Form-Generating Truing Devices	Swiveling diamond holder post with adjustable pivot location, arm length, and swivel arc, mounted on angularly adjustable cross slides with controlled traverse movement, permits the generation of various straight and circular profile elements, kept in specific mutual locations.	Such devices are made in various degrees of complexity for the positionally controlled interrelation of several different profile elements. Limited to regular straight and circular sections, yet offers great flexibility of setup, very accurate adjustment, and unique versatility for handling a large variety of frequently changing profiles.

**Table 1. (Continued) Tools and Methods for Grinding Wheel Dressing and Truing**

Designation	Description	Application
Contour-Duplicating Truing Devices	The form of a master, called cam or template, shaped to match the profile to be produced on the wheel, or its magnified version, is translated into the path of the diamond point by means of mechanical linkage, a fluid actuator, or a pantograph device.	Preferred single-point truing method for profiles to be produced in quantities warranting the making of special profile bars or templates. Used also in small- and medium-volume production when the complexity of the profile to be produced excludes alternate methods of form generation.
Grinding Wheel Contouring by Crush Truing	A hardened steel or carbide roll, which is free to rotate and has the desired form of the workpiece, is fed gradually into the grinding wheel, which runs at slow speed. The roll will, by crushing action, produce its reverse form in the wheel. Crushing produces a free-cutting wheel face with sharp grains.	Requires grinding machines designed for crush truing, having stiff spindle bearings, rigid construction, slow wheel speed for truing, etc. Due to the cost of crush rolls and equipment, the process is used for repetitive work only. It is one of the most efficient methods for precisely duplicating complex wheel profiles that are capable of grinding in the 8- $\mu$ m. (0.2032 $\mu$ m) AA range. Applicable for both surface and cylindrical grinding.
Rotating Diamond Roll-Type Grinding Wheel Truing	Special rolls made to agree with specific profile specifications have their periphery coated with a large number of uniformly distributed diamonds, held in a matrix into which the individual stones are set by hand (for larger diamonds) or bonded by a plating process (for smaller elements).	The diamond rolls must be rotated by an air, hydraulic, or electric motor at about one-fourth of the grinding wheel surface speed and in opposite direction to the wheel rotation. Whereas the initial costs are substantially higher than for single-point diamond truing the savings in truing time warrants the method's application in large-volume production of profile-ground components.
Diamond Dressing Blocks	Made as flat blocks for straight wheel surfaces, are also available for radius dressing and profile truing. The working surface consists of a layer of electroplated diamond grains, uniformly distributed and capable of truing even closely toleranced profiles.	For straight wheels, dressing blocks can reduce dressing time and offer easy installation on surface grinders, where the blocks mount on the magnetic plate. Recommended for small- and medium-volume production for truing intricate profiles on regular surface grinders, because the higher pressure developed in crush dressing is avoided.

**Guidelines for Dressing and Truing with Single-Point Diamonds.**—The diamond nib should be canted at an angle of 10 to 15 degrees in the direction of the wheel rotation and also, if possible, by the same amount in the direction of the cross feed traverse during the truing (see diagram). The dragging effect resulting from this “angling,” combined with the occasional rotation of the diamond nib in its holder, will prolong the diamond life by limiting the extent of wear facets and will also tend to produce a pyramid shape of the diamond tip. The diamond may also be set to contact the wheel at about  $\frac{1}{8}$  to  $\frac{1}{4}$  inch (3.2–6.4 mm) below its centerline.

**Depth of Cut:** This amount should not exceed 0.001 inch (0.025 mm) per pass for general work, and will have to be reduced to 0.0002 to 0.0004 inch (0.005–0.010 mm) per pass for wheels with fine grains used for precise finishing work.

**Diamond crossfeed rate:** This value may be varied to some extent depending on the required wheel surface: faster crossfeed for free cutting, and slower crossfeed for

producing fine finishes. Such variations, however, must always stay within the limits set by the grain size of the wheel. Thus, the advance rate of the truing diamond per wheel revolution should not exceed the diameter of a grain or be less than half of that rate. Consequently, the diamond crossfeed must be slower for a large wheel than for a smaller wheel having the same grain size number. Typical crossfeed values for frequently used grain sizes are given in Table 2.

**Table 2. Typical Diamond Truing and Crossfeeds**

Grain Size	Crossfeed per Wheel Rev.		Grain Size	Crossfeed per Wheel Rev.	
	inch	mm		inch	mm
30	0.014–0.024	0.35–0.61	60	0.006–0.010	0.15–0.25
36	0.012–0.019	0.30–0.48	80	0.004–0.007	0.10–0.18
46	0.008–0.014	0.20–0.35	120	0.0025–0.004	0.06–0.10
50	0.007–0.012	0.18–0.30	...	...	...

These values can be easily converted into the more conveniently used inch-per-minute units, simply by multiplying the crossfeed rate in inches by the rpm of the grinding wheel.

*Example:* For a 20-inch diameter wheel, Grain No. 46, running at 1200 rpm: Crossfeed rate for roughing-cut truing, approximately 17 ipm; for finishing-cut truing, approximately 10 ipm.

*Coolant* should be applied before the diamond comes into contact with the wheel and must be continued in generous supply while truing.

*The speed of the grinding wheel* should be at the regular grinding rate, or not much lower. For that reason, the feed wheels of centerless grinding machines usually have an additional speed rate higher than functionally needed, that speed being provided for wheel truing only.

*The initial approach of the diamond* to the wheel surface must be carried out carefully to prevent sudden contact with the diamond, resulting in penetration in excess of the selected depth of cut. It should be noted that the highest point of a worn wheel is often in its center portion and not at the edge from which the crossfeed of the diamond starts.

*The general conditions* of the truing device are important for best truing results and for assuring extended diamond life. A rigid truing spindle, well-seated diamond nib, and firmly set diamond point are mandatory. Sensitive infeed and smooth traverse movement at uniform speed also must be maintained.

*Resetting of the diamond point.* Never let the diamond point wear to a degree where the grinding wheel is in contact with the steel nib. Such contact can damage the setting of the diamond point and result in its loss. Expert resetting of a worn diamond can repeatedly add to its useful life, even when applied to lighter work because of reduced size.

**Size Selection Guide for Single-Point Truing Diamonds.**—There are no rigid rules for determining the proper size of the diamond for any particular truing application because of the very large number of factors affecting that choice. Several of these factors are related to the condition, particularly the rigidity, of the grinding machine and truing device, as well as to such characteristics of the diamond itself as purity, crystalline structure, etc. Although these factors are difficult to evaluate in a generally applicable manner, the expected effects of several other conditions can be appraised and should be considered in the selection of the proper diamond size.

The recommended sizes in [Table 3](#) must be considered as informative only and as representing minimum values for generally favorable conditions. Factors calling for larger diamond sizes than listed are the following:

Silicon carbide wheels ([Table 3](#) refers to aluminum oxide wheels)

Dry truing

Grain sizes coarser than No. 46

Bonds harder than M

Wheel speed substantially higher than 6500 sfm (1981 m/min).

It is advisable to consider any single or pair of these factors as justifying the selection of one size larger diamond. As an example: for truing an SiC wheel, with grain size No. 36 and hardness P, select a diamond that is two sizes larger than that shown in [Table 3](#) for the wheel size in use.

**Table 3. Recommended Minimum Sizes for Single-Point Truing Diamonds**

Diamond Size in Carats <sup>a</sup>	Index Number (Wheel Dia. × Width, Inches)	Examples of Max. Grinding Wheel Dimensions (inches)	
		Diameter	Width
0.25	3	4	0.75
0.35	6	6	1
0.50	10	8	1.25
0.60	15	10	1.50
0.75	21	12	1.75
1.00	30	12	2.50
1.25	48	14	3.50
1.50	65	16	4.00
1.75	80	20	4.00
2.00	100	20	5.00
2.50	150	24	6.00
3.00	200	24	8.00
3.50	260	30	8.00
4.00	350	36	10.00

<sup>a</sup> One carat equals 0.2 gram.

Single-point diamonds are available as loose stones, but are preferably procured from specialized manufacturers supplying the diamonds set into steel nibs. Expert setting, comprising both the optimum orientation of the stone and its firm retainment, is mandatory for assuring adequate diamond life and satisfactory truing. Because the holding devices for truing diamonds are not yet standardized, the required nib dimensions vary depending on the make and type of different grinding machines. Some nibs are made with angular heads, usually hexagonal, to permit occasional rotation of the nib either manually, with a wrench, or automatically.

### Diamond Wheels

**Diamond Wheels.**—A diamond wheel is a special type of grinding wheel in which the abrasive elements are diamond grains held in a bond and applied to form a layer on the operating face of a non-abrasive core. Diamond wheels are used for grinding very hard or highly abrasive materials. Primary applications are the grinding of cemented carbides, such as the sharpening of carbide cutting tools; the grinding of glass, ceramics, asbestos, and cement products; and the cutting and slicing of germanium and silicon.

**Shapes of Diamond Wheels.**—The industry-wide accepted Standard (ANSI B74.3-2003 (R2014)) specifies ten basic diamond wheel core shapes which are shown in Table 1 with the applicable designation symbols. The applied diamond abrasive layer may have different cross-sectional shapes. Those standardized are shown in Table 2. The third aspect which is standardized is the location of the diamond section on the wheel as shown by the diagrams in Table 3. Finally, modifications of the general core shape together with pertinent designation letters are given in Table 4.

