Excellent cold workability. Uses: bridge bearing plates, locator bars, fuse clips, sleeve bushings, springs, switch parts, truss wire, wire brushes, chemical hardware, perforated sheets, textile machinery.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C52100 Phosphor bronze, 8% C	92.0 Cu, 8.0 Sn, trace P	55-140	24-80	70	20	Good cold workability for blanking, drawing, forming and bending, shearing, stamping. Uses: generally for more severe service conditions than C51000.
C52400 Phosphor bronze, 10% D	90.0 Cu, 10.0 Sn, trace P	66-147	28	70	20	Good cold workability for blanking, forming and bending, shearing. Uses: heavy bars and plates for severe compression, bridge and expansion plates and fittings, articles requiring good spring qualities, resilience, fatigue resistance, good wear and corrosion resistance.
C54400	88.0 Cu, 4.0 Pb, 4.0 Zn, 4.0 Sn	44-75	19-63	50	80	Excellent machinability; good cold workability. Fabricated by blanking, drawing, bending, machining, shearing, stamping. Uses: bearings, bushings, gears, pinions, shafts, thrust washers, valve parts.
C60800	95.0 Cu, 5.0 Al	60	27	55	20	Good cold workability; fair hot formability. Uses: condenser, evaporator and heat-exchanger tubes, distiller tubes, ferrules.
C61000	92.0 Cu, 8.0 Al	52-60	17-27	45	20	Good hot and cold workability. Uses: bolts, pump parts, shafts, tie rods, overlay on steel for wearing surfaces.
C61300	90.3 Cu, 0.35 Sn, 6.8 Al, 0.35 Sn	70-85	30-58	42	30	Good hot and cold formability. Uses: nuts, bolts, corrosion resistant vessels and tanks, structural components, machine parts, condenser tube and piping systems, marine protective sheathing and fasteners, munitions mixing troughs and blending chambers.
C61400 Aluminum bronze, D	91.0 Cu, 7.0 Al, 2.0 Fe	76-89	33-60	45	20	Similar to C61300.
C61500	90.0 Cu, 8.0 Al, 2.0 Ni	70-145	22-140	55	30	Good hot and cold workability. Fabricating characteristics similar to C52100. Uses: hardware, decorative metal trim, interior furnishings and other articles requiring high tarnish resistance.
C61800	89.0 Cu, 1.0 Fe, 10.0 Al	80-85	39-42.5	28	40	Fabricated by hot forging and hot pressing. Uses: bushings, bearings, corrosion-resistant applications, welding rods.
C61900	86.5 Cu, 4.0 Fe, 9.5 Al	92-152	49-145	30		Excellent hot formability for fabricating by blanking, forming, bending, shearing, and stamping. Uses: springs, contacts, and switch components.
C62300	87.0 Cu, 3.0 Fe, 10.0 Al	75-98	35-52	35	50	Good hot and cold formability. Fabricated by bending, hot forging, hot pressing, forming, and welding. Uses: bearings, bushings, valve guides, gears, valve seats, nuts, bolts, pump rods, worm gears, and cams.
C62400	86.0 Cu, 3.0 Fe, 11.0 Al	90-105	40-52	18	50	Excellent hot formability for fabrication by hot forging and hot bending. Uses: bushings, gears, cams, wear strips, nuts, drift pins, tie rods.
C62500	82.7 Cu, 4.3 Fe, 13.0 Al	100 (As extruded)	55	1	20	Excellent hot formability for fabrication by hot forging and machining. Uses: guide bushings, wear strips, cams, dies, forming rolls.
C63000	82.0 Cu, 3.0 Fe, 10.0 Al, 5.0 Ni	90-118	50-75	20	30	Good hot formability. Fabricated by hot forming and forging. Uses: nuts, bolts, valve seats, plunger tips, marine shafts, valve guides, aircraft parts, pump shafts, structural members.
C63200	82.0 Cu, 4.0 Fe, 9.0 Al, 5.0 Ni	90-105	45-53	25	30	Good hot formability. Fabricated by hot forming and welding. Uses: nuts, bolts, structural pump parts, shafting requiring corrosion resistance.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C63600	95.5 Cu, 3.5 Al, 1.0 Si	60-84		64	40	Excellent cold workability; fair hot formability. Fabricated by cold heading. Uses: components for pole-line hardware, cold-headed nuts for wire and cable connectors, bolts and screw products.
C63800	95.0 Cu, 2.8 Al, 1.8 Si, 0.40 Co	82-130	54-114	36		Excellent cold workability and hot formability. Uses: springs, switch parts, contacts, relay springs, glass sealing, and porcelain enameling.
C64200	91.2 Cu, 7.0 Al, 1.8 Si	75-102	35-68	32	60	Excellent hot formability. Fabricated by hot forming, forging, machining. Uses: valve stems, gears, marine hardware, pole-line hardware, bolts, nuts, valve bodies, and components.
C65100 Low-silicon bronze, B	98.5 Cu, 1.5 Si	40-105	15-71	55	30	Excellent hot and cold workability. Fabricated by forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, squeezing and swaging. Uses: hydraulic pressure lines, anchor screws, bolts, cable clamps, cap screws, machine screws, marine hardware, nuts, pole-line hardware, rivets, U-bolts, electrical conduits, heat-exchanger tubing, welding rod.
C65500 High-silicon bronze, A	97.0 Cu, 3.0 Si	56-145	21-71	63	30	Excellent hot and cold workability. Fabricated by blanking, drawing, forming and bending, heading and upsetting, hot forging and pressing, roll threading and knurling, shearing, squeezing and swaging. Uses: similar to C65100 including propeller shafts.
C66700 Manganese brass	70.0 Cu, 28.8 Zn, 1.2 Mn	45.8-100	12-92.5	60	30	Excellent cold formability. Fabricated by blanking, bending, forming, stamping, welding. Uses: brass products resistance welded by spot, seam, and butt welding.
C67400	58.5 Cu, 36.5 Zn, 1.2 Al, 2.8 Mn, 1.0 Sn	70-92	34-55	28	25	Excellent hot formability. Fabricated by hot forging and pressing, machining. Uses: bushings, gears, connecting rods, shafts, wear plates.
C67500 Manganese bronze, A	58.5 Cu, 1.4 Fe, 39.0 Zn, 1.0 Sn, 0.1 Mn	65-84	30-60	33	30	Excellent hot workability. Fabricated by hot forging and pressing, hot heading and upsetting. Uses: clutch discs, pump rods, shafting, balls, valve stems and bodies.
C68700 Aluminum brass, arsenical	77.5 Cu, 20.5 Zn, 2.0 Al, trace As	60	27	55	30	Excellent cold workability for forming and bending. Uses: condenser, evaporator- and heat-exchanger tubing, condenser tubing plates, distiller tubing, ferrules.
C68800	73.5 Cu, 22.7 Zn, 3.4 Al, 0.40 Co	82-129	55-114	36		Excellent hot and cold formability. Fabricated by blanking, drawing, forming and bending, shearing and stamping. Uses: springs, switches, contacts, relays, drawn parts.
C69000	73.3 Cu, 3.4 Al, 0.6 Ni, 22.7 Zn	82-130	52-117	35		Fabricating characteristics same as C68800. Uses: contacts, relays, switches, springs, drawn parts.
C69400 Silicon red brass	81.5 Cu, 14.5 Zn, 4.0 Si	80-100	40-57	25	30	Excellent hot formability for fabrication by forging, screw-machine operations. Uses: valve stems where corrosion resistance and high strength are critical.
C70400 Copper nickel, 5%	92.4 Cu, 1.5 Fe, 5.5 Ni, 0.6 Mn	38-77	40-76	46	20	Excellent cold workability; good hot formability. Fabricated by forming, bending, and welding. Uses: condensers, evaporators, heat exchangers, ferrules, salt water piping, lithium bromide absorption tubing, shipboard condenser intake systems.

**Table 3. (Continued) Properties and Applications of Wrought Coppers and Copper Alloys**

Name and Number	Nominal Composition (%)	Strength (ksi)		Elongation in 2 in. (%)	Machinability Rating <sup>a</sup>	Fabricating Characteristics and Typical Applications
		Tensile	Yield			
C70600 Copper nickel, 10%	88.6 Cu, 1.4 Fe, 10.0 Ni	44-60	16-57	42	20	Good hot and cold workability. Fabricated by forming and bending, welding. Uses: condensers, condenser plates, distiller tubing, evaporator and heat-exchanger tubing, ferrules.
C71000 Copper nickel, 20%	79.0 Cu, 21.0 Ni	49-95	13-85	40	20	Good hot and cold formability. Fabricated by blanking, forming and bending, welding. Uses: communication relays, condensers, condenser plates, electrical springs, evaporator and heat-exchanger tubes, ferrules, resistors.
C71500 Copper nickel, 30%	69.5 Cu, 30.0 Ni, 0.5 Fe	54-75	20-70	45	20	Similar to C70600.
C72200	82.2 Cu, 16.5 Ni, 0.8 Fe, 0.5 Cr	46-70	18-66	46		Good hot and cold formability. Fabricated by forming, bending, and welding. Uses: condenser tubing, heat-exchanger tubing, saltwater piping.
C72500	88.2 Cu, 9.5 Ni, 2.3 Sn	55-120	22-108	35	20	Excellent cold and hot formability. Fabricated by blanking, brazing, coining, drawing, etching, forming and bending, heading and upsetting, roll threading and knurling, shearing, spinning, squeezing, stamping, and swaging. Uses: relay and switch springs, connectors, brazing alloy, lead frames, control and sensing bellows.
C73500	72.0 Cu, 10.0 Zn, 18.0 Ni	50-100	15-84	37	20	Fabricating characteristics same as C74500. Uses: hollow ware, medallions, jewelry, base for silverplate, cosmetic cases, musical instruments, name plates, contacts.
C74500 Nickel silver, 65-10	65.0 Cu, 25.0 Zn, 10.0 Ni	49-130	18-76	50	20	Excellent cold workability. Fabricated by blanking, drawing, etching, forming and bending, heading and upsetting, roll threading and knurling, shearing, spinning, squeezing, and swaging. Uses: rivets, screws, slide fasteners, optical parts, etching stock, hollow ware, nameplates, platers' bars.
C75200 Nickel silver, 65-18	65.0 Cu, 17.0 Zn, 18.0 Ni	56-103	25-90	45	20	Fabricating characteristics similar to C74500. Uses: rivets, screws, table flatware, truss wire, zippers, bows, camera parts, core bars, temples, base for silverplate, costume jewelry, etching stock, hollow ware, nameplates, radio dials.
C75400 Nickel silver, 65-15	65.0 Cu, 20.0 Zn, 15.0 Ni	53-92	18-79	43	20	Fabricating characteristics similar to C74500. Uses: camera parts, optical equipment, etching stock, jewelry.
C75700 Nickel silver, 65-12	65.0 Cu, 23.0 Zn, 12.0 Ni	52-93	18-79	48	20	Fabricating characteristics similar to C74500. Uses: slide fasteners, camera parts, optical parts, etching stock, name plates.
C76390	61 Cu, 13 Zn, 24.5 Ni, 1 Pb, 0.5 Sn	90	85	6	40	Fabricated by machining, roll threading, and knurling. Uses: hardware, fasteners, connectors for electronic applications.
C77000 Nickel silver, 55-18	55.0 Cu, 27.0 Zn, 18.0 Ni	60-145	27-90	40	30	Good cold workability. Fabricated by blanking, forming and bending, and shearing. Uses: optical goods, springs, and resistance wire.
C78200	65.0 Cu, 2.0 Pb, 25.0 Zn, 8.0 Ni	53-91	23-76	40	60	Good cold formability. Fabricated by blanking, milling, and drilling. Uses: key blanks, watch plates, watch parts.

**Copper-Silicon and Copper-Beryllium Alloys**

**Everdur.**—This copper-silicon alloy is available in five slightly different nominal compositions for applications that require high strength, good fabricating and fusing qualities, immunity to rust, free-machining and a corrosion resistance equivalent to copper. The following table gives the nominal compositions and tensile strengths, yield strengths, and percent elongations for various tempers and forms.

**Table 4. Nominal Composition and Properties of Everdur**

Desig. No.	Nominal Composition					Temper <sup>a</sup>	Strength				Elongation (%)
							Tensile		Yield		
	Cu	Si	Mn	Pb	Al		ksi	MPa	ksi	MPa

<sup>a</sup> Symbols used are HRA for hot-rolled and annealed tank plates; CRA for cold-rolled sheets and strips; CRHH for cold-rolled half hard strips; and CRH for cold-rolled hard strips. For round, square, hexagonal, and octagonal rods: A for annealed; H for hard; and XHB for extra-hard bolt temper (in coils for cold-heading). For pipe and tube: AP for annealed; and HP for hard. For castings: AC for as cast.

<sup>b</sup> Percent elongation in 4 times the diameter or thickness of the specimen. All other values are percent elongation in 2 inches.

Designation numbers are those of the American Brass Co.

The values given for tensile strength, yield strength, and elongation are all minimum values. Where ranges are shown, the first values given are for the largest diameter or largest size specimens. Yield strength values were determined at 0.50 percent elongation under load.

**Copper-Beryllium Alloys.**—Alloys of copper and beryllium present health hazards. Particles produced by machining may be absorbed into the body through the skin, the mouth, the nose, or an open wound, resulting in a condition requiring immediate medical attention. Working of these alloys requires protective clothing or other shielding in a monitored environment. Copper-beryllium alloys involved in a fire give off profuse toxic fumes that must not be inhaled.

These alloys contain copper, beryllium, cobalt, and silver, and fall into two groups. One group, whose beryllium content is greater than one percent, is characterized by its high strength and hardness, and the other, whose beryllium content is less than one percent, by its high electrical and thermal conductivity. The alloys have many applications in the electrical and aircraft industries or wherever strength, corrosion resistance, conductivity, non-magnetic and nonsparking properties are essential. Beryllium copper is obtainable in the form of strips, rods and bars, wire, platers, bars, billets, tubes, and casting ingots.

*Composition and Properties:* Table 5 lists some of the more common wrought alloys and gives some of their mechanical properties.

**Table 5. Wrought Copper–Beryllium Properties**

<sup>a</sup>Composition (in percent) of alloys is as follows: alloy 25: 1.80–2.05 Be, 0.20–0.35 Co, balance Cu; alloy 165: 1.6–1.8 Be, 0.20–0.35 Co, balance Cu; alloy 10: 0.4–0.7 Be, 2.35–2.70 Co, balance Cu; alloy 50, 0.25–0.50 Be, 1.4–1.7 Co, 0.9–1.1 Ag, balance Cu; alloy 35, 0.25–0.50 Be, 1.4–1.6 Ni, balance Cu.

<sup>b</sup>Temper symbol designations: A, solution annealed; H, hard; HT, heat treated from hard; At, heat treated from solution annealed.

### Aluminum and Aluminum Alloys

Pure aluminum is a silver-white metal characterized by a slightly bluish cast. It has a specific gravity of 2.70, resists the corrosive effects of many chemicals, and has a malleability approaching that of gold. When alloyed with other metals, numerous properties are obtained that make these alloys useful over a wide range of applications.

Aluminum alloys are light in weight compared with steel, brass, nickel, or copper; can be fabricated by all common processes; are available in a wide range of sizes, shapes, and forms; resist corrosion; readily accept a wide range of surface finishes; have good electrical and thermal conductivities; and are highly reflective to both heat and light.

**Characteristics of Aluminum and Aluminum Alloys.**—Aluminum and its alloys lose part of their strength at elevated temperatures, although some alloys retain good strength at temperatures from 400 to 500°F (204 to 260°C). At subzero temperatures, however, their strength increases without loss of ductility so that aluminum is a particularly useful metal for low-temperature applications.

When aluminum surfaces are exposed to the atmosphere, a thin invisible oxide skin forms immediately that protects the metal from further oxidation. This self-protecting characteristic gives aluminum its high resistance to corrosion. Unless exposed to some substance or condition that destroys this protective oxide coating, the metal remains protected against corrosion. Aluminum is highly resistant to weathering, even in industrial atmospheres. It is also corrosion resistant to many acids. Alkalis are among the few substances that attack the oxide skin and therefore are corrosive to aluminum. Although the metal can safely be used in the presence of certain mild alkalis with the aid of inhibitors, in general, direct contact with alkaline substances should be avoided. Direct contact with certain other metals should be avoided in the presence of an electrolyte; otherwise, galvanic corrosion of the aluminum may take place in the contact area. Where other metals must be fastened to aluminum, the use of a bituminous paint coating or insulating tape is recommended.

Aluminum is one of the two common metals having an electrical conductivity high enough for use as an electric conductor. The conductivity of electric-conductor (EC) grade is about 62 percent that of the International Annealed Copper Standard. Because aluminum has less than one-third the specific gravity of copper, however, a pound of aluminum will go almost twice as far as a pound of copper when used as a conductor. Alloying lowers the conductivity somewhat so that wherever possible the EC grade is used in electric conductor applications. However, aluminum takes a set, which often results in loosening of screwed connectors, leading to arcing and fires. Special clamping designs are therefore required when aluminum is used for electrical wiring, especially in buildings.

Aluminum has nonsparking and nonmagnetic characteristics that make the metal useful for electrical shielding purposes, such as in bus bar housings or enclosures for other electrical equipment, and for use around inflammable or explosive substances.

Aluminum can be cast by any method known. It can be rolled to any desired thickness down to foil thinner than paper and in sheet form can be stamped, drawn, spun, or roll-formed. The metal also may be hammered or forged. Aluminum wire, drawn from rolled rod, may be stranded into cable of any desired size and type. The metal may be extruded into a variety of shapes. It may be turned, milled, bored, or otherwise machined in equipment often operating at their maximum speeds. Aluminum rod and bar may readily be employed in the high-speed manufacture of parts made on automatic screw-machine.

Almost any method of joining is applicable to aluminum—riveting, welding, or brazing. A wide variety of mechanical aluminum fasteners simplifies the assembly of many products. Resin bonding of aluminum parts has been successfully employed, particularly in aircraft components.

For the majority of applications, aluminum needs no protective coating. Mechanical finishes such as polishing, sandblasting, or wire brushing meet the majority of needs. When additional protection is desired, chemical, electrochemical, and paint finishes are

all used. Vitreous enamels have been developed for aluminum, and the metal may also be electroplated.

**Temper Designations for Aluminum Alloys.**—The temper designation system adopted by the Aluminum Association and used in industry pertains to all forms of wrought and cast aluminum and aluminum alloys except ingot. It is based on the sequences of basic treatments used to produce the various tempers. The temper designation follows the alloy designation, being separated by a dash.

Basic temper designations consist of letters. Subdivisions of the basic tempers, where required, are indicated by one or more digits following the letter. These digits designate specific sequences of basic treatments, but only operations recognized as significantly influencing the characteristics of the product are indicated. Should some other variation of the same sequence of basic operations be applied to the same alloy, resulting in different characteristics, then additional digits are added.

The basic temper designations and subdivisions are as follows:

-*F, as fabricated*: Applies to products that acquire some temper from shaping processes not having special control over the amount of strain-hardening or thermal treatment. For wrought products, there are no mechanical property limits.

-*O, annealed, recrystallized (wrought products only)*: Applies to the softest temper of wrought products.

-*H, strain-hardened (wrought products only)*: Applies to products that have their strength increased by strain-hardening with or without supplementary thermal treatments to produce partial softening.

The -H is always followed by two or more digits. The first digit indicates the specific combination of basic operations, as follows:

-*H1, strain-hardened only*: Applies to products that are strain-hardened to obtain the desired mechanical properties without supplementary thermal treatment. The number following this designation indicates the degree of strain-hardening.

-*H2, strain-hardened and then partially annealed*: Applies to products that are strain-hardened more than the desired final amount and then reduced in strength to the desired level by partial annealing. For alloys that age-soften at room temperature, the -H2 tempers have approximately the same ultimate strength as the corresponding -H3 tempers. For other alloys, the -H2 tempers have approximately the same ultimate strengths as the corresponding -H1 tempers and slightly higher elongations. The number following this designation indicates the degree of strain-hardening remaining after the product has been partially annealed.

-*H3, strain-hardened and then stabilized*: Applies to products which are strain-hardened and then stabilized by a low-temperature heating to slightly lower their strength and increase ductility. This designation applies only to the magnesium-containing alloys that, unless stabilized, gradually age-soften at room temperature. The number following this designation indicates the degree of strain-hardening remaining after the product has been strain-hardened a specific amount and then stabilized.

The second digit following the designations -H1, -H2, and -H3 indicates the final degree of strain-hardening. Numeral 8 has been assigned to indicate tempers having a final degree of strain-hardening equivalent to that resulting from approximately 75 percent reduction of area. Tempers between -O (annealed) and 8 (full hard) are designated by numerals 1 through 7. Material having an ultimate strength about midway between that of the -O temper and that of the 8 temper is designated by the numeral 4 (half hard); between -O and 4 by the numeral 2 (quarter hard); and between 4 and 8 by the numeral 6 (three-quarter hard). (*Note*: For two-digit -H tempers whose second figure is odd, the standard limits for ultimate strength are exactly midway between those for the adjacent two-digit -H tempers whose second figures are even.) Numeral 9 designates extra-hard tempers.

The third digit, when used, indicates a variation of a two-digit -H temper, and is used when the degree of control of temper or the mechanical properties are different from but close to those for the two-digit -H temper designation to which it is added. (*Note:* The minimum ultimate strength of a three-digit -H temper is at least as close to that of the corresponding two-digit -H temper as it is to the adjacent two-digit -H tempers.) Numerals 1 through 9 may be arbitrarily assigned and registered with the Aluminum Association for an alloy and product to indicate a specific degree of control of temper or specific mechanical property limits. Zero has been assigned to indicate degrees of control of temper or mechanical property limits negotiated between the manufacturer and purchaser that are not used widely enough to justify registration with the Aluminum Association.

The following three-digit -H temper designations have been assigned for wrought products in all alloys:

*-H111:* Applies to products that are strain-hardened less than the amount required for a controlled H11 temper.

*-H112:* Applies to products that acquire some temper from shaping processes not having special control over the amount of strain-hardening or thermal treatment, but for which there are mechanical property limits, or require mechanical property testing.

The following three-digit H temper designations have been assigned for wrought products in alloys containing more than a normal 4 percent magnesium.

*-H311:* Applies to products that are strain-hardened less than the amount required for a controlled H31 temper.

*-H321:* Applies to products that are strain-hardened less than the amount required for a controlled H32 temper.

*-H323:* Applies to products that are specially fabricated to have acceptable resistance to stress-corrosion cracking.

*-H343:* Applies to products that are specially fabricated to have acceptable resistance to stress-corrosion cracking.

The following three-digit -H temper designations have been assigned for

Patterned or Embossed Sheet	Fabricated Form
-H114	-O temper
-H124, -H224, -H324	-H11, -H21, -H31 temper, respectively
-H134, -H234, -H334	-H12, -H22, -H32 temper, respectively
-H144, -H244, -H344	-H13, -H23, -H33 temper, respectively
-H154, -H254, -H354	-H14, -H24, -H34 temper, respectively
-H164, -H264, -H364	-H15, -H25, -H35 temper, respectively
-H174, -H274, -H374	-H16, -H26, -H36 temper, respectively
-H184, -H284, -H384	-H17, -H27, -H37 temper, respectively
-H194, -H294, -H394	-H18, -H28, -H38 temper, respectively
-H195, -H395	-H19, -H39 temper, respectively

*-W, solution heat treated:* An unstable temper applicable only to alloys that spontaneously age at room temperature after solution heat treatment. This designation is specific only when the period of natural aging is indicated.

*-T, thermally treated to produce stable tempers other than -F, -O, or -H:* Applies to products that are thermally treated, with or without supplementary strain-hardening, to produce stable tempers. The -T is always followed by one or more digits. Numerals 2 through 10 have been assigned to indicate specific sequences of basic treatments, as follows:

*-T1, naturally aged to a substantially stable condition:* Applies to products for which the rate of cooling from an elevated temperature-shaping process, such as casting or extrusion, is such that their strength is increased by room-temperature aging.

*-T2, annealed (cast products only):* Designates a type of annealing treatment used to improve ductility and increase dimensional stability of castings.

*-T3, solution heat treated and then cold-worked:* Applies to products that are cold-worked to improve strength, or in which the effect of cold-work in flattening or straightening is recognized in applicable specifications.

*-T4, solution heat treated and naturally aged to a substantially stable condition:* Applies to products that are not cold-worked after solution heat treatment, or in which the effect of cold-work in flattening or straightening may not be recognized in applicable specifications.

*-T5, artificially aged only:* Applies to products that are artificially aged after an elevated-temperature rapid-cool fabrication process, such as casting or extrusion, to improve mechanical properties or dimensional stability, or both.

*-T6, solution heat treated and then artificially aged:* Applies to products that are not cold-worked after solution heat treatment, or in which the effect of cold-work in flattening or straightening may not be recognized in applicable specifications.

*-T7, solution heat treated and then stabilized:* Applies to products that are stabilized to carry them beyond the point of maximum hardness, providing control of growth or residual stress or both.

*-T8, solution heat treated, cold-worked, and then artificially aged:* Applies to products that are cold-worked to improve strength, or in which the effect of cold-work in flattening or straightening is recognized in applicable specifications.

*-T9, solution heat treated, artificially aged, and then cold-worked:* Applies to products that are cold-worked to improve strength.

*-T10, artificially aged and then cold-worked:* Applies to products that are artificially aged after an elevated-temperature rapid-cool fabrication process, such as casting or extrusion, and then cold-worked to improve strength.

Additional digits may be added to designations -T1 through -T10 to indicate a variation in treatment that significantly alters the characteristics of the product. These may be arbitrarily assigned and registered with The Aluminum Association for an alloy and product to indicate a specific treatment or specific mechanical property limits.

These additional digits have been assigned for wrought products in all alloys:

*-T\_\_51, stress-relieved by stretching:* Applies to products that are stress-relieved by stretching the following amounts after solution heat treatment:

Plate	1½ to 3 percent permanent set
Rod, Bar and Shapes	1 to 3 percent permanent set
Drawn tube	0.5 to 3 percent permanent set

Applies directly to plate and rolled or cold-finished rod and bar.

These products receive no further straightening after stretching.

Applies to extruded rod and bar shapes and tube when designated as follows:

*-T\_\_510:* Products that receive no further straightening after stretching.

*-T\_\_511:* Products that receive minor straightening after stretching to comply with standard tolerances.

*-T\_\_52, stress-relieved by compressing:* Applies to products that are stress-relieved by compressing after solution heat treatment to produce a nominal permanent set of 2½ percent.

*-T\_\_54, stress-relieved by combined stretching and compressing:* Applies to die forgings that are stress-relieved by restriking cold in the finish die.

The following two-digit -T temper designations have been assigned for wrought products in all alloys:

-T42: Applies to products solution heat treated and naturally aged that attain mechanical properties different from those of the -T4 temper.

-T62: Applies to products solution heat treated and artificially aged that attain mechanical properties different from those of the -T6 temper.

**Aluminum Alloy Designation Systems.**—Aluminum casting alloys are listed in many specifications of various standardizing agencies. The numbering systems used by each differ and do not always correlate. Casting alloys are available from producers who use a commercial numbering system; this system is used in the tables of aluminum casting alloys given in this section.

Table 6a lists the nominal composition of commonly used aluminum casting alloys, and Table 6b and Table 6c list the typical tensile properties of separately cast bars.

**Table 6a. Nominal Compositions (in percent) of Common Aluminum Casting Alloys (AA/ANSI)**

<sup>a</sup> S = sand cast; P = permanent mold cast. The sum of those "Others," metallic elements 0.010 percent or more each, is expressed to the second decimal before determining the sum. Source: *Standards for Aluminum Sand and Permanent Mold Castings*, courtesy of the Aluminum Association.

<sup>b</sup> Also contains 0.40–1.0 percent silver.

<sup>c</sup> Also contains 0.05 max. percent tin.

<sup>d</sup> If iron exceeds 0.45 percent, manganese content should not be less than one-half the iron content.

<sup>e</sup> Also contains 0.04–0.07 percent beryllium.

<sup>f</sup> Also contains 5.5–7.0 percent tin.

<sup>a</sup>F indicates "as cast" condition.

<sup>b</sup>Mechanical properties for these alloys depend on the casting process. For further information consult the individual foundries.

<sup>c</sup>The T4 temper of Alloy 520.0 is unstable; significant room temperature aging occurs within life expectancy of most castings. Elongation may decrease by as much as 80 percent.

<sup>a</sup>F indicates "as cast" condition.

A system of four-digit numerical designations for wrought aluminum and wrought aluminum alloys was adopted by the Aluminum Association in 1954. This system is used by the commercial producers and is similar to that used by the SAE, the difference being the addition of two prefix letters.

The first digit of the designation identifies the alloy type: 1) indicating an aluminum of 99.00 percent or greater purity; 2) copper; 3) manganese; 4) silicon; 5) magnesium; 6) magnesium and silicon; 7) zinc; 8) some element other than those aforementioned; and 9) unused (not assigned at present).

If the second digit in the designation is zero, it indicates that there is no special control on individual impurities; integers 1 through 9 indicate special control on one or more individual impurities.

In the 1000 series group for aluminum of 99.00 percent or greater purity, the last two of the four digits indicate to the nearest hundredth the amount of aluminum above 99.00 percent. Thus designation 1030 indicates 99.30 percent minimum aluminum. In the 2000 to 8000 series groups, the last two of the four digits have no significance but are used to identify different alloys in the group. At the time of adoption of this designation system, most of the existing commercial designation numbers were used for these last two digits; for example, 14S became 2014, 3S became 3003, and 75S became 7075. When new alloys are developed and are commercially used, these last two digits are assigned consecutively beginning with -01, skipping any numbers previously assigned at the time of initial adoption.

Experimental alloys are also designated in accordance with this system, but they are indicated by the prefix X, which is dropped upon standardization.

Table 7a shows the product forms and nominal compositions of common wrought aluminum alloys, and Table 7b lists typical mechanical properties of wrought aluminum alloys.

**Table 7a. Nominal Compositions of Common Wrought Aluminum Alloys**

Alloy	Alloying Elements — Aluminum and Normal Impurities Constitute Remainder												
	Si	Cu	Mn	Mg	Cr	Ni	Zn	Ti	Pb	Bi	V	Z	Fe
1050			99.50 percent minimum aluminum										
1060			99.60 percent minimum aluminum										
1100		0.12	99.00 percent minimum aluminum										
1145			99.45 percent minimum aluminum

<sup>a</sup> Based on 500,000,000 cycles of completely reversed stress using the R. R. Moore type of machine and specimen.

<sup>b</sup> 1350-O wire should have an elongation of approximately 23 percent in 10 inches.

<sup>c</sup> 1350-H19 wire should have an elongation of approximately 1.5 percent in 10 inches.