The characteristics of the wheel shape listed in these four tables make up the components of the standard designation symbol for diamond wheel shapes. An example of that symbol with arbitrarily selected components is shown in Fig. 1.

Fig. 1. A Typical Diamond Wheel Shape Designation Symbol

An explanation of these components is as follows:

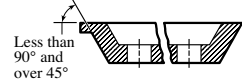

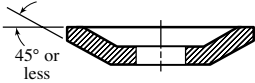

**Basic Core Shape:** This portion of the symbol indicates the basic shape of the core on which the diamond abrasive section is mounted. The shape is actually designated by a number. The various core shapes and their designations are given in Table 1.

**Diamond Cross-Sectional Shape:** This, the second component, consisting of one or two letters, denotes the cross-sectional shape of the diamond abrasive section. The various shapes and their corresponding letter designations are given in Table 2.

**Diamond Section Location:** The third component of the symbol consists of a number which gives the location of the diamond section, i.e., periphery, side, corner, etc. An explanation of these numbers is shown in Table 3.

**Modification:** The fourth component of the symbol is a letter designating some modification, such as drilled and counterbored holes for mounting or special relieving of diamond section or core. This modification position of the symbol is used only when required. The modifications and their designations are given in Table 4.

**Table 1. Diamond Wheel Core Shapes and Designations ANSI B74.3-2003 (R2014)**

 C	 ER	 H	 P	 Y
 CH	 ET	 J	 Q	

**Table 3. Designations for Location of Diamond Section on Diamond Wheel ANSI B74.3-2003 (R2014)**

Designation No. and Location	Description	Illustration
1 — Periphery	The diamond section shall be placed on the periphery of the core and shall extend the full thickness of the wheel. The axial length of this section may be greater than, equal to, or less than the depth of diamond, measured radially. A hub or hubs shall not be considered as part of the wheel thickness for this definition.	
2 — Side	The diamond section shall be placed on the side of the wheel and the length of the diamond section shall extend from the periphery toward the center. It may or may not include the entire side and shall be greater than the diamond depth measured axially. It shall be on that side of the wheel which is commonly used for grinding purposes.	
3 — Both Sides	The diamond sections shall be placed on both sides of the wheel and shall extend from the periphery toward the center. They may or may not include the entire sides, and the radial length of the diamond section shall exceed the axial diamond depth.	
4 — Inside Bevel or Arc	This designation shall apply to the general wheel types 2, 6, 11, 12, and 15 and shall locate the diamond section on the side wall. This wall shall have an angle or arc extending from a higher point at the wheel periphery to a lower point toward the wheel center.	
5 — Outside Bevel or Arc	This designation shall apply to the general wheel types 2, 6, 11, and 15 and shall locate the diamond section on the side wall. This wall shall have an angle or arc extending from a lower point at the wheel periphery to a higher point toward the wheel center.	
6 — Part of Periphery	The diamond section shall be placed on the periphery of the core but shall not extend the full thickness of the wheel and shall not reach to either side.	
7 — Part of Side	The diamond section shall be placed on the side of the core and shall not extend to the wheel periphery. It may or may not extend to the center.	
8 — Throughout	Designates wheels of solid diamond abrasive section without cores.	

**Table 3.** (Continued) Designations for Location of Diamond Section on Diamond Wheel ANSI B74.3-2003 (R2014)

Designation No. and Location	Description	Illustration
9 — Corner	Designates a location which would commonly be considered to be on the periphery except that the diamond section shall be on the corner but shall not extend to the other corner.	
10 — Annular	Designates a location of the diamond abrasive section on the inner annular surface of the wheel.	

**Composition of Diamond and Cubic Boron Nitride Wheels.**— According to American National Standard ANSI B74.13-2016, a series of symbols is used to designate the composition of these wheels. An example is shown below.

Prefix	Abrasive	Grain Size	Grade	Concentration	Bond Type	Bond Modification	Depth of Abrasive	Manufacturer's Identification Symbol
<b>M</b>	<b>D</b>	<b>120</b>	<b>R</b>	<b>100</b>	<b>B</b>	<b>56</b>	$\frac{1}{8}$	<b>*</b>

Fig. 2. Designation Symbols for Composition of Diamond and Cubic Boron Nitride Wheels

The meaning of each symbol is indicated by the following list:

1) *Prefix*: The prefix is a manufacturer's symbol indicating the exact kind of abrasive. Its use is optional.

2) *Abrasive Type*: The letter (B) is used for cubic boron nitride and (D) for diamond.

3) *Grain Size*: The grain sizes commonly used and varying from coarse to very fine are indicated by the following numbers: 8, 10, 12, 14, 16, 20, 24, 30, 36, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 220. The following additional sizes are used occasionally: 240, 280, 320, 400, 500, and 600. The wheel manufacturer may add to the regular grain number an additional symbol to indicate a special grain combination.

4) *Grade*: Grades are indicated by letters of the alphabet from A to Z in all bonds or processes. Wheel grades from A to Z range from soft to hard.

5) *Concentration*: The concentration symbol is a manufacturer's designation. It may be a number or a symbol.

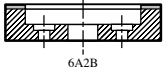

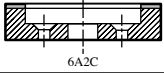

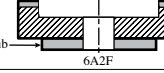

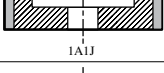

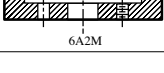

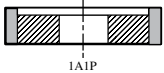

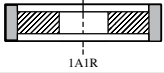

6) *Bond*: Bonds are indicated by the following letters: B, resinoid; V, vitrified; M, metal.

7) *Bond Modification*: Within each bond type a manufacturer may have modifications to tailor the bond to a specific application. These modifications may be identified by either letters or numbers.

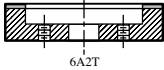

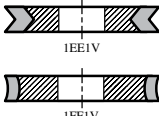

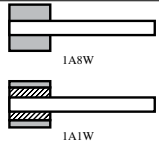

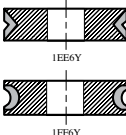

8) *Abrasive Depth*: Abrasive section depth, in inches or millimeters (inches illustrated), is indicated by a number or letter which is the amount of total dimensional wear a user may expect from the abrasive portion of the product. Most diamond and CBN wheels are made with a depth of coating on the order of  $\frac{1}{16}$  in.,  $\frac{1}{8}$  in., (1.6 mm, 3.2 mm) or more as specified. In some cases the diamond is applied in thinner layers, as thin as one thickness of diamond grains. The L is included in the marking system to identify a layered type product.

9) *Manufacturer's Identification Symbol*: The use of this symbol is optional.

**Table 4. Designation Letters for Modifications of Diamond Wheels**  
ANSI B74.3-2003 (R2014)

Designation Letter	Description	Illustration
B — Drilled and Counterbored	Holes drilled and counterbored in core.	 6A2B
C — Drilled and Countersunk	Holes drilled and countersunk in core.	 6A2C
F — Hub	Hub on basic wheel cover	 6A2F Hub
H — Plain Hole	Straight hole drilled in core.	 6A2H
J — Recess One Side		 1A1J
JJ — Recess Two Sides		 1A1JJ
K — Keyway	Arbor hole with keyway	 6A2K
M — Holes Plain and Threaded	Mixed holes, some plain, some threaded, are in core.	 6A2M
N — Nonsteel Core	Nonsteel core for 1A1R and related shapes	
P — Relieved One Side	Core relieved on one side of wheel. Thickness of core is less than wheel thickness.	 1A1P
R — Relieved Two Sides	Core relieved on both sides of wheel. Thickness of core is less than wheel thickness.	 1A1R
S — Segmented-Diamond Section	Wheel has segmental diamond section mounted on core. (Clearance between segments has no bearing on definition.)	 1A1S
SS — Segmental and Slotted	Wheel has separated segments mounted on a slotted core.	 1A1SS

**Table 4. (Continued) Designation Letters for Modifications of Diamond Wheels**  
ANSI B74.3-2003 (R2014)

Designation Letter	Description	Illustration
T — Threaded Holes	Threaded holes are in core.	 6A2T
Q — Diamond Inserted	Three surfaces of the diamond section are partially or completely enclosed by the core.	 1A6Q
V — Diamond Inverted	Any diamond cross section that is mounted on the core so that the interior point of any angle, or the concave side of any arc, is exposed shall be considered inverted. <i>Exception:</i> Diamond cross section AH shall be placed on the core with the concave side of the arc exposed.	 1EE1V 1FF1V
W — Wheels Affixed on a Mandrel		 1A8W 1A1W
Y — Diamond Inserted and Inverted	See definitions for Q and V.	 1EE6Y 1FF6Y

**The Selection of Diamond Wheels.**—Two general aspects must be defined: (a) The shape of the wheel, also referred to as the basic wheel type and (b) The specification of the abrasive portion.

**Table 5. General Diamond Wheel Recommendations for Wheel Type and Abrasive Specification**

Typical Applications or Operation	Basic Wheel Type	Abrasive Specification	
Single Point Tools (offhand grinding)	D6A2C	<i>Rough:</i>	MD100-N100-B $\frac{1}{4}$
		<i>Finish:</i>	MD220-P75-B $\frac{1}{4}$
Single Point Tools (machine ground)	D6A2H	<i>Rough:</i>	MD180-J100-B $\frac{1}{4}$
		<i>Finish:</i>	MD320-L75-B $\frac{1}{4}$
Chip Breakers	D1A1		MD150-R100-B $\frac{1}{4}$
Multitooth Tools and Cutters (face mills, end mills, reamers, broaches, etc.)	D11V9	<i>Rough:</i>	MD100-R100-B $\frac{1}{4}$
Sharpening and Backing off		<i>Combination:</i>	MD150-R100-B $\frac{1}{4}$
		<i>Finish:</i>	MD220-R100-B $\frac{1}{4}$
Fluting	D12A2		MD180-N100-B $\frac{1}{4}$
Saw Sharpening	D12A2		MD180-R100-B $\frac{1}{4}$
Surface Grinding (horizontal spindle)	D1A1	<i>Rough:</i>	MD120-N100-B $\frac{1}{4}$
		<i>Finish:</i>	MD240-P100-B $\frac{1}{4}$
Surface Grinding (vertical spindle)	D2A2T		MD80-R75-B $\frac{1}{4}$

**Table 5.** (Continued) **General Diamond Wheel Recommendations for Wheel Type and Abrasive Specification**

Typical Applications or Operation	Basic Wheel Type	Abrasive Specification
Cylindrical or Centertype Grinding	D1A1	MD120-P100-B $\frac{1}{4}$
Internal Grinding	D1A1	MD150-N100-B $\frac{1}{4}$
Slotting and Cutoff	D1AIR	MD150-R100-B $\frac{1}{4}$
Lapping	Disc	MD400-L50-B $\frac{1}{4}$
Hand Honing	DH1, DH2	<i>Rough:</i> MD220-B $\frac{1}{4}$ <i>Finish:</i> MD320-B $\frac{1}{4}$

General recommendations for the dry grinding, with resin bond diamond wheels, of most grades of cemented carbides of average surface to ordinary finishes at normal rates of metal removal with average size wheels, as published by Cincinnati Milacron, are listed in [Table 5](#).

A further set of variables are the *dimensions of the wheel*, which must be adapted to the available grinding machine and, in some cases, to the configuration of the work.

The general abrasive specifications in [Table 5](#) may be modified to suit operating conditions by the following suggestions:

- Use softer wheel grades for harder grades of carbides, for grinding larger areas or larger or wider wheel faces.
- Use harder wheel grades for softer grades of carbides, for grinding smaller areas, for using smaller and narrower face wheels and for light cuts.
- Use fine grit sizes for harder grades of carbides and to obtain better finishes.
- Use coarser grit sizes for softer grades of carbides and for roughing cuts.
- Use higher diamond concentration for harder grades of carbides, for larger diameter or wider face wheels, for heavier cuts, and for obtaining better finish.

**Guidelines for the Handling and Operation of Diamond Wheels.**—Grinding machines used for grinding with diamond wheels should be of the precision type, in good service condition, with true running spindles and smooth slide movements.

*Mounting of Diamond Wheels:* Wheel mounts should be used which permit the precise centering of the wheel, resulting in a runout of less than 0.001 inch (0.0254 mm) axially and 0.0005 inch (0.0127 mm) radially. These conditions should be checked with a 0.0001-inch (0.001 mm) type dial indicator. Once mounted and centered, the diamond wheel should be retained on its mount and stored in that condition when temporarily removed from the machine.

*Truing and Dressing:* Resinoid bonded diamond wheels seldom require dressing, but when necessary a soft silicon carbide stick may be hand-held against the wheel. Peripheral and cup type wheels may be sharpened by grinding the cutting face with a 60 to 80 grit silicon carbide wheel. This can be done with the diamond wheel mounted on the spindle of the machine, and with the silicon carbide wheel driven at a relatively slow speed by a specially designed table-mounted grinder or by a small table-mounted tool post grinder. The diamond wheel can be mounted on a special arbor and ground on a lathe with a tool post grinder; peripheral wheels can be ground on a cylindrical grinder or with a special brake-controlled truing device with the wheel mounted on the machine on which it is used. Cup and face type wheels are often lapped on a cast iron or glass plate using a 100 grit silicon carbide abrasive. Care must be used to lap the face parallel to the back, otherwise they must be ground to restore parallelism. Peripheral diamond wheels can be trued and dressed by grinding a silicon carbide block or a special diamond impregnated bronze block in a manner similar to surface grinding. Conventional diamonds must not be used for truing and dressing diamond wheels.

**Speeds and Feeds in Diamond Grinding.**—General recommendations are as follows:

*Wheel Speeds:* The generally recommended wheel speeds for diamond grinding are in the range of 5000 to 6000 surface feet per minute (1525–1830 m/min), with this upper limit as a maximum to avoid harmful “overspeeding.” Exceptions from that general rule are diamond wheels with coarse grains and high concentration (100 percent) where the wheel wear in dry surface grinding can be reduced by lowering the speed to 2500–3000 sfpm (760–915 m/min). However, this lower speed range can cause rapid wheel breakdown in finer grit wheels or in those with reduced diamond concentration.

**Work Speeds:** In diamond grinding, work rotation and table traverse are usually established by experience, adjusting these values to the selected infeed so as to avoid excessive wheel wear.

**Infeed per Pass:** Often referred to as downfeed and usually a function of the grit size of the wheel. The following are general values which may be increased for raising the productivity, or lowered to improve finish or to reduce wheel wear.

Wheel Grit Size Range	Infeed per Pass
100 to 120	0.001 inch (0.025 mm)
150 to 220	0.0005 inch (0.013 mm)
250 and finer	0.00025 inch (0.006 mm)

### Grinding Wheel Safety

**Safety in Operating Grinding Wheels.**—Grinding wheels, although capable of exceptional cutting performance due to hardness and wear resistance, are prone to damage caused by improper handling and operation. Vitrified wheels, comprising the major part of grinding wheels used in industry, are held together by an inorganic bond which is actually a type of pottery product and therefore brittle and breakable. Although most of the organic bond types are somewhat more resistant to shocks, it must be realized that all grinding wheels are conglomerates of individual grains joined by a bond material whose strength is limited by the need of releasing the dull, abrasive grains during use.

It must also be understood that during the grinding process very substantial forces act on the grinding wheel, including the centrifugal force due to rotation, the grinding forces resulting from the resistance of the work material, and shocks caused by sudden contact with the work. To be able to resist these forces, the grinding wheel must have a substantial minimum strength throughout that is well beyond that needed to hold the wheel together under static conditions.

Finally, a damaged grinding wheel can disintegrate during grinding, liberating dormant forces which normally are constrained by the resistance of the bond, thus presenting great hazards to both operator and equipment.

To avoid breakage of the operating wheel and, should such a mishap occur, to prevent damage or injury, specific precautions must be applied. These safeguards have been formulated into rules and regulations and are set forth in the American National Standard ANSI B7.1-2017, entitled the American National Standard Safety Requirements for the Use, Care, and Protection of Abrasive Wheels.

**Handling, Storage and Inspection.**—Grinding wheels should be hand carried, or transported, with proper support, by truck or conveyor. A grinding wheel must not be rolled around on its periphery.

The storage area, positioned not far from the location of the grinding machines, should be free from excessive temperature variations and humidity. Specially built racks are recommended on which the smaller or thin wheels are stacked lying on their sides and the larger wheels in an upright position on two-point cradle supports consisting of appropriately spaced wooden bars. Partitions should separate either the individual wheels, or a small group of identical wheels. Good accessibility to the stored wheels reduces the need of undesirable handling.

Inspection will primarily be directed at detecting visible damage, mostly originating from handling and shipping. Cracks which are not obvious can usually be detected by "ring testing," which consists of suspending the wheel from its hole and tapping it with a non-metallic implement. Heavy wheels may be allowed to rest vertically on a clean, hard floor while performing this test. A clear metallic tone, a "ring", should be heard; a dead sound being indicative of a possible crack or cracks in the wheel.

**Machine Conditions.**—The general design of the grinding machines must ensure safe operation under normal conditions. The bearings and grinding wheel spindle must be dimensioned to withstand the expected forces and ample driving power should be provided to ensure maintenance of the rated spindle speed. For the protection of the operator, stationary machines used for dry grinding should have a provision made for connection to an exhaust system and when used for off-hand grinding, a work support must be available.

Wheel guards are particularly important protection elements and their material specifications, wall thicknesses and construction principles should agree with the Standard's specifications. The exposure of the wheel should be just enough to avoid interference with the grinding operation. The need for access of the work to the grinding wheel will define the boundary of guard opening, particularly in the direction of the operator.

**Grinding Wheel Mounting.**—The mass and speed of the operating grinding wheel makes it particularly sensitive to imbalance. Vibrations that result from such conditions are harmful to the machine, particularly the spindle bearings, and they also affect the ground surface, i.e., wheel imbalance causes chatter marks and interferes with size control. Grinding wheels are shipped from the manufacturer's plant in a balanced condition, but retaining the balanced state after mounting the wheel is quite uncertain. Balancing of the mounted wheel is thus required, and is particularly important for medium and large size wheels, as well as for producing accurate and smooth surfaces. The most common way of balancing mounted wheels is by using balancing flanges with adjustable weights. The wheel and balancing flanges are mounted on a short balancing arbor, the two concentric and round stub ends of which are supported in a balancing stand.