<sup>d</sup> Tempers T361 and T861 were formerly designated T36 and T86, respectively.

<sup>e</sup> Based on 10<sup>7</sup> cycles using flexural type testing of sheet specimens.

<sup>f</sup> T7451, although not previously registered, has appeared in the literature and in some specifications as T73651.

The data given in this table are intended only as a basis for comparing alloys and tempers, and should not be specified as engineering requirements or used for design purposes. The indicated typical mechanical properties for all except O temper material are higher than the specified minimum properties. For O temper products, typical ultimate and yield values are slightly lower than specified (maximum) values.

**Heat-Treatability of Wrought Aluminum Alloys.**—In high-purity form, aluminum is soft and ductile. Most commercial uses, however, require greater strength than pure aluminum affords. This extra strength is achieved in aluminum first by the addition of other elements to produce various alloys, which singly or in combination impart strength to the metal. Further strengthening is possible by means that classify the alloys roughly into two categories, non-heat-treatable and heat-treatable.

*Non-heat-treatable alloys:* The initial strength of alloys in this group depends upon the hardening effect of elements such as manganese, silicon, iron and magnesium, singly or

in various combinations. The non-heat-treatable alloys are usually designated, therefore, in the 1000, 3000, 4000, or 5000 series. These alloys are work-hardenable, so further strengthening is made possible by various degrees of cold-working, denoted by the "H" series of tempers. Alloys containing appreciable amounts of magnesium when supplied in strain-hardened tempers are usually given a final elevated-temperature treatment called *stabilizing* for improving property stability.

*Heat-treatable alloys:* The initial strength of alloys in this group is enhanced by the addition of alloying elements such as copper, magnesium, zinc, and silicon. These elements singly or in various combinations show increasing solid solubility in aluminum with increasing temperature, so it is possible to subject them to thermal treatments that will impart pronounced strengthening.

The first step, called *heat treatment* or *solution heat treatment*, is an elevated-temperature process designed to put the soluble element in solid solution. This step is followed by rapid quenching, usually in water, which momentarily "freezes" the structure and for a short time renders the alloy very workable. Some fabricators retain this more workable structure by storing the alloys at below freezing temperatures until they can be formed. At room or elevated temperatures the alloys are not stable after quenching, however, and precipitation of the constituents from the supersaturated solution begins. After a period of several days at room temperature, termed *aging* or *room-temperature precipitation*, the alloy is considerably stronger. Many alloys approach a stable condition at room temperature, but some alloys, particularly those containing magnesium and silicon or magnesium and zinc, continue to age-harden for long periods of time at room temperature.

Heating for a controlled time at slightly elevated temperatures provides even further strengthening and property stabilization. This process is called *artificial aging* or *precipitation hardening*. By application of the proper combination of solution heat treatment, quenching, cold-working and artificial aging, the highest strengths are obtained.

**Clad Aluminum Alloys.**—The heat-treatable alloys in which copper or zinc are major alloying constituents are less resistant to corrosive attack than the majority of non-heat-treatable alloys. To increase their corrosion resistance in sheet and plate form, these alloys are often clad with high-purity aluminum, a low magnesium-silicon alloy, or an alloy containing 1 percent zinc. The cladding, usually from 2½ to 5 percent of the total thickness on each side, not only protects the composite due to its own inherently excellent corrosion resistance but also exerts a galvanic effect that further protects the core material.

Special composites, such as clad non-heat-treatable alloys for extra corrosion protection, for brazing purposes, or for special surface finishes, may be obtained. Some alloys in wire and tubular form are clad for similar reasons, and on an experimental basis extrusions also have been clad.

**Aluminum Alloys, Wrought, Sheet.**—*Physical Properties:* In sheet form, tensile strength varies from 35,000 psi (241 MPa) for soft temper to 62,000 (427 MPa) psi for heat-treated sheets, and the elongation in 2 inches (5.08 cm) from 12 to 18 percent. The yield strength of a heat-treated sheet is about 40,000 psi (276 MPa) minimum.

**Characteristics of Principal Aluminum Alloy Series Groups.**—*1000 series:* These alloys are characterized by high corrosion resistance, high thermal and electrical conductivity, low mechanical properties and good workability. Moderate increases in strength may be obtained by strain-hardening. Iron and silicon are the major impurities.

*2000 series:* Copper is the principal alloying element in this group. These alloys require solution heat treatment to obtain optimum properties; in the heat-treated condition mechanical properties are similar to, and sometimes exceed, those of mild steel. In some instances artificial aging is employed to further increase the mechanical properties. This treatment materially increases yield strength, with attendant loss in elongation; its effect on tensile (ultimate) strength is not as great. Alloys in the 2000 series have reduced corrosion resistance compared to most other aluminum alloys, and under certain

conditions they may be subject to intergranular corrosion. Therefore, these alloys in the form of sheet are usually clad with a high-purity alloy or a magnesium-silicon alloy of the 6000 series, which provides galvanic protection to the core material and thus greatly increases resistance to corrosion. Alloy 2024 is perhaps the best known and most widely used aircraft alloy.

*3000 series:* Manganese is the major alloying element of alloys in this group, which are generally non-heat-treatable. Because only a limited percentage of manganese, up to about 1.5 percent, can be effectively added to aluminum, it is used as a major element in only a few instances. One of these, however, is the popular 3003, used for moderate-strength applications requiring good workability.

*4000 series:* The major alloying element of this group is silicon, which can be added in sufficient quantities to cause substantial lowering of the melting point without producing brittleness in the resulting alloys. For these reasons aluminum-silicon alloys are used in welding wire and as brazing alloys where a lower melting point than that of the parent metal is required. Most alloys in this series are non-heat-treatable, but, when used in welding heat-treatable alloys, they will pick up some of the alloying constituents of the latter and so respond to heat treatment to a limited extent. The alloys containing appreciable amounts of silicon become dark gray when anodic oxide finishes are applied and hence are in demand for architectural applications.

*5000 series:* Magnesium is one of the most effective and widely used alloying elements for aluminum. When it is used as the major alloying element or with manganese, the result is a moderate to high strength non-heat-treatable alloy. Magnesium is considerably more effective than manganese as a hardener, about 0.8 percent magnesium being equal to 1.25 percent manganese, and it can be added in considerably higher quantities. Alloys in this series possess good welding characteristics and good resistance to corrosion in marine atmospheres. However, certain limitations should be placed on the amount of cold-work and on safe operating temperatures permissible for the higher magnesium content alloys (over about 3½ percent for operating temperatures over about 150°F or 66°C) to avoid susceptibility to stress corrosion.

*6000 series:* Alloys in this group contain silicon and magnesium in approximate proportions to form magnesium silicide, thus making them capable of being heat treated. The major alloy in this series is 6061, one of the most versatile of the heat-treatable alloys. Though not as strong as most of the 2000 or 7000 alloys, the magnesium-silicon (or magnesium-silicide) alloys possess good formability and corrosion resistance, with medium strength. Alloys in this heat-treatable group may be formed in the -T4 temper (solution heat treated but not artificially aged) and then reach full -T6 properties by artificial aging.

*7000 series:* Zinc is the major alloying element in this group, and when coupled with a smaller percentage of magnesium results in heat-treatable alloys of very high strength. Other elements, such as copper and chromium, are usually added in small quantities. A notable member of this group is 7075, which is among the highest strength aluminum alloys available and is used in air-frame structures and for highly stressed parts.

**Type Metal.**—Antimony gives to metals the property of expansion on solidification. Hence, it is used in type metal for casting type for the printing trades to insure the molds are completely filled. Type metals are generally made with from 5 to 25 percent of antimony, and with lead, tin and sometimes a small percentage of copper as the other alloying metals.

The compositions of a number of type metal alloys are as follows (figures given are percentages): lead 77.5, tin 6.5, antimony 16; lead 70, tin 10, antimony 18, copper 2; lead 63.2, tin 12, antimony 24, copper 0.8; lead 60.5, tin 14.5, antimony 24–25, copper 0.75; lead 60, tin 35, antimony 5; and lead 55.5, tin 40, antimony 4.5.

A high grade of type metal is composed of the following percentages: lead 50; tin 25; and antimony 25.

### Magnesium Alloys

**Magnesium Alloys.**—Magnesium is the lightest of all structural metals. Silver-white in color, pure magnesium is relatively soft, so it is rarely used for structural purposes in the pure state. Principal metallurgical uses for pure magnesium are as an alloying element for aluminum and other metals; as a reducing agent in the extraction of such metals as titanium, zirconium, hafnium, and uranium; as a nodularizing agent in the manufacture of ductile iron; and as a sulfur removal agent in steel manufacture. Magnesium alloys are made by alloying up to about 10 percent of other metals and have low density and an excellent combination of mechanical properties, as shown in [Table 8a](#), resulting in high strength-to-weight ratios.

Magnesium alloys are the easiest of all the structural metals to machine, and these alloys have very high weld efficiencies. Magnesium is readily processed by all the standard casting and fabrication techniques used in metalworking, especially by pressure die casting. Because the metal work hardens rapidly, cold forming is limited to mild deformation, but magnesium alloys have excellent working characteristics at temperatures between 300 and 500°F (149 and 260°C).

These alloys have relatively low elastic moduli, so they will absorb energy with good resistance to dents and high damping capacities. Fatigue strength also is good, particularly in the low-stress, high-cycle range. The alloys can be precipitation hardened, so mechanical properties can be improved by solution heat treatment and aging. Corrosion resistance was greatly improved recently, when methods were found to limit heavy metal impurities to “parts per million.”

**Applications of Magnesium Alloys.**—Magnesium alloys are used in a wide variety of structural applications including industrial, materials handling, automotive, consumer-durable, and aerospace equipment. In industrial machinery, the alloys are used for parts that operate at high speeds, which must have light weight to allow rapid acceleration and minimize inertial forces. Materials handling equipment applications include hand trucks, dockboards, grain shovels, and gravity conveyors. Automotive applications include wheels, gearboxes, clutch housings, valve covers, and brake pedal and other brackets. Consumer durables include luggage, softball bats, tennis rackets, and housings for cameras and projectors. Their high strength-to-weight ratio suits magnesium alloys to use in a variety of aircraft structures, particularly helicopters. Very intricate shapes that are uneconomical to produce in other materials are often cast in magnesium, sometimes without draft. Wrought magnesium alloys are made in the form of bars, forgings, extrusions, wire, sheet, and plate.

**Alloy and Temper Designation.**—Magnesium alloys are designated by a standard four-part system established by the ASTM, and now also used by the SAE, that indicates both chemical composition and temper. Designations begin with two letters representing the two alloying elements that are specified in the greatest amount; these letters are arranged in order of decreasing percentage of alloying elements or alphabetically if they are present in equal amounts. The letters are followed by digits representing the respective composition percentages, rounded off to whole numbers, and then by a serial letter indicating some variation in composition of minor constituents. The final part, separated by a hyphen, consists of a letter followed by a number, indicating the temper condition. The letters that designate the more common alloying elements are A, aluminum; E, rare earths; H, thorium; K, zirconium; M, manganese; Q, silver; S, silicon; T, tin; Z, zinc.

The letters and numbers that indicate the temper designation are F, as fabricated; O, annealed; H10, H11, strain hardened; H23, H24, H26, strain hardened and annealed; T4, solution heat treated; T5, artificially aged; T6, solution heat treated and artificially aged; and T8, solution heat treated, cold-worked, and artificially aged.

The nominal composition and typical properties of magnesium alloys are listed in [Table 8a](#) and [Table 8b](#).

### Nickel and Nickel Alloys

**Characteristics of Nickel and Nickel Alloys.**—Nickel is a white metal, similar in some respects to iron but with good oxidation and corrosion resistances. Nickel and its alloys are used in a variety of applications, usually requiring specific corrosion resistance or high strength at high temperature. Some nickel alloys exhibit very high toughness; others have very high strength, high proportional limits, and high moduli compared with steel. Commercially, pure nickel has good electrical, magnetic, and magnetostrictive properties. Nickel alloys are strong, tough, and ductile at cryogenic temperatures, and several of the nickel-based superalloys have good strength at temperatures up to 2000°F (1095°C).

Most wrought nickel alloys can be hot- and cold-worked, machined, and welded successfully; an exception is the most highly alloyed nickel compound—forged nickel-based superalloys—in which these operations are more difficult. The casting alloys can be machined or ground, and many can be welded and brazed.

There are five categories into which the common nickel-based metals and alloys can be separated: the pure nickel and high nickel (over 94 percent Ni) alloys; the nickel-molybdenum and nickel-molybdenum-chromium superalloys, which are specifically for corrosive or high-temperature, high-strength service; the nickel-molybdenum-chromium-copper alloys, which are also specified for corrosion applications; the nickel-copper (Monel) alloys, which are used in actively corrosive environments; and the nickel-chromium and nickel-chromium-iron superalloys, which are noted for their strength and corrosion resistance at high temperatures.

Descriptions and compositions of some commonly used nickel and high nickel alloys are shown in [Table 9](#).

### Titanium and Titanium Alloys

Titanium is a gray, light metal with a better strength-to-weight ratio than any other metal at room temperature and is used in corrosive environments or in applications that take advantage of its light weight, good strength, and nonmagnetic properties. Titanium is available commercially in many alloys, but multiple requirements can be met by a single grade of the commercially pure metal. The alloys of titanium are of three metallurgical types: alpha, alpha-beta, and beta, with these designations referring to the predominant phases present in the microstructure.

Titanium has a strong affinity for hydrogen, oxygen, and nitrogen gases, which tend to embrittle the material; carbon is another embrittling agent. Titanium is outstanding in its resistance to strongly oxidizing acids, aqueous chloride solutions, moist chlorine gas, sodium hypochlorite, and seawater and brine solutions. Nearly all nonaircraft applications take advantage of this corrosion resistance. Its uses in aircraft engine compressors and in airframe structures are based on both its high corrosion resistance and high strength-to-weight ratio.

Procedures for forming titanium are similar to those for forming stainless steel. Titanium and its alloys can be machined and abrasive ground; however, sharp tools and continuous feed are required to prevent work hardening. Tapping is difficult because the metal galls.

Titanium castings can be produced by investment or graphite mold methods; however, because of the highly reactive nature of the metal in the presence of oxygen, casting must be done in a vacuum.

Generally, titanium is welded by gas-tungsten arc or plasma arc techniques, and the key to successful welding lies in proper cleaning and shielding. The alpha-beta titanium alloys can be heat treated for higher strength, but they are not easily welded. Beta and alpha-beta alloys are designed for formability; they are formed in the soft state, and then heat treated for high strength.

The properties of some wrought titanium alloys are shown in [Table 10](#).

**Table 9. Common Cast and Wrought Nickel and High Nickel Alloys — Designations, Compositions, Typical Properties, and Uses**

UNS Designation	Description and Common Name	Nominal Composition (Weight %)	Typical Room-Temperature Properties			Form	Typical Uses
			Tensile (ksi)	0.2% Yield (ksi)	Elong. (%)		
N02200	Commercially pure Ni (Nickel 200)	99.5 Ni	67	22	47	Wrought	Food processing and chemical equipment.
N04400	Nickel-copper alloy (Monel 400)	65 Ni, 32 Cu, 2 Fe	79	30	48	Wrought	Valves, pumps, shafts, marine fixtures and fasteners, electrical and petroleum refining equipment.
N05500	Age-hardened Ni-Cu alloy (Monel K 500)	65 Ni, 30 Cu, 2 Fe, 3 Al + Ti	160	111	24	Wrought	Pump shafts, impellers, springs, fasteners, and electronic and oil well components.
N06002	Ni-Cr Alloy (Hastelloy X)	60 Ni, 22 Cr, 19 Fe, 9 Mo, 0.6 W	114	52	43	Wrought	Turbine and furnace parts, petrochemical equipment.
N06003	Ni-Cr alloy (Nichrome V)	80 Ni, 20 Cr	100	60	30	Wrought	Heating elements, resistors, electronic parts.
N06333	Ni-Cr alloy (RA 333)	48 Ni, 25 Cr, 18 Fe, 3 Mo, 3 W, 3 Co	100	50	50	Wrought	Turbine and furnace parts.
N06600	Ni-Cr alloy (Inconel 600)	75 Ni, 15 Cr, 10 Fe	90	36	47	Wrought	Chemical, electronic, food processing and heat-treating equipment; nuclear steam generator tubing.
N06625	Ni-Cr alloy (Inconel 625)	61 Ni, 21 Cr, 2 Fe, 9 Mo, 4 Nb	142	86	42	Wrought	Turbine parts, marine and chemical equipment.
N07001	Age-hardened Ni-Cr alloy (Waspalloy)	58 Ni, 20 Cr, 14 Co, 4 Mo, 3 Al, 1.3 Ti, B, Zr	185	115	25	Wrought	Turbine parts.
N07500	Age-hardened Ni-Cr alloy (Udimet 500)	52 Ni, 18 Cr, 19 Co, 4 Mo, 3 Al, 3 Ti, B, Zr	176	110	16	Wrought & Cast	Turbine parts.
N07750	Age-hardened Ni-Cr alloy (Inconel X-750)	73 Ni, 16 Cr, 7 Fe, 2.5 Ti, 1 Al, 1 Nb	185	130	20	Wrought	Turbine parts, nuclear reactor springs, bolts, extrusion dies, forming tools.
N08800	Ni-Cr-Fe alloy (Incoloy 800)	32 Ni, 21 Cr, 46 Fe, 0.4 Ti, 0.4 Al	87	42	44	Wrought	Heat exchangers, furnace parts, chemical and power plant piping.
N08825	Ni-Cr-Fe alloy (Incoloy 825)	42 Ni, 22 Cr, 30 Fe, 3 Mo, 2 Cu, 1 Ti, Al	91	35	50	Wrought	Heat-treating and chemical handling equipment.
N09901	Age-hardened Ni-Cr-Fe alloy (Incoloy 901)	43 Ni, 12 Cr, 36 Fe, 6 Mo, 3 Ti + Al, B	175	130	14	Wrought	Turbine parts.
N10001	Ni-Mo alloy (Hastelloy B)	67 Ni, 28 Mo, 5 Fe	121	57	63	Wrought	Chemical handling equipment.
N10004	Ni-Cr-Mo alloy (Hastelloy W)	59 Ni, 5 Cr, 25 Mo, 5 Fe, 0.6 V	123	53	55	Wrought	Weld wire for joining dissimilar metals, engine repair and maintenance.
N10276	Ni-Cr-Mo alloy (Hastelloy C-276)	57 Ni, 15 Cr, 16 Mo, 5 Fe, 4 W, 2 Co	116	52	60	Wrought	Chemical handling equipment.
N13100	Ni-Co alloy (IN 100)	60 Ni, 10 Cr, 15 Co, 3 Mo, 5.5 Al, 5 Ti, 1 V, B, Zr	147	123	9	Cast	Turbine parts.

## CORROSION

Corrosion is a chemical or electrochemical process by which a material and/or its properties deteriorate due to interaction with one or more external substances. Environmental conditions, surface conditions, and component stresses can initiate or accelerate corrosion. Effects of corrosion are many, ranging from merely aesthetic changes to interference with electrical connections and weakening of a structural or mechanical part that can lead to failure. Of particular concern are common material changes, such as pitting corrosion and stress corrosion cracking, which are difficult to detect, yet can result in sudden component failure.

### Corrosion Types and Methods of Prevention

Consideration of material properties—including chemical compatibility, galvanic potential, and reaction to anticipated environmental conditions—is important in minimizing corrosion and maximizing the design life of metal and alloy parts and assemblies. However, the mechanisms of corrosion can result in a wide variety of corrosion patterns and processes, and different types and mechanisms of corrosion may occur simultaneously. Thus, corrosion protection often requires a multipronged approach.

**Uniform (General) Corrosion.**—This process describes either a chemical or electrochemical attack that uniformly affects an entire exposed surface. The corroding part will gradually thin; corrosive substances may accumulate on the surface. Usually, uniform corrosion can be predicted and measured, so designers can provide for and monitor it to ensure safety.

Methods of preventing general corrosion include using appropriate materials, passivation, polishing, coatings and other barriers, and environmental controls, as well as reducing stresses on components. To prevent corrosive interaction between incompatible materials, parts can be separated electrically from each other or electrolyte solutions with gaskets or coatings. Gaskets or sealants also can minimize moisture intrusion into joints to further reduce corrosion, though materials interactions should be investigated. For instance, graphite, often found in carbon black rubber and gaskets, should not be used in contact with stainless steels in seawater.

**Chemical Corrosion.**—This type of corrosion generally refers to various chemical interactions. In most cases, damage results from the destructive reaction of a contacting substance directly acting on and degrading a material, for instance, an acid affecting a metal. Chemical corrosion also may result in oxide formation or deposition of other surface coatings.

**Dry and High-Temperature Corrosion.**—Dry corrosion, also called *scaling*, generally is caused by chemicals (gases, molten salts, or solids) acting on a surface in a dry atmosphere (i.e., no aqueous electrolyte), though particulate abrasion also may be involved. Material selection and effective environmental controls can significantly reduce damage; numerous specialized protective coatings also are available.

High-temperature corrosion takes place when dry corrosion occurs and/or accelerates due to a high-temperature environment. Critical temperature and rate of corrosion depend on the materials involved and environmental conditions. As this form of corrosion may become a risk at temperatures as low as 194° F (90° C) in some applications (such as oil pipelines), it may simply be identified as dry corrosion. Common results of high-temperature corrosion include oxidation (in air, this is a problem above the material's scaling temperature), carburization, chlorination, and sulfidation.

**Electrochemical Corrosion.**—This occurs when an electrically active material is exposed to an electrolyte, forming an electrical cell in which ionization occurs and electrons move from an anodic (active) material to a cathodic (noble) material. As a result, the anode corrodes through oxidation, while the cathode absorbs the free electrons through a reduction reaction. With sufficient oxygen, the cathode often will develop a protective

oxide layer. Areas of oxygen deprivation can become anodic, resulting in hidden pockets of accelerated corrosion.

*Wet and damp/atmospheric corrosion* occur when water and contaminants in the environment form an electrolyte liquid or damp film on the surface of a part, facilitating electrochemical corrosion. Wet corrosion rates generally are highest, while atmospheric corrosion rates depend on the amount and type of moisture.

To minimize electrochemical corrosion, the best course of action is to avoid mixing different metals in an assembly and match the potentials of the part(s) to the environment. The next lines of defense are barriers and protective area ratios (see *Galvanic Corrosion*, below). When those methods are not enough, it is common practice to add one or more auxiliary anodes or cathodes to the system. Current from an external DC power supply may be applied to change the electrical potential of the target material and control the flow of electrons. Some systems can monitor and optimize conditions in the cell by using a reference electrode.

*Cathodic Protection:* Adding one or more sacrificial anodes (either a part or a coating) to a system can protect a part that otherwise would be the anode in an electrochemical reaction. Buried or submerged metal pipes are commonly protected passively by the addition of a sacrificial magnesium anode placed nearby and connected by a wire. An impressed current system includes a DC power supply to supply current, which improves system performance and extends anode life. Cathodic protection is broadly applicable for all metals and alloys, but it is often not suitable for corrosive environments and can accelerate hydrogen embrittlement.

*Anodic Protection:* This newer method employs additional cathodes and an applied current to shift the target material's potential into passive range. Anodic protection applies to corrosive environments and can be achieved with much lower current density than cathodic protection would require. This method is limited to materials that exhibit active-passive behavior (material surfaces can change from active to passive when exposed to oxidizers or applied current). Steel, titanium, and nickel alloys are included in this group.

**Galvanic Corrosion.**—In this electrochemical corrosion process, sometimes called *bi-metallic corrosion*, dissimilar metals or alloys interact when electrically coupled by a conductive fluid. If the two metals or alloys have different electrochemical potentials, current will flow from the more active (anodic) metal to the more noble (cathodic) metal. In this galvanic couple, the anode will experience dissolution (usually oxidation), while the cathode will experience reduction. In practical terms, the anode will corrode faster or differently than it would alone in the electrolyte, and the cathode usually will be protected. The metals or alloys usually are in direct contact with each other, but this is not necessary for corrosion to occur—it can expand into the entire wetted area if the fluid is highly conductive. Parts in direct contact will experience the most corrosion; as separation between parts increases, corrosion decreases.

Intensity of the corrosion process depends on differences in electrochemical potential between two metals, distance between the metals, wetted surface areas of the parts, and conductivity of the surrounding fluid. Other factors include oxygenation, fluid pH, metal composition and variations, presence of films or deposits, passive film stability, and exposure of metals to processes such as cold-working or welding. Corrosion often will intensify as oxygen levels in the electrolyte drop, and oxygen depletion frequently occurs in crevices and other stagnant areas.

*Galvanic Compatibility:* The US military published empirical compatibility information in MIL-STD-889B, “Dissimilar Metals.” Data in [Table 1](#) represents those results. Because many factors influence galvanic corrosion, this data should be used only as a general guide.

**Table 1. Galvanic Compatibility of Metals in Select Environments**

		Active (Anodic) → Noble (Cathodic)

Values  
 I = Incompatible (risk of significant galvanic interaction)  
 C = Compatible (negligible galvanic interaction likely)

Position of Compatibility Values (1,2,3)  
 1 = Industrial atmosphere  
 2 = Marine atmosphere  
 3 = Seawater immersion

Example: C,C,I = Compatible in industrial atmosphere (1)  
 Compatible in marine atmosphere (2)  
 Incompatible in seawater immersion (3)

Selecting metals with similar electrochemical potentials usually minimizes galvanic corrosion. One method of comparing potentials involves referencing a *galvanic series*. While it should be representative of anticipated environmental conditions, this tool is not used to predict corrosion rates, but rather provides a qualitative evaluation of coupled metal behavior.

To develop a series, a reference half-cell and samples of the target metals are immersed together in an electrolyte solution chosen and circulated to match the expected environmental conditions. Over time, potentials of the target metals are measured relative to the reference half-cell. There are several standard reference half-cell compositions that will yield different values; the appropriate reference is compatible with the electrolyte. A useful standard is ASTM G82-98 (2014), “Standard Guide for Development and Use of a Galvanic Series for Predicting Galvanic Corrosion Performance.”

Most published galvanic series data applies to specific flowing seawater environment conditions. While saltwater is highly conductive, freshwater has low conductivity, and dynamic electrolyte conditions will greatly affect potential measurements. Therefore, for critical applications, it is good practice to develop application-specific series data, rather than using published galvanic series information.

For examples of seawater applications, refer to Table 2, which is based on Army Missile Command Report RS-TR-67-11, “Practical Galvanic Series.” Materials closer together along the arrow in the series have less corrosion-inducing potential difference between them in that environment. However, use this data with caution in predicting whether corrosion will be a risk. This series indicates which material will be the anode in a couple, though polarity reversals can occur in which a metal normally anodic to another will become cathodic to that same metal. Examples include high-temperature reversals of zinc/iron, aluminum/iron, and aluminum/zinc.

**Table 2. Sample Galvanic Series, General Seawater Environment**

Active (Anodic)			Noble (Cathodic)		
Magnesium	Stainless Steel 410 (active)	Stainless Steel 201 (active)

	Monel 400				

Another galvanic compatibility guide is an *anodic index*. Table 3 is an example based on US military specification MIL-F-14072, "Finishes for Ground Based Electronic Equipment." This table shows electrochemical potentials normalized relative to a gold reference. Subtract one index value from another to determine the electrochemical potential difference between the metals. The standard recommends differential limits for three types of non-immersed application environments (controlled, normal, and harsh). Again, use caution when referring to any anodic index, because, as with a galvanic series, actual conditions can significantly change the corrosion behavior of a galvanic couple.

**Table 3. Anodic Index (Gold Reference)**

Metals and Alloys	Anodic Index (V)	
Gold, Gold-Platinum Alloys, Wrought Platinum	-0.00	Cathodic (Noble) ↑ Anodic (Active)
Rhodium Plated on Silver-Plated Copper	-0.10	
Silver, High Silver Alloys	-0.15	
Nickel, Monel, High Nickel-Copper Alloys, Titanium Alloys	-0.30	
Copper, Low Brasses or Bronzes, Silver Solder, High Copper-Nickel-Zinc Alloys, Nickel-Chromium Alloys	-0.35	
Yellow Brasses and Bronzes	-0.40	
High Brasses and Bronzes, Naval Brass, Muntz Metal	-0.45	
18% Chromium-type Stainless Steels (includes 300 Series)	-0.50	
Chromium Plated, Tin Plated, 12% Chromium-type Stainless Steels (some 400 Series Steels)	-0.60	
Tin Plate, Tin-Lead Solder, Terneplate (Lead-Tin Alloy)	-0.65	
Lead, High Lead Alloys	-0.70	
2000 Series Wrought Aluminum	-0.75	
Plain Carbon Steels, Low Alloy Steels, Wrought Iron, Gray Malleable Iron	-0.85	
Wrought Aluminum Alloys other than 2000 Series, Cast Aluminum-Silicon Alloys	-0.90	
Cast Aluminum Alloys other than Silicon Type, Cadmium, Cadmium Chromate	-0.95	
Hot-Dip Zinc Plate, Galvanized Steel	-1.20	
Wrought Zinc, Zinc Die-Casting Alloys, Zinc Plate	-1.25	
Magnesium, Magnesium Alloys	-1.75	
Beryllium	-1.85	

**Evaluation of Galvanic Couples in Various Environments**

Environmental Conditions	Maximum Differential (V)
Controlled: Temperature and humidity are controlled, as in laboratory or office spaces.	0.50
Normal: Industrial environments like warehouses where temperature and humidity are not controlled.	0.25
Harsh: Outdoors, high humidity, or salt exposure environments.	0.15

Note that the "Electrochemical Series," also known as the "Electromotive Force (EMF) Series," which ranks metals with respect to inherent reactivity, from active to noble, depends on theoretical, static conditions. Therefore, galvanic corrosion of metals listed is likely to vary in real-world environments.

*Protective Area Ratios for Galvanic Couples:* The wetted cathode/anode area ratio for parts in contact has a significant effect on the rate of galvanic corrosion: if the wetted cathode is large and the wetted anode is small (high ratio), corrosion is intensified; if the cathode is small and the anode is large (low ratio), corrosion slows. Protective area ratios can offset large potential differences between coupled metals. This effect makes it possible to use stainless steel screws to anchor large aluminum parts in conductive environments. By contrast, use of zinc or galvanized fasteners to secure large stainless steel parts will result in intense fastener corrosion in the presence of moisture. When choosing which part to coat in a galvanic couple, coat the more noble (cathodic) part; if only the more active metal (anodic) is coated, intense corrosion can occur at sites of small coating defects due to the resulting high area ratio.

### Effects of Corrosion

Corrosion can result in many different effects on a material. The following sections describe some common effects on materials induced at least in part or enhanced by corrosion, as well as mitigation methods.