Such stands are of two types: 1) the parallel straight-edged, which must be set up precisely level; and 2) the disk type having two pairs of ball bearing mounted overlapping disks, which form a V for containing the arbor ends without hindering the free rotation of the wheel mounted on that arbor.

The wheel will then rotate only when it is out of balance and its heavy spot is not in the lowest position. Rotating the wheel by hand to different positions will move the heavy spot, should such exist, from the bottom to a higher location where it can reveal its presence by causing the wheel to turn. Having detected the presence and location of the heavy spot, its effect can be cancelled by displacing the weights in the circular groove of the flange until a balanced condition is accomplished.

Flanges are commonly used means for holding grinding wheels on the machine spindle. For that purpose, the wheel can either be mounted directly through its hole or by means of a sleeve which slips over a tapered section of the machine spindle. Either way, the flanges must be of equal diameter, usually not less than one-third of the new wheel's diameter. The purpose is to securely hold the wheel between the flanges without interfering with the grinding operation even when the wheel becomes worn down to the point where it is ready to be discarded. Blotters or flange facings of compressible material should cover the entire contact area of the flanges.

One of the flanges is usually fixed while the other is loose and can be removed and adjusted along the machine spindle. The movable flange is held against the mounted grinding wheel by means of a nut engaging a threaded section of the machine spindle. The sense of that thread should be such that the nut will tend to tighten as the spindle revolves. In other words, to remove the nut, it must be turned in the direction that the spindle revolves when the wheel is in operation.

**Safe Operating Speeds.**—Safe grinding processes are predicated on the proper use of the previously discussed equipment and procedures, and are greatly dependent on the application of adequate operating speeds.

The Standard establishes maximum speeds at which grinding wheels can be operated, assigning the various types of wheels to several classification groups. Different values are listed according to bond type and to wheel strength, distinguishing between low, medium and high strength wheels.

For the purpose of general information, the accompanying [Table 1](#) shows an abbreviated version of the Standard's specification. However, for the governing limits, the authoritative source is the manufacturer's tag on the wheel which, particularly for wheels of lower strength, might specify speeds below those of the table.

All grinding wheels of 6 inches or greater diameter must be test run in the wheel manufacturer's plant at a speed that for all wheels having operating speeds in excess of 5000 sfpm is 1.5 times the maximum speed marked on the tag of the wheel.

The table shows the permissible wheel speeds in surface feet per minute (sfpm) units, whereas the tags on the grinding wheels state, for the convenience of the user, the maximum operating speed in revolutions per minute (rpm). The sfpm unit has the advantage of remaining valid for worn wheels whose rotational speed may be increased to the applicable sfpm value. The conversion from either one to the other of these two kinds of units is a matter of simple calculation using the formulas:

$$\text{sfpm} = \text{rpm} \times \frac{D}{12} \times \pi \quad \text{or} \quad \text{rpm} = \frac{\text{sfpm} \times 12}{D \times \pi}$$

where  $D$  = maximum diameter of the grinding wheel, in inches. [Table 2](#), showing the conversion values from surface speed into rotational speed, can be used for the direct reading of the rpm values corresponding to several different wheel diameters and surface speeds.

**Special Speeds:** Continuing progress in grinding methods has led to the recognition of certain advantages that can result from operating grinding wheels above, sometimes even higher than twice, the speeds considered earlier as the safe limits of grinding wheel operations. Advantages from the application of high speed grinding are limited to specific processes, but the Standard admits, and offers code regulations for the use of wheels at special high speeds. These regulations define the structural requirements of the grinding machine and the responsibilities of the grinding wheel manufacturers, as well as of the users. High speed grinding should not be applied unless the machines, particularly guards, spindle assemblies, and drive motors, are suitable for such methods. Also, appropriate grinding wheels expressly made for special high speeds must be used and, of course, the maximum operating speeds indicated on the wheel's tag must never be exceeded.

**Portable Grinders.**—The above discussed rules and regulations, devised primarily for stationary grinding machines apply also to portable grinders. In addition, the details of various other regulations, specially applicable to different types of portable grinders are discussed in the Standard, which should be consulted, particularly for safe applications of portable grinding machines.

**Table 1. Maximum Peripheral Speeds for Grinding Wheels (Based on ANSI 7.1-2017)**

Maximum Operating Speeds Depending on Strength of Bond					
Classification No and Types of Wheels <sup>a</sup>		Inorganic Bonds		Organic Bonds	
		sfp/m	m/min	sfp/m	m/min
1	Straight wheels—Type 1, except classifications 6, 9, 11, and 12, 13 and 14 below	5500–8500	1675–2590	6500–9500	1980–2895
	Recessed Wheels—Types 5 and 7 Type 20, 21, 22, 23, 24, 25, 26				
2	Taper Side Wheels—Type 4 <sup>b</sup>	5000–6500	1525–1980	6500–9500	1980–2895
	Dish wheels—Type 12 Saucer wheels—Type 13 Cones and plugs—Types 16, 17, 18, 19 Cylinder wheels—Type 2 Segments				
3	Cup shape tool grinding wheels—Types 6 and 11 (for fixed base machines)	4500–6000	1370–1830	6000–8500	1830–2590
4	Cup shape snagging wheels—Types 6 and 11 (for portable machines)	4500–6500	1370–1980	6000–9500	1830–2895
5	Abrasive disks and Cylinder Type Discs Solid and Segmental	5500–6500	1675–1980	5500–8500	1675–2590
6	Reinforced wheels—except cutting-off wheels (depending on diameter and thickness)	...	...	9500–16000	2895–4875
7	Type 1 wheels for Bench and Pedestal Grinders, Types 1, 5 and 7 also in certain sizes for surface grinders	5500–7550	1675–2300	6500–9500	1980–2895
8	Diamond and cubic boron nitride wheels	to 6500	to 1980	to 9500	to 2895
	Metal bond Steel centered cutting off	... to 16000	to 3660 to 4875	... to 16000	... to 4875
9	Cutting-off wheels—Maximum 4-inch diameter (including reinforced organic)	...	...	14200–20000	4330–6100
	Cutting-off wheels—Maximum 16-inch diameter (including reinforced organic)	...	...	9500–16000	2895–4875
	Cutting-off wheels—Larger than 16-inch diameter (incl. reinforced organic)	...	...	9500–14200	2895–4330
	Non-Reinforced All Diameters	...	...	9500–14200	2895–4330

### Cylindrical Grinding

Cylindrical grinding designates a general category of various grinding methods that have the common characteristic of rotating the workpiece around a fixed axis while grinding outside surface sections in controlled relation to that axis of rotation.

The form of the part or section being ground in this process is frequently cylindrical, hence the designation of the general category. However, the shape of the part may be tapered or of curvilinear profile; the position of the ground surface may also be perpendicular to the axis; and it is possible to grind concurrently several surface sections, adjacent or separated, of equal or different diameters, located in parallel or mutually inclined planes, etc., as long as the condition of a common axis of rotation is satisfied.

*Size Range of Workpieces and Machines:* Cylindrical grinding is applied in the manufacture of miniature parts, such as instrument components and, at the opposite extreme, for grinding rolling mill rolls weighing several tons. Accordingly, there are cylindrical grinding machines of many different types, each adapted to a specific work-size range. Machine capacities are usually expressed by such factors as maximum work diameter, work length and weight, complemented, of course, by many other significant data.

**Plain, Universal, and Limited-Purpose Cylindrical Grinding Machines.**—The plain cylindrical grinding machine is considered the basic type of this general category, and is used for grinding parts with cylindrical or slightly tapered form.

The universal cylindrical grinder can be used, in addition to grinding the basic cylindrical forms, for the grinding of parts with steep tapers, of surfaces normal to the part axis, including the entire face of the workpiece, and for internal grinding independently or in conjunction with the grinding of the part's outer surfaces. Such variety of part configurations requiring grinding is typical of work in the tool room, which constitutes the major area of application for universal cylindrical grinding machines.

Limited-purpose cylindrical grinders are needed for special work configurations and for high-volume production, where productivity is more important than flexibility of adaptation. Examples of limited-purpose cylindrical grinding machines are crankshaft and camshaft grinders, polygonal grinding machines, roll grinders, etc.

**Traverse or Plunge Grinding.**—In traverse grinding, the machine table carrying the work performs a reciprocating movement of specific travel length for transporting the rotating workpiece along the face of the grinding wheel. At each or at alternate stroke ends, the wheel slide advances for the gradual feeding of the wheel into the work. The length of the surface that can be ground by this method is generally limited only by the stroke length of the machine table. In large roll grinders, the relative movement between work and wheel is accomplished by the traverse of the wheel slide along a stationary machine table.

In plunge grinding, the machine table, after having been set, is locked and, while the part is rotating, the wheel slide continually advances at a preset rate, until the finish size of the part is reached. The width of the grinding wheel is a limiting factor of the section length that can be ground in this process. Plunge grinding is required for profiled surfaces and for the simultaneous grinding of multiple surfaces of different diameters or located in different planes.

When the configuration of the part does not make use of either method mandatory, the choice may be made on the basis of the following general considerations: traverse grinding usually produces a better finish, and the productivity of plunge grinding is generally higher.

**Work Holding on Cylindrical Grinding Machines.**—The manner in which the work is located and held in the machine during the grinding process determines the configuration of the part that can be adapted for cylindrical grinding and affects the resulting accuracy of the ground surface. The method of work holding also affects the attainable production rate, because the mounting and dismounting of the part can represent a substantial portion of the total operating time.

Whatever method is used for holding the part on cylindrical types of grinding machines, two basic conditions must be satisfied: 1) the part should be located with respect to its correct axis of rotation; and 2) the work drive must cause the part to rotate, at a specific speed, around the established axis.

The lengthwise location of the part, although controlled, is not too critical in traverse grinding; however, in plunge grinding, particularly when shoulder sections are also involved, it must be assured with great accuracy.

Table 1 presents a listing, with brief discussions, of work-holding methods and devices that are most frequently used in cylindrical grinding.

**Table 1. Work-Holding Methods and Devices for Cylindrical Grinding**

Designation	Description	Discussion
Centers, nonrotating ("dead"), with drive plate	Headstock with nonrotating spindle holds the center. Around the spindle, an independently supported sleeve carries the drive plate for rotating the work. Tailstock for opposite center.	The simplest method of holding the work between two opposite centers is also the potentially most accurate, as long as correctly prepared and located center holes are used in the work.
Centers, driving type	Work held between two centers obtains its rotation from the concurrently applied drive by the live headstock spindle and live tailstock spindle.	Eliminates the drawback of the common center-type grinding with driver plate, which requires a dog attached to the workpiece. Driven spindles permit the grinding of the work up to both ends.
Chuck, geared, or cam-actuated	Two, three, or four jaws moved radially through mechanical elements, hand-, or power-operated, exert concentrically acting clamping force on the workpiece.	Adaptable to workpieces of different configurations and within a generally wide capacity of the chuck. Flexible in uses that, however, do not include high-precision work.
Chuck, diaphragm	Force applied by hand or power of a flexible diaphragm causes the attached jaws to deflect temporarily for accepting the work, which is held when force is released.	Rapid action and flexible adaptation to different work configurations by means of special jaws offer varied uses for the grinding of disk-shaped and similar parts.
Collets	Holding devices with externally or internally acting clamping force, easily adaptable to power actuation, assuring high centering accuracy.	Limited to parts with previously machined or ground holding surfaces, because of the small range of clamping movement of the collet jaws.
Faceplate	Has four independently actuated jaws, any or several of which may be used, or entirely removed, using the base plate for supporting special clamps.	Used for holding bulky parts, or those of awkward shape, which are ground in small quantities not warranting special fixtures.
Magnetic plate	Flat plates, with pole distribution adapted to the work, are mounted on the spindle like chucks and may be used for work with the locating face normal to the axis.	Applicable for light cuts such as are frequent in tool making, where the rapid clamping action and easy access to both the O.D. and the exposed face are sometimes of advantage.
Steady rests	Two basic types are used: (a) the two-jaw type supporting the work from the back (back rest), leaving access by the wheel; (b) the three-jaw type (center rest).	A complementary work-holding device, used in conjunction with primary work holders, to provide additional support, particularly to long and/or slender parts.
Special fixtures	Single-purpose devices, designed for a particular workpiece, primarily for providing special locating elements.	Typical workpieces requiring special fixturing are, as examples, crankshafts where the holding is combined with balancing functions; or internal gears located on the pitch circle of the teeth for O.D. grinding.

**Selection of Grinding Wheels for Cylindrical Grinding.**—For cylindrical grinding, as for grinding in general, the primary factor to be considered in wheel selection is the work material. Other factors are the amount of excess stock and its rate of removal (feeds and speeds), the desired accuracy and surface finish, the ratio of wheel and work diameter, wet or dry grinding, etc. In view of these many variables, it is not practical to set up a complete

list of grinding wheel recommendations with general validity. Instead, examples of recommendations embracing a wide range of typical applications and assuming common practices are presented in Table 2. This is intended as a guide for the starting selection of grinding wheel specifications which, in case of a not entirely satisfactory performance, can be refined subsequently. The content of the table is a version of the grinding wheel recommendations for cylindrical grinding by the Norton Company using, however, non-proprietary designations for the abrasive types and bonds.

**Table 2. Wheel Recommendations for Cylindrical Grinding**

Material	Wheel Marking	Material	Wheel Marking
Aluminum	SFA46-18V	Forgings	A46-M5V
Armatures (laminated)	SFA100-18V	Gages (plug)	SFA80-K8V
Axles (auto & railway)	A54-M5V	General-purpose grinding	SFA54-L5V
Brass	C36-KV	Glass	BFA220-011V
Bronze		Gun barrels	
Soft	C36-KV	Spotting and O.D.	BFA60-M5V
Hard	A46-M5V	Nitralloy	
Bushings (hardened steel)	BFA60-L5V	Before nitriding	A60-K5V
Bushings (cast iron)	C36-JV	After nitriding	
Cam lobes (cast alloy)		Commercial finish	SFA60-18V
Roughing	BFA54-N5V	High finish	C100-1V
Finishing	A70-P6B	Reflective finish	C500-19E
Cam lobes (hardened steel)		Pistons (aluminum)	SFA46-18V
Roughing	BFA54-L5V	(cast iron)	C36-KV
Finishing	BFA80-T8B	Plastics	C46-JV
Cast iron	C36-JV	Rubber	
Chromium plating		Soft	SFA20-K5B
Commercial finish	SFA60-J8V	Hard	C36-KB
High finish	A150-K5E	Spline shafts	SFA60-N5V
Reflective finish	C500-19E	Sprayed metal	C60-JV
Commutators (copper)	C60-M4E	Steel	
Crankshafts (airplane)		Soft	
Pins	BFA46-K5V	1 in. dia. and smaller	SFA60-M5V
Bearings	A46-L5V	over 1 in dia.	SFA46-L5V
Crankshafts (automotive		Hardened	
pins and bearings)		1 in. dia. and smaller	SFA80-L8V
Finishing	A54-N5V	over 1 in. dia.	SFA60-K5V
Roughing & finishing	A54-O5V	300 series stainless	SFA46-K8V
Regrinding	A54-M5V	Stellite	BFA46-M5V
Regrinding, sprayed		Titanium	C60-JV
metal	C60-JV	Valve stems (automotive)	BFA54-N5V
Drills	BFA54-N5V	Valve tappets	BFA54-M5V

*Note:* Prefixes to the standard designation "A" of aluminum oxide indicate modified abrasives as follows: BFA = Blended friable (a blend of regular and friable), SFA = Semifriable.

**Operational Data for Cylindrical Grinding.**—In cylindrical grinding, similarly to other metalcutting processes, the applied speed and feed rates must be adjusted to the operational conditions as well as to the objectives of the process. Grinding differs, however, from other types of metalcutting methods in regard to the cutting speed of the tool which, in grinding, is generally not a variable; it should be maintained at, or close to the optimum rate, commonly 6500 feet per minute (1980 m/min) peripheral speed.

In establishing the proper process values for grinding, of prime consideration are the work material, its condition (hardened or soft), and the type of operation (roughing or finishing). Other influencing factors are the characteristics of the grinding machine (stability, power), the specifications of the grinding wheel, the material allowance, the rigidity and balance of the workpiece, as well as several grinding process conditions, such as wet or dry grinding, the manner of wheel truing, etc.

Variables of the cylindrical grinding process, often referred to as *grinding data*, comprise the speed of work rotation (measured as the surface speed of the work); the infeed (in inches per pass for traverse grinding, or in inches per minute for plunge grinding); and, in the case of traverse grinding, the speed of the reciprocating table movement (expressed either in feet per minute, or as a fraction of the wheel width for each revolution of the work).

For the purpose of starting values in setting up a cylindrical grinding process, a brief listing of basic data for common cylindrical grinding conditions and involving frequently used materials, is presented in Table 3.

**Table 3. Basic Process Data for Cylindrical Grinding**

Traverse Grinding								Traverse for Each Work Revolution, In Fractions of the Wheel Width	
Work Material	Material Condition	Work Surface Speed, fpm m/min		Infeed per Pass					
				inch		mm			
				Rough	Finish	Rough	Finish	Rough	Finish
Plain Carbon Steel	Annealed	100	30.5	0.002	0.0005	0.05	0.013	½	¼

Plunge Grinding, Infeed per Revolution of the Work				
Work Material	Inch		Millimeter	
	Roughing	Finishing	Roughing	Finishing
Steel, soft	0.0005	0.0002	0.013	0.005
Plain carbon steel, hardened	0.0002	0.000050	0.005	0.0013
Alloy and tool steel, hardened	0.0001	0.000025	0.003	0.00064

These data, which are, in general, considered conservative, are based on average operating conditions and may be modified subsequently by: a) reducing the values in case of unsatisfactory quality of the grinding or the occurrence of failures; and b) increasing the rates for raising the productivity of the process, particularly for rigid workpieces, substantial stock allowance, etc.