**Crevice Corrosion.**—In small gaps, holes, and crevices, such as those between contacting parts, the fluid medium can be stagnant and undergo chemical changes with oxygen depletion. This corrosion is difficult to detect due to its location. Where possible, it helps to eliminate features that can trap fluid, use full welds instead of fasteners, and seal joints with grease or nonporous gaskets.

**Pitting Corrosion.**—Localized pitting corrosion is difficult to detect and can be destructive and unpredictable. Pits characteristic of this process may be small or large, may exist singly or in groups, and may be masked by corrosion-protection products. Pitting corrosion can be initiated by damage to a coating or oxide layer; surface contaminants or inclusions; or acid, chloride, or other caustic chemical exposure. Pits can act as stress risers and cause premature part failure due to fatigue or stress corrosion cracking.

**Microbiologically Influenced Corrosion (MIC).**—Also called *microbial corrosion* or *biocorrosion*, this process usually takes the form of crevice and/or pitting corrosion under a fouling biofilm that has formed on part surfaces. Chemistry changes due to static conditions under the film, metabolic waste from the microorganisms, and metabolic reduction of oxygen all contribute to corrosive attack. Many different biological organisms, both aerobic and anaerobic, can participate in this corrosion process. Elimination of fouling biofilms is the best defense. Also applicable are the stated methods for reducing pitting or crevices and using corrosion-resistant materials where possible. For example, in seawater applications, titanium is highly resistant to MIC, though it is not immune in all environments.

**Intergranular Corrosion.**—Localized attack along microstructural grain boundaries of a material can occur due to segregation or precipitation of elements at those boundaries. The unique material composition at the grain boundaries can preferentially corrode or cause galvanic corrosion to occur. The resulting changes in material properties can lead to intergranular stress corrosion cracking or disintegration.

This type of corrosion is a risk for stainless steel welded in multiple passes, which can cause sensitization of material. Depletion of chromium and/or formation of carbides in the heat-affected zone can lead to a type of intergranular corrosion known as *weld decay*, or *knife-line attacks* in alloys stabilized with niobium. Aluminum alloys, particularly extruded or heavily worked pieces, also are susceptible to intergranular corrosion; a subtype called *exfoliation corrosion* may occur where the surface grain is thinner than the rolled grain. Prevention methods include heat treatment of sensitized parts.

**Selective Leaching (Dealloying).**—This process involves preferential corrosion of the least noble element in an alloy. Dezincification of unstabilized brass (leaving porous copper) and iron depletion of gray cast iron (leaving graphite) are examples of selective leaching corrosion. This type of corrosion is difficult to detect visually, but structural weakening can be profound. To reduce the likelihood of selective leaching, vulnerable parts may be heat treated to improve homogeneity.

**Stress Corrosion Cracking.**—Potentially devastating cracks can start and grow slowly in metals and alloys exposed to both static tensile stress (applied and/or residual) and a corrosive environment. Rather than propagating on surfaces, such cracks usually are fine, branching, transgranular, and penetrating, and, thus, difficult to detect. Environmental conditions that induce this process are very specific and depend on materials, applied processes, and part uses. Weldments and heavily worked parts are particularly vulnerable, due to the potential for high levels of residual stress. Methods to guard against stress corrosion cracking include using stress-relieving parts with heat treatment or mechanical

loading and introducing surface compressive stress through methods such as shot peening, laser peening, or grit blasting.

**Tribocorrosion.**—When a material degrades due to a combination of erosion/wear and corrosion, the process is called *tribocorrosion*. Mechanical wear often accelerates the corrosion process; in turn, corrosion attack on the material often accelerates wear. There are two commonly encountered subtypes of tribocorrosion:

*Fretting Corrosion:* This occurs when two parts, exposed to a corrosive medium, rub forcibly against each other in a repetitive manner. The movements typically are very small; vibration is a common culprit. Contact surfaces experience mechanical wear and corrosive attack simultaneously, often leading to crack formation and fatigue failure. Bolted joints are especially vulnerable, as are bearings that undergo oscillating movements. Mitigation methods include eliminating movement between parts (particularly small oscillating movements), employing protective lubricants or sealants, adjusting hardness of one or both parts, and reducing contact loading, if possible.

*Erosion Corrosion:* Parts exposed to a flowing corrosive medium may exhibit localized areas where mechanical erosion occurs and corrosion is intensified. Optimizing flow geometry and velocity can help reduce turbulence and prevent such cavitation. Other methods include filtering out abrasive particles in the fluid, smoothing surfaces to remove imperfections, and minimizing edges.

**Hydrogen Embrittlement.**—High-strength steels, titanium alloys, and aluminum alloys are particularly susceptible to this type of attack. When hydrogen is absorbed into the material, this can cause embrittlement and cracking along grain boundaries, posing a risk of sudden failure. Processes that can cause excess hydrogen exposure include arc welding (unless low-hydrogen electrodes are used), electroplating, pickling, and phosphating. Mitigation steps include limiting hydrogen exposure, baking off hydrogen after exposure, relieving residual stresses, using barrier coatings, and substituting less vulnerable materials. Note that cathodic protection accelerates hydrogen embrittlement, especially in acid environments, so it should be used with caution when working with susceptible materials and processes.

**Corrosion Fatigue.**—Fatigue failure can occur prematurely in parts exposed to a corrosive environment while experiencing cyclic or alternating loading conditions. Cracks formed in this process usually are nonbranching and transgranular, form early, and grow at an accelerated rate, leading to substantially reduced fatigue life of parts. Prevention includes reducing loads and stresses, as well as normal corrosion mitigation methods.

## PLASTICS

## Properties of Plastics

## Characteristics of Important Plastics Families

ABS (acrylonitrile- butadiene-styrene)	Rigid, relatively low-cost thermoplastic, easily machined and thermoformed.
Acetal, POM	Engineering thermoplastic with good strength, wear resistance, and dimensional stability. More dimensionally stable than nylon under wet and humid conditions.
Acrylic, PMMA	Clear, transparent, strong, break-resistant thermoplastic with excellent chemical resistance and weatherability.
CPVC (chlorinated PVC)	Thermoplastic with properties similar to PVC, but operates to a 40–60°F (14–16°C) higher temperature.
Fiberglass	Thermosetting composite with high strength-to-weight ratio, excellent dielectric properties, and unaffected by corrosion.
Liquid crystal polymer (LCP)	Aromatic, highly inert polymer, with excellent mechanical properties, as well as chemical, fire, and temperature resistance.
Nylon	Thermoplastic with excellent impact resistance, ideal for wear applications such as bearings and gears, self-lubricating under some circumstances.
PEEK (polyetherether- ketone)	Engineering thermoplastic, excellent temperature resistance, suitable for continuous use above 500°F (260°C), excellent flexural and tensile properties.
Polyester, PET (polyethylene- terephthalate)	Dimensionally stable thermoplastic with superior machining characteristics compared to acetal.
Phenolic	Thermosetting family of plastics with minimal thermal expansion, high compressive strength, excellent wear and abrasion resistance, and a low coefficient of friction. Used for bearing applications and molded parts.
Polycarbonate, PC	Transparent tough thermoplastic with high impact strength, excellent chemical resistance and electrical properties, and good dimensional stability.
Polypropylene, PP	Good chemical resistance combined with low moisture absorption and excellent electrical properties, retains strength up to 250°F (120°C).
Polystyrene, PS	Transparent, colorless, and relatively low-cost amorphous thermoplastic. Relatively rigid with good electrical properties but brittle with poor chemical and ultraviolet properties.
Polysulfone, PSU	Durable thermoplastic, good electrical properties, operates at temperatures in excess of 300°F (150°C).
Polyurethane	Thermoplastic, excellent impact and abrasion resistance, resists sunlight and weathering.
Teflon, PTFE (polytetrafluoro- ethylene)	Thermoplastic, low coefficient of friction, withstands up to 500°F (260°C), inert to chemicals and solvents, self-lubricating with a low thermal-expansion rate.
PVC (polyvinyl chloride)	Thermoplastic, resists corrosive solutions and gases both acid and alkaline, good stiffness.
PVDF (polyvinylidene- fluoride)	Thermoplastic, outstanding chemical resistance, excellent substitute for PVC or polypropylene. Good mechanical strength and dielectric properties.

**Plastics Materials.**—Plastics encompass a wide range of materials that consist of long chains of carbon atoms with attached atoms of other elements, mainly hydrogen, and small, repeating chemical functional groups that influence the plastics' properties. Some other elements found in plastics are oxygen, nitrogen, chlorine, sulfur, and fluorine. A special class, the *silicones*, have chains of alternating silicon and oxygen atoms with small carbon-based side groups. These repeating chain segments are called *mers*, giving the term *polymers* for these materials. The pure (*neat*) materials are also known as *resins*. Commercial plastics are resins containing additives in amounts ranging from trace quantities to 50 percent or more. In any sample of resin, molecular chain lengths will generally vary widely, but the average typically exceed several thousand mer units if the resin is to possess good mechanical properties. There are two main classes of resins: *thermoplastics* (which includes *elastomers*) and *thermosets*.

*Thermoplastics:* Plastics that soften when heated are called thermoplastics. These plastics can be repeatedly melted by heating and then solidified by cooling. This reversible change may actually be repeated several times until a final product is made. For example, freshly polymerized polypropylene is a fine powder that is converted into pelletized feedstock by extrusion. The extruder compacts and melts the powder and pumps it through a strand die, where the emerging strands are water-chilled and sliced into  $\frac{1}{4}$ -inch (10 mm) BB-sized pellets. A sheet maker may then reprocess the pellets in an extruder to produce long rolls of thin sheet or shorter slabs of thicker sheet. These can be used by a thermoformer, which again heat-softens the sheet and pulls it down over a chilled mold to make packages from the thin sheet or wastebaskets from the thicker ones.

Some examples of commodity thermoplastic families are polystyrenes (PS), olefins including polyethylenes (PE) and polypropylenes (PP), acrylics (PMMA), cellulotics (e.g., cellulose acetate butyrate, CAB), and polyvinyls. Engineering thermoplastics, such as the nylon family, acetal resins, polycarbonate, and others listed in the preceding table, generally have superior strength, toughness, and resistance to heat and chemicals. Although the heating/cooling cycle can be repeated, each recycling tends to reduce mechanical properties and appearance.

*Thermosets:* Thermosetting plastics, such as amino, epoxy, phenolic, and unsaturated polyesters, are supplied to the final processor as partially polymerized mixtures of chemically active, long-chain molecules. When they are heated during molding, the mixture components react to form chemical bonds, called *cross-links*, between the original chains, forming huge three-dimensional molecules. Such products generally have improved mechanical properties and heat resistance. However, if heated above their molding temperatures, they do not melt but instead decompose. They cannot be reprocessed, so opportunities for salvaging scrap for recycling are limited. Many rubbers that are processed by vulcanizing, such as butyl, latex, neoprene, nitrile, polyurethane, and silicone, also are classified as thermosets.

*Elastomers and Rubbers:* Raw natural or synthetic rubber, initially thermoplastic, is mixed with finely divided carbon and sulfur. During molding, these materials undergo cross-linking by sulfur, a process called *vulcanizing*. Elastomers typically have low elastic moduli (stiffness) but high elasticity (stretch). Many, if stretched to twice their length (or much more) and then released, will snap back resiliently to their original length and shape. Thermoplastic elastomers are often used in place of rubber, and also may be used as additives in other thermoplastic resins for improving impact strength of rigid thermoplastics.

**Thermoplastic Structures.**—Thermoplastics can be classified by their structures into three categories:

*Amorphous:* These randomly structured materials are sometimes called *noncrystalline*. Such thermoplastics include acrylates, polycarbonate (PC), polystyrene, acrylonitrile-butadiene-styrene (ABS), styrene acrylonitrile (SAN), and polyvinylchloride (PVC) and its acetate copolymers.

*Semi-Crystalline:* Half or even more of the chains in crystalline thermoplastics are organized into tiny regular regions called *crystallites*. Representative members are nylons,

acetals, polyethylene (PE), polypropylene (PP), and polyethylene terephthalate (PET). The crystallites are linked by amorphous zones; the resulting microstructures make these materials stronger and stiffer than similar materials without crystallinity. They generally possess higher end-use chemical and temperature resistance, and melt at higher temperatures, with more sharply defined melting ranges than amorphous resins.

**Liquid-Crystalline Polymers (LCP):** These contain crystal-like structures even in the melted resin. They have highly ordered, rod-like microstructures with good mechanical properties and high melting temperatures. They have the lowest shrinkage and warpage of the three types of thermoplastics.

**Copolymers, Blends, Additives, and Reinforcements.**—Plastics can be manipulated to modify mechanical, chemical, electrical, and cost characteristics.

**Copolymers:** Combining two or more different polymers can create a new material with properties that are quite different from those of the individual polymers (*homopolymers*) from which they are made. The copolymers are alloyed: mechanically blended from the two or more different polymers, often with special additives to make them compatible. These “alloys” are compounded so as to retain the most desirable characteristics of each constituent, especially impact strength and flame resistance. The properties usually are between those of the constituent homopolymer materials.

Copolymers such as SAN and ABS have long been commercially available. While tens of thousands of grades have been developed, less common blends and alloys are not always readily available in sheets or in standard industry stock shapes supplied for machining.

**Additives and Fillers:** Plastics compounds with desired sets of properties are produced from “neat” resins by adding many types of other chemicals and materials. Antioxidants, lubricants, pigments and dyes, fire retardants, and ultraviolet protectants in small percentages usually do not significantly alter mechanical and physical properties. *Larger* quantities of particulate fillers, such as wood flour or fibers, silica powder, glass or phenolic microballoons, and carbon and metal powders, are often used to tune density, thermal and electrical conductivity, mechanical properties, and unit cost. The use of such additives makes available many grades of a given plastic type from each commercial plastics manufacturer. Such additives can increase value in application but also may increase difficulty in recycling.

**Plasticizers:** Plasticizers soften and toughen the base resins with which they are compounded. While they are used in several resin families to some extent, polyvinyl chloride resins (PVC) and related plastics use plasticizers and many other additives in high percentages. These modified resins produce a myriad of grades of PVC from the familiar rigid pipe material (the dominant consumer of PVC) to wire coatings, flooring, and elastomers used in footwear.

**Fibers:** Plastics, which have much lower moduli and strengths than glass and metals, can be made stiffer and stronger by incorporating glass, graphite or other fibers. Short chopped fibers in fractions up to about 40 percent, randomly oriented in molding compounds, provide substantial increases in stiffness and strength. But more dramatic improvements are obtained by incorporating longer fibers in carefully chosen directions, as in fishing rods and golf club shafts, where content of glass or carbon fiber may be more than 50 percent by weight. Historically, sturdy composites have been and still are made by compression molding multilayer canvas, paper, or cotton-felt sheets impregnated with phenolic or other thermosetting resins. (See also *Plastics Gears* on page 606.) A relatively recent reinforcement material is *oriented aramid* (aromatic polyamide, Kevlar), whose strength and modulus rival those of metals. Its most familiar use has been in “bullet-proof” vests for law-enforcement and military personnel.

**Cellular Plastics.**—Many rigid and flexible thermoplastic and thermosetting resin families are available as foamed plastics in the form of sheets, boards, bars, and cylinders, as well as molded shapes. The internal structure of plastic foam consists of tiny gas-filled cells bounded by shared membranes of the resin.

In *closed cell* foams, each cell is a tiny polyhedral cavity adjacent to, but not opening into, other cells. Foamed polystyrene hot liquid beverage cups are an example of closed

cell foams. In *open cell* foams, the cells are not completely closed but instead form continuous connecting tunnels with other cells in all directions throughout the object. Kitchen sponges are open cell foams.

Densities of plastics foams range from 90 percent of the resin's unfoamed density down to just a few percent. Foaming may be accomplished physically by injection of a gas or volatile solvent during extrusion or molding, or by mixing a chemical blowing agent with the resin. When the mix is processed, the unstable blowing agent decomposes in the melt, generating bubbles. Foams have many uses: as low-cost space filling, cushioning, thermal and electrical insulation, and as the interlayer member of sandwich materials. Polystyrene, polyethylene, and polyurethane (rigid and flexible) are important foam families.

**Application and Physical Properties.**—Selecting a plastic for a specific application requires knowledge of many different kinds of properties of candidate materials. Density and mechanical properties will be important considerations in most cases. The plastics must be able to bear tensile, compressive, or bending loads; resist or allow twisting or stretching; survive impacts; withstand thousands or even millions of repeated stress cycles; and resist abrasion. Special service environments—extremely low or high temperatures and humidities, outdoor exposure, and the presence of active solvents and chemicals—will modify the selection criteria. Thermal or electrical properties, such as coefficients of thermal expansion, thermal or electrical conductivity, heat capacity (specific heat), dielectric strength, and dielectric-loss factor, may sometimes be important.

Over many years, Committee D-20 of ASTM (formerly American Society for Testing Materials) has developed thousands of characterization and test methods for plastics and their products. ASTM Standards, Section 8, "Plastics," is updated and reissued annually by ASTM. All leading US resin makers and many compounders can furnish the product designer with the results of batteries of tests made on their materials according to numbered ASTM standards. For example, ASTM Test D638, "Tensile Properties," prescribes the preparation and dimensions of specimens to be tested by pulling from both ends. Several useful mechanical-property values are obtained from this test: tensile modulus, yield strength, tensile strength at break, and elongation (percent stretching) at break. Most plastics products are made by molding from a molten or pre-polymer condition by processes such as extrusion or injection- or compression-molding. Products so made are apt to have a somewhat different microstructure close to the surface than in their interiors. In theory, the behavior of a simple test bar in bending should be calculable from the straight tensile-test modulus  $E$ , as it is with metals. However, because of the "skin effects" found in molded plastics such predictions are not very reliable. For this reason, ASTM Committee D-20 developed Method D790 for flexural properties. Flexural moduli, theoretically the same as  $E$ , actually tend to be somewhat higher in molded thermoplastics, as are their flexural strengths. While tensile and flexural specimens are typically  $1/8$ -inch (3.2 mm) thick, properties do vary with part thickness and processing conditions, so designs should be developed with appropriate safety factors and validation.

Even with homogeneous plastics whose properties are expected to be about the same in all principal directions, certain processing conditions, such as stretching while the heat-softened plastic is cooling, can cause alignment *orientation* of the long polymer chains or crystallites in the stretching or flow direction. This will increase tensile strength in that direction but with some reduction in the perpendicular cross directions. Even more striking anisotropic effects are achieved with long-fiber reinforcements, in which the modulus and strength may be a factor of two or greater in the fiber direction than in the cross-fiber direction.

Suppliers of unreinforced sheet, bar, and rod stock for machining can relieve stress by controlled annealing of any residual stresses developed in processing, thereby preventing distortions related to the relief of residual strains during machining. Machining or heating of un-annealed stock can release residual stresses in the material, causing significant dimensional variations and warpage that can be difficult to resolve.

Some of the more important application properties are defined here.

**Density and Specific Gravity:** These properties are closely linked. *Density* is the mass (or weight) per unit volume of a material, used mainly to calculate the mass of material required to make a part whose volume has been calculated from its dimensions. In the plastics industry, commonly used units are lb/in<sup>3</sup> or g/cm<sup>3</sup>. *Specific gravity* is the ratio of a material's density to that of water, both measured at the same temperature, at 23°C (73.4°F) for plastics. Since the density of water at typical room temperatures is very close to 1.00 gm/cm<sup>3</sup>, specific gravity and density measured in metric units are numerically almost equal. In US customary units, water density equals 0.0361 lb/in<sup>3</sup>. Specific gravities of neat resins range from 0.83 for polymethylpentene to 2.20 for polytetrafluoroethylene (PTFE, Teflon). Because specific gravity is a ratio of densities of like units, it is dimensionless. See also *Specific Gravity* on page 377.

Unlike specific gravity, *specific volume* is not dimensionless, but is defined as the reciprocal of density, with units of in<sup>3</sup>/lb or cm<sup>3</sup>/g.

**Shrinkage:** This is the difference in measurement between a linear dimension of a mold and the corresponding dimension of a plastic article made in the mold, divided by the mold dimension, and expressed in/in, mils/in, or percent. The dominant material property here is the *coefficient of linear thermal expansion* since the shrinkage is mainly due to cooling from the high temperature of the melt as it solidifies under pressure in the mold to room temperature after its removal from the mold. Expansion coefficients of plastics are much larger, 20 to over 100 times those of metals and ceramics. For type-66 nylon, which freezes at 260°C (500°F), shrinkage may be as much as 20 mils/in (0.02 cm/cm), i.e., 2 percent. Shrinkage can also be affected by other molding conditions and by additive content. Amorphous and liquid-crystalline thermoplastics have lower shrinkages than crystalline materials. Glass- or carbon-reinforced and mineral-filled compounds have lower shrinkage than their neat resins. For accurate assessment of shrinkage, test moldings at the target part thickness are advised before mold-cavity dimensions are finalized.

**Water Absorption:** This is the increase in weight of a test specimen due to absorption of water, expressed as a percentage of the original dry weight. Standard test specimens (ASTM Method D570) are first dried for 24 hours, then weighed before and after immersion in water at 23°C (73.4°F) for a specified time. Absorption of water affects not only the dimensions of plastics parts but also mechanical and electrical properties. Parts made from materials with low water absorption tend to have greater dimensional stability.

**Transparency:** This is a measure of the percentage of incident light that is transmitted through a test specimen. It is quantified as *luminous transmittance*, the ratio of transmitted to incident light. *Haze* measures the percentage of light entering a specimen that is scattered more than 2.5 degrees from the incident beam.

**Elasticity:** Most solid materials are initially elastic, such that when small stresses causing deformation are removed, the material will recover its original shape and dimensions. A more precisely formulated definition of "elastic" is "a material that obeys Hooke's law of proportionality of strain to stress up to its proportional limit" (see page 565). The *modulus of elasticity* is Hooke's law constant *E*, the quotient of stress divided by strain in the proportional region. In a tensile test, strain is the ratio of observed displacement, relative to the original length, reached under a given stress. Because plastics generally deviate from strict linearity, the moduli reported are usually "one percent moduli," that is, the quotient of stress and strain at 1 percent strain. For most materials the limit of recoverable strain is a few percent or less. For rubbers and a handful of thermoplastic elastomers, maximum recoverable strain may be as high as 100 percent or more. Stress and strain in relation to plastics part design is discussed on page 563.

**Plasticity:** This refers to the deformation exhibited when materials are stressed beyond their elastic limits without breaking (i.e., when stress exceeds the *yield point*). In this mode, there can be considerable flow within the microstructure of the material, and permanent changes in the dimensions and shape of the deformed article occur. Plastic deformation continues with small increases in stress until finally there is rupture. Plasticity is exhibited to some degree by most unreinforced plastics. While parts are normally

designed to operate in their material's elastic ranges, and plastic deformation may render a part useless for its designed function, plastic deformation *can* be used to prevent catastrophic failure with a fail-safe design. A few plastics have such compliant plasticity that they can be cold-formed by metalworking methods—rolled, stretched, or even forged into final products. This property in metals is called *ductility* and also applies to plastics.

**Toughness:** This property governs the ability of a material to absorb mechanical energy without cracking or breaking. Often it depends on the rate at which the specimen is deformed. In a standard tensile test (ASTM D638), the strain rate is fairly low—from 0.15 to 15 (in/in)/min. In a tensile-impact test (ASTM D1822) the specimen is abruptly stretched to failure in milliseconds at a strain rate of about 20,000 (in/in)/min. The tensile tester of D638 generates a graph of stress (psi) versus strain (in/in). The area under this curve is the energy in ft-lb<sub>f</sub>/in<sup>3</sup> absorbed by the gage volume as it is stretched and finally broken. The impact tester, on the other hand, directly determines how many foot-pounds of energy are needed to stretch and break the specimen. That value, too, can be converted to energy per unit of specimen volume, but the impact energy usually will be very different from the tensile energy to failure. A widely used test of toughness for plastics is the Izod impact test (ASTM D256), in which a falling pendulum strikes and breaks off the upper half of a cantilever test bar whose leading face has a 0.1 in. (2.54 mm) deep, V-shaped notch across it just above the clamping point. This test (the oldest in ASTM's Plastics list, first published in 1926) indicates not only toughness but also the *notch-sensitivity* of the plastic. The test result is expressed in ft-lb<sub>f</sub>/in of notch width. Izod-test values for 1/8-inch (3.2 mm) wide specimens of neat thermoplastics range from 0.4 for crystal polystyrene or wood-flour-filled phenolics to 14 for polycarbonate and phenolics with a high content of glass fiber. Particulate fillers may increase or decrease Izod impact strength; fibrous reinforcements usually increase it. Thus, applying tabulated toughness values to plastics part design is not a simple task.

**Brittleness:** Lack of toughness, characterized in plastics by Izod impact test values below 1.0 ft-lb<sub>f</sub>/in (53 J/m) or by abrupt fracture with little or no yield in tensile tests, is referred to as brittleness.

**Notch Sensitivity:** This measurement indicates the ease with which a crack progresses through a material from an existing notch, crack, or sharp corner.

**Hardness:** The ability of a material to resist deformation by surface indentation or abrasion, hardness is often related to modulus, strength, and wear resistance. Several ASTM test methods are in use for plastics, the Rockwell hardness test (ASTM D785) being a popular one. One of three hardened steel balls is pressed into the test specimen, first with a low force, then a much higher one, while a micrometer indicates the increase in depth of impression. Five scales are available for plastics: R, L, M, E, and K, in order of increasing hardness, requiring progressively smaller balls and stronger forces. The scale *must* be identified in the report of Rockwell hardness numbers. When an article is expected to suffer abrasion in service, the abrasion loss of candidate plastics may be experimentally determined with an abrasion machine (ASTM D1242).

**Homogeneous** plastics have the same composition throughout a part down to the microstructural level, but not to the molecular level as in simple chemical compounds. A 3/16 inch (5 mm) BB-sized pellet of a neat resin contains many long-chain molecules of various chain lengths. However, even compounds containing several additives, pigments, and powdery fillers behave in molded articles as if they were homogeneous.

**Heterogeneous (inhomogeneous)** plastics vary in composition and structure. A compound reinforced with centimeter-long, randomly oriented, chopped glass fibers will not look homogeneous under 50× magnification, yet it may be safely treated as such in the design of parts that are larger than the test samples whose properties have been measured.

**Isotropy and Anisotropy:** These properties are related to homogeneous and heterogeneous types of plastics. In *isotropic* materials, measured properties are equal in all directions. Cast metals and unfilled, amorphous plastics tend to be isotropic. Processing effects such as flow orientation that do not change homogeneity can create substantial directional differences in properties. This effect is called *anisotropy*. In plastic films made by

extruding molten resin onto chilled rolls, the films are usually stronger in the “stretch” direction, weaker in the lateral or cross direction. Laminates made of laid-up reinforcing fibers or woven cloths can be nearly biaxially isotropic in the laminate plane, but their interlaminar shear is low because no fibers cross through the plane. Extremely anisotropic are unidirectional laminates in which all the fibers are parallel, as in golf club shafts reinforced with graphite fibers.

Wood (see page 382) is a natural anisotropic material, strong and stiff in the grain (growth) direction, less so in the perpendicular and tangential directions. Commercially important fibers, both natural and synthetic, are also highly anisotropic with their greatest strength and moduli aligned with length.

As the degree of anisotropy increases, the number of physical constants (moduli) required to define a material's stress-strain behavior also increases, up to a maximum of 21. Absence of such complete information on complex laminates and the inadequacy of simple analysis methods point to the need for extensive end-use testing of plastics parts before approval of critical application requirements. Computer modeling using finite element analysis (FEA) techniques can help in the successful implementation of these materials. Detailed properties data are required for reliable and accurate modeling.

In addition to mechanical properties, isotropy and anisotropy can affect manufactured plastic part dimensions. Anisotropic shrinkage caused by patterns of flow during processing is important in molding crystalline and fiber-reinforced plastics, for which different shrinkage values are experienced in the flow and cross-flow directions. These values are of most concern to the tool designer and molder; however, the existence and severity of anisotropic shrinkage must be considered when a material is chosen for a part having tight tolerances.

*Coefficient of Friction:* This property comes into play in plastics gears and bearings and other applications where low dynamic (kinetic) friction is desired between moving surfaces in contact. When a weighted block of a plastic is dragged at a steady velocity along a horizontal slab of the same or different material and the contact surfaces are smooth, the coefficient of friction is defined as the ratio of the horizontal drag force to the total weight of the block, called the normal force. In general, the observed coefficients will be different for different pairs of materials, so a test report must identify both materials. While some coefficients were (long ago) determined in this basic manner, ASTM D3028 now prescribes a sophisticated machine (“frictionometer”) for measuring the property. Coefficients of friction change with temperature. Materials such as 66-nylon, acetal resin, and polytetrafluoroethylene containing molybdenum disulfide, which have low self-coefficients, typically enjoy long operating life in unlubricated gears and bearings.

*Significance of Elasticity, Homogeneity, and Isotropy in Plastics:* In the section *The Basics of Stress and Strain in Plastics* on page 563, formulas for stress and strain in a wide variety of structural geometries are based on the assumptions that 1) the materials are perfectly isotropic and elastic, obeying Hooke's law in tension, compression, and shear; and 2) the only mechanical properties needed are the elastic modulus  $E$ , the shear modulus  $G$ , and, occasionally, Poisson's ratio  $\nu$ . See pages 564 and 565.

For discussion purposes, consider the structural material low-carbon steel, which obeys these assumptions at temperatures below dull red heat. For this metal,  $E = 30,000$  kpsi (206.8 GPa),  $G = 11,400$  kpsi (78.6 GPa), and Poisson's ratio  $\nu = 0.32$ . The elastic limit is about 40 kpsi (276 MPa), which indicates that its elongation in tension at that limit is only 0.13 percent. Its stress-strain graph up to the elastic limit is practically a straight line. If it is loaded up to half its elastic limit and maintained at that load for a couple of decades, when the loading is removed, the 0.065 percent elongation will be instantly and completely recovered. The rate and duration of loading in normal applications do not affect the steel's apparent properties.

Plastics, in contrast, are *viscoelastic* materials. They are complex aggregates of many different elastic and fluid elements and therefore display properties between those of crystalline metals and very viscous fluids. Their stress-strain graphs tend not to be linear.

Even at low stresses, they are sensitive to rate of loading and to temperature, as shown generically in Fig. 1. Curves A and B identify the stress-strain behavior of brittle materials that will tend to fail suddenly under increasing strain. By comparison, curves C through E show how increasing temperatures both increase ductility and extend the strain to failure curve, albeit with decreased stiffness.

Fig. 1. Generic Tensile-Test Graphs for Plastics, Showing Typical Range of Behavior from Brittle to Highly Ductile with Increasing Temperatures

Structural analysis during design of components uses two independent constants, Young's modulus ( $E$ ) and Poisson's ratio ( $\nu$ ), but these two constants are sufficient only for elastic, isotropic materials that respond linearly to loads (when load is proportional to deformation). Designers often use the same values for these constants everywhere in the structure, which is correct only if the structure is homogeneous.