**High-Speed Cylindrical Grinding.**—The maximum peripheral speed of the wheels in regular cylindrical grinding is generally 6500 feet per minute (1980 m/min); the commonly used grinding wheels and machines are designed to operate efficiently at this speed. Recently, efforts were made to raise the productivity of different grinding methods, including cylindrical grinding, by increasing the peripheral speed of the grinding wheel to a substantially higher than traditional level, such as 12,000 feet per minute (3658 m/min) or more. Such methods are designated by the distinguishing term of high-speed grinding.

For high-speed grinding, special grinding machines have been built with high dynamic stiffness and static rigidity, equipped with powerful drive motors, extra-strong spindles and bearings, reinforced wheel guards, etc., and using grinding wheels expressly made and tested for operating at high peripheral speeds. The higher stock-removal rate accomplished by high-speed grinding represents an advantage when the work configuration and material permit, and the removable stock allowance warrants its application.

**CAUTION:** High-speed grinding must *not* be applied on standard types of equipment, such as general types of grinding machines and regular grinding wheels. Operating

grinding wheels, even temporarily, at higher than approved speed constitutes a grave safety hazard.

**Areas and Degrees of Automation in Cylindrical Grinding.**—Power drive for the work rotation and for the reciprocating table traverse are fundamental machine movements that, once set for a certain rate, will function without requiring additional attention. Loading and removing the work, starting and stopping the main movements, and applying infeed by hand wheel are carried out by the operator on cylindrical grinding machines in their basic degree of mechanization. Such equipment is still frequently used in tool room and jobbing-type work.

More advanced levels of automation have been developed for cylindrical grinders and are being applied in different degrees, particularly in the following principal respects:

a) *Infeed*, in which different rates are provided for rapid approach, roughing and finishing, followed by a spark-out period, with presetting of the advance rates, the cutoff points, and the duration of time-related functions.

b) *Automatic cycling* actuated by a single lever to start work rotation, table reciprocation, grinding-fluid supply, and infeed, followed at the end of the operation by wheel slide retraction, the successive stopping of the table movement, the work rotation, and the fluid supply.

c) *Table traverse dwells* (tarry) in the extreme positions of the travel, over preset periods, to assure uniform exposure to the wheel contact of the entire work section.

d) *Mechanized work loading*, clamping, and, after termination of the operation, unloading, combined with appropriate work-feeding devices such as indexing-type drums.

e) *Size control* by in-process or post-process measurements. Signals originated by the gage will control the advance movement or cause automatic compensation of size variations by adjusting the cutoff points of the infeed.

f) *Automatic wheel dressing* at preset frequency, combined with appropriate compensation in the infeed movement.

g) *Numerical control* obviates the time-consuming setups for repetitive work performed on small- or medium-size lots. As an application example: shafts with several sections of different lengths and diameters can be ground automatically in a single operation, grinding the sections in consecutive order to close dimensional limits, controlled by an in-process gage, which is also automatically set by means of the program.

The choice of the grinding machine functions to be automated and the extent of automation will generally be guided by economic considerations, after a thorough review of the available standard and optional equipment. Numerical control of partial or complete cycles is being applied to modern cylindrical and other grinding machines.

**Cylindrical Grinding Troubles and Their Correction.**—Troubles that may be encountered in cylindrical grinding may be classified as work defects (chatter, checking, burning, scratching, and inaccuracies), improperly operating machines (jumpy infeed or traverse), and wheel defects (too hard or soft action, loading, glazing, and breakage). The Landis Tool Company has listed some of these troubles, their causes, and corrections as follows:

*Chatter*: Sources of chatter include: 1) faulty coolant; 2) wheel out of balance; 3) wheel out of round; 4) wheel too hard; 5) improper dressing; 6) faulty work support or rotation; 7) improper operation; 8) faulty traverse; 9) work vibration; 10) outside vibration transmitted to machine; 11) interference; 12) wheel base; and 13) headstock.

Suggested procedures for correction of these troubles are:

1) *Faulty coolant*: Clean tanks and lines. Replace dirty or heavy coolant with correct mixture.

2) *Wheel out of balance*: Rebalance on mounting before and after dressing. Run wheel without coolant to remove excess water. Store a removed wheel on its side to keep retained water from causing a false heavy side. Tighten wheel mounting flanges. Make sure wheel center fits spindle.

3) *Wheel out of round*: True before and after balancing. True sides to face.

4) *Wheel too hard*: Use coarser grit, softer grade, more open bond. See *Wheel Defects* on page 1322.

5) *Improper dressing*: Use sharp diamond and hold rigidly close to wheel. It must not overhang excessively. Check diamond in mounting.

6) *Faulty work support or rotation*: Use sufficient number of work rests and adjust them more carefully. Use proper angles in centers of work. Clean dirt from footstock spindle and be sure spindle is tight. Make certain that work centers fit properly in spindles.

7) *Improper operation*: Reduce rate of wheel feed.

8) *Faulty traverse*: See *Uneven Traverse or Infeed of Wheel Head* on page 1322.

9) *Work vibration*: Reduce work speed. Check workpiece for balance.

10) *Outside vibration transmitted to machine*: Check and make sure that machine is level and sitting solidly on foundation. Isolate machine or foundation.

11) *Interference*: Check all guards for clearance.

12) *Wheel base*: Check spindle bearing clearance. Use belts of equal lengths or uniform cross section on motor drive. Check drive motor for unbalance. Check balance and fit of pulleys. Check wheel feed mechanism to see that all parts are tight.

13) *Headstock*: Put belts of same length and cross section on motor drive; check for correct work speeds. Check drive motor for unbalance. Make certain that headstock spindle is not loose. Check work center fit in spindle. Check wear of faceplate and jackshaft bearings.

*Spirals on Work (traverse lines with same lead on work as rate of traverse)*: Sources of spirals include: 1) machine parts out of line; and 2) truing.

Suggested procedures for correction of these troubles are:

1) *Machine parts out of line*: Check wheel base, headstock, and footstock for proper alignment.

2) *Truing*: Point truing tool down 3 degrees at the workwheel contact line. Round off wheel edges.

*Check Marks on Work*: Sources of check marks include: 1) improper operation; 2) improper heat treatment; 3) improper size control; 4) improper wheel; and 5) improper dressing.

Suggested procedures for correction of these troubles are:

1) *Improper operation*: Make wheel act softer. See *Wheel Defects*. Do not force wheel into work. Use greater volume of coolant and a more even flow. Check the correct positioning of coolant nozzles to direct a copious flow of clean coolant at the proper location.

2) *Improper heat treatment*: Take corrective measures in heat-treating operations.

3) *Improper size control*: Make sure that engineering establishes reasonable size limits. See that they are maintained.

4) *Improper wheel*: Make wheel act softer. Use softer-grade wheel. Review the grain size and type of abrasive. A finer grit or more friable abrasive or both may be called for.

5) *Improper dressing*: Check that the diamond is sharp, of good quality, and well set. Increase speed of the dressing cycle. Make sure diamond is not cracked.

*Burning and Discoloration of Work*: Sources of burning and discoloration are improper operation, and improper wheel.

Suggested procedures for correction of these troubles are:

1) *Improper operation*: Decrease rate of infeed. Don't stop work while in contact with wheel.

2) *Improper wheel*: Use softer wheel or obtain softer effect. See *Wheel Defects*. Use greater volume of coolant.

*Isolated Deep Marks on Work:* Source of trouble is an unsuitable wheel. Use a finer wheel and consider a change in abrasive type.

*Fine Spiral or Thread on Work:* Sources of this trouble are: 1) improper operation; and 2) faulty wheel dressing.

Suggested procedures for corrections of these troubles are:

1) *Improper operation:* Reduce wheel pressure. Use more work rests. Reduce traverse with respect to work rotation. Use different traverse rates to break up pattern when making numerous passes. Prevent edge of wheel from penetrating by dressing wheel face parallel to work.

2) *Faulty wheel dressing:* Use slower or more even dressing traverse. Set dressing tool at least 3 degrees down and 30 degrees to the side from time to time. Tighten holder. Don't take too deep a cut. Round off wheel edges. Start dressing cut from wheel edge.

*Narrow and Deep Regular Marks on Work:* Source of trouble is that the wheel is too coarse. Use finer grain size.

*Wide, Irregular Marks of Varying Depth on Work:* Source of trouble is too soft a wheel. Use a harder grade wheel. See *Wheel Defects*.

*Widely Spaced Spots on Work:* Sources of trouble are oil spots or glazed areas on wheel face. Balance and true wheel. Keep oil from wheel face.

*Irregular "Fish-tail" Marks of Various Lengths and Widths on Work:* Source of trouble is dirty coolant. Clean tank frequently. Use filter for fine finish grinding. Flush wheel guards after dressing or when changing to finer wheel.

*Wavy Traverse Lines on Work:* Source of trouble is wheel edges. Round off. Check for loose thrust on spindle and correct if necessary.

*Irregular Marks on Work:* Cause is loose dirt. Keep machine clean.

*Deep, Irregular Marks on Work:* Source of trouble is loose wheel flanges. Tighten and make sure blotters are used.