Assumptions of linear elasticity, isotropy, and homogeneity are reasonable for many analyses and provide a good starting point, but use of these assumptions can lead to significant design errors with plastics, particularly with glass-reinforced and liquid crystalline polymers, which are highly anisotropic. In this discussion, plastics are assumed to be linearly elastic, homogeneous, and isotropic to allow a simpler presentation of mechanical properties in line with the data provided in plastics manufacturers' marketing data sheets. The standard equations of structural analysis (bending, torsion, pressure in a pipe, etc.) also require these assumptions.

**Creep:** When plastics are subjected to sustained high loads, they *creep*. That is, they tend to slowly deform (flow), exhibiting the viscous side of their nature. If the load is removed, the stressed object will usually not return completely to its original shape and dimensions. Creep is more rapid at higher temperatures, even at temperatures expected in normal service. Laboratory stress-strain curves obtained according to ASTM D638 at moderate strain rates and 23°C (73.4°F) or other temperatures will resemble those in Fig. 2. Most plastics have no true proportional limits, instead exhibiting curved dependence of stress versus strain even at strains less than 1 percent. Tangent moduli from D638 therefore tend to be subjective and inaccurate when used for predicting deformation. The isometric diagram of Fig. 2 shows the dependence of stress in Styron 475, a rigid modified polystyrene, at various strains and times. Note the logarithmic time scale (0.01 h = 36 s, 10,000 h = 1.14 yr). The curve on the left panel, for 0.01 h, is the stress-strain graph one might obtain at one of the slower testing rates of ASTM D638. The stress ordinate at the left edge, front, i.e., 600 psi (4.1 MPa) for a strain of 0.15 percent, corresponds to a short-time modulus for this resin of 400 kpsi (2.8 MPa), in agreement with values reported elsewhere. When this small strain was maintained for 1000 hours (6 weeks), the stress had decayed along the first curve (left rear to right front) to about 400 psi (2.8 MPa), two-thirds of its initial value.

Fig. 2. Isometric Plot for High-Impact Polystyrene Showing Stress Response to Imposed Strains over Three Decades

Some hygroscopic resins can absorb water from the air, with stress-strain behavior ranging from curve B or C of Fig. 1 when very dry to curve D or E at high moisture contents. Polyamides (nylons), classified as engineering resins with superior properties, exemplify this moisture dependence, picking up about 0.3 percent in very dry climates, and 2.5 percent or more in very humid ones.

Modulus and strength values reported from ASTM D638 testing should not be used in the design of plastics products that must sustain loads over long periods; the addition of reinforcements, such as glass fiber (GF), is observed to significantly increase the modulus and strength of both thermoplastics (e.g., PP) and thermosets (e.g., epoxy). Properties for various plastics are included in the plastics properties table on page 387.

**The Basics of Stress and Strain in Plastics.**—The mechanical behavior of plastics is similar in many ways to that of metals, but there are important differences that must be kept in mind in the design of plastics products and parts.

**Stress:** A three-dimensional body having a balanced system of external forces  $F_1$  through  $F_5$  acting on it such that the body is at rest is shown in Fig. 3. Such a body develops internal forces to transfer and distribute the external loads. If the body is cut at an arbitrary cross section and one part is removed, as shown at the right in Fig. 3, a new system of forces acting on the cut surface is developed to balance the remaining external forces. Similar forces (stresses) exist within the uncut body.

Stresses must be defined by both magnitude and direction. The stress  $S$  acting in the direction shown in Fig. 3 on point  $P$  of the cut surface has two stress components. One of these components,  $\sigma$ , acts perpendicular to the surface and is called a *normal stress*. The other stress,  $\tau$ , acts parallel to the surface and is called a *shear stress*.

Fig. 3. Internal Forces and Stresses in a Body

Fig. 4. Simple Tension Load

*Normal stress* ( $\sigma$ ) is illustrated by the simple tension test shown in Fig. 4, where the direct stress is the ratio of applied load to the original cross-sectional area in  $\text{lb}_f/\text{in}^2$ . In the **Système International (SI or metric system, see page 2872 and Table 39 on page 2863)** the stress  $\sigma$  is expressed in newtons/meter<sup>2</sup> ( $\text{N}/\text{m}^2$ ).

$$\text{Stress} = \frac{\text{Load}}{\text{Area}} \quad \text{or} \quad \sigma = \frac{F}{A} \quad (1)$$

If the load is applied as shown in Fig. 4, the test piece is in tension, and if reversed, it is in compression.

*Normal strain* ( $\epsilon$ ) is also illustrated by the diagram in Fig. 4, where the load or stress applied to the test piece causes it to change its length. If the bar has an original length  $L$  and changes its length by  $\Delta L$ , the strain,  $\epsilon$ , is defined as

$$\text{Strain} = \frac{\text{Change of Length}}{\text{Original Length}} \quad \text{or} \quad \epsilon = \frac{\Delta L}{L} \quad (2)$$

Strain is the ratio between the amount of deformation of the material and its original length. It is a dimensionless quantity. Extensions of most materials under load are generally very small. Strain ( $\mu\epsilon$  or microstrain in most metals) is measured and expressed in microinches (millionths of an inch) per inch, or  $10^{-6}$  in/in ( $10^{-6}$  cm/cm). Alternatively, strain is expressed as a percentage. The three methods compare as follows:

$$1000\mu\epsilon = 0.001 = 0.1 \text{ percent strain}$$

$$10000\mu\epsilon = 0.010 = 1 \text{ percent strain}$$

*Modulus of Elasticity E:* Most metals and plastics have deformations that are proportional to the imposed loads over a range of loads. Stress is proportional to load, and strain is proportional to deformation, so stress is proportional to strain and is expressed by Hooke's law:

$$\frac{\text{Stress}}{\text{Strain}} = \text{Constant} = E \quad (3)$$

The constant  $E$  is called by various names: the *modulus of elasticity*, *Young's modulus*, or, in the plastics industry, *tensile modulus*. Referring to Fig. 4, tensile modulus is given by the formula:

$$E = \frac{\sigma}{\epsilon} = \frac{F/A}{\Delta L/L} = \frac{FL}{A\Delta L} \quad (4)$$

Thus, the modulus is the slope of the initial portion of the stress-strain curve. An elastic material does not necessarily obey Hooke's law, since it is possible for a material to return to its original shape without the stress being proportional to the strain. If a material does obey Hooke's law, however, it is elastic.

The straight portion of the stress-strain curve for many plastics is difficult to locate, and it is necessary to construct a straight line tangent to the initial portion of the curve to use as a modulus. The shape of a line so obtained is called the *initial modulus*. In some plastics the initial modulus can be misleading, owing to the nonlinear elasticity of the material. Some suppliers therefore provide the so-called 1 percent secant modulus, which is the ratio of stress to strain at 1 percent strain on the stress-strain curve. In the illustration of typical stress-strain curves in Fig. 5, the secant modulus at the point  $E$  is the slope of the line  $OE$ .

Fig. 5. Typical Stress-Strain Curves

For metals, Young's modulus is expressed in terms of  $10^6 \text{ lb}_f/\text{in}^2$ ,  $\text{N}/\text{m}^2$ , or Pa, as convenient (see *Units of Pressure and Stress* starting on page 2861.)

*Secant modulus* is the ratio of stress to corresponding strain at any point on the stress-strain curve (see *Modulus of Elasticity E*).

*Proportional limit* is the greatest stress at which a material is capable of sustaining the applied load without losing the proportionality of stress to strain. This limit is the point on the stress-strain curve where the slope begins to change, as shown at *A* on each of the curves in Fig. 5. Proportional limit is expressed in  $\text{lb}_f/\text{in}^2$  (MPa or GPa).

*Yield point* is the first point on the stress-strain curve where an increase in strain occurs without an increase in stress, indicated by *B* on some of the curves in Fig. 5. The slope of the curve is zero at this point; however, some materials do not have a yield point.

*Ultimate strength* is the maximum stress a material withstands when subjected to a load, and is indicated by *C* in Fig. 5. Ultimate strength is expressed in  $\text{lb}_f/\text{in}^2$  (MPa or GPa).

*Elastic limit* is indicated by *D* on the stress-strain curve in Fig. 5 and is the level beyond which a material is permanently deformed when the load is removed.

Although many materials can be loaded beyond their proportional limit and still return to zero strain when the load is removed, some plastics have no proportional limit in that no region exists where the stress is proportional to strain (i.e., where the material obeys Hooke's law).

*Yield strength* is the stress at which a material shows a specified deviation from stress to strain proportionality. Some materials do not show a yield strength clearly, and it may be desirable to choose an arbitrary stress level beyond the elastic limit, especially with plastics that have a very high strain at the yield point, to establish a realistic yield strength. Such a point is seen at *F* on some of the curves in Fig. 5 and is defined by constructing a line parallel to *OA* at a specified offset strain *H*. The stress at the intersection of the line with the stress-strain curve at *F* would be the yield strength at *H* offset. If *H* were at 2 percent strain, *F* would be described as the yield strength at a 2 percent strain offset.

*Poisson's Ratio*  $\nu$  is the ratio of the lateral contraction to longitudinal elongation. Under a tensile load, a rectangular bar of length *L* with sides of widths *b* and *d* lengthens by an amount  $\Delta L$ , producing a longitudinal strain of

$$\epsilon = \frac{\Delta L}{L} \quad (5)$$

The bar is reduced in its lateral dimensions and the associated lateral strains will be opposite in sign, resulting in

$$\epsilon = -\frac{\Delta b}{b} = -\frac{\Delta d}{d} \quad (6)$$

If the deformation is within the elastic range, Poisson's ratio of the lateral to the longitudinal strains will be constant. The formula is:

$$\nu = \frac{\text{Lateral Strain}}{\text{Longitudinal Strain}} = \frac{\Delta d/d}{\Delta L/L} \quad (7)$$

When a bar like that in Fig. 4 is stretched in tension, mass must be conserved; if there is no change in diameter, the average density diminishes inversely as the strain increases. If the area decreases in percentage as much as length increases in percentage, the stretched volume would equal the original volume, and density would be preserved. In fact, most real materials do contract laterally when stretched, but not enough to preserve constant density; therefore, density usually does diminish with elongation.

Values of  $\nu$  for most engineering materials lie between 0.20 and 0.40, and these values hold for unfilled rigid thermoplastics. Values of  $\nu$  for filled or reinforced rigid thermoplastics fall between 0.10 and 0.40 and for structural foam between 0.30 and 0.40. Rigid thermoset plastics have Poisson's ratios between 0.20 and 0.40, whether filled or unfilled, and elastomers can approach 0.5.

Table 1 lists values of  $\nu$  determined at 73°F (23°C) for some plastics by measuring of lateral contraction and longitudinal elongation in tensile tests.

**Table 1. Poisson's Ratio at 23 °C for Resins and Compounds**

Plastic	Poisson's Ratio, $\nu$	Plastic	Poisson's Ratio, $\nu$
ABS, unfilled	0.35	Polycarbonate	0.37
Acetal	0.35	Polyester, thermoplastic, gfr <sup>a</sup>	0.35–0.41
Acrylic (PMMA)	0.35–0.40	Polyester, thermoset, gfr <sup>a</sup>	0.24
Alkyd, mineral filled	0.17	Polyetherimide	0.36
Diallyl phthalate	0.27	Polyethylene, HD	0.45
FEP resin	0.48	Polyphenylene ether	0.35
PC, gfr <sup>a</sup>	0.38	Polyphenylene oxide	0.27–0.38
PCTFE	0.33	Polypropylene	0.42
Phenolic, cellulose-filled	0.24	Polystyrene, cross-linked	0.35
Phenolic, gfr <sup>a</sup>	0.2	Polyethersulfone	0.4
Polyamide, min-filled, gfr <sup>a</sup>	0.32	PTFE	0.46
Polyamide 6, dry, gfr <sup>a</sup>	0.36	PVF	0.4
Polyamide 66, dry, gfr <sup>a</sup>	0.32	PVDF	0.34

<sup>a</sup> gfr = glass-fiber reinforced, 30 or 33%.

Mineral fillers and glass-fiber reinforcements in plastics reduce Poisson's ratio. In anisotropic structures such as uni- and bi-directional laminates, Poisson's ratio may be different in orthogonal (i.e., perpendicular) directions. Usually, the value perpendicular to the reinforcing fibers will be the one most likely to be relevant. Vulcanized gum rubber has exceptional behavior; its Poisson ratio = 0.5, and it conserves density. This must be kept in mind in designing items to be compressed, such as rubber cushions and bumpers. When a rubber specimen is compressed it is shortened and its sides must be free to bulge out; otherwise the incompressibility of the rubber would not allow it to deform at all.

*Shear stress* is described on page 219. Any block of material is subject to a set of equal and opposite shearing forces  $Q$ . If the block is envisaged as an infinite number of infinitesimally thin layers as shown diagrammatically in Fig. 6, it is easy to imagine a tendency for one layer subject to a force to slide over the next layer, producing a shear form of deformation or failure. The shear stress  $\tau$  is defined as

$$\tau = \frac{\text{Shear Load}}{\text{Area Resisting Load}} = \frac{Q}{A} \quad (8)$$

Shear stress is always tangential to the area on which it acts. Shearing strain is the angle of deformation  $\gamma$  and is measured in radians.

Fig. 6. Shear Stress Is Visualized as a Force  $Q$  Causing Infinitely Thin Layers of a Component to Slide Past Each Other, Producing a Shear Form of Failure

*Example:* In Fig. 7a, shear stress in the overlapped zone equals the tensile force  $F$  divided by the contact area of the adhesive. That is,  $\tau = F/(WL)$ . As  $F$  is increased, the joint will finally fail in shear, either in the adhesive layer or in the material of one of the bars, depending on which material has the greater shear strength.

Fig. 7a. Adhesive Lap Joint

Fig. 7b. Riveted Lap Joint

In Fig. 7b, a similar lap joint is joined with a rivet of diameter  $D$ . In this case, the shear area in the rivet is  $\pi D^2/4$ , a much smaller area. But what if the rivet were aluminum and much stronger than the plastic being joined? A second, very different shear area comes into play, shown as a free body in the lower portion of Fig. 7b, the small bar-end volume adjacent to the rivet. The area shown shaded is equal to  $L \times t$  and is  $1/2$  of the shear area, so the total shear area equals  $2Lt$ . Thus, the shear stress  $\tau$  exerted by the rivet and trying to push the plug out of each bar end is  $F/(2Lt)$ . As the force  $F$  is increased, the mode of failure in the rivet or the bar end will be decided by which of these shear stresses first exceeds the shear strength of the material on which it is acting.

Geometries like those in Fig. 7a and Fig. 7b are not useful for determining shear modulus because there is very little recordable shear deformation prior to failure at the shear strength. However, the very simple shear geometry shown in Fig. 8 is used in ASTM D732 test to measure the shear strengths of plastics. The washer-shaped test sample has an outer diameter of 2 inches (50.8 mm) and a central hole of about  $9/16$  inch (14.3 mm) to allow the half-inch (12.7 mm) bolt to pass freely through the specimen. The thickness may be any measured value between 0.05 and 0.5 inch (1.27 and 12.7 mm). In this test, the shear area is given by  $\pi \times$  punch diameter  $\times$  disk thickness. The results of such tests are often described in manufacturers' marketing data sheets as the shear strength of the material. The shear strength reported from such a test is not a pure shear strength because a considerable part of the load is transferred by bending or compressing, or both, rather than by pure shear, and results can be affected by the susceptibility of the material to the sharpness of the load faces in the test apparatus. Thus, the test cannot be used to develop shear stress-strain curves or to determine the shear modulus. Shear strengths reported from this test have coefficients of variation of about 4 percent.

When analyzing plastics in a pure shear situation or when the maximum shear stress is calculated in a complex stress environment, designers often use a shear strength value of about half the tensile strength, or the direct shear strength obtained from the test referred to above, whichever is least.

Fig. 8. Setup for Testing Shear Strength of Plastics in ASTM Test D732.  
Specimen may be Molded or Cut from Sheet

*Shear modulus*  $G$  is a constant otherwise called the *modulus of rigidity*. For materials that behave according to Hooke's law, it is directly comparable to the modulus of elasticity used in direct stress calculations. The constant is derived from

$$G = \frac{\text{Shear Stress}}{\text{Shear Strain}} = \frac{\tau}{\gamma} \quad (9)$$

For isotropic materials in their Hooke's-law range at low deformations, it may be assumed that the modulus in compression is equal to  $E$ . Then a simple theoretical relationship links the tensile and shear moduli with Poisson's ratio:

$$G = \frac{E}{2(1 + \nu)} \quad (10)$$

ASTM D1043 provides a method for determining the shear modulus  $G$  of plastic specimens at various temperatures by a torsion test. Material suppliers can furnish values of  $G$  for their compounds.

*Relating Material Constants:* Although only two material constants are required to characterize a material that is linearly elastic, homogeneous, and isotropic, three such constants have been introduced here. These three constants are tensile modulus  $E$ , Poisson's ratio  $\nu$ , and shear modulus  $G$ , and they are related by Equation (10) or rewritten in the following form, based on elasticity principles:

$$\frac{E}{G} = 2(1 + \nu) \quad (11)$$

This relationship holds for most metals and is generally applicable to injection-moldable thermoplastics. It must be remembered, however, that most plastics, particularly fiber-reinforced and liquid crystalline materials, are inherently either nonlinear, anisotropic, or both.

*Bulk Modulus  $B$ :* When a sample of material is subjected to high pressure from all sides, its volume diminishes with a corresponding increase in density. Bulk modulus  $B$  is defined as the increase in pressure divided by the fractional decrease in specific volume:

$$B = \frac{\Delta P}{(\Delta V)/V} \rightarrow \frac{dP}{d \ln V} \quad (12)$$

Since  $\rho = \frac{1}{V}$ , it follows that

$$\frac{1}{B} = \frac{(\Delta \rho)/\rho}{\Delta P} \rightarrow \frac{d \ln \rho}{dP} \quad (13)$$

The dimensions of  $B$  are pressure per unit of fractional volume contraction. In English units  $B$  is in Mpsi/(in<sup>3</sup>/in<sup>3</sup>), or just Mpsi; the SI units for  $B$  are GPa/(cm<sup>3</sup>/cm<sup>3</sup>) or just GPa. The last equation indicates that what happens to volume (and specific volume) also happens in the same degree to density, but with the opposite sign, i.e., as the volume increases, the density decreases and vice versa.

For isotropic elastic materials it has been shown that bulk modulus is linked to Young's modulus and Poisson's ratio by the equation

$$B = \frac{E}{3(1 - 2\nu)} \quad (14)$$

Thus, all three moduli,  $E$ ,  $G$ , and  $B$ , are linked through Poisson's ratio.

*True stress and true strain* are terms not in frequent use. In Fig. 5 the stress, sometimes called the *engineering stress*, is calculated from an increasing load  $F$ , acting over a constant area  $A$ . Because the cross-sectional area is reduced with most materials, use of that smaller cross-sectional area in the calculation yields what is called the *true stress*. In addition, the direct strain referred to earlier, that is, the total change in length divided by the original length, is often called the *engineering strain*. The true strain would be the instantaneous deformation divided by the instantaneous length. Therefore, the shape of such a stress-strain curve would not be the same as a simple stress-strain curve. Modulus values and stress-strain curves are almost universally based on engineering stress and strain.

**Other Measures of Strength and Modulus.**—Tensile and compression properties of many engineering materials, which are treated as linearly elastic, homogeneous, and isotropic, are often considered to be identical so as to eliminate the need to measure properties in compression. Also, if tension and compression properties are identical, under standard beam bending theory, there is no need to measure the properties in bending. In a concession to the nonlinear, anisotropic nature of most plastics, these properties, particularly flexural properties, are often reported on manufacturers' marketing data sheets.

*Compression Strength and Modulus:* Because of the relative simplicity of testing in tension, the elastic modulus of a material is usually measured and reported as a tension value. For design purposes it often is necessary to know the stress-strain relationship for compression loading. With most elastic materials at low stress levels, the tensile and compressive stress-strain curves are nearly equivalent. At higher stress levels, the compressive strain is less than the tensile strain. Unlike tensile loading, which usually results in a clear-cut failure, stressing in compression produces a slow and indefinite yielding that seldom leads to failure. Because of this phenomenon, compressive strength is customarily expressed as the amount of stress in  $\text{lb}_f/\text{in}^2$  (or Pa) required to deform a standard plastics test specimen to a certain strain. Compression modulus is not always reported because defining a stress at a given strain is equivalent to reporting a secant modulus. If a compression modulus is given, it is usually an initial modulus.

*Bending Strength and Modulus:* When a beam of rectangular cross section is bent under a vertical load midway between the beam supports, the bottom surface is stretched in tension while the top surface is compressed. Extending from end to end along the vertical center of the beam is a plane of zero stress called the *neutral axis*. Whatever the shape of the cross section—constant along the beam—the neutral axis is located at the center of gravity (centroid) of that cross-sectional area. The theory of bending for simple beams makes the following assumptions: the beam is initially straight, unstressed, and symmetric; the material is linearly elastic, homogeneous, and isotropic; the proportional limit is not exceeded; Young's modulus for the material is the same in tension and compression; and all deflections are small so that cross sections remain planar during bending.

For a beam of length  $L$  with a rectangular section of width  $b$  and depth  $h$  carrying a central load  $F$ , the formula for the maximum bending stress  $\sigma$  at the bottom surface is

$$\sigma = \frac{3FL}{2bh^2} \quad (15)$$

and the formula for the maximum deflection at the center of the beam is

$$y = \frac{FL^3}{4Ebh^3} \quad (16)$$

Note that, if the deflection equation is solved for  $E$ , Young's modulus, the modulus can be estimated by measuring the deflection of a beam under a known central force:

$$E = \frac{FL^3}{4ybh^3} \quad (17)$$

This is the basis for ASTM Test D790 for the flexural modulus and strength of plastics. The flexural modulus reported is usually the initial modulus from the load/deflection curve. Most plastics parts undergo bending, so use of flexural values, which tend to be higher than tensile values for many molded plastics, should give more conservative and hence trustworthy results in product design.

**Rate Dependence of Mechanical Properties:** Tensile and flexural data in manufacturers' literature are measured at specific displacement rates. These rates are usually not consistent with the loading environment encountered in use of the product. The same plastics material, under differing rates or in other environmental conditions, can produce different stress-strain curves. Designers should be aware of the loading rates in specific applications and request the appropriate data. End-use testing must always be considered, particularly when adequate data are not available.

**Time-Related Mechanical Properties.**—Mechanical properties discussed previously were related to loads applied gradually and applied for short periods. Long-term and very short-term loading may give somewhat different results. With high-performance thermoplastics it is important to consider creep, impact, fatigue, and related issues. Even the best laboratory test methods do not always predict structural response of production parts accurately, and other factors may also affect results.

*Creep* is defined as increasing strain over time at constant stress. The rate of creep for a given material depends on applied stress, temperature, and time.

Creep behavior of a material is an important, even crucial, issue with plastics when parts are to be subjected to loads for extended periods and the maximum allowable deflection is critical. To determine creep behavior, test samples may be loaded in tension, compression, or flexure in a constant-temperature environment. Under constant loads, deflection is recorded at regular intervals over suitable periods. Results are generally obtained for four or more stress levels and recorded as creep curves of strain versus logarithmically scaled time. In general, crystalline materials have lower creep rates than amorphous plastics. Glass reinforcement substantially improves the creep resistance. Fig. 9 shows the great differences in creep-rupture behavior that exist among different plastics at several temperatures.

Fig. 9. Plots Showing Diminishing Strengths of Several Plastics as Creep Period is Extended (Curves are Steeper at Higher Temperatures)

**Apparent or Creep Modulus:** If the deflection of a part subjected to continuous loading is calculated using the short-test modulus of elasticity  $E$ , results are likely to be disappointing or even disastrous because the effects of creep have not been considered. If the stress level and temperature are known and creep curves are available for the temperature in question, an apparent, or creep, modulus  $E_{app}$  can be calculated from the creep curves by the formula:  $E_{app} = \sigma/\epsilon_c$ , where  $\sigma$  is the calculated stress level and  $\epsilon_c$  is the strain from the creep curve at

the expected time and temperature. This value  $E_{app}$  can be used instead of  $E$  in predicting the maximum beam deflection from the traditional equation given earlier.

Fig. 10. 1000-Hour Creep Moduli of Several Plastics at Room Temperature and Higher

Manufacturers' data often include curves of creep modulus (or log creep modulus) versus log time at either constant stress or constant strain derived from creep data. The bar graphs of Fig. 10 show 1000-hour creep moduli for several engineering resins at 73°F (23°C). This kind of information may also be provided as tables of values at constant stress and temperature for various time periods.

Creep rupture data are obtained in the same manner as creep data except that higher stresses are used and time is measured to failure. Such failures may be brittle or ductile with some degree of necking. Results are generally plotted as log stress versus log time to failure.

*Stress relaxation* occurs when plastics parts are assembled into a permanent deflected condition, as in a press fit, a bolted assembly, or some plastics springs. Under constant strain over a period of time the stress level decreases due to the same internal molecular movement that produces creep. Stress relaxation is important with such applications as bolt preloading and springs, where loading must be maintained. The relaxation can be assessed by applying a fixed strain to a sample and measuring the load over time. A relaxation modulus similar to the creep modulus can be derived from the relaxation data. Relaxation data are not as readily available as creep data, but the decrease in load due to stress relaxation can be approximated by using the creep modulus  $E_{app}$  calculated from the creep curves.

Plastics parts often fail due to imposition of excessive fixed strains over extended periods of time, for example, a plastics tube that is a press fit over a steel shaft. No relaxation rupture equivalent to creep rupture exists, so for initial design purposes, a strain limit of 20 percent of the strain at the yield point or yield strength is suggested for high-elongation plastics. For low-elongation brittle plastics that have no yield point, 20 percent of the elongation at break is also recommended. These figures should be regarded only as guidelines for development of initial design concepts; prototype parts should be thoroughly tested under end-use conditions to confirm the suitability of the design. Higher or lower property limits may also be indicated in manufacturers' data on specific materials.

Extrapolating creep and relaxation data must be done with caution. When creep and relaxation data are plotted as log property against log time, the curves are generally less pronounced, facilitating extrapolation. This procedure is common practice, particularly with creep modulus and creep rupture data. Extrapolation should not exceed one unit of

log time, and the strain limit of 20 percent of the yield or ultimate strength mentioned above should not be exceeded.

*Impact loading* describes a situation in which a load is applied extremely rapidly. Any moving body has kinetic energy, and when the motion is stopped by a collision, the energy is dissipated. Ability of a plastic part to absorb energy is determined by the shape, size, thickness, and type of material. Impact-testing methods now available do not provide designers with information that can be used analytically. The tests can be used for comparing relative notch sensitivity or relative impact resistance, and so can be useful in choosing a series of materials to be evaluated for an application or in grading materials within a series. Impact testing by the Izod and Charpy (ASTM Method D6110) methods, in which a pendulum arm is swung from a certain height to impact a notched test specimen, is the most widely used for measuring impact strength. Impact with the test specimen reduces the energy remaining in the arm, and this energy loss is recorded in ft-lb<sub>f</sub> (J). The value of such tests is that they permit comparison of the relative notch toughness of two or more materials under specific conditions.

Table 2b provides the mean and range of the notched Izod impact strength (measured in J/cm) for different thermoplastic and thermoset (TS) materials. In general, materials with higher strain to failure will exhibit greater impact resistance. Thermosetting materials tend to have lower impact resistance than thermoplastics, though thermosets with flexible and unsaturated networks (e.g. rubber and polyester) can have high impact resistance. The addition of reinforcements, such as glass fiber (GF), tends to increase modulus and strength but lower strain to failure and thus reduce the impact properties of composite systems. While such Izod and Charpy impact tests provide comparative data about material performance, the tensile impact test mentioned earlier helps in ranking materials, because it represents more realistic conditions that are encountered by actual parts in certain applications.

*Fatigue tests* measure the ability of plastics materials to withstand repeated stresses or other cyclic phenomena. Example applications are a snap-action or snap-fit latch that is frequently opened and closed, a gear tooth, a bearing, and a structural component subject to vibration or to repeated impacts. Cyclic loading can cause mechanical deterioration and progressive fracture, leading to failure in service. Typical fatigue tests are carried out on machines designed to subject a cantilever test piece to reversing flexural loading cycles at different stress levels. ASTM Test D671 is of this type, with a cycle rate of 30 Hz. The number of cycles to failure is recorded for each stress level. Data are normally presented in plots of stress (S) versus the log of the number of cycles (N) called S-N curves for specific cycle rates and environmental temperatures.

*Tensile impact* tests mount the test specimen on the swinging arm. Attached to the test specimen is a cross-piece that is arrested by a notched anvil as the bar swings down, allowing the energy stored in the arm to break the specimen under tension as it passes through the notch. Another impact test used for plastics allows a weighted, round-ended cylindrical "dart" to fall on a flat disk of the plastics to be tested. This test is good for ranking materials because it represents conditions encountered by actual parts in certain applications.

**Thermal Properties.**—Melting temperatures of highly crystalline thermoplastics are sharp and clearly defined, but amorphous and liquid-crystalline materials soften and become more fluid over wider temperature ranges. Melting points have greater significance in molding and assembly operations than in product design, which usually deals with the product's service temperatures well beneath the melting range.

*Glass transition* is a reversible change that occurs in an amorphous polymer or in amorphous regions of a partly crystalline polymer when it is heated from a very low temperature into a certain range, peculiar to each polymer, characterized by a rather sudden change from a hard, glassy, or brittle condition to a flexible or rubbery condition. Physical properties such as coefficient of thermal expansion, specific heat, and density usually undergo distinct changes in their temperature derivatives at the same time. The symbol for the glass-transition temperature is  $T_g$ .

Statistical summary of available grades submitted by material suppliers (data courtesy of MatWeb.com).

*Vicat softening point* is the temperature at which a small, circular, lightly gravity-loaded, heated probe penetrates a specific distance into a thermoplastics test specimen. This test (ASTM D1525) measures the ability of a thermoplastics material to withstand short-term contact with a heated surface and is most useful for crystalline plastics. Amorphous thermoplastics tend to creep during the test, which reduces its usefulness for such materials.

*Deflection temperature under load (DTUL)* is the temperature at which a test bar of 0.5 inch (12.7 mm) thickness, loaded to a specified bending stress, will deflect by 0.010 inch (0.25 mm). This ASTM test (D648) is run at bending stresses of 66 lb<sub>f</sub>/in<sup>2</sup> (0.455 MPa) or 264 lb<sub>f</sub>/in<sup>2</sup> (1.82 MPa) or both. The value obtained is referred to as the *heat deflection temperature (HDT)*, also called heat distortion temperature, and is an indication of the ability of the material to perform at elevated temperatures under load. Both stress and deflection for a specific design of test bar are given, so the test may be regarded as establishing the temperature at which the flexural modulus is reduced to particular values—35,200 psi (242.7 MPa) at 66 psi stress, and 140,000 psi (965.3 MPa) at 264 psi stress. **Tables 2a and 2b** provides the range of HDTs for some common thermoplastics and thermosets. The addition of reinforcements, such as glass fiber (GF), can increase the HDT, so that the parts may be used at higher service temperatures than unreinforced grades.

Like metals, thermoplastic materials expand when heated and contract when cooled. For a given temperature range, most plastics change dimensions much more than metals. The coefficient of *linear thermal expansion* ( $\alpha$ ) is the ratio of the fractional change in a linear dimension for a unit change of temperature and is expressed as in/in-F, or cm/cm-C. Typical average values for common materials and selected plastics are shown in **Table 8**, page 372. ASTM Method D696 directs that samples should be prepared so as to give a minimum of anisotropy, but if anisotropy is suspected, specimens shall be cut so as to measure  $\alpha$  along the principal axes of anisotropy. The values in **Table 8**, page 372, may be presumed to have been measured according to those instructions.

*Thermal conductivity* is the rate at which a material conducts heat energy along its length or through its thickness. For example, if a tightly covered plastic insulated cooler at 32°F (0°C) is filled with ice and chilled beverage cans and the outside is 80°F (27°C), heat from the surrounding warm air passes slowly through the box wall, melting the ice inside. A low thermal conductivity of the wall resists this heat flow. The property is defined by *Fourier's law of heat conduction* as follows:

$$Q_x = k \frac{\Delta T}{x}$$

where  $Q_x$  = flux, i.e., the rate of heat flow per unit area of the wall surface,

$k$  = thermal conductivity of the box-wall material,

$\Delta T$  = temperature difference from the hot side to the cold side, and

$x$  = wall thickness.

English units for  $k$  are Btu/h-in<sup>2</sup> (°F/in); SI units are J/s-m<sup>2</sup>(K/m).

In sharp contrast to metals, plastics are poor heat conductors but excellent insulators, and plastic foams even more so. Plastics are also good electrical insulators. These insulating properties are valuable in many applications. Conductivities can be enhanced where needed by loading the plastics with copper or aluminum powder. In anisotropic materials, thermal conductivity may differ along major axes. Thermal conductivities for plastics are listed in the table *Typical Properties of Plastics Materials* on page 387.

*Aging at elevated temperatures* may affect physical, mechanical, electrical, or thermal properties of plastics materials. Data from tests on specimens stored at specific temperatures for suitable periods are presented as plots of properties versus aging time at various temperatures, and may be used as an indication of thermal stability of the material.

*Temperature index* is a rating by Underwriters Laboratories (UL) of electrical and mechanical properties (with and without effects of impacts) of plastics materials used in electrical equipment for certain continuous operating conditions.

*Flammability* ratings also are produced by Underwriters Laboratories. UL tests measure the ability to continue burning after a flame is removed, and the percentage of oxygen needed for the material to continue burning. Other tests measure combustibility, ignition temperatures, and smoke generation. The importance of flammability testing for plastics is reflected by ASTM's listing of ten different tests under the index subject "Flammability—Plastics." The high carbon and hydrogen content of plastics means they are usually flammable. Some exceptions are fluorocarbons and chlorofluoroplastics, which are not flammable. Silicones and rigid PVC will not sustain fire by themselves. Compounders can significantly reduce any plastic's flammability by judiciously choosing from among hundreds of available fire-retarding additives.

**Effect of Temperature on Mechanical Properties.**—The equivalence of high strain rates and low temperatures (and vice versa) must be kept in mind when designing with plastics materials. Stress-strain curves for tests performed with one strain rate at several temperatures are similar to those for tests with one temperature and several strain rates. That is, very high strain rates and very low temperatures produce similar responses in materials. Conversely, the effects of very low strain rates, that is, creep effects, can be determined more quickly by testing at elevated temperatures and employing time-temperature superposition methods to estimate creep at lower temperatures and longer times. End-use testing at temperatures near or above the highest values expected in everyday use of a product helps the designer estimate long-term performance of components.

Strength, modulus, and elongation behavior are similar for tensile, compressive, flexural, and shear properties. Generally, strength and modulus decrease with increasing temperature. The effect of temperature increase is shown by the curves in Fig. 11 for crystalline and amorphous materials, where a gradual drop in modulus is seen as the glass-transition temperature  $T_g$  is approached. The deflection temperature marks a flexural modulus of 35,200 psi (242.7 MPa) at a test stress of 66 psi (455 kPa), giving rise to the horizontal dashed line in Fig. 11. Above the glass-transition temperature, amorphous materials suffer rapid diminution of modulus, and, even with glass-fiber and other reinforcements, modulus drops rapidly above  $T_g$ . Some crystalline resins maintain usable moduli at temperatures approaching the crystalline melting point ( $T_m$ ). Glass-fiber reinforcement can substantially improve the modulus of crystalline materials between the glass-transition and melting temperatures. Generally, strength-versus-temperature curves exhibit shapes like modulus curves, while, as expected, elongations increase with rising temperatures.

Fig. 11. Schematic of Modulus Behavior of Semi-Crystalline and Amorphous Plastics Showing  $T_g$  and  $T_m$  and the Beneficial Effect of Reinforcement on Deflection Temperature Under Load (DTUL)

As temperatures drop significantly below normal ambient values, most plastics materials become brittle and lose much of their room-temperature impact strength, although a few

materials show only a gradual decrease. Concern over failures at low temperatures led to the development of ASTM D746, "Brittleness Temperature of Plastics," in 1943. In this test, small, unnotched test bars are set up as cantilever beams in groups of five or more, brought to a preset low temperature, and struck by a weighted, blunt-nosed bar falling at 2 m/s. The experiment is repeated at other temperatures, higher and lower, and the fraction of breaks is plotted versus temperature on normal-probability graph paper. From the plot, the temperature at which half the bars break is estimated and reported as the brittleness temperature. Plastics reinforced with long glass fibers have relatively high impact values, both notched and unnotched, at room temperature. They retain much of these values at lower temperatures.

**Electrical Properties.**—The most notable electrical property of plastics is that they are good insulators, but there are many other electrical properties that must be considered in plastics part design.

*Conductivity* in solids depends on the availability and mobility of movable charge carriers within the material. Metals are good conductors because the metal atom has a loosely held, outermost electron, and the close proximity of the atoms allows these outer electrons to break free and move within the lattice structure. These free electrons give metals the ability to conduct large currents, even at low voltages. Outer electrons in materials such as glass, porcelain, and plastics are tightly bound to the atoms or molecules so there are no free electrons. Electrical current cannot be conducted, and the materials act as insulators.

*Volume resistivity* is the electrical resistance of a material when a steady electromotive force (emf) difference is applied to a sample of the material that is made part of an electric circuit. Ohm's law governs the flow of direct current:

$$I = \frac{V}{R}$$

where  $I$  = current, amperes (A)

$V$  = emf difference across the test element, volts (V)

$R$  = resistance, ohms ( $\Omega$ )

$R$  is determined by the element's dimensions and the material's electrical resistivity:

$$R = \rho \frac{L}{A}$$

where  $L$  = length of the element, cm

$A$  = cross-sectional area perpendicular to the current direction,  $\text{cm}^2$

$\rho$  = resistivity of the conductor material, ohm-cm

Materials having resistivities above  $10^8$  ohm-cm are considered insulators, and materials with values between  $10^8$  and  $10^3$  ohm-cm are considered partial conductors. Most plastics have volume resistivities in the range of  $10^{12}$  to  $10^{18}$  ohm-cm.

*Surface resistivity* is a measure of the susceptibility of an electrical insulating material to surface contamination, particularly moisture, which makes it electrically conductive. The tests use parallel electrodes that are placed on the same surface of the material. Measured resistance is multiplied by the width of the electrodes and divided by the distance between them and reported as ohms per square. Methods for determining both volume and surface resistivities of insulating materials are spelled out in ASTM D257.

The results of such measurements are sometimes reported in terms of their reciprocals, *volume conductivity* (siemens/cm) and *surface conductivity* (siemens). The unit siemens is the reciprocal of resistance,  $1/R$  (with units  $1/\Omega$ .) The siemens was formerly known as the mho.

*Dielectric strength* is a measure of the voltage required to cause an insulator to break down and allow an electric current to pass through the resulting conductive path. It may be measured (ASTM Test D149) at any or several frequencies from 0 Hz (direct current) to 800 Hz; the results are expressed in volts per mil (0.001 inch, or 0.0254 mm) of thickness. High values of this property are desired in capacitor films and wire coverings. Variables that may affect test results include temperature, frequency, sample contamination,

internal voids, rate of voltage increase, and duration of test. Although the use of volts/mil units in test results suggests that the same dielectric strength value should apply to different film thicknesses, tests show that thinner films fail at lower V/mil than thicker ones.

*Dielectric constant or permittivity* is a dimensionless constant that indicates how easily a material can become polarized by imposition of an electrical field on an insulator. Polarization occurs because of charge-carrying atoms or functional groups (dipoles) in materials. When the field is applied, these groups try to align their positive and negative ends with the field. Reversal of the direction of the electric field results in reversal of the polarization. The dielectric constant is the ratio of the permittivity of the material in normal ambient conditions to the permittivity of a vacuum. Permittivity is important when plastics are used as insulating materials in capacitors and high-frequency electrical apparatus. Changes in temperature, humidity, electrical frequency, and part thickness may affect the dielectric constant. Dielectric constants for a dozen various engineering thermoplastics are listed in Table 3, page 577. Many others are included in the main table of plastics properties, *Typical Properties of Plastics Materials* on page 387.

If a polar material is subjected to an alternating electric field, its dipoles reverse their orientation twice per cycle. This movement encounters frictional resistance at the molecular level, and at high frequencies that friction can generate considerable heat, as detected by the electrical phase angle between voltage and current. This effect is called the *heat dissipation factor*. The heat dissipation factor is a measure of heat energy dissipated by rapidly repeated reversals of polarization, as with an alternating current. The dissipation factor can also be thought of as the ratio of electrical energy lost to that transmitted at a representative frequency, such as 1 MHz ( $10^6$  cycles/s). This high-frequency heat generation, undesired in many insulation uses, can be used to preheat thermosetting materials just before molding. It is also the basis for electronic heat-sealing, widely used in the fabrication of articles from plasticized-PVC films. Some heat dissipation factor values are shown in Table 3.

**Table 3. Typical Values of Dielectric Constants and Heat Dissipation Factors for Several Thermoplastics at Room Temperature**

Material	Dielectric Constant	Heat Dissipation Factor	Material	Dielectric Constant	Heat Dissipation Factor
Acetal	3.7-3.9	0.001-0.007	Polypropylene	2.3-2.9	0.003-0.014
Acrylic	2.1-3.9	0.001-0.060	Polysulfone	2.7-3.8	0.0008-0.009
ABS	2.9-3.4	0.006-0.021	Modified PPO	2.4-3.1	0.0002-0.005
Nylon 6/6	3.1-8.3	0.006-0.190	Polyphenylene sulfide	2.9-4.5	0.001-0.002
Polycarbonate	2.9-3.8	0.0006-0.026	Polyarylate	2.6-3.1	0.001-0.022
TP Polyester	3.0-4.5	0.0012-0.022	Liquid crystal	3.7-10	0.010-0.060

*Arc resistance* as determined by ASTM D495 is the length of time (seconds) required for an electric arc applied on the surface of an insulating material to develop a conductive path. Materials that resist such a development are preferred for switchgear parts and other high-voltage apparatus. This test is used mostly for thermosetting materials because, unlike thermoplastics which tend to melt in the arc, thermosets decompose and do produce conductive paths.

The *Comparative Tracking Index (CTI)* is a UL test with an ASTM counterpart (D3638) that is similar to the arc resistance test except that the surface to be tested is precoated with an ammonium chloride electrolyte. The test measures the voltage required to cause a conductive path to form between the electrodes and indicates the arc resistance of a contaminated surface, a condition often found in electrical and electronic equipment.

**End-Use Environmental Considerations.**—The environment that will be encountered by the product is a prime consideration at the design stage. Problems with cracking, crazing, discoloration, loss of properties, melting, or dissolving can be encountered in the

presence of high or low temperatures, chemical substances, energy sources, and radiation. Design also must consider that plastics components may be stressed by processing, assembly, finishing, and cleaning operations that affect their end-use properties.

The stress level in the plastics product greatly affects performance. Generally, increased stress levels resulting from injection molding, forming, assembly work, and end-use forces reduce resistance to environmental factors. Although many plastics are hygroscopic and absorption of water results in dimensional and property changes, plastics are widely accepted because of their relative compatibility with the environment compared to metals. Some chemicals attack the polymer chain directly by reaction, resulting in a progressive lowering of the molecular weight of the polymer and changes in the short-term mechanical properties; others dissolve the material, although high-molecular-weight plastics dissolve very slowly. Swelling, changes in weight and dimensions, and loss of properties are evidence of solvation.

Plasticization may result if the chemical is miscible with the polymer, resulting in loss of strength, stiffness, and creep resistance, and increased impact resistance. The material may swell and warp due to relaxation of molded-in stresses. Environmental stress cracking may cause catastrophic failure when plastics are stressed, even when the product appears to be unaffected by exposure to a chemical.

Chemical compatibility data are obtained from standard test bars exposed to or placed in the chemical of study and tested as previously described for such properties as tensile strength, flexural modulus, dimensional change, weight, and discoloration. Chemical resistances from some commonly used thermoplastics materials are shown in Table 4, but these are only general guidelines and cannot substitute for values derived from tests on the end product. More extensive tests expose samples to a chemical in the presence of fixed stress or fixed strain distribution along its length, followed by examination for the stress or strain location at which damage begins.

While the preceding tests may provide useful data about chemical compatibility, they do not generate reliable information on performance properties for design purposes. The only tests that provide such information are the creep modulus and rupture tests, conducted at appropriate temperatures in the environment that will be encountered by the product, preferably on prototype parts. Many plastics are slowly degraded to varying degrees by ultraviolet light (UV), which causes fading, chalking, and embrittlement. Acrylics and a few others are not damaged by UV. However, hundreds of additives are available that, when compounded into neat resins, will give compounds that are resistant to heat, burning, UV, staining, etc.

**Mechanical Properties.**—Almost all end-use applications involve some degree of loading, so mechanical properties are of prime importance in designing with plastics. Material selection is usually based on manufacturers' marketing data sheets listing tensile strength, modulus of elasticity ( $E$ ), elongation, impact strength, stress and strain behavior, and shear strength. Suppliers' data often are generated under standard test conditions, so they may not be directly transferable to the components produced.

Determination of the governing mechanical properties and their relation to end-use requirements is of vital importance in design. In practical applications materials are seldom subjected to steady deformation without the influence of other factors such as environment and temperature. A thorough understanding of mechanical properties and tests used to determine such properties and of the effects of adverse or beneficial conditions on mechanical properties over long time periods is extremely important. Some resin suppliers and contract manufacturers offer design and technical advice to customers who need design assistance.

### Design Analysis

**Structural Analysis.**—Plastics parts may be subjected to stresses caused by assembly, handling, temperature variations, and other environmental effects. Simple analysis using information in *Moment of Inertia* on page 239 and *Beam Calculations* on page 256 can be used to make sure that newly designed parts can withstand these stresses. These methods may also be used for product improvement, cost reduction, and failure analysis of existing parts.

A — minimal effect; B — some effect; C — generally not recommended.

This information is presented for instructional purposes and is not intended for design. The data were extracted from numerous sources, making consistent rating assignments difficult. Furthermore, the response of any given material to specific chemicals in any one class can vary significantly. Indeed, during the preparation of the table, the effect on one plastics of various chemicals in the same category ranged from essentially no effect to total dissolution. Therefore, an "A" rating for a particular plastics exposed to a particular class of chemicals should not be interpreted as applying to all chemicals in that class. The rating simply means that for the chemicals in that class found in the literature reviewed, the rating was generally an "A." There may be other chemicals in the same class for which the rating would be "C." Finally, the typical chemicals listed do not necessarily correspond to the ones on which the individual ratings are based.

Room temperature except for hot water, steam, and materials marked with a \* = 200°F (93.3°C). Generally, data covering extended exposure (more than a week) were used.

**Safety Factors:** In setting safety factors for plastics parts, there are no hard and fast rules. The most important consideration is the consequence of failure. For example, a little extra deflection in an outside wall or a crack in one of six internal screw bosses may not cause much concern, but the failure of a pressure vessel or water valve might have serious safety or product liability implications. Tests should be run on actual parts at the most extreme operating conditions that could possibly be encountered during product life. For example, maximum working load should be applied at the maximum temperature and in the presence of any chemicals that might be encountered in service. Loads, temperatures, and chemicals to which a product may be exposed prior to its end use also should be investigated. Impact loading tests should be performed at the lowest temperature expected, including during assembly and shipping. Effects of variations in resin lots and molding conditions must also be considered.

Failures in testing of preproduction lots often can be corrected by increasing the wall thickness, using ribs or gussets, and eliminating stress concentrations. Changing the material to another grade of the same resin or to a different plastics with more suitable mechanical properties is another possible solution. Reviews of product data and discussions with experienced engineers suggest the design stresses shown in Table 5 are suitable for use with the structural analysis information indicated above and the equations presented here, for preliminary design analysis and for evaluating general product dimensions. Products designed under these guidelines must be thoroughly tested before being marketed.

**Table 5. Design Stresses for Preliminary Part Designs Expressed as a Percentage of Manufacturers' Data Sheet Strength Values**

	Failure Not Critical	Failure Critical
Intermittent (nonfatigue) loading	25–50%	10–25%
Continuous loading (creep or fatigue)	10–25%	5–10%

**Failure Criteria:** Specification of failure criteria is beyond the scope of this section, which is intended to give only basic general information on plastics. Designers who wish to rationalize complex stress states and analyses might consider the calculated Von Mises stresses relative to the stress limits expressed in Table 5 or investigate the maximum shear theory of failure (otherwise known as Coulomb or Tresca theory). It is further suggested that the shear strength be taken as the manufacturer's published shear strength, or half the tensile strength, whichever is lower.

**Pressure Vessels:** The most common plastic pressure vessel is a cylindrical tube with internal pressure. In selecting a wall thickness for the tube it is convenient to use the thin-wall hoop stress equation:

$$\text{hoop stress } \sigma = \frac{Pd_i}{2t} \quad (18)$$

where  $P$  = uniform internal pressure in the tube,  $d_i$  = inside diameter of the tube, and  $t$  = tube-wall thickness. This equation is reasonably accurate for tubes where the wall thickness is less than  $0.1 \times d$ . Also, it is easy to solve for the wall thickness  $t$  required to support an internal pressure  $P$  with an allowable hoop stress  $\sigma$ . For wall thicknesses greater than  $0.1d$ , the maximum hoop stress on the wall surface inside the tube can be calculated from

$$\text{hoop stress } \sigma = P \frac{d_o^2 + d_i^2}{d_o^2 - d_i^2} \quad \text{or} \quad \sigma = P \frac{1 + R}{1 - R} \quad (19)$$

where  $d_i$  and  $d_o$  are the inside and outside diameters of the tube, and  $R = (d_i/d_o)^2$ .

By substituting  $d_o = d_i + t$  into the left equation one can solve it for the required wall thickness  $t$  to provide a working equation for design. The result is

$$t = \frac{d_i}{2} \left( \sqrt{\frac{\sigma + P}{\sigma - P}} - 1 \right) \quad (20)$$

In the above equations, all units must be consistent.

*Press Fits:* Press fits are used widely in assembly work for speed and convenience, although they sometimes are unsatisfactory with thermoplastics parts. Common applications are to a plastics hub or boss accepting a plastics or metal shaft or pin. Forcing the pin into the hole expands the hub, creating a tensile or hoop stress.

If the interference is too great, very high strain and stress develop, and the plastics part may a) fail immediately by developing a crack parallel to the hub axis to relieve the stress, a typical hoop stress failure; b) survive assembly but fail prematurely due to creep rupture caused by the high induced-stress levels; or c) undergo stress relaxation sufficient to reduce the stress to a level that can be sustained, which can result in slippage during end use.

For a typical press fit, the allowable design stress depends on the particular plastics material, temperature, and other environmental considerations. Hoop stress equations for such a design make use of a geometry factor  $\gamma$ :

$$\gamma = \frac{1 + (d_s/d_o)^2}{1 - (d_s/d_o)^2} \quad (21)$$

where  $d_s$  = diameter of the pin to be inserted and  $d_o$  = outside diameter of the boss.

When both the shaft and the hub are of the same or essentially the same materials, the hoop stress  $\sigma$  given the diametral interference  $i = d_s - d_i$  is

$$\sigma = \frac{i}{d_s} E_p \frac{\gamma}{\gamma + 1} \quad (22)$$

and the allowable interference  $i_a$  given the permissible design stress  $\sigma_a$  is

$$i_a = d_s \frac{\sigma_a}{E_p} \frac{\gamma + 1}{\gamma} \quad (23)$$

When the shaft is metal and the hub is plastic, the hoop stress given  $i$  is obtained from

$$\sigma = \frac{i}{d_s} E_p \frac{\gamma}{(\gamma + \nu_p)} \quad (24)$$

and the allowable interference  $i_a$  given the permissible design stress for plastic's  $\sigma_a$  is

$$i_a = d_s \frac{\sigma_a}{E_p} \frac{\gamma + \nu_p}{\gamma} \quad (25)$$

where  $E_p$  = modulus of elasticity of plastics and  $\nu_p$  = Poisson's ratio for plastics.

*Pipe Threads:* Pipe threads on plastics pipes and other parts used in plastics plumbing and pneumatic assemblies typically require only hand tight assembly to effect a good seat, especially if a compatible sealant tape or compound is used. Assembling a tapered male pipe thread into a mating female thread in a plastics part is analogous to driving a cone into a round hole and may result in a split boss. Sometimes straight threads and an O-ring seal can avoid the need for pipe threads. When pipe threads must be used, torque control is essential.

When mating metal to plastics pipe threads, the threaded plastics component should be the male member, so that the plastics are in compression. If torque can be controlled during assembly, fluoroplastics tape should be used on female plastics pipe threads. If torque cannot be controlled, an external hoop ring, either pressed on or molded in, should be considered. Flats should not be designed into plastics parts for assembly purposes because they can encourage overtightening. If some provision for improved gripping must be made, wings or a textured surface may be used. An approximate formula for the hoop stress  $\sigma$  produced in a plastics boss with internal pipe threads is

$$\sigma = \frac{3T}{idL} \quad (26)$$

where  $T$  = torque in in-lb,  $t$  = wall thickness of the plastics boss in inches,  $d$  = pipe outside diameter in inches, and  $L$  = length of thread engagement in inches.

Equation (26) assumes certain geometric relationships and a coefficient of friction of 0.15. If compatible thread lubricants are used during assembly, the torque must be reduced. To ensure safety and reliability, all threaded assemblies must be subjected to long-term testing under operating pressures, temperatures, and stresses caused by installation procedures exceeding those likely to be encountered in service.

**Thermal Stresses.**—When materials with different coefficients of thermal expansion are bolted, riveted, bonded, crimped, pressed, welded, or fastened by any method that prevents relative movement between the parts, there is potential for thermal stress to exist. Typical examples are joining of nonreinforced thermoplastics parts with materials such as metals, glass, or ceramics which usually have much lower coefficients of thermal expansion than plastics. The basic relationship for thermal expansion is

$$\Delta L = \alpha L \Delta T \quad (27)$$

where  $\Delta L$  = change in length,  $\alpha$  = coefficient of thermal expansion (see Table 8, page 372),  $L$  = linear dimension under consideration (including hole diameters), and  $\Delta T$  = temperature change.

If the plastics component is constrained so that it cannot expand or contract, the strain  $\epsilon_T$ , induced by a temperature change, is calculated by

$$\epsilon_T = \frac{\Delta L}{L} = \alpha \Delta T \quad (28)$$

The stress can then be calculated by multiplying the strain  $\epsilon_T$  by the tensile modulus of the material at the temperature involved. A typical example is of a plastics part to be mounted to a metal part, such as a window in a housing. Both components expand with changes in temperature. The plastics imposes insignificant load to the metal, but considerable stress is generated in the plastics. For such an example, the approximate thermal stress  $\sigma_T$  in the plastics is given by

$$\sigma_T = (\alpha_m - \alpha_p) E_p \Delta T \quad (29)$$

where  $\alpha_m$  = coefficient of thermal expansion of the metal,  $\alpha_p$  = coefficient of thermal expansion of the plastics, and  $E_p$  = tensile modulus of the plastics at the temperature involved. Other equations for thermal expansion in various situations are shown in Fig. 12.

Most plastics expand more than metals with temperature increase, and their modulus drops. The result is a compressive load in the plastics that often results in buckling. Conversely, as the temperature drops, the plastics shrinks more than the metal and develops an increased tensile stress. These conditions can cause tensile rupture of the plastics part. Clearances around fasteners, warpage, creep, or failure, or yield of adhesives tend to relieve the thermal stress. Allowances must be made for temperature changes, especially with large parts subjected to wide variations. Provision is often made for relative motion  $\Delta L_{rel}$  between two materials, as illustrated in Fig. 12:

$$\Delta L_{rel} = (\alpha_p - \alpha_m) L \Delta T \quad (30)$$

**Designing for Stiffness.**—The designer must take full advantage of the ability of plastics to be easily formed into a desired shape, in contrast to woods where every shape must be machined or assembled from planks or blocks. To a lesser degree, the same is often true of metals, although die-castable metals have a considerable shape versatility. Though the modulus of elasticity is much less in plastics than in metals, *stiffness* is a property not just of the material but also of the *structure* that can be made from it. When the product must support bending loads, as in a bookshelf, a simple beam of rectangular cross section would be the logical approach if the shelf material were pine or mahogany. If the material is plastic, other cross sections of higher stiffness per unit weight can be considered to take advantage of plastics' ease of formability and low density. Fig. 13 shows some alternatives to the traditional rectangular cross section that achieve greater stiffness with less material.

**Manufacture of Plastics Products**

The main processes for manufacturing large quantities of plastics products are extrusion, injection molding, blow molding, and sheet thermoforming for thermoplastic materials; compression molding, transfer molding, prepreg molding, and pultrusion for thermosetting materials.

Fig. 12. Thermal Expansion Equations for Various Combinations of Materials and Situations

Fig. 13. Placing Most of the Material Far from the Centroid Achieves Far Higher Bending Stiffness per Unit Weight of Plastics

More tonnage of thermoplastics pass through extrusion machines than any type of plastics forming machines. The dominant type of extruder is the single-screw extruder. A feed hopper supplies small plastic granules to a thick-barreled, heated cylinder, inside which turns a sturdy, precisely contoured screw. A powerful variable-speed motor drive turns the screw at speeds typically between 10 and 1000 rpm. At the delivery end is attached a die, a block of metal with a specially shaped orifice. The screw has two main jobs: 1) to melt by friction and thoroughly mix the feed, transforming it from cold, solid particles into a homogeneous hot, viscous melt; 2) to develop the

very high pressure (1,000–8,000 psi, or 14–55 MPa) needed to pump the melt through the die. This produces a continuous length of product whose cross section resembles that of the die opening. Extruders are widely employed in intermediate processing of material in the plastics industry. Some final consumer products made by this process are pipes, sheets and films, garden hoses, electrical wires, netting, fishing lines and leaders, and house sidings. Many extruded products are parts of other industrial or consumer products. For example, huge quantities of ABS sheet and flexible vinyl gasketing go into refrigerators and freezers each year. Mop handles are extruded tubing cut to the length needed. Produce bags are made from extruded tubular blown polyethylene film that is laid flat, printed, heat-sealed across and perforated for tear-off at intervals, then wound onto roll cores for delivery to supermarkets. An important class of extruded products includes rods, bars, and tubes from which machinists fabricate smaller quantities of objects, such as prototypes for testing prior to mass production.

**Sheet Thermoforming.**—Also known as vacuum or pressure forming, these widely used molding processes respectively operate at significantly less than or greater than atmospheric pressure to form feedstock in the form of sheet. The process begins with a sheet of plastic from which a single product or sometimes up to several dozen small products are to be made per operating cycle. Mounted in a frame, the sheet to be formed is preheated in an oven between paired radiant heaters at the thermoforming press until it begins to sag. The temperature is still well below that at which the same resin would be injection molded. The sheet is then positioned over the mold, which, in the original and simplest variant of the process, is a female mold made porous by drilling many small holes through it. The mold is enclosed in a chamber (vacuum or pressure box) so that a vacuum can be drawn from below (or a pressure applied from above). The softened sheet is clamped to the mold around its edges, and the pressure difference is applied to press the sheet against the mold surface. Cooling and solidification of the part is done with fans, water mist, or cooling channels in the mold. The unclamped molding is then indexed to a die-cutting table where the edges are trimmed and the part(s) cut out. Trim scrap, which may be as much as 20 percent of the sheet area, is recycled to the sheet extruder.

Because the drawn sheet contacts the upper areas of the mold early in the mold cycle and the bottom last, the wall thickness of the finished part is thinner at the bottom than the upper areas when using a female mold. Often, at least average thickness is needed in the bottom areas to satisfy the design service and service life requirements. Over the years, techniques such as plug assist, male forming, and others have been developed that permit draw depths of more than twice the clamping width with much more uniform wall thickness. Polystyrene cups for cold drinks are now made in this way. Fig. 14 shows the steps in a more sophisticated variant vacuum air-cushion forming, in which a male mold component provides plug assistance without actually touching the softened plastic membrane. Clearly, though, thermoforming cannot match the tight tolerances of injection molding. Nor can it produce intricate components that require substantial or abrupt variations in wall thickness. Because of the low pressure, thermoforming molds can be made much more cheaply of aluminum—even plaster for short runs—and usually do not need the extensive polishing and hard-chrome plating as typical with injection molds. Also, thermoforming machines are much less massive for equal part sizes than injection machines. Production efficiency is higher in multi-station machines but requires a higher financial investment.

**Blow Molding.**—In its most common form, blow molding couples an extruder with a chilled aluminum mold to make a hollow object such as a 2-liter soda bottle. A cross-head die attached to the extruder extrudes a tube of hot melt (*parison*) downward between the mold halves, as in Fig. 15. The parison-inflating air injection at stage 4 is done through a needle that typically, but not always, penetrates the pinched-off melt at the inverted top of the bottle. Bottles with capacities from 2 ml to 10 gallons (38 liters) and myriad other hollow objects are produced by this process. Close tolerances are

maintained on the threaded closures where the mold halves meet; elsewhere they are looser, comparable to those of sheet thermoforming. As in thermoforming, when a particular product, such as a half-gallon or 2-liter bottle, warrants a very high production rate, highly automated, multi-station machines are economical.