*Isolated Deep Marks on Work:* Sources of trouble are: 1) grains pull out; 2) coolant too strong; coarse grains or foreign matter in wheel face; and 3) improper dressing.

Respective suggested procedures for corrections of these troubles are: 1) decrease soda content in coolant mixture; 2) dress wheel; and 3) use sharper dressing tool.

Brush wheel after dressing with stiff bristle brush.

*Grain Marks on Work:* Sources of trouble are: 1) improper finishing cut; 2) grain sizes of roughing and finishing wheels differ too much; 3) dressing too coarse; and 4) wheel too coarse or too soft.

Respective suggested procedures for corrections of these troubles are: start with high work and traverse speeds; finish with high work speed and slow traverse, letting wheel "spark-out" completely; finish out better with roughing wheel or use finer roughing wheel; use shallower and slower cut; and use finer grain size or harder-grade wheel.

*Inaccuracies in Work:* Work out-of-round, out-of-parallel, or tapered.

Sources of trouble are: 1) misalignment of machine parts; 2) work centers; 3) improper operation; 4) coolant; 5) wheel; 6) improper dressing; 7) spindle bearings; and 8) work.

Suggested procedures for corrections of these troubles are:

1) *Misalignment of machine parts:* Check headstock and tailstock for alignment and proper clamping.

2) *Work centers:* Centers in work must be deep enough to clear center point. Keep work centers clean and lubricated. Check play of footstock spindle and see that footstock spindle is clean and tightly seated. Regrind work centers if worn. Work centers must fit taper of work-center holes. Footstock must be checked for proper tension.

3) *Improper operation:* Don't let wheel traverse beyond end of work. Decrease wheel pressure so work won't spring. Use harder wheel or change speeds and feeds to make wheel

act harder. Allow work to “spark-out.” Decrease feed rate. Use proper number of work rests. Allow proper amount of tarry. Workpiece must be balanced if it is an odd shape.

4) *Coolant*: Use greater volume of coolant.

5) *Wheel*: Rebalance wheel on mounting before and after truing.

6) *Improper dressing*: Use same positions and machine conditions for dressing as in grinding.

7) *Spindle bearings*: Check clearance.

8) *Work*: Work must come to machine in reasonably accurate form.

*Inaccurate Work Sizing (when wheel is fed to same position, it grinds one piece to correct size, another oversize, and still another undersize)*: Sources of trouble are: 1) improper work support or rotation; 2) wheel out of balance; 3) loaded wheel; 4) improper infeed; 5) improper traverse; 6) coolant; 7) misalignment; and 8) work.

Suggested procedures for corrections of these troubles are:

1) *Improper work support or rotation*: Keep work centers clean and lubricated. Regrind work-center tips to proper angle. Be sure footstock spindle is tight. Use sufficient work rests, properly spaced.

2) *Wheel out of balance*: Balance wheel on mounting before and after truing.

3) *Loaded wheel*: See *Wheel Defects*.

4) *Improper infeed*: Check forward stops of rapid feed and slow feed. When readjusting position of wheel base by means of the fine feed, move the wheel base back after making the adjustment and then bring it forward again to take up backlash and relieve strain in feed-up parts. Check wheel spindle bearings. Don't let excessive lubrication of wheel base slide cause “floating.” Check and tighten wheel feed mechanism. Check parts for wear. Check pressure in hydraulic system. Set infeed cushion properly. Check to see that pistons are not sticking.

5) *Improper traverse*: Check traverse hydraulic system and the operating pressure. Prevent excessive lubrication of carriage ways with resultant “floating” condition. Check to see if carriage traverse piston rods are binding. Carriage rack and driving gear must not bind. Change length of tarry period.

6) *Coolant*: Use greater volume of clean coolant.

7) *Misalignment*: Check level and alignment of machine.

8) *Work*: Workpieces may vary too much in length, permitting uneven center pressure.

*Uneven Traverse or Infeed of Wheel Head*: Sources of uneven traverse or infeed of wheel head are: carriage and wheel head, hydraulic system, interference, unbalanced conditions, and wheel out of balance. Suggested procedures for correction of these troubles are:

1) *Carriage and wheel head*: Ways may be scored. Be sure to use recommended oil for both lubrication and hydraulic system. Make sure ways are not so smooth that they press out oil film. Check lubrication of ways. Check wheel feed mechanism, traverse gear, and carriage rack clearance. Prevent binding of carriage traverse cylinder rods.

2) *Hydraulic systems*: Remove air and check pressure of hydraulic oil. Check pistons and valves for oil leakage and for gumminess caused by incorrect oil. Check worn valves or pistons that permit leakage.

3) *Interference*: Make sure guard strips do not interfere.

4) *Unbalanced conditions*: Eliminate loose pulleys, unbalanced wheel drive motor, uneven belts, or high spindle keys.

5) *Wheel out of balance*: Balance wheel on mounting before and after truing.

*Wheel Defects*: When wheel is acting too hard, such defects as glazing, some loading, lack of cut, chatter, and burning of work result.

Suggested procedures for correction of these faults are: 1) Increase work and traverse speeds as well as rate of in-feed; 2) decrease wheel speed, diameter, or width; 3) dress more sharply; 4) use thinner coolant; 5) don't tarry at end of traverse; 6) select softer wheel grade and coarser grain size; 7) avoid gummy coolant; and 8) on hardened work select finer grit, more fragile abrasive or both to get penetration. Use softer grade.

When *wheel is acting too soft*, such defects as wheel marks, tapered work, short wheel life, and not-holding-cut result.

Suggested procedures for correction of these faults are: 1) Decrease work and traverse speeds as well as rate of in-feed; 2) increase wheel speed, diameter, or width; 3) dress with little in-feed and slow traverse; 4) use heavier coolants; 5) don't let wheel run off work at end of traverse; and 6) select harder wheel or less fragile grain or both.

*Wheel Loading and Glazing*: Sources of the trouble of wheel loading or glazing are: 1) Incorrect wheel; 2) improper dress; 3) faulty operation; 4) faulty coolant; and 5) gummy coolant.

Suggested procedures for correction of these faults are:

1) *Incorrect wheel*: Use coarser grain size, more open bond, or softer grade.

2) *Improper dressing*: Keep wheel sharp with sharp dresser, clean wheel after dressing, use faster dressing traverse, and deeper dressing cut.

3) *Faulty operation*: Control feeds and speeds to soften action of wheel. Use less in-feed to prevent loading; more in-feed to stop glazing.

4) *Faulty coolant*: Use more, cleaner and thinner coolant, and less oily coolant.

5) *Gummy coolant*: To stop wheel glazing, increase soda content and avoid the use of soluble oils if water is hard. In using soluble oil coolant with hard water a suitable conditioner or "softener" should be added.

*Wheel Breakage*: Suggested procedures for the correction of a radial break with three or more pieces are: 1) Reduce wheel speed to or below rated speed; 2) mount wheel properly, use blotters, tight arbors, even flange pressure and be sure to keep out dirt between flange and wheel; 3) use plenty of coolant to prevent over-heating; 4) use less in-feed; and 5) don't allow wheel to become jammed on work.

A radial break with two pieces may be caused by excessive side strain. To prevent an irregular wheel break, don't let wheel become jammed on work; don't allow striking of wheel; and never use wheels that have been damaged in handling. In general, do not use a wheel that is too tight on the arbor since the wheel is apt to break when started. Prevent excessive hammering action of wheel. Follow rules of the American National Standard Safety Requirements for the Use, Care, and Protection of Abrasive Wheels (ANSI B7.1-2017).

### Centerless Grinding

In centerless grinding the work is supported on a work rest blade and is between the grinding wheel and a regulating wheel. The regulating wheel generally is a rubber bonded abrasive wheel. In the normal grinding position the grinding wheel forces the work downward against the work rest blade and also against the regulating wheel. The latter imparts a uniform rotation to the work giving it its same peripheral speed which is adjustable.

The higher the work center is placed above the line joining the centers of the grinding and regulating wheels the quicker the rounding action. Rounding action is also increased by a high work speed and a slow rate of traverse (if a through-feed operation). It is possible to have a higher work center when using softer wheels, as their use gives decreased contact pressures and the tendency of the workpiece to lift off the work rest blade is lessened.

Long rods or bars are sometimes ground with their centers below the line-of-centers of the wheels to eliminate the whipping and chattering due to slight bends or kinks in the rods or bars, as they are held more firmly down on the blade by the wheels.

There are three general methods of centerless grinding which may be described as through-feed, in-feed, and end-feed methods.

**Through-Feed Method of Grinding.**—The through-feed method is applied to straight cylindrical parts. The work is given an axial movement by the regulating wheel and passes between the grinding and regulating wheels from one side to the other. The rate of feed depends upon the diameter and speed of the regulating wheel and its inclination which is adjustable. It may be necessary to pass the work between the wheels more than once, the number of passes depending upon such factors as the amount of stock to be removed, the roundness and straightness of the unground work, and the limits of accuracy required.

The work rest fixture also contains adjustable guides on either side of the wheels that directs the work to and from the wheels in a straight line.