Fig. 14. Five Stages in the Cycle of Air-Cushion Vacuum Forming with Controlled Air Pressures at Stages 3 and 4. Removal and Trimming Follow Stage 5.

Fig. 15. Six Stages of Extrusion/Blow Molding

**Processing of Thermosets.**—While some thermosetting materials have been adapted to injection molding processes, most are still processed by compression molding, transfer molding, prepreg molding, sprayup, and hand layup. Commonly used *compression molding* is a process in which precompounded and catalyzed resins, still thermoplastically formable, are performed into buns or bricks of known weight. One or more bricks are preheated in convection or electronic ovens and quickly positioned in the female half of a horizontal mold. It and the hovering male half are at the molding temperature. The mold is closed and brought to high pressure, squeezing the softened bricks, which, ideally, flow into all parts of the mold cavity. Pressure is maintained for the time required to complete the chemical cross-linking reaction and to solidify the molding, after which it is ejected from the mold, any slight leakage at the parting line (*flash*) is trimmed, and it is set aside to cool. With the correct choice and dose of catalyst, time in the mold need not be long. As with injection molding, the high pressures dictate massive molds and presses.

Compression molding is also an efficient way to process unsaturated polyesters, perhaps the most versatile and user-friendly resins available for reinforced plastics processing. When reinforced with chopped glass and mixed to a dough-like consistency, these compounds, known as premix or “gunk,” have been widely used in the automotive and boat industries. Compression molding is also used with sheet-molding compounds. Glass-fiber cloths are preimpregnated with resin and need only heat and pressure to cure them into finished products.

If a mold is provided with both heating and cooling, thermoplastics, too, may be compression molded, an obviously slow process, but sometimes convenient for making prototypes and test pieces. The use of heated and cooled molds with compression is also used in *thermal imprint lithography* to form micro- and nano-sized features on the cavity surface.

In *transfer molding*, also called *plunger molding*, the thermosetting compound is preheated in a separate cylinder (the pot) until it is fully fluid, then forced by a plunger through a runner into the final mold. This process is capable of molding complex parts that cannot be made by compression molding, and also offers closer dimensional tolerances and glossier surfaces than the latter. Multi-cavity molds and short cycle times are feasible with transfer molding. Transfer molding has been used widely in the electronics industry and in molding and overmolding of silicone products, including medical devices.

Another popular method of processing thermosets into unidirectionally reinforced products is *pultrusion*, in which continuous glass roving or mat is pulled through a resin bath or impregnator and then into a preforming fixture where the cross section is partly shaped. The preliminary profile continues through dies where curing mechanisms are applied, and finally to a cut-off saw to produce shapes such as channels, rods, and tubes. Ladder rails, fishing rods, tool handles, tent poles, and numerous other parts are made by this process.

**Polyurethanes.**—Polyurethanes (PUR) are among the most versatile of polymers, both as thermoplastic and thermosetting, as well as the most ubiquitous in everyday products. For example, the flexible thermoplastic members of the family are mainly elastomers that are favorites for athletic shoes, while the rigid, transparent thermoplastics are vying with polycarbonate for the high-value market in eyeglass lenses. Cast rigid PUR is available in rod, tube, and bar stock form.

The thermosets are formed by linking two reactive components, an isocyanate and a polyol. Toluene diisocyanate and diphenylmethane diisocyanate are the most used isocyanates, while a variety of polyols are commonly used. Short-chain, low-molecular-weight types result in rigid plastics, and longer-chain types form flexible materials. About 70 percent of all PURs worldwide go into automotive, building and construction, mattresses, and furniture including frame members produced by reaction injection molding. Densities of rigid PUR foams range from 1 to 8 lb/ft<sup>3</sup> (16–128 kg/m<sup>3</sup>) and much higher in furniture members. Flexible PUR foams range from near that of the parent plastic down to 1 lb/ft<sup>3</sup> (16 kg/m<sup>3</sup>). Since the reactive components must be mixed instantly and thoroughly at the moment of application, a special industry of PUR processing machinery has developed to deal with that requirement.

**Reinforced Plastics.**—For superior strength and modulus, many items are reinforced with cloths of various fibers and weaves. Felted mats are often cross-layered and then impregnated with liquid resin (e.g., polyester or epoxy) prior to being cured to make final products. Some of these products, if not too large, can be compression molded. But with judicious catalysis, the resin can be cured at room temperature, facilitating manufacture at low pressure, with or without heat, of large structures such as boats and storage tanks for liquids. With layup one can handily distribute the reinforcing web in accordance with the stress distribution expected when the product is placed in service. Fig. 16 shows four increasingly positive (and more costly) ways of curing hand layups. Also, many laminates are produced in sheets, typically 4 ft by 8 ft (122 by 244 cm), for subsequent fabrication into final products. The familiar decorative laminates (Formica), for example, are produced in large presses with multiple steam-heated platens interleaved between laminates, permitting production of dozens of sheets in one pressing. Properties of some reinforced plastics available in sheet form are given in Table 6.

**Injection Molding.**—This process produces the majority of plastics consumer and industrial products. The modern injection molding machine consists of an extruder, much like the one described previously, but with the added feature that the screw can be driven forward to quickly inject the stored-up hot melt into the second main part, the mold. A nozzle at the end of the extruder presses tightly into a recess (*sprue*) in the stationary half of the mold. The two halves of the mold, with a vertical parting surface, are made from heavy steel and mounted on thick steel tie-bars. Within the mold is a network of *runners* distributing melt from the sprue to the mold cavities that determine the dimensions of the molded product. The mold halves are clamped together with high pressure by a hydraulic piston or toggle mechanism driven by hydraulic or electric means. Coolant channels passing near the cavities keep the mold cold, well below the freezing range of the plastic. The screw moves forward, forcing the melt through the runners and into the cavities, and maintains melt pressure (5,000–15,000 psi, 34–103 MPa) while the moldings cool and freeze. Then the far half of the mold is withdrawn, activating ejection pins that push the moldings and runners out of the mold. Meanwhile the extruder rotates the screw to generate more hot melt, while retracting the screw. Typically the process is highly automated with computer controls. Injection machines are rated by their melting capacity, shot size, platen size,

#### Contact Molding

Resin in contact with air. Layup normally cures at room temperature; heat may accelerate cure. A smoother exposed side may be achieved by wiping on cellophane.

#### Vacuum Bag

Cellophane or polyvinyl acetate is placed over the layup. Joints are sealed with plastic; vacuum is drawn. Resultant atmospheric pressure eliminates voids and forces out entrapped air and excess resin.

#### Pressure Bag

Tailored bag – normally rubber sheeting – is placed against layup. Air or steam pressure up to 50 psi (345 kPa) is applied between pressure plate and bag.

#### Autoclave

Modification of the pressure bag method; after layup, the entire assembly is placed in steam autoclave at 50–100 psi (345–690 kPa). Additional pressure achieves higher glass loadings and improved removal of air.

Fig. 16. Variants of Hand-Layup Method of Reinforced Plastics Molding with Cloth or Mat Provide Improved Control of Final Product Qualities.

and clamping force. They range from machines for forming micron-sized gears up to meter-sized garbage dumpsters.

Injection molding is capable of making identical items with very close tolerances on dimensions, so it is ideal for the production of interchangeable industrial parts destined for complex assemblies. Undercut shapes can be molded with the aid of side-draw mold sections. For example, millions of bottle caps are molded in automatic unscrewing molds. Producing mold cavities and their male halves in fine tool steels is costly, so one should be quite certain that the part design is accurate before finishing the mold cavities. Successful production requires the inputs of all persons connected with the project: the product designer, the mold designer, the mold maker, the molder and the customer. Because of the high investment in the mold, injection molding is seldom considered for very short runs, especially in view of available 3D printing technologies. For more on this topic, see *Metal Additive Manufacturing* on page 1555. However, inexpensive molds that may serve to make a few hundred parts have been made from metal-filled epoxy casting compounds, while CNC machining of aluminum and other rapidly produced metal molds is still widely used for production of tens of thousands of parts that have tolerances and surface finishes that exceed the capabilities of most current 3D printing processes.

**Design for Injection Molding.**—Product analysis is a good starting point in the design process for plastics molding. Make a detailed checklist of the functions the new part will have to perform and the operating conditions it will encounter. If the part will replace an older design that required fabrication from other materials and, perhaps, subassembly with fasteners or adhesives, the new design may be able to take advantage of injection molding's versatility to meld the several functions into a single new part design.

*Properties Checklist:* Identify potential candidate materials that can fulfill required functions. Preliminary analysis using relevant properties should reduce the list to a few materials that can do the job and the required volume (in<sup>3</sup> or cm<sup>3</sup>) of each.

Considerations and questions to ask in this phase of the project are:

- 1) What are the strength, structural stiffness, impact loading, exposure to chemicals, operating temperature range (and possible overheating and cooling), electrical factors, and other relevant material factors?
- 2) What certifications or government regulations are involved?
- 3) Must the design be approved by clients or in-house managers?
- 4) Has the marketing group determined the anticipated production run?
- 5) Input from the prospective mold builder and molder (often not the same) should be sought before the design is made final.
- 6) The cost for each part produced of the plastics to be used.

**Relative Plastics Costs:** The list of some comparative material costs in [Table 7](#) should serve to narrow materials choices, but current quantity quotations from various suppliers must be obtained. It is important to account for material density when calculating material costs, since the density of thermoplastics may vary significantly. For injection molding of a large production run, a crude estimate of part cost is double the material cost to account for amortized mold cost, as well as the molder's processing costs.

**Table 7. Volumetric Costs of Plastics**

Type/Material	Price (US \$)		Type/Material	Price (US \$)	
	Per Pound	Per Kilogram		Per Pound	Per Kilogram
<b>Thermoplastics</b>			PSU	5.50	12.13
ABS	1.24	2.73	PTFE	7.35	16.20
Acetal, POM	1.41	3.11	PVC	0.89	1.96
HDPE	0.70	1.54	TPU	2.06	4.54
LCP	6.40	14.11	<b>Recycled Thermoplastics</b>		
LDPE	0.78	1.72	HDPE	0.68	1.50
PA66, Nylon	1.64	3.62	Recycled LDPE	0.39	0.86
PC	1.77	3.90	Recycled PET	0.61	1.34
PEEK	45.00	99.21	Recycled PP	0.34	0.75
PEI	8.80	19.40	<b>Thermoset</b>

PS	1.10	2.43	Polyurethane		
			Thermoset Urea	1.07	2.36

Based on 2018 market prices. Recycled material prices are for pelletized feed stock and vary with quality.

**Wall Thicknesses:** Wall thickness throughout the part, referred to as the nominal wall thickness, is one of the most critical design parameters. Nominal dimensions and tolerances should be calculated and decided before the mold is made, since modifications are costly. In general, wall thicknesses should be kept as thin as needed to meet the part's design requirements and as uniform as possible. Ideally, the flow of molten plastic should be arranged to flow through thicker sections into thinner ones rather than the reverse. This is accomplished—in consultation with the mold builder—by gating cavities in the thick sections. The mold builder will help, too, with the decisions on how many cavities are needed, how to arrange them in the mold for optimal temperature control, the best runner layout and sizing, and what size mold and injection machine will be economical for the production desired. Most injection-molded plastics parts have wall thicknesses in the range from 0.02 to 0.25 inch (0.5 to 6 mm). For compounds containing half-inch (12.7 mm) and longer glass fibers, and for thermoplastic polyurethanes, the range shifts upward by a factor of 2 or more.

When the plastics selection for the part has been finalized, the suppliers of the plastic resin can provide recommendations of grades and wall thicknesses appropriate to those grades. Table 8 shows typical nominal wall thicknesses for various thermoplastics.

**Table 8. Typical Nominal Wall Thicknesses for Various Classes of Thermoplastics**

Thermoplastics Group	Typical Working Range		Thermoplastics Group	Typical Working Range	
	inch	mm		inch	mm
Acrylonitrile-butadiene-styrene (ABS)	0.045–0.140	1.14–3.56	Polyester elastomer	0.025–0.125	0.64–3.18
Acetal	0.030–0.120	0.76–3.05	Polyethylene	0.030–0.200	0.76–5.08
Acrylic	0.025–0.150	0.64–3.81	Polyphenylene sulfide	0.020–0.180	0.51–4.57
Liquid-crystal polymer	0.008–0.120	0.20–3.05	Polypropylene	0.025–0.150	0.64–3.81
Long-fiber-reinforced plastics	0.075–1.000	1.91–25.4	Polystyrene	0.035–0.150	0.89–3.81
Modified polyphenylene ether	0.045–0.140	1.14–3.56	Polysulfone	0.050–0.150	1.27–3.81
Nylon	0.010–0.115	0.25–2.92	Polyurethane	0.080–0.750	2.03–19.05
Polyarylate	0.045–0.150	1.14–3.81	Polyvinyl chloride (PVC)	0.040–0.150	1.02–3.81
Polycarbonate	0.040–0.150	1.02–3.81	Styrene-acrylonitrile (SAN)	0.035–0.150	0.89–3.81
Polyester	0.025–0.125	0.64–3.18	...	...	...

If the plastics part is to carry loads, load-bearing areas should be analyzed for stress and deflection. When stress or deflection is too high, solutions are to use ribs or contours to increase section modulus; to use a higher-strength, higher-modulus (fiber-reinforced) material; or to increase the wall thickness if it is not already too thick. Where space allows, adding or thickening ribs can increase structural integrity without thickening walls.

Equations (15), (16), and (17) on pages 569–570 can be related to formulas using the section modulus and moment of inertia on page 257, where for Case 2, stress at the beam center is given by  $\sigma = -Wl/4Z$ .

On page 256, note that  $Z = I \div$  distance from neutral axis to extreme fiber ( $h \div 2$  in the plastics example). The rectangular beam section diagrammed on page 242 gives the equivalent of  $I = bh^3/12$  for the rectangular section in the plastics example. Therefore,

$$Z = \frac{I}{h/2} = \frac{bh^3}{12} \times \frac{2}{h} = \frac{bh^2}{6}$$

In  $\sigma = -Wl/4Z$ , the (–) sign indicates that the beam is supported at the ends, so that the upper fibers are in compression and the lower fibers are in tension. Also,  $W = F$  and  $l = L$  in the respective equations, so that stress,  $\sigma = FL/4(bh^2)/6$ , and  $\sigma = 3FL/2bh^2$ .

To calculate the maximum deflection  $y$  at load, equate Equation (16) from page 569 and  $Y = Wl^3/48EI$  from page 257, where  $W = F$ ,  $l = L$ ,  $E = E$ , and  $I = bh^3/12$ . Therefore,

$$y = \frac{FL^3}{48E(bh^3/12)} = \frac{FL^3}{4Ebh^3}$$

*Example:* Assume that a beam (see Fig. 17) as described in connection with Equations (15), (16), and (17) on pages 569–570 is 0.75 inch wide with a constant wall thickness of 0.08 inch, so that the cross-sectional area is 0.06 in<sup>2</sup>, and there is a central load  $W$  of 5 lb. Based on a bending or flexural modulus of 300,000 lb/in<sup>2</sup>, the maximum stress is calculated at 6250 lb/in<sup>2</sup> and the maximum deflection at 0.694 inch. Both the stress and the deflection are too high, so a decision is made to add a rib measuring 0.04 inch thick by 0.4 inch deep, with a small draft of 1/2 degree per side to reinforce the structure.

The equations in the *BEAMS* section starting on page 256, the drawing on page 248 representing the ribbed section (neglecting fillets), and the accompanying formulas permit calculation of the maximum stress and deflection for the ribbed section.

With the new cross-sectional area only slightly larger at 0.0746 in<sup>2</sup>, the calculated stress is reduced to 2270 lb/in<sup>2</sup>, and the deflection goes down to 0.026 inch, which is acceptable for both the material and the application. To achieve the same result from a heavier beam would require a thickness of 0.239 inch, tripling the weight of the beam and increasing molding difficulties. The rib adds only 24.3 percent to the total section weight.

Use of ribs allows the structural characteristics of a part to be tailored to suit its function, but ribs can increase the size of the product and cause warping, as well as appearance problems, so they are best avoided when not structurally necessary. If the first parts produced require strengthening, ribs can be added or thickened without high cost after the tool is finished because the work consists only of removing steel from the mold. In general, ribs should have a base thickness of about 70 percent the thickness of the adjacent wall and be kept as thin as possible where they are positioned near faces that need to have a good appearance.

Fig. 17. (a) Original Beam; (b) Original Central Section; (c) Cross Section of Center with Rib Added to Reinforce the Structure

Note: Dimensions in parentheses are for example on page 590.

Where structural strength is more important than appearance, or when materials are used that have low shrinkage, ribs can be made 75 or 100 percent of the wall thickness. However, where the rib base joins the main molding, there is locally increased thickness, forming a heavy mass of material. Shrinkage of this mass can produce a cavity or void, a hollow area or sink, or can distort the molding. If the mass is very large, cooling time may be prolonged, leading to low output from the machine. Large masses of material in other parts of a molding are also best avoided. These problems can usually be addressed by good mold design.

Ribs need not be of constant height or width and are often varied in proportions to suit the stress distribution in the part. All ribs should have a minimum of  $\frac{1}{2}$  degree of draft per side for ease of removal from the mold and a minimum radius of 0.005 inch (0.127 mm) at the base to avoid stress-raising corners. Higher draft angles are needed when molding textured surfaces or fiber-filled resins that are difficult to eject. Draft and thickness requirements will usually limit the height of the rib, which can be from 1.5 to 5 times the base thickness, and several evenly spaced ribs are generally preferred to a single large one. Smooth transitions (chamfers, fillets, and gussets) should be made to other structural features such as bosses, walls, and pads.

Other ways to improve section properties include use of top-hat and corrugated sections, crowning or doming of some areas, and reinforcement with metal or other inserts that are placed in the mold before it is closed. To keep molded parts uniform in wall thickness, cores or projections may be provided in the mold to prevent a space being filled with molding material. Blind holes can be cored by pins that are supported on only one side of the mold and through holes by pins that pass through both sides. The length-to-width ratio should be kept as low as possible to prevent bending or breakage under the high pressures used in the injection molding process.

Agency approvals for resistance to flammability or heat, electrical properties, or other characteristics are usually based on specific wall thicknesses. These restrictions sometimes necessitate thicker walls than are required for structural strength purposes.

When determining wall thickness, design engineers must also have some knowledge of mold design and should consider the ability of plastics to flow into the narrow mold channels. The degree and rate of flow depend on temperature and pressure to some extent but vary for different materials, as shown in Fig. 18. Spiral flow tests provide much more accurate information about the achievable flow lengths for a given wall thickness than melt flow indices (MFI), since they are performed with shear rates similar to those of molded parts. However, spiral flow tests tend to overestimate flow lengths relative to real applications, because they calculate the maximum effect of the moving melt's heat convection relative to radial flow fronts that often occur in mold filling.

Fig. 18. Typical Spiral-Flow Curves for (1) Nylon 6/6, (2) Polyester Thermoplastics PBT, Liquid-Crystal-Glass-Reinforced, and Polyphenylene-Sulfide-Glass-Reinforced, (3) Acetal Copolymer, and (4) PBT-Glass-Reinforced Plastics Materials

**Stresses and Deflections in Load-Bearing Parts.**—If the plastic part is to carry loads, load-bearing areas should be analyzed for stress and deflection according to the principles presented earlier. If stress or deflection is found to be too high, solutions include using ribs or contours to increase section modulus; using a higher-strength or higher-modulus (i.e., fiber-reinforced) material; or increasing the wall thickness if it is not already excessive. Where space allows, adding or thickening ribs can increase structural integrity without making walls thicker.

Formulas given in *Beam Calculations* starting on page 256, which presume elastic behavior, can be used if care is taken to use moduli and strengths related to anticipated service times and temperatures.

*Example:* Consider a simple case of a beam with rectangular cross section  $b$  wide and  $h$  deep, of length  $l$  centrally loaded and freely supported at its ends. This is an example of Case 2 on page 257 with a beam cross section depicted generically in the first diagram of *Moments of Inertia, Section Moduli, and Radii of Gyration* on page 241. Applicable formulas for the moment of inertia  $I$  of the beam cross section, the section modulus  $Z$ , and the maximum tensile stress  $s$  beneath the central load are

$$I = \frac{bh^3}{12} \quad Z = \frac{I}{(h/2)} = \frac{bh^2}{6} \quad \sigma = \frac{Wl}{4Z} = \frac{6Wl}{4bh^2}$$

From the last box for Case 2, the maximum deflection at the beam center is given by

$$y = \frac{Wl^3}{48EI} = \frac{Wl^3}{4Ebh^3}$$

Consider the example of a small beam whose width = 19 mm, depth (wall thickness) = 2.0 mm, and length between supports = 102 mm. The beam is to support a central load of 22.24 N (5 lb). This beam's cross section is depicted in Fig. 17. As it has very little depth, hence a low sectional modulus, it may not handle the job. The plastic's flex modulus is 2069 MPa (300,000 psi). Using the formulas above, the four quantities to be calculated are

$$I = \frac{19(2^3)}{12} = 12.67 \text{ mm}^4$$

$$Z = \frac{(12.666667)2}{2} = 12.67 \text{ mm}^3$$

$$\sigma = \frac{6(22.24)102}{4(19)^2} = 44.77 \text{ MPa}$$

$$y = \frac{(22.24)(102^3)}{(4)(2068.5)(19)(2^3)} = 18.77 \text{ mm}$$

Both the stress and the deflection are too high. The wall thickness could be increased, but instead a rib will be added that will run along the underside and center of the beam, changing its cross section to that shown in Fig. 17. The rib will be 10 mm deep but only 1.0 mm thick, with a slight draft of 0.5 degree per side. Following the formulas given in the table *Moments of Inertia, Section Moduli, and Radii of Gyration* starting on page 241, see the third row of the T-sections for the one with the tapered rib; the new cross-sectional area is 47.548 mm<sup>2</sup>, and the location of the neutral axis is 9.87 mm above the most extreme material at the bottom of the rib. The new cross-sectional moment of inertia  $I$  is 339.6 mm<sup>4</sup>, 27 times greater than the original  $I$ . The section modulus  $Z = 339.6/9.87 = 34.4 \text{ mm}^3$ . The recomputed maximum stress is 16.5 MPa, and the maximum deflection is 0.70 mm, acceptable for both the material and the application. To achieve the same result from a heavier rectangular-section beam would require a thickness (depth) of 5.99 mm, tripling the beam's weight and increasing molding difficulties, whereas the new rib adds only 25 percent to the total section weight. As shown in Fig. 17, a fillet should be added at the bottom of the rib with a radius equal to half the nominal wall thickness to assist molding and avoid stress concentrations.

*Draft:* Most molded parts have features that must be cut into the mold perpendicular to the parting line. Removal of these parts from the mold is easier if they are tapered in the direction of mold opening. This taper is called *draft* in the line of draw or mold movement, and it allows the part to break free of the mold by creating a clearance as soon as the mold starts to open. The drawing of Fig. 19 defines draft and the dimensions associated with it. Plastics materials shrink as they cool, so they grip mold projections very tightly and ejection can be difficult without sufficient draft. A draft of 1/2 degree on each side of a projection on the part is generally considered the minimum, although up to 3 degrees per side is often used.

The exact relationship between the draft angle  $\alpha$  and the dimensional difference from the top to the bottom of the draw depth  $D$  is given by

$$d = D \tan \alpha \quad (31)$$

where  $\tan$  is the tangent of the draft angle. An excellent approximation is

$$d = 0.0175\alpha D \quad (32)$$

This is accurate to the nearest 0.001 inch (0.025 mm) for draft angles up to 5 degrees and draw depths up to 10 inches (254 mm).

Fig. 19. Defining Dimensions Related to Draft and Draft Angle

Where minimal variation in wall thickness is needed to produce sidewalls that are perpendicular to the direction of draw, the mold can be designed with parallel draft, as indicated at the left in Fig. 19. The amount of draft also depends on the surface finish of the mold walls. Any texturing of the surface will increase the draft requirement by at least 1 degree per side for every 0.001 inch (0.025 mm) of texture depth.

Most plastics parts are so designed that they can be ejected parallel with the direction of mold parting. Complex parts with undercuts may require mold designs with cavity-forming projections that must move at an angle to the direction of opening. Between these two extremes lie such items as “windows,” or simple openings in the side of a molding, which can be produced by the normal interaction of the two main parts of the mold.

**Fillets, Radii, and Undercuts:** Sharp corners are always to be avoided in injection-molded part designs because they represent points of stress concentration. Sharp corners in metal parts often are less important because the stresses are low compared with the strength of the material or because local yielding redistributes the loads. Sharp inside corners are particularly to be avoided in moldings because severe molded-in stresses are generated as the material shrinks onto the mold corner. Sharp corners also cause poor material flow patterns, reduced mechanical properties, and increased tool wear. Therefore, inside corner radii should be equal to half the nominal wall thickness (as shown in Fig. 17 for a 1 mm rib thickness) with a minimum of 0.020 inch (0.51 mm) for parts subject to stress, and 0.005 inch (0.127 mm) radius for stress-free parts. Outside corner radius should equal the inside corner radius plus the wall thickness.

With an inside radius of half the wall thickness, a stress concentration of 1.5 is a reasonable assumption, and for radii down to 0.1 times the wall thickness, a stress concentration of 3 is likely. More information on stress concentrations is found in *Working Stress* on page 212. A suitable value for  $q$  in Equation (8) on page 212, for plastics materials, is 1. That is, the actual stress-concentration factor equals the theoretical value.

**Impact Resistance:** The impact resistance of a plastics part is directly related to its ability to absorb mechanical energy without fracture or deformation, and this ability depends on the material properties and the part geometry. Increasing wall thickness may improve impact resistance but may also hurt impact resistance by making the part too stiff so that it is unable to deflect and distribute the force. Validation is required in critical applications.

**Melt Flow in the Mold.**—The designer of plastics products needs a basic appreciation of what goes on during injection molding and the special properties of plastics that affect molding. Some of these, such as thermal properties, have been previously described. It is the flow properties of molten plastics that dominate mold filling. Foremost are the very high viscosities of thermoplastic melts—thousands to hundreds of thousands times that of room-temperature water—requiring pressures ( $P$ ) of 5,000–30,000 psi (35–206 MPa) to move the melt quickly from the injection cylinder through the mold runners and into the cavities. Second is the strong dependence of viscosity on temperature, so the transfer to the chilled mold must be nearly instantaneous to obtain fully filled cavities and accurately dimensioned products. Because of the high viscosities and rapid flow, frictional heat is dissipated within the melt, helping to keep it warm during its travel. Another property,

also helpful, is more subtle: plastic melts have non-Newtonian physical properties. That is, viscosity depends not only on temperature, as with ordinary liquids, but also on the flow rate and pressure drop  $\Delta P$ . Doubling the injection pressure may triple or quadruple the flow rate through the mold passages, but the pressure itself squeezes molecules closer together and tends to increase viscosity and freezing point. Unpredictable results can be obtained if the melt temperature is too near the freezing range.

If the product designer is calling for thin wall sections, *Melt Flow Rate (MFR)*, formerly known as *Melt Flow Index (MFI)*, can be used as a selection property characteristic among grades of candidate plastics. The higher the flow rate, the easier it will likely be to fill thin sections during molding. Flow rate values are obtained by testing (ASTM Test D 1238) in a simple extrusion plastometer. In this device, a small sample of resin is loaded into a 9.55-mm diameter well in a heated cylinder and brought to a test temperature above the plastic's melting range. At the bottom of the well is a die 2.1 mm in bore diameter and 8 mm long.

A weighted piston drives the melt through the die while a timer runs. Extrudate is collected and weighed, and the flow rate is reported in grams per 10-minute interval. To accommodate the wide range of plastics flow behaviors, 36 standard conditions specifying both the melt temperature in  $^{\circ}\text{C}$  and the total piston weight in kg have been adopted. *MFR* values are meaningless without the condition numbers. Most polypropylenes (PP), for example, are tested at condition 230/2.16, meaning a PP resin reported to have an *MFR* of 8 (230/2.16 assumed) would be one that at  $230^{\circ}\text{C}$  under a piston weighing 2.16 kg, produced a flow rate of 8 g/10 min. Resin and compound suppliers can supply the *MFR* values for their grades. Product designers should obtain all three numbers.

A somewhat more practical way of judging resin flows under actual molding conditions uses a spiral-flow mold. This injection molding method was in common use by the early 1950s. A similar mold is the basis for testing the flow of transfer-molding compounds (ASTM D 3123). A half-round or shallow-trapezoidal groove,  $\frac{1}{8}$  inch (3.2 mm) wide and beginning at the center, circles outward with the spiral radius increasing about  $\frac{3}{8}$  inch (9.5 mm) per turn, to a total channel length of 70 to 100 inches (178 to 254 cm). Inch numerals and 0.1-inch marks are engraved in the flat upper half of the mold. The injection nozzle fills the mold from its center and, under specified melt and mold temperatures and injection pressure, holds pressure until flow stops. The mold is opened, and the flow distance is read off the molded spiral and recorded. With careful control of molding conditions, flow distances of 40 inches (102 cm) and more can be closely reproduced in repeated shots. Many resin suppliers have spiral-flow data available for product designers and processors.

**Design for Assembly.**—An advantage of the flexibility of plastics parts compared to other materials is that they can often be designed for assembly by means of molded-in snap-fit, press-fit, pop-on, and thread fasteners. With careful design, no additional fasteners, adhesives, solvents, or special equipment is required, significantly reducing assembly time and costs. Improper assembly can be minimized, but tooling is often made more complex and disassembly may be difficult with these methods.

*Mechanical fasteners* designed for metals are generally usable with plastics, and there are many other fasteners designed specifically for plastics. Typical are bolts, self-tapping and thread-forming screws, rivets, threaded inserts, and spring clips. Care must be taken to avoid overstressing the parts. Creep can result in loss of preload in poorly designed systems.

*Snap-fit* designs are widely used, a typical application being to battery compartment covers. All snap-fit designs have a molded part that must flex like a spring, usually past a designed-in interference, then return to its unflexed position to hold the parts together. The design must have sufficient holding power without exceeding the elastic or fatigue limits of the material. With the typical snap-fit designs in Fig. 20, beam equations can be used to calculate the maximum strain during assembly. If the stress is kept below the yield point of the material, the flexing finger returns to its original position.

With some materials the calculated bending stress can exceed the yield point stress considerably if the movement is done rapidly. In other words, the flexing finger passes through its maximum deflection or strain and the material does not respond as it should if the yield stress has been greatly exceeded. It is common to evaluate snap-ins by calculating the strain instead of stress. Dynamic strain  $\epsilon$  for the straight beam, is calculated from

$$\epsilon = \frac{3Yh_o}{2L^2}$$

and for the tapered beam, from

$$\epsilon = \frac{3Yh_0}{2L^2K}$$

The derived values should be compared with the permissible dynamic strain limits for the material in question, if known. A tapered finger provides more uniform stress distribution and is recommended where possible. Sharp corners or structural discontinuities that will cause stress concentrations can be avoided through the use of judicious fillets.

Snap-in arrangements usually require undercuts produced by a sliding core in the mold as shown in Fig. 21. Sometimes the snap finger can simply be popped off when the mold is opened. An alternative to the sliding core is shown in Fig. 21, which requires an opening in the molding at the base of the flexing finger. Other snap-in assembly techniques that take advantage of the flexibility of plastics are shown in Fig. 22.

Molded-in threads in holes usually are formed by cores that require some type of unscrewing or collapsing mechanism, leading to tooling complications. External threads can often be molded by positioning them across the parting plane of the mold. Molding of threads finer than 28 threads per inch (0.9 mm pitch) is sometimes not practical.

**Chemical Bonding.** Chemical bonding is suited to applications that must be leak-tight or where stresses due to assembly must be minimized. However, adhesives and solvents can be hazardous, and their preparation and cure times can be prolonged. Properly applied cyanoacrylate adhesives achieve moderate strength in seconds or minutes and work well with assemblies that can be brought together very quickly after applying the bonding agent.

Chemical bonding may use solvents, solvents bodied with resin, or so-called "100% solids" adhesives, such as epoxies and cyanoacrylates. Use of solvents is limited to compatible materials that can be dissolved by the same solvent. Because most of the solvent must gradually diffuse out of the joint, solvent cementing is used mostly where a very thin film of the solvent can be applied to the accurately mating surface(s) to be joined, followed by rapid assembly, usually with clamping. Bodied solvent cements permit more flexibility in such operations. Safety precautions must be observed in handling the solvents to protect workers and in solvent recovery.

Adhesives that set up or cure with little or no loss of volatiles include epoxies, acrylics, polyurethanes, phenolics, rubbers, polyesters, and vinyls. Cyanoacrylates are often used because of their rapid setting with many materials, both similar and dissimilar, and because they are naturally catalyzed by atmospheric humidity. Their downside is the very short working time they allow for assembly.

Recommendations of both plastics suppliers and adhesives suppliers should be sought because many adhesives contain active components that can partly dissolve the plastics' surfaces, giving improved adhesion. However, some adhesives attack certain plastics, causing crazing and even joint failure. The main disadvantages of adhesives are that their bonds require time to reach full strength, may need long clamp times, may require fixtures and may involve special ovens or curing conditions. Also, surface preparation may be difficult because of the presence of grease or mold-release compounds; even a fingerprint can spoil a bond. Some adhesion-resistant materials such as polyolefins, nylons, and fluorocarbons usually need pretreatment with surface-activating primers or flame or plasma treatment prior to applying an adhesive. Some materials may need mechanical roughening to improve joint strength.

**Welding Plastics:** Plastics welding techniques include ultrasonic, hot-plate, spin, induction, and microwave energy, melt-bead sealing, and hot-gas welding. Thermal methods are also used for staking, swaging, and other post-thermoforming procedures. Materials must be melt-compatible and have similar melting temperatures.

Plastics welding encompasses a variety of processes in which a film melt is created at the surfaces to be joined. *Ultrasonic welding* is frequently used for joining small- and medium-sized parts of a single material or melt-compatible materials that share the same melting-temperature range. High-frequency (20 to 40 kHz) acoustic vibrational energy is briefly applied to the surfaces to be joined, creating localized molecular excitation that causes a thin layer to melt. The surfaces are pressed and held together while the melt freezes. With proper joint designs, welds can be made in two seconds or less and on cooling can be as strong as the base resins. The lower part of the assembly is supported in a rigid nest fixture and the upper part is aligned, usually by the joint design. This upper part has the freedom to couple acoustically when it is in contact with the horn through which the ultrasonic energy is transmitted. Fig. 23 shows two typical joint designs for this process. The example on the left shows a simple butt-type, energy-director design that works well with amorphous materials. The inverted-cone projection, known as an *energy director*, concentrates the energy in a small area on both faces of the joint. This area melts quickly and the material flows as the parts are pressed together. Shown at the right in Fig. 23 is a shear-interference joint. Melting of both components starts in the small initial contact area, and flow continues along the near-vertical wall as the parts are pressed together, creating a continuous, leakproof joint with a strength that often equals that of the parts joined.

With hygroscopic plastics, welding should be done as soon as possible after molding because even small amounts of moisture can weaken bonds. Drying immediately before welding may be advisable. Drawbacks of ultrasonic welding are the following: design, quality control, equipment maintenance, and settings are of critical importance for consistent, high-strength welds; the equipment is costly; the process uses large amounts of electric power especially with large parts; and parts to be joined must be of the same or compatible plastics. Filled and fiber-reinforced materials are more difficult to weld.

Although horn frequencies in ultrasonic welding are not audible to the ear, sounds that cause discomfort may be generated when plastics parts vibrate at lower frequencies, necessitating sound-proofing.

Fig. 23. (left) Energy-Director Type of Ultrasonic Weld Joint for Molded-Part Assembly and (right) Typical Shear-Interference Joint

**Vibration Welding:** Vibration welding resembles ultrasonic welding except that the parts to be joined are rubbed together to produce frictional heat that melts the faces. The energy is transferred in the form of high-amplitude, low-frequency, reciprocating motion. After a short period of vibration, the weld area cools and solidifies while the parts are held in the

alignment provided by the welding fixture. Typical frequencies used are 120 to 240 Hz, and amplitudes range between 0.10 and 0.20 inch (2.54–5.08 mm). When the geometry or assembly design prevents linear movement, vibration-welding equipment can be designed to produce angular displacement of parts. Like ultrasonic welding, vibration welding produces high-strength joints and is better suited to large parts and irregular joint faces.

*Spin Welding:* Like vibration welding, spin welding uses frictional heat to melt the faces of circular joint surfaces. It is a rapid and economical method of joining melt-compatible parts. The process is completed in about three seconds and is easily automated. Frictional heat is generated by rotating one part against its mate (usually fixed) with a controlled pressure. When rotation is stopped, pressure is maintained during cooling and solidification of the joint. Simple equipment such as a drill press can serve for this process.

*Hot-Gas Welding:* Hot-gas welding is a process resembling acetylene brazing and welding of metals. Used mostly with polyolefins, which do not accept adhesives, the hot-gas welding equipment consists of an electric hot-gas “gun” that provides, through any of several interchangeable nozzles, a stream of hot air or preferably hot nitrogen at a temperature above the melting range of the plastic to be worked. A welding rod of the same material provides the melt that forms the joint to be made between two parts. The parts to be joined are set up in their final orientation in a jig. A groove will usually be machined in one or both to accept the molten plastic. The operator directs the hot gas stream along the joint surfaces while feeding and melting the welding rod into the joint. The welded structure is then allowed to cool several hours. Some huge tanks have been fabricated from thick polyethylene sheets by this technique. It is also useful for repairing broken polyolefin parts. Hot-gas welding can produce joints with 85 percent of the strength of the parent material. Hot-gas welding is not recommended for use with substrates less than  $\frac{1}{16}$  inch (1.6 mm) thick.

*Dielectric Welding:* Dielectric welding is also known as *radio-frequency welding*. This process utilizes the dielectric loss that occurs in many plastics when they are placed in a rapidly reversing electric field. It is widely used with flexible thermoplastics films and sheets of materials—typically plasticized PVC and polyurethane—and for joining some injection-molded parts. The parts to be joined are brought together between two electrodes that also supply joining pressure. The field passes through the material, generating heat throughout the volume between the electrodes until it reaches melting range. The field is then turned off and pressure is maintained until the joined parts freeze. Polyolefins and some other plastics are so nonpolar that their dielectric loss is too small to permit welding them by this method.

*Electromagnetic or Induction Welding:* This form of welding uses inductive heating to generate fusion temperatures in thermoplastics as shown at the top in Fig. 24. Fine iron particles embedded in a gasket, preform, filament, ribbon, adhesive, or molded part are excited by the rapidly alternating magnetic field, generating eddy currents that, through resistive loss, cause distributed local heating. The heated parts are pressed together, and, as the temperature rises, the material of the particle carrier flows under pressure through the joint interface, filling voids and cavities and becoming an integral part of the weld. Ideally, the melted material should be contained and subjected to internal pressure by the surrounding component surfaces. Proper joint design is essential to successful induction welding.

Requirements of the preform often add cost to this welding method, but the cost is offset by low reject rates resulting from good reliability of the welds. Structural, hermetic welds can be produced in most thermoplastics materials, and automation can be used for large-volume production. The process also offers great latitude in joint size, configuration, tolerance requirements, and ability to bond some dissimilar materials. A limitation is that no ferrous metal can be near the joint line during the energizing of the inductor coil. All components of an assembly (except the weld medium) to be induction-welded must therefore be nonferrous, or ferrous components must be placed where they will not be subjected to the high-frequency field from the inductor.

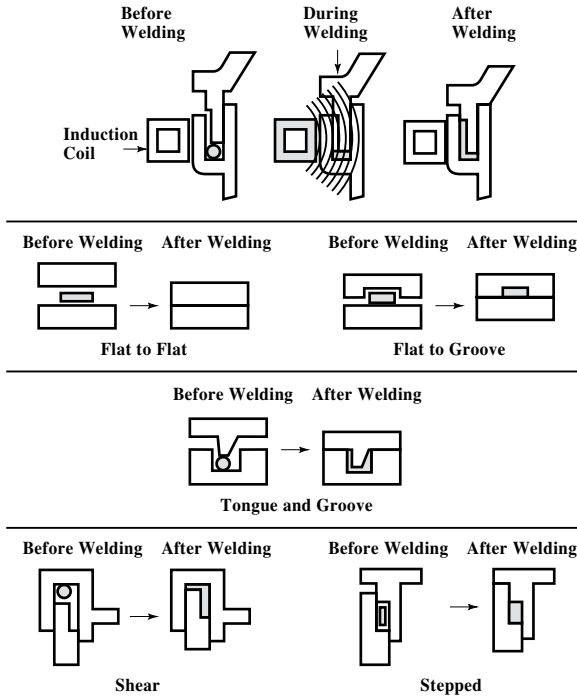

Fig. 24. Typical Joint Designs Used in Induction-Welding Plastics Assembly

**Assembly with Fasteners.**—Metal fasteners of high strength can overstress plastics parts, so torque-controlled tightening or special design provisions are needed. Examples of poor and preferred designs are shown in Fig. 25. The shoulder of the metal screw shown in the lower right portion of Fig. 25 meets the metal component when it is tightened, sparing the plastic part from over-compression. Where force cannot be satisfactorily controlled, even with a shoulder screw, various types of washers can be used to spread the compression force over wider areas.

Metal inserts are available in a wide range of shapes and sizes for permanent installation in plastics parts. Inserts are typically installed in molded bosses, designed with holes to suit the insert to be used. Some inserts are pressed into place and others are installed by methods designed to limit stress and increase strength. Generally, the outside of the insert is knurled or otherwise provided with projections of various configurations that penetrate the plastics and prevent movement under normal torques exerted during assembly. “Helicoil” inserts have large standard threads on the outside and receive a smaller standard screw inside, thus lowering the assembly torque on the plastic by distributing it to the larger outside contact area. Inserts can also be installed with equipment similar to that used for ultrasonic welding, the plastics being melted to enhance contact with the metal and reduce insertion stresses.

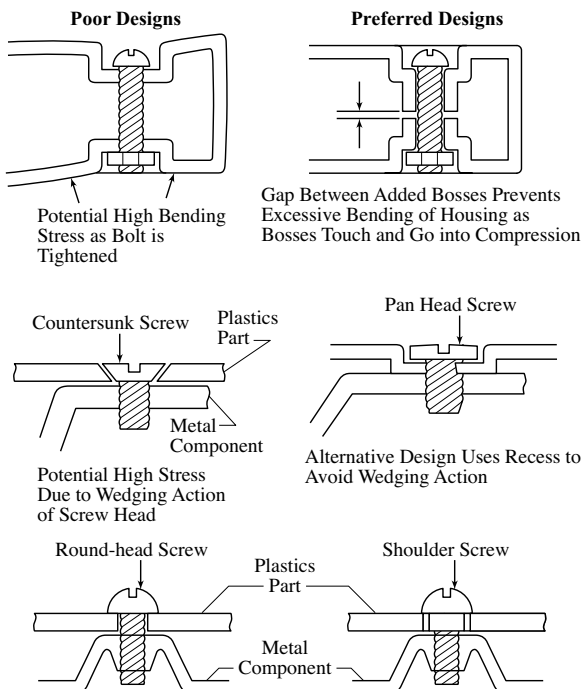

Fig. 25. Examples of Bad and Good Designs in Assembling Plastics with Metal Fasteners

Thread-cutting and -forming screws are widely used with plastics parts. Information on standard self-threading screws is found in *SELF-THREADING SCREWS* starting on page 1833. Thread-forming screws must be used carefully with high-modulus, low-creep plastics, as high hoop stresses can be generated during insertion. Screws with multiple lobes and screws with alternating low and high threads have excellent holding power in plastics. Molded holes must have sufficient depth to prevent bottoming, and boss walls must be thick enough to resist stresses. As a general rule of thumb, the outside diameter of the boss should be double the major diameter of the screw. Gussets and ribs can be used to increase the torsional strength of bosses.

Hollow aluminum or other metal rivets are often used in plastics assembly, as are stamped sheet metal components, especially push-on or -in designs. Molded plastics fasteners are also frequently used.

**Machining Plastics.**—Plastics can be molded into complex shapes and so do not usually need to be machined. However, machining is sometimes more cost-effective than making a complex tool, especially when requirements are for prototype development, low-volume production, undercuts, angular holes, or other openings that are difficult to produce in a mold. Special methods for development of prototypes are discussed on page 611. All

machining of plastics requires dust control, adequate ventilation, safety guards, and eye protection.

Like some metals, plastics may need to be annealed before machining to avoid warpage. Some commercially available bar and rod stock are sold already annealed. If annealing is necessary, instructions can be obtained from plastics suppliers. Plastics moduli are small fractions—2 to 10 percent—of those of metals, and this lower stiffness permits much greater deflection of the work material during cutting. Thermoplastics materials must be held and supported firmly to prevent distortion, and sharp tools are essential to minimize normal forces and avoid excess heat generation.

Plastics recover elastically during and after machining so that drilled or tapped holes often end up tapered or of smaller diameter than the tool. Turned diameters also can end up larger or smaller than the dimensions measured immediately after the finishing cut. The low thermal conductivity of plastics causes much of the heat generated in cutting to be absorbed by the tool. Heat in the plastics tends to stay near the surface. The heat must be removed by an air blast or a liquid coolant for optimum surface finishes and close tolerances. A non-aromatic, water-soluble misting or flood coolant is suggested.

Plastics have thermal expansion coefficients some 10 times higher than those of metals so that even though actual heat generation during machining may be less than with metals there can easily be more expansion. Adequate tool clearances must be provided to minimize heating. Compared with most structural metals, temperatures at which plastics soften, deform and flow are quite low. Allowing frictional heat to build up causes gumming, discoloration, poor tolerance control, and rough finishes. These effects are more pronounced with plastics such as polystyrene and polyvinyl chloride that have low melting points than with plastics that have higher melting points, such as nylons, fluoroplastics, and polyphenylene sulfide. Sufficient clearances must be provided on cutting tools to prevent rubbing contact between the tool and the work. Tool surfaces that will come into contact with plastics during machining should be polished to reduce frictional drag and resulting temperature increases. Proper rake angles depend on depth of cut, cutting speed, and the type of plastic being cut. Large rake angles should be used to produce continuous-type cuttings, but they should not be so large as to cause brittle fracture of the work and resulting discontinuous chips.

**Turning and Cutting Off:** High-speed steel and carbide tools are commonly used with cutting speeds of 300–600 and 600–1200 ft/min (91–183 and 183–366 m/min), respectively. Water-soluble coolants can be used to keep down temperatures at the shear zone and improve the finish, except when they react with the work material. Chatter may result from the low modulus of elasticity and can be reduced by close chucking and follow rests. Box tools are good for long, thin parts. Tools for cutting off plastics require greater front and side clearances than are needed for metal. Cutting speeds should be about half those used for turning operations.

**Drilling:** This is the most common machining operation because small-diameter holes are more easily drilled than molded. However, plastics are rather difficult to drill without some damage. Many difficulties not encountered in drilling metals, such as gumming, burning in the drilled hole, cracks around the edges or growth of cracks after drilling, can occur. Two reasons for these difficulties are that swarf flow (chip removal) in drilling is poor and cutting speeds vary from the center to the periphery of the drill, so that drilling imposes severe loading on the workpiece. Some drill types used with plastics are shown in Fig. 26.

Drills of high-speed steel or premium high-speed steel (T15, M33, or M41–M47) are recommended, with low helix angles, point angles of 70–120 degrees, and wide, highly polished flutes to ease chip exit. Normal feed rates are in the range of 0.001–0.012 in/rev (0.025–0.3 mm/rev) for holes of 1/16 to 2 inch (1.6–51 mm) diameter, and speeds of 100–250 ft/min (30.5–76.2 m/min), with lower speeds used for deep and blind holes. Point angles of 60 to 90 degrees (included) are used for many plastics, but an angle of 120 degrees should be used for rigid polyvinyl chloride and acrylic (polymethyl methacrylate).

Fig. 26. Drill Designs Used for Drilling Plastics

Clearance angles of 9 to 15 degrees are usually sufficient to prevent the drill flanks from rubbing in the bottom of the hole, but acrylic materials require angles of 12–20 degrees. Tests may be needed to determine the drill diameter for accurately sized holes, allowing for thermal expansion and elastic recovery. Reaming may be used to size holes accurately, but even those diameters produced may also be affected by thermal expansion of the plastics. Close-fitting bushings in drill jigs may increase friction on the drill and cause swarf to plug up the drill flutes. For positioning accuracy, removable templates may be used to spot the hole position, then set aside for the drilling to be completed. Pilot holes are not necessary, except when the hole is to be reamed or counterbored. Frequent pull-out (peck drilling) to remove chips and compressed air cooling may be needed, especially for deep holes.

Drilling and reaming speed and feed suggestions for various materials are shown in Table 9. These speeds and feeds are approximate, and can be increased where there is no melting, burning, discoloration, or poor surface finish. Drilling is best done with commercially available drills designed for plastics (Fig. 26), usually having large helix angles, narrow lands, and highly polished or chromium-plated flutes to expel swarf rapidly and minimize frictional heating. Circle cutters are often preferred for holes in thin materials. Drills must be kept sharp and cool, and carbide tools may be needed in high production, especially with glass-reinforced materials. They must be cooled with clean compressed air to avoid contamination. Aqueous solutions are used for deep drilling because metal cutting fluids and oils may degrade or attack the plastics and may cause a cleaning problem. Plastics parts must be held firmly during drilling to counter the tendency for the tooling to grab and spin the work.

**Table 9. Suggested Approximate Speeds and Feeds for Drilling Various Thermoplastics<sup>a</sup>**

Material	1/16 in. Diameter		1/4 in. Diameter		1 in. Diameter

<sup>a</sup>Using a two-fluted drill.

**Tapping and Threading of Plastics:** Many different threaded fasteners can be used with plastics, including thread-tapping and -forming screws, threaded metal inserts, and molded-in threads, but threads must sometimes be machined after molding. For tapping of through holes in thin-cast, molded, or extruded thermoplastics and thermosets, a speed of 50 ft/min (15.2 m/min) is appropriate. Tapping of filled materials is done at 25 ft/min (7.6 m/min). These speeds should be reduced for deep or blind holes and when the percentage of thread is greater than 65–75 percent. Taps should be of M10, M7, or M1 molybdenum high-speed steel, with finish-ground and -polished flutes. Two-flute taps are recommended for holes up to 0.125 inch (3.2 mm) diameter. Oversize taps may be required to make up for elastic recovery of the plastics. The danger of retapping on the return stroke can be reduced by blunting the withdrawal edges of the tool.

**Sawing Thermoset Cast or Molded Plastics:** Circular or band saws may be used for sawing. Circular saws provide smoother cut faces than band saws, but, because band saws run cooler, they are often preferred even for straight cuts. Projection of the circular saw above the table should be minimized. Saws should have skip teeth or buttress teeth with zero front rake and a raker set. Precision-tooth saw blades should be used for thicknesses up to 1 inch (25.4 mm), and saws with buttress teeth are recommended for thicknesses above 1 inch (25.4 mm). Dull edges to the teeth cause chipping of the plastics and may cause breakage of the saw. Sawing speeds and other recommendations for using blades of high-carbon steel are shown in Table 10.

**Table 10. Speeds and Numbers of Teeth for Sawing Plastics Materials with High-Carbon Steel Saw Blades**

Material Thickness		Number of Teeth/inch on Blade	Peripheral Speed			
			Thermoset Cast or Molded Plastics		Thermoplastics (and Epoxy, Melamine, Phenolic and Allyl Thermosets)

<sup>a</sup> 2-fluted, 1 in. end mill

**Milling of Plastics:** Peripheral cutting with end mills is used for edge preparation, slotting and similar milling operations; end cutting can also be used for facing operations. Some recommended approximate speeds and feeds are provided in [Table 11](#) for peripheral end milling of common thermoplastics; as per standard machining practice, speeds and feeds must be adjusted with observation of the machining relative to the quality requirements. Slower speeds are generally used for face and other milling operations, with some thermoplastics being machined at 300–500 ft/min (91–152 m/min), and some thermosets at 150–300 ft/min (46–91 m/min). Adequate support and suitable feed rates are very important. A table feed that is too low will generate excessive heat and cause surface cracks, loss of dimensional accuracy, and poor surface finish. Too high a feed rate will produce a rough surface. High-speed steel tools (M2, M3, M7, or T15) are generally used, but for glass-reinforced nylon, silicone, polyimide, and allyl, carbide (C2) is recommended.

**Turning of Plastics:** Plastics can be processed on commercially available lathes. A fine-grained, C2 carbide cutter, with a small cutting radius and broad-nosed finishing cutting edge, is recommended to avoid material build-up. Recommended approximate feed speeds are provided in [Table 12](#). When feasible, turning at higher cutting speeds is recommended, using a cutting depth of at least 0.004 inch. Compressed air is a common and acceptable method for cooling, though misted and flooded coolants can be used if available. If the diameter of the plastic workpiece is small or workpiece rigidity is an issue, then a live center or lunette is recommended to stabilize the component and provide improved tolerances and surface finish.

**Table 12. Suggested Approximate Speeds and Feeds for Turning Various Thermoplastics**

*Other Machining Techniques:* Lasers can be used for machining plastics, especially sheet laminates, although their use may generate internal stresses. Ultrasonic machining has no thermal, chemical, or electrical reaction with the workpiece and can produce holes down to 0.003 inch (0.0762 mm) diameter; tight tolerances, 0.0005 inch (0.0127 mm); and very smooth finishes, 0.15  $\mu$ inch (0.381  $\mu$ m) with No. 600 boron carbide abrasive powder. Water-jet cutting using pressures up to 60,000 lb/in<sup>2</sup> (414 N/mm<sup>2</sup>) is widely used for plastics and does not introduce stresses into the material. Tolerances of  $\pm 0.004$  inch ( $\pm 0.102$  mm) can be held, depending on the equipment available. Process variables, pressures, feed rates, and the nozzle diameter depend on the material being cut. This method does not work reliably with hollow parts unless they can be filled with a solid core.

*Machining Hard Rubber:* Hard rubber, or ebonite, is the oldest rigid manmade plastic, and has been used since the 1840s. The base material is a highly vulcanized natural or, today, synthetic rubber, empirical formula C5H8S, containing 32 percent sulfur. A range of compositions containing various amounts of fillers is available. Unfilled ebonite has a specific gravity = 1.18, tensile strength = 9,000 psi (62 N/mm<sup>2</sup>), elongation = 3 percent, and Izod impact strength = 0.5 ft-lb<sub>f</sub>/in (26.7 J/m) of notch. Its continued use is due to its good insulating characteristics, good chemical resistance, and ease of machining. Tools suitable for steel, high-speed steel, or tungsten carbide may be used with hard rubber with no top or side rake angles and 10 to 20 degrees clearance angles.

Without coolant, surface speeds of 200 ft/min (60 m/min) are recommended for turning, boring and facing; they may be increased to 300 surface ft/min (90 m/min) with coolant.

Drilling of hard rubber requires high-speed steel drills of 35 to 40 degrees helix angle to obtain maximum cutting speeds and drill life. Feed rates for drilling range up to 0.015 in/rev (0.38 mm/rev). Deep-fluted taps are best for threading hard rubber and should be 0.002 to 0.005 inch (0.05-0.13 mm) oversize if close tolerances are to be held. Machine oil is used as the lubricant. Hard rubber may be sawed with band saws having 5 to 10 teeth per inch, running at about 3000 ft/min (915 m/min), or it may be cut with abrasive wheels. Use of coolant in grinding ebonite gives a smoother finish.

Piercing and blanking of hard-rubber sheet is best performed with the rubber and dies warmed. Straightening of the often-distorted blanks may be accomplished by dropping them into a pan of hot water.

**Plastics Gears.**—Plastics gears may be cut from blanks, as are metal gears, or molded to shape in an injection-molding machine for lower production costs, though tooling may cost more. Cut plastics gears may be of similar design to their metal counterparts, but molded gears are usually of modified form to suit material characteristics, including sensitivity to temperature and humidity. Plastics materials also may be preferred for gears

because of superior sliding properties with reduced noise and less need for lubrication, chemical or electrical properties, or resistance to wear. However, plastics gear teeth slide more smoothly and easily against metal teeth than do plastics against plastics, and wear is less. For power transmission, plastics gear teeth are usually of involute form. See also *Non-Metallic Gearing* on page 2324.

Most plastics gears are made from nylons and acetals, although acrylonitrile-butadiene-styrenes (ABS), polycarbonates, polysulfones, phenylene oxides, polyurethanes, liquid crystal polymers, and thermoplastic polyesters have also been used. Gears can be made from virtually any plastic, including polypropylene and polyethylene. But care must be taken to manage deflection and stresses, even in low-load and low-speed applications. Additives used in plastics for gears include glass and carbon fiber for added strength and stiffness, and fibers, beads, and powders for reduced thermal expansion and better dimensional stability. Other materials, such as molybdenum disulfide, polytetrafluoroethylene powder (PTFE), and silicones may be incorporated as integral lubricants to reduce friction and wear.

Choice of plastics gear material depends on requirements for size and nature of loads to be transmitted, designated speeds, required life, working environment, time of cooling, lubrication, and operating precision. Because of cost, plastics gears are sometimes not enclosed in sealed housings and are often given only a single coating of lubricant grease. Overloading of lubricated plastics gear teeth will usually cause tooth fracture, and unlubricated teeth often suffer excessive wear. Thermoplastics strength varies with temperature, with higher temperatures reducing root stress and permitting tooth deformation. In calculating power to be transmitted by spur, helical, and straight bevel gearing, the following formulas should be used with the factors given in Table 13, Table 14, and Table 15:

	US Customary Units		Metric Units
Internal and External Spur Gears	$HP = \frac{S_s F Y V}{55(600 + V) P C_s}$	(33a)	$KW = \frac{F Y m S_s V}{327(3.05 + V) C_s}$
Internal and External Helical Gears	$HP = \frac{S_s F Y V}{423(78 + \sqrt{V}) P_n C_s}$	(34a)	$KW = \frac{F Y m S_s V}{179(5.56 + \sqrt{V}) C_s}$
Straight Bevel Gears	$HP = \frac{S_s F Y V (C - F)}{55(600 + V) P C C_s}$	(35a)	$KW = \frac{F Y m S_s V (C - F)}{327(3.05 + V) C_s C}$

$S_s$  = safe stress in bending (from Table 14);  $F$  = face width in inches (mm);  $Y$  = tooth form factor (from Table 13);  $m$  = module, mm;  $C$  = pitch cone distance in inches (mm);  $C_s$  = service factor (from Table 15);  $P$  = diametral pitch;  $P_n$  = normal diametral pitch; and  $V$  = velocity at pitch circle diameter in ft/min (m/s).

*Example:* As an example, assume that a material is to be selected for a spur gear that must transmit  $\frac{1}{8}$  hp at 350 rpm for 8 hours/day under a steady load. The gear is to have 75 teeth, 32 diametral pitch, 20 degree pressure angle, 0.375 inch face width, and a pitch diameter of 2.3438 inches. Using Equation (33a),

$$HP = \frac{S_s F Y V}{55(600 + V) P C_s} \quad \text{or} \quad S_s = \frac{55(600 + V) P C_s HP}{F Y V}$$

$$HP = 0.125 \quad Y = 0.434 \quad \text{and}$$

$$V = \frac{rpm \times \pi \times D}{12} = \frac{350 \times 3.1416 \times 2.3438}{12} = 215 \text{ ft/min}$$

therefore, 
$$S_s = \frac{55(600 + 215)32 \times 1.00 \times 0.125}{0.375 \times 0.434 \times 215} = 5,124 \text{ lb/in}^2$$

**Table 13. Tooth Form Factors  $Y$  for Plastics Gears**

Number of Teeth	14½-degree Involute or Cycloidal	20-degree Full Depth Involute	20-degree Stub Tooth Involute	20-deg Internal Full Depth	
				Pinion	Gear
12	0.210	0.245	0.311	0.327	...
13	0.220	0.261	0.324	0.327	...
14	0.226	0.276	0.339	0.330	...
15	0.236	0.289	0.348	0.330	...
16	0.242	0.259	0.361	0.333	...
17	0.251	0.302	0.367	0.342	...
18	0.261	0.308	0.377	0.349	...
19	0.273	0.314	0.386	0.358	...
20	0.283	0.320	0.393	0.364	...
21	0.289	0.327	0.399	0.371	...
22	0.292	0.330	0.405	0.374	...
24	0.298	0.336	0.415	0.383	...
26	0.307	0.346	0.424	0.393	...
28	0.314	0.352	0.430	0.399	0.691
30	0.320	0.358	0.437	0.405	0.679
34	0.327	0.371	0.446	0.415	0.660
38	0.336	0.383	0.456	0.424	0.644
43	0.346	0.396	0.462	0.430	0.628
50	0.352	0.480	0.474	0.437	0.613
60	0.358	0.421	0.484	0.446	0.597
75	0.364	0.434	0.496	0.452	0.581
100	0.371	0.446	0.506	0.462	0.565
150	0.377	0.459	0.518	0.468	0.550
300	0.383	0.471	0.534	0.478	0.534
Rack	0.390	0.484	0.550	...	...

These values assume a moderate temperature increase and some initial lubrication. With bevel gearing, divide the number of teeth by the cosine of the pitch angle and use the data in the table. For example, if a 20-degree PA bevel gear has 40 teeth and a pitch angle of 58 degrees, 40 divided by the cosine of 58 degrees =  $40 \div 0.529919 = 75$ , and  $Y = 0.434$ .

**Table 14. Safe Bending Stress Values for Plastics Gears**

Plastics Type	Safe Stress			
	Unfilled		Glass-Filled	
	lb/in <sup>2</sup>	MPa	lb/in <sup>2</sup>	MPa
ABS	3,000	20.68	6,000	41.37
Acetal	5,000	34.47	7,000	48.26
Nylon	6,000	41.37	12,000	82.74
Polycarbonate	6,000	41.37	9,000	62.05
Polyester	3,500	24.13	8,000	55.16
Polyurethane	2,500	17.24	...	...

**Table 15. Service Factors for Plastics Gears**

Type of Load	8–10 hr/day	24 hr/day	Intermittent, 3 hr/day	Occasional, ½ hr/day
Steady	1.00	1.25	0.80	0.50
Light shock	1.25	1.5	1.00	0.80
Medium shock	1.5	1.75	1.25	1.00
Heavy shock	1.75	2.00	1.5	1.25

From Table 14 it is apparent that the gear could be molded from several materials. Available physical and chemical characteristics must now be considered in relation to the operating environment for the gear. Strengths of plastics materials decrease with increasing temperatures, and not all plastics resist the effects of some liquids, including some lubricants. Some plastics deteriorate when in sunlight for long periods; some are more dimensionally stable than others; and wear resistance varies from one to another. Manufacturers' data sheets will answer some of these questions.

**Backlash:** Plastics gears should be so dimensioned that they will provide sufficient backlash at the highest temperatures likely to be encountered in service. Dimensional allowances must also be made for gears made of hygroscopic plastics that may be exposed to damp service conditions. Teeth of heavily loaded gears usually have tip relief to reduce effects of deflection, and have full fillet radii to reduce stress concentrations. Such modifications to tooth form are also desirable in plastics gears. If the pinion in a pair of gears has a small number of teeth, undercutting may result. Undercutting weakens teeth, causes undue wear, and may affect continuity of action. The undercutting can be reduced by using the long-short addendum system, which involves increasing the addendum of the pinion teeth and reducing that of the gear teeth. The modified addendum method will also reduce the amount of initial wear that takes place during initial stages of contact between the teeth.

**Accuracy:** The Gear Handbook, AGMA 390-03a-1980, Part 2, Gear Classification, provides a system whereby results of gear accuracy measurements are expressed in terms of maximum tooth-to-tooth and composite tolerances. This system uses AGMA quality numbers related to maximum tolerances, by pitch and diameter, and is equally applicable to plastics and metal gears. AGMA quality numbers must be chosen for a pair of mating gears early in the design process, and the finished gears must be inspected by being run in close mesh with a master gear in a center-distance measuring instrument to make sure that the errors do not exceed the specified tolerances.

To prevent failure from fatigue and wear caused by excessive flexing of the teeth, plastics gears must be made to similar standards of accuracy as metal gears. Solidification shrinkage of plastics requires that dimensions of molds for gears be larger than the dimensions of the parts to be produced from them. The amount of the shrinkage is usually added to the mold dimension (with the mold at operating temperature). However, this procedure cannot be followed for the tooth profile as it would introduce large errors in the pressure angle. Increases in pressure angle cause gear teeth to become wider at the root and more pointed. Sliding conditions are improved and the teeth are stronger, so that higher loading values can be used.

Shrinkage allowances have the greatest effect on the accuracy of the molded gears, so tooth profiles must be calculated extremely carefully in terms of mold profile. If a tooth is merely made larger by using a standard hobbing cutter to cut the tool, whereby the teeth in the mold are electroeroded, differential shrinkage caused by the molded tooth being thicker at the root than at the tip will distort the shape of the molded tooth, making it thinner at the tip and thicker at the root. With two mating gears these faulty shapes will affect the pressure angle, resulting in binding, wear, and general malfunction. If tooth thickness limits for a molded gear are to be held to +0.000 inch, -0.001 inch (-0.025 mm), the outside diameter must be permitted to vary up to 0.0027 inch (0.069 mm) for 20 degree and 0.0039 inch (0.099 mm) for 14½-deg pressure angle gears. All high-accuracy gears should be specified with AGMA quality numbers and inspected with center-distance measuring machines if the required accuracy is to be achieved.

**Polishing Plastics.**—Plastics can be highly polished for optical and tooling applications, low-friction surfaces, aesthetic purposes, and other uses. This can be achieved with buffing methods similar to those used on metals. But experiments typically are required to determine appropriate speed and forces, based on effects of various polishing media and frictional heat.

To minimize surface heating during machine polishing, it is recommended to avoid lingering at any one location, and to keep speeds and forces low. Otherwise, surfaces can quickly heat to temperatures of 400°F (205°C), and many plastics will soften and melt at these temperatures. Heating also can cause plastics to give off toxic gases. So machine polishing should be performed in vented enclosures, and masks worn during manual polishing to filter gases and dust.

As with metals, polishing operations proceed from coarser to finer surfaces. If molding, additive manufacturing, or machining processes left a rough surface, sanding may be needed prior to polishing. Larger defects, including parting lines, imperfections, scratches, saw lines, and scars resulting from fabrication, also can be treated with abrasives prior to buffing. Wet or dry abrasives, such as silicon carbide or aluminum oxide, generally are used in grain sizes from 60 to as fine as 1000. Surfaces are ready for fine polishing when a satin finish is achieved.

If the plastic parts are sufficiently robust, tumble polishing can be used with abrasive media in a vibratory bowl. Tumbling processes can operate as a batch process, with high loadings of parts. Cycle times are typically a few hours, with the usual media to parts ratio approximately 2 or 3 to 1 by volume. A wide variety of abrasive media are available, varying in shape, density, hardness, and grit. For burnishing and polishing of plastics parts, angle-cut cylinders, with finer grit and lower density and hardness, are recommended to avoid excessive material removal and loss of feature detail. Tumbling of plastics parts in ceramic media usually works best when used as a wet process, with intermittent or continuous filtering of the generated particulates.

Economical polishing of edges—for example, of acrylic sheets—may be accomplished by flame polishing. If the surface is rough, edges should first be sanded with 320 grit paper. Quickly passing an oxy-acetylene torch over the edge surface melts it with the local flow and solidification results in a polished appearance. To minimize rounding of melted edges, a small strip of plastic or other material can be clamped on each side. Note that polycarbonate and many other plastics may not be easily flame polished, given their propensity to oxidative degradation and flammability.

Polishing with buffer wheels is common, with speeds for polishing comparable to those for turning (see [Table 12](#)), typically 800 to 1,500 feet (360 to 580 meters) per minute, with rotation speeds varying with the buffer wheel size. For example, a wheel measuring 6 in. (150 mm) operating at 750 rpm will provide a linear velocity of 1,180 feet/minute (360 meters/minute). For most plastics, soft cotton buffs are best, using a wet or greasy tripoli or silica compound. If a cleaning solvent is used, it should be checked to see that it does not dissolve the plastic and used only in a well-ventilated area. Each round of polishing should be performed with a separate, clean polishing bonnet.

**Finishing and Decorating Plastics.**—There are a number of other methods for finishing and decorating the surfaces of plastic parts, such as spray painting, vacuum metallizing, hot stamping, silk screening, and even plating. Conductive coatings may be applied to inside surfaces, usually by flame- or arc-spraying, to dissipate static electricity and provide electromagnetic shielding. Thorough cleaning is essential. Materials such as polyethylene, polypropylene, and acetal have waxlike surfaces that may not be painted easily or may need pretreatment or special primers. Many amorphous plastics are easy to paint. Suitable coatings include polyurethane-, epoxy-, acrylic-, alkyd-, and vinyl-based paints. Oven curing must be carried out at temperatures well below the deflection temperatures of the plastics in order to avoid distortion of parts. See [Deflection temperature under load \(DTUL\)](#) on page 574.

*Vacuum Metallizing and Sputter Coating* require application of a special base lacquer and protective clear top coat before and after treatment. Resistance heating or an electron beam can be used to melt the coating metals such as aluminum, silver, copper, and gold, which usually are pure elements. Wires of the coating metal are hung from tungsten heating elements in an array that gives them direct views of the surfaces to

be coated. Sputter plating uses a plasma to produce the metallic vapor, requires line-of-sight setup, and can use brass as well as the other metals mentioned. The appearance of gold or brass is often simulated with vacuum-metallized aluminum by tinting the overcoating lacquer. Chromium plating requires etched surfaces to ensure good adhesion.

**Development of Plastics Prototypes.**—Model prototypes are made for testing of properties, such as stress and fatigue resistance, to find ways to improve quality and reliability, to improve tooling design, and to reduce time to market. Prototyping may answer questions about finish, sink marks that result from contraction, witness lines from mold joints, ejector pin marks, knit or weld lines, texturing, moldability, shrinkage, mechanical strength, insert pull-out resistance electrical properties, and problems of mating with other parts.

Prototypes of moldings are made in five major steps: design, refining the design, making a model (physical or computer), making a mold, and producing parts. The model may be made from wood, plaster, plastics (by machining), or metal. The majority of prototypes utilize CAD/CAM methods that enable dimensional tolerances to be held to 2 to 3 percent of drawing specifications. (See *CAD/CAM* on page 1390.) However, ongoing advancements in sophisticated additive manufacturing (AM) processes, commonly known as 3D printing, are steadily increasing the number of plastics prototypes, as well as parts, being produced using such methods.

After the initial investment, use of AM processes to produce plastics prototypes can be less expensive and more efficient than producing prototypes with CNC machines, freeing up the more costly CNC machines for production. CNC systems generally require more floor space than 3D printers and, as a subtractive process, use more material and produce scrap that must be recycled or otherwise disposed of, whereas AM machines use only the amount of material needed.

### Additive Manufacturing Plastics

Plastics prototyping was the motivation for development of the first AM process, known as stereolithography (SLA). This process patent was filed in 1984, granted in 1986, and commercialized in 1987 by 3D Systems. Since then, other AM processes for making plastics prototypes and production parts have been developed and refined, including selective laser sintering, fused deposition modeling, binder jetting, material jetting, and multijet fusion. In all of these processes, a part is built up one layer at a time, adding material to produce a shape.

In all AM methods, as in CNC machining and other computerized manufacturing systems, the objective shape is represented in a three-dimensional (3D) CAD file. The CAD file may be made by a designer or by scanning an object into a solid modeling package. Software embedded within the printer “slices” the CAD model into layers; it then determines the toolpath for fabricating each layer. The “tool” in this case is an extruder, laser, or printhead, as described in the following sections.

Unlike CNC systems, AM does not require external programming of the toolpath. With the new programs and interfaces, the skill level required to program and operate a 3D printer and create unique plastic models in-house is less. Alternatively, parts designers can take advantage of 3D printing services to produce affordable prototypes. Thus, prototypes can be produced more frequently, providing efficiencies in product design and development time. At the same time, production parts are increasingly being manufactured with this technology.

Operating principles and features of various plastic AM processes follows. [Table 1](#) summarizes attributes of plastic 3D printing processes. For more on the plastics mentioned here, see *Plastics Materials* on page 556.

**Table 1. Plastics Processes and Materials for 3D Printing**

Process	Materials	Feedstock Form	Resolution						Layer Thickness		Surface Finish
			Accuracy		Diameter of Hole		Thickness of Wall		inch	mm	Roughness Average (Ra)
			inch	mm	inch	mm	inch	mm			
Stereolithography (SLA)	Thermoset plastics: PP-like, ABS-like, PC-like, heat-resistant, flexible	Photosensitive liquid resin	0.002	0.05	0.02	0.5	0.02	0.5	0.001–0.004	0.03–0.10	3–5
Selective Laser Sintering (SLS)	Thermoplastics: nylon, carbon-filled nylon, glass-filled nylon, aluminum-filled nylon	Polymer powders	0.012	0.30	0.06	1.5	0.03	0.8	0.001–0.004	0.03–0.10	10–20
Fused Deposition Modeling (FDM)	Thermoplastics: ABS, PC, PLA, Ultem high-temperature	Polymer filament	0.02	0.5	0.08	2.0	0.03	0.8	0.004–0.012	0.10–0.30	20–50
Binder Jetting (BJ)	Plaster, starch	Plaster starch powders; water-based binders	0.02	0.5	0.04	1.0	0.04	1.0	0.004–0.012	0.10–0.30	10–20
Material Jetting (MJ)	Thermoset plastics: ABS-like, PP-like, rubber	Photosensitive polymer resin	0.004	0.10	0.02	0.5	0.04	1.0	0.0006–0.002	0.015–0.05	5–10
Multijet Fusion (MJF)	Nylon	Polymer particles; liquid binder and detail agents	0.012	0.30	0.02	0.5	0.02	0.5	0.002–0.005	0.05–0.13	5–10

**Stereolithography (SLA).**—Under the action of light energy supplied by a laser beam, individual molecules in a photosensitive liquid resin cross-link into a long-chain molecule to form a solid polymer. Motion of the laser spot is controlled by galvanometer-driven mirrors to trace a two-dimensional (2D) slice of the three-dimensional (3D) CAD model.

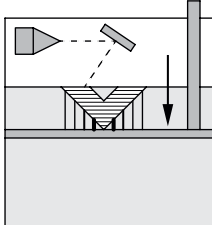

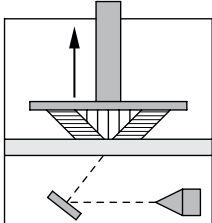

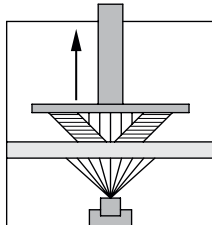

Commonly, the part is built from bottom up, as shown in **Table 2A**. First, the bottom slice of the part is produced on a platform that moves in the vertical direction. The platform is then lowered into a vat of photosensitive liquid resin, by one layer thickness (see **Table 1**). An arm sweeps across the surface to smooth it, and the next slice is traced by the laser. This action sequence is repeated until the part specified by the CAD file is produced.

In a variation of this process, the platform is moved upward, while the laser beam projects from below onto the bottom of a transparent tray containing photosensitive liquid resin, as shown in **Table 2B**. In this case, the top slice of the part is produced first, the build platform moves upward, in one layer thickness, and each new slice is added in a top-down approach. This method initially requires much less resin than the bottom-up approach.

A version of the top-down SLA method, shown in **Table 2C**, uses a digital light processor (DLP) to convert each layer of liquid resin into a solid 2D slice with a flash of light; this sequence is repeated until each slice of the 3D part is produced. The DLP consists of millions of tiny, movable micro-mirrors, whose tilt angles are individually computer controlled to reflect a single light source toward or away from the layer of resin. Those mirrors tilted toward the resin solidify the entire shape at once, while those tilted away reflect light onto a nonreflecting surface.

In all SLA approaches, support structures are printed with the part to support overhanging sections of the part that otherwise would sag under gravity. Supports are removed from the finished part and the affected surfaces smoothed, though SLA produces the smoothest finish of all plastic 3D printing processes. It also produces the most accurate parts (approximately 0.002 in. or 0.05 mm) of the 3D printing processes. With SLA's ability to produce parts with high resolution and good surface finish, this process is suitable for functional prototypes of mechanisms, patterns for fine investment casting (such as jewelry), and form-and-fit models.

**Table 2. Three Configurations of the Stereolithography (SLA) Process**

 <p style="text-align: center;">A</p>	<p>(a) <i>Bottom-up build by SLA with ultraviolet (UV) laser projecting from above:</i> The build platform descends into a vat of photosensitive polymer, one layer at a time. A UV laser scans the cross section of the part on the top surface. As the laser moves across this surface, it solidifies the polymer, incrementally transforming each slice of the model into a layer of the 3D part.</p>
 <p style="text-align: center;">B</p>	<p>(b) <i>Top-down build by SLA with UV laser projecting from below:</i> The build platform moves upward, one layer at a time, over a build tray containing photosensitive polymer. A UV laser scans the cross section of the part through the transparent base of the build tray. As the laser moves across and projects through the build tray, it solidifies the polymer, incrementally transforming each slice of the model into a layer of the 3D part.</p>
 <p style="text-align: center;">C</p>	<p>(c) <i>Top-down build by SLA with digital light projector (DLP) projecting from below:</i> The build platform moves upward, one layer at a time, over a build tray containing photosensitive polymer. A DLP projects through the transparent base of the build tray. As the DLP projects the complete shape of each slice on the build tray, it solidifies the polymer, transforming the slice of the model into a layer of the 3D part all at once.</p>

**Selective Laser Sintering (SLS).**—In this powder-bed layered process, parts are built within a build box on a build plate that moves vertically. First, a thin layer of polymer powder is spread on the build plate by a roller, blade, or hopper. Then an infrared laser travels across the surface, guided by galvanometer-driven mirrors (as in the bottom-up SLA process described earlier) and traces the 2D layer of the 3D part to be produced. Polymer powders within the laser spot are heated and fused together by sintering. Thus, thermoplastic materials are used in SLS processes.

The build plate is moved down by one layer thickness (see Table 1) and a new layer of powder is spread, followed by the laser trace. This sequence is repeated until the 3D part is completed. Unused powder is removed from the build box, the part is brushed off to remove residual powder, and the unused powder is saved for reuse (supplemented by new powder) in future builds.

Unprinted powder provides support for powder bonded by the laser, so supports are not added to parts produced using SLS printers. As a result, material is not wasted in supports, and multiple layers of parts can be produced in one build, improving productivity of SLS

machines. SLS parts have a rougher surface finish than SLA parts, and feature resolution is less. Applications of SLS include functional prototypes, design evaluation models, short-run bridge production, and casting patterns.

**Fused Deposition Modeling (FDM).**—Also called *material extrusion*, this process involves feeding a thermoplastic filament from a coil into a heated nozzle, which melts the plastic and extrudes it into a fine filament, typically 0.004 in. (0.102 mm) in diameter (Fig. 1). The nozzle is attached to a precision XYZ motion system that traces the first 2D layer, as defined by the sliced CAD file, onto a platform. The platform then moves down one layer thickness, and the next layer is traced; this process is repeated until the defined model is completed.

Since the extruded plastic is soft, it requires supports, extending from the build platform upward to any overhangs of the part; after the part is completed and separated from the build platform, supports are easily broken off. Because the part is made of extruded filaments, the surface will be bumpy. Surface finishing can be accomplished by sanding or exposing the part to boiling acetone, which dissolves the surface slightly and allows it to reflow to a smooth finish.

Fig. 1. Fused Deposition Modeling (FDM) Process

FDM machines are the least expensive plastics prototyping machines because they do not involve a laser and the heated extrusion head is widely available. Filaments for FDM are readily made by extrusion of thermoplastic feedstocks. Some feedstocks include reinforcing particles of glass or chopped graphite fiber, adding strength to printed parts.

One FDM method uses two nozzles and can produce multicolored parts. Or one of the nozzles can extrude a water-soluble support material that can be removed easily by soaking parts in water, reducing post-processing labor.

Another FDM process includes a separate nozzle for inserting continuous fibers of graphite, fiberglass, or Kevlar. This type of machine produces parts with selective reinforcement in high-stress areas.

Applications for FDM are based on its low cost but limited resolution. These include proof-of-concept models, low-cost prototyping, sand casting patterns, and jigs and fixtures. Because of its low cost, FDM has brought AM to a large number of nontechnical users, such as hobbyists, experimenters, and model-makers. In addition, FDM machines have provided a convenient and low-cost vehicle for introduction of students at all levels to the basic concepts of design and manufacturing.

**Binder Jetting (BJ).**—In this process, a layer of powder is spread on a build plate in a build box, similar to SLS. However, instead of bonding powder by sintering with the heat of an infrared laser, droplets of binder are jetted from a printhead, with thousands of jets, as it passes over the powder layer, creating a 2D layer. After each pass, the build platform is lowered by one layer thickness, a new layer of powder is spread, and the print head passes over the new layer. This process is repeated until the complete 3D part is produced.

Binder droplets can be thought of as dots that combine to produce each slice of the CAD file. The binder not only bonds particles within each droplet, it also bonds each dot to its neighbors and penetrates to the slice below to ensure strength for subsequent handling. Because the droplet mass is negligible, bonded powder particles have the same density as unbonded particles, and supports are not required. The finished part is removed from the build box, and the unbonded powder is removed and reused. Starch or plaster powder is commonly used in binder jetting. To add strength to the part, it may be infiltrated or painted with epoxy and cured.

**Material Jetting (MJ).**—Something of a hybrid process, material jetting involves printing fine droplets of light-curable resin onto a build plate. Immediately after the printhead deposits the resin droplets, a light bar passes over the build plate, solidifying the resin in a polymerization process similar to SLA, producing thermoset plastics. Overhangs require supports to prevent sagging of solidified material.

Some advanced versions of MJ involve multiple printheads; each one can be set up to jet a different resin. Various resins harden into solid polymers of different color and hardness. As a result, material jetting can be used to produce product prototypes and parts with varying material properties, such as a toothbrush with a rigid handle, soft grip, and stiff bristles.

**Multijet Fusion (MJF).**—A powder bed fusion process like binder jetting, multijet fusion uses two types of binders for selective fusion. A layer of plastic powder is spread, a printhead deposits the two binders, and intense infrared radiation is applied to the layer. One binder is a dark color that absorbs infrared radiation and fuses the polymer particles together; it is deposited by multiple jets where the part is to be made. The second, lighter binder, which prevents fusion, is deposited in other areas to provide sharp definition of part boundaries and features. MJF produces highly accurate parts and is useful for prototype development and form-and-fit models.

### AM Considerations for Tooling and Parts

All plastic AM processes build parts layer by layer. This characteristic enables production of much more complex shapes than can be made by conventional machining, casting and molding, or other forming operations. Because AM processes do not involve forming tools, overhangs and re-entrant corners can be produced readily. In addition, internal cavities and channels that are neither round nor straight are feasible—overcoming limitations of conventional drilling.

On the other hand, the per-part cost of AM parts is greater than that of conventional mass production processes. The cost of powder or filament feedstocks is higher than the same materials in conventional form, and the processes are much slower than conventional processes. These advantages and limitations are illustrated as cost break-even points in [Fig. 30a](#) and [Fig. 30b](#) in *Additive Manufacturing Workflow* on page 1555.

A major application that fits within these limits is production of tooling for conventional processes. Applications include jigs and fixtures for machining, grinding, and welding; dimension-checking fixtures and gages for quality control; masking and non-marring of critical surfaces; organizing tools; and robotic end effectors. In addition, high-strength AM plastic dies are used for short-run thermoforming and injection molding. Composite layup tools and sand casting patterns also are produced economically by plastic AM processes.

Probably the most widely used AM tooling application is in fixtures for dimensioning first production articles and/or for periodic checks. Such fixtures normally are CNC machined from aluminum or assembled from machined aluminum segments, but in most cases, the strength of aluminum is not required. Furthermore, fixtures can be produced by the FDM process in a day or two, rather than the far longer lead time required for CNC programming and production or assembly.

An example of the benefits of AM for fixtures is shown by a fixture needed for dimension and distortion measurement of investment casting for a household sweeper. Fabricating the fixture using a CNC machine would require delivery time of four weeks and cost \$450 if it were made from aluminum, \$350 if made from high-density polyethylene (HDPE). Producing the part from ABS plastic by FDM cost \$50 and was delivered in one day.

Similar savings of time and money are realized in AM production of plastic assembly jigs. For example, AM is being used on automotive assembly lines to produce low-run parts, such as jigs for emblem or medallion attachment.

While AM processes and procedures currently are not capable of economically producing the large numbers of components needed for full-scale automotive production, rapid evolution of AM processes and procedures will soon lead to mass (or *serial*) production of small parts. In the meantime, AM is being used in the automotive industry to produce customized features, such as whimsical front-end “face” coverings, with shark skin, dimple, and whisker details. Race car and other custom shops have used AM for many years to produce custom spoilers for wind tunnel testing, vents to enhance engine performance, and other specialized parts. AM also is used to make parts such as air intakes and fender vents for luxury automobiles. For vintage vehicles, from cars to airplanes, AM software and systems can scan, analyze, and replicate outdated replacement parts. For this purpose, in addition to making plastic parts directly, plastic-based AM processes also are used to produce tooling for other manufacturing processes.

Such applications of plastic AM include making patterns and molds for metal and composite casting and molding, as well as dies for sheet metal forming processes. FDM, SLS, and MJ processes can be used to produce thermoforming dies in much less time than machining aluminum (see *Sheet Thermoforming* on page 584). One of the most visible applications is the use of SLA to print custom molds for thermoforming of Invisalign dental braces.

Plastic tooling made by AM processes has enough strength to be used for forming simple shapes in sheet metal. In one case, a nose gear failure during landing on an aircraft carrier at sea damaged two sheet metal parts in the nose of the plane, removing it from service. Replacement parts were not available, so two forming dies, used for forming such replacement sheet metal parts, were made by FDM at a seaside base and then flown to the carrier at sea. The aircraft was repaired and in service within a week, instead of waiting longer to receive replacement parts from the original equipment manufacturer or aftermarket parts supplier.

SLA, FDM, and MJ processes also are used to produce injection molding tools for short runs between 100 and 1,000 parts (see *Sheet Thermoforming* on page 584). A major advantage of making injection molding tools by AM processes is that conformal internal cooling channels can be printed into tools. Because the cooling channels have the same profile as the tool, heat is removed from the part rapidly and uniformly, reducing injection molding cycle time and improving quality by practically eliminating warping of molded parts.

Patterns for sandcasting are being made by FDM to shorten time to mold production. While patterns are commonly made by machining aluminum or composition, using FDM reduces delivery time from weeks to days. The pattern materials must resist the heavy pressures and abrasion of sand impact during mold compaction around the pattern and be impervious to the binding agents and mold-release chemicals used in casting (see *Patterns* on page 1498). ABS and Ultem patterns produced on FDM machines meet these conditions. Printed patterns may be sanded, smoothed by acetone treatment, or sealed with epoxy to provide a smoother finish.

Plastic AM is also used to produce patterns for investment casting (see *Precision Investment Casting* on page 1504). Patterns are produced by SLA, SLS, and FDM processes, and then used in the conventional investment casting sequence of coating the pattern with plaster or refractory materials, melting or burning out the pattern material, and pouring liquid metal into the mold. Plastics have been developed for this purpose that leave very

small amounts of ash to contaminate the investment casting. In addition, because loads on patterns for investment casting are low, the patterns are made in the form of a shell with a honeycomb internal structure, reducing the amount of material in the pattern.

Tooling for composite layups is increasingly being made by FDM because of their rapid turnaround. Various approaches are used to heat and pressurize the composite layers into a finished part, such as a blade for a wind turbine. (See *Reinforced Plastics* on page 587 for curing practices used in plastic composite forming.) ABS and PC can withstand curing process temperatures up to 270°F (132°C) and pressures up to 100 psi (690 kPa). For greater temperatures and pressures, FDM tools made from ULTEM 1010 are used.

Some of the largest parts made by AM processes are composite layup tools using the FDM process with filament containing chopped graphite fibers. Use of such filament drastically reduces thermal distortion and sagging during production of large parts. The largest of these 3D printers has a production envelope of length, width, and height, respectively, of 20 by 7.5 by 6 feet (6 by 2.3 by 1.8 meters). This process supports segmented printing of prototype vehicles and even building parts.

Production of parts by AM is useful in several ways beyond prototyping. In some cases, a duplicate of the actual part can be made by AM and used to set up assembly jigs or inspection fixtures while waiting for the first article from a molding or casting process. In addition, AM parts can be used as a bridge to production by accelerating rapid product changes, enabling short runs to gain market insertion without having to wait for conventional tooling and mass production.

A further use of AM is providing spare parts, particularly for systems near the end of their lifecycle, if their inventory has been depleted. This capability is important for machinery, such as older amusement park rides, that have been in operation for decades. Production of legacy and other on-demand parts on location for defense systems is a similar opportunity.

### DRAFTING PRACTICES

While there are many national standards-based drafting practices throughout the world, three sets of standards practices predominate internationally. These sets of practices include the American National Standards Institute (ANSI); American Society of Mechanical Engineers (ASME); those modeled on standards developed by the International Organization for Standardization (ISO); and to a lesser extent, those based on Japanese Industry Standards (JIS). However since JIS has committed to adopting ISO practices, coverage will be limited to ANSI/ASME practice and select ISO practices where appropriate. In general, there are several ANSI/ASME Standards for use in preparing engineering drawings and related documents.

#### Standard Drafting Practices

**Sizes of Drawing Sheets.**—Recommended trimmed sheet sizes are shown in [Table 1](#). Customary inch sizes are documented in US ANSI/ASME ANSI/Y14.1-2012, are based on commercial letterhead paper ( $8\frac{1}{2} \times 11$  in.), and are in general use throughout the United States. Each successive size beginning with  $8\frac{1}{2} \times 11$  in. (A) is double the size of the previous (except size F). Using sizes based on commercial letterhead paper size, and its multiples, permits filing small prints and folded larger prints in the same commercial standard letter files. For drawings requiring trimmed metric sheets, sizes are based on ANSI/ASME Y14.1M-2012 in the United States and ISO 5457 in other countries. Metric sizes are consistent across US and ISO standards. As with the customary inch sheet sizes, each successive metric size sheet beginning with commercial letterhead paper size A4 is double the previous size also for ease of folding and filing.

Metric sizes are based on the width-to-length ratio of 1 to  $\sqrt{2}$ . Note that the metric size designators increase as the paper decreases in area. Virtually all CAD systems include both inch and metric size paper templates. Most countries outside the United States use metric paper sizes, so for foreign correspondence it is recommended that the metric sheet sizes be used. For additional sizes and details see the respective standards.

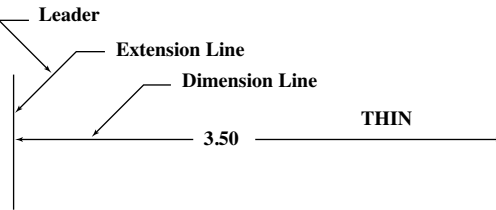

**Table 1. Drawing Sheet Sizes**

US Customary Size, inches (ANSI/ASME Y14.1-2012)				Metric Size, millimeters (ANSI/ASME Y14.1M-2012)			
A	$8\frac{1}{2} \times 11$	D	$22 \times 34$	A4	$210 \times 297$	A1	$594 \times 841$
B	$11 \times 17$	E	$34 \times 44$	A3	$297 \times 420$	A0	$841 \times 1189$
C	$17 \times 22$	F	$28 \times 40$	A2	$420 \times 594$