**In-Feed Method of Centerless Grinding.**—When parts have shoulders, heads or some part larger than the ground diameter, the in-feed method usually is employed. This method is similar to “plungecut” form grinding on a center type of grinder. The length or sections to be ground in any one operation are limited by the width of the wheel. As there is no axial feeding movement, the regulating wheel is set with its axis approximately parallel to that of the grinding wheel, there being a slight inclination to keep the work tight against the end stop.

**End-Feed Method of Grinding.**—The end-feed method is applied only to taper work. The grinding wheel, regulating wheel, and the work rest blade are set in a fixed relation to each other and the work is fed in from the front mechanically or manually to a fixed end stop. Either the grinding or regulating wheel, or both, are dressed to the proper taper.

**Automatic Centerless Grinding.**—The grinding of relatively small parts may be done automatically by equipping the machine with a magazine, gravity chute, or hopper feed, provided the shape of the part will permit using these feed mechanisms.

**Internal Centerless Grinding.**—Internal grinding machines based upon the centerless principle utilize the outside diameter of the work as a guide for grinding the bore which is concentric with the outer surface. In addition to straight and tapered bores, interrupted and “blind” holes can be ground by the centerless method. When two or more grinding operations such as roughing and finishing must be performed on the same part, the work can be rechucked in the same location as often as required.

**Centerless Grinding Troubleshooting.**—A number of troubles and some corrective measures compiled by a manufacturer are listed here for the through-feed and in-feed methods of centerless grinding.

*Chattermarks* are caused by having the work center too high above the line joining the centers of the grinding and regulating wheels; using too hard or too fine a grinding wheel; using too steep an angle on the work support blade; using too thin a work support blade; “play” in the set-up due to loosely clamped members; having the grinding wheel fit loosely on the spindle; having vibration either transmitted to the machine or caused by a defective drive in the machine; having the grinding wheel out-of-balance; using too heavy a stock removal; and having the grinding wheel or the regulating wheel spindles not properly adjusted.

*Feed lines or spiral marks* in through-feed grinding are caused by too sharp a corner on the exit side of the grinding wheel which may be alleviated by dressing the grinding wheel to a slight taper about  $\frac{1}{2}$  inch (1.27 mm) from the edge, dressing the edge to a slight radius, or swiveling the regulating wheel a bit.

*Scored work* is caused by burrs, abrasive grains, or removed material being imbedded in or fused to the work support blade. This condition may be alleviated by using a coolant with increased lubricating properties and if this does not help a softer grade wheel should be used.

*Work not ground round* may be due to the work center not being high enough above the line joining the centers of the grinding and regulating wheels. Placing the work center higher and using a softer grade wheel should help to alleviate this condition.

*Work not ground straight* in through-feed grinding may be due to an incorrect setting of the guides used in introducing and removing the work from the wheels, and the existence of convex or concave faces on the regulating wheel. For example, if the work is tapered on the front end, the work guide on the entering side is deflected toward the regulating wheel. If tapered on the back end, then the work guide on the exit side is deflected toward the regulating wheel. If both ends are tapered, then both work guides are deflected toward the regulating wheel. The same barrel-shaped pieces are also obtained if the face of the regulating wheel is convex at the line of contact with the work. Conversely, the work would be ground with hollow shapes if the work guides were deflected toward the grinding wheel or if the face of the regulating wheel were concave at the line of contact with the work. The use of a warped work rest blade may also result in the work not being ground straight and the blade should be removed and checked with a straight edge.

In in-feed grinding, in order to keep the wheel faces straight which will insure straightness of the cylindrical pieces being ground, the first item to be checked is the straightness and the angle of inclination of the work rest blade. If this is satisfactory then one of three corrective measures may be taken: the first might be to swivel the regulating wheel to compensate for the taper, the second might be to true the grinding wheel to that angle that will give a perfectly straight workpiece, and the third might be to change the inclination of the regulating wheel (this is true only for correcting very slight tapers up to 0.0005 inch or 0.0127 mm).

*Difficulties in sizing* the work in in-feed grinding are generally due to a worn in-feed mechanism and may be overcome by adjusting the in-feed nut.

*Flat spots* on the workpiece in in-feed grinding usually occur when grinding heavy work and generally when the stock removal is light. This condition is due to insufficient driving power between the work and the regulating wheel which may be alleviated by equipping the work rest with a roller that exerts a force against the workpiece; and by feeding the workpiece to the end stop using the upper slide.

### Surface Grinding

The term surface grinding implies, in current technical usage, the grinding of surfaces which are essentially flat. Several methods of surface grinding, however, are adapted and used to produce surfaces characterized by parallel straight line elements in one direction, while normal to that direction the contour of the surface may consist of several straight line sections at different angles to each other (e.g., the guideways of a lathe bed); in other cases the contour may be curved or profiled (e.g., a thread cutting chaser).

**Advantages of Surface Grinding.**—Alternate methods for machining work surfaces similar to those produced by surface grinding are milling and, to a much more limited degree, planing. Surface grinding, however, has several advantages over alternate methods that are carried out with metal-cutting tools. Examples of such potential advantages are as follows:

- 1) Grinding is applicable to very hard and/or abrasive work materials, without significant effect on the efficiency of the stock removal.
- 2) The desired form and dimensional accuracy of the work surface can be obtained to a much higher degree and in a more consistent manner.
- 3) Surface textures of very high finish and—when the appropriate system is utilized—with the required lay, are generally produced.
- 4) Tooling for surface grinding as a rule is substantially less expensive, particularly for producing profiled surfaces, the shapes of which may be dressed into the wheel, often with simple devices, in processes that are much more economical than the making and the maintenance of form cutters.

5) Fixturing for work holding is generally very simple in surface grinding, particularly when magnetic chucks are applicable, although the mechanical holding fixture can also be simpler, because of the smaller clamping force required than in milling or planing.

6) Parallel surfaces on opposite sides of the work are produced accurately, either in consecutive operations using the first ground surface as a dependable reference plane or, simultaneously, in double face grinding, which usually operates without the need for holding the parts by clamping.

7) Surface grinding is well adapted to process automation, particularly for size control, but also for mechanized work handling in the large volume production of a wide range of component parts.

**Principal Systems of Surface Grinding.**—Flat surfaces can be ground with different surface portions of the wheel, by different arrangements of the work and wheel, as well as by different interrelated movements. The various systems of surface grinding, with their respective capabilities, can best be reviewed by considering two major distinguishing characteristics:

1) *The operating surface of the grinding wheel*, which may be the periphery or the face (the side);

2) *The movement of the work during the process*, which may be traverse (generally reciprocating) or rotary (continuous), depending on the design of a particular category of surface grinders.

The accompanying [Table 1](#) and the text that follows provides a concise review of the principal surface grinding systems, defined by the preceding characteristics. It should be noted that many surface grinders are built for specific applications, and do not fit exactly into any one of these major categories.

*Operating Surface, Periphery of Wheel: Movement of Work, Reciprocating:* Work is mounted on the horizontal machine table that is traversed in a reciprocating movement at a speed generally selected from a steplessly variable range. The transverse movement, called cross feed of the table or of the wheel slide, operates at the end of the reciprocating stroke and assures the gradual exposure of the entire work surface, which commonly exceeds the width of the wheel. The depth of the cut is controlled by the downfeed of the wheel, applied in increments at the reversal of the transverse movement.

*Operating Surface, Periphery of Wheel: Movement of Work, Rotary:* Work is mounted, usually on the full-diameter magnetic chuck of the circular machine table that rotates at a preset constant or automatically varying speed, the latter maintaining an approximately equal peripheral speed of the work surface area being ground. The wheelhead, installed on a cross slide, traverses over the table along a radial path, moving in alternating directions, toward and away from the center of the table. Infeed is by vertical movement of the saddle along the guideways of the vertical column, at the end of the radial wheelhead stroke. The saddle contains the guideways along which the wheelhead slide reciprocates.

*Operating Surface, Face of Wheel: Movement of Work, Reciprocating:* Operation is similar to the reciprocating table-type peripheral surface grinder, but grinding is with the face, usually with the rim of a cup-shaped wheel, or a segmental wheel for large machines. Capable of covering a much wider area of the work surface than the peripheral grinder, thus frequently no need for cross feed. Provides efficient stock removal, but is less adaptable than the reciprocating table-type peripheral grinder.

*Operating Surface, Face of Wheel: Movement of Work, Rotary:* The grinding wheel, usually of segmental type, is set in a position to cover either an annular area near the periphery of the table or, more commonly, to reach beyond the table center. A large circular magnetic chuck generally covers the entire table surface and facilitates the mounting of workpieces, even of fixtures, when needed. The uninterrupted passage of the work in contact with the large wheel face permits a very high rate of stock removal and the machine, with single or double wheelhead, can be adapted also to automatic operation with continuous part feed by mechanized work handling.

**Table 1. Principal Systems of Surface Grinding — Diagrams**

*Operating Surface, Face of Wheel: Movement of Work, Traverse Along Straight or Arcuate Path:* The grinding wheel, usually of segmental type, is set in a position to cover either an annular area near the periphery of the table or, more commonly, to reach beyond the table center. A large circular magnetic chuck generally covers the entire table surface and facilitates the mounting of workpieces, even of fixtures, when needed. The uninterrupted passage of the work in contact with the large wheel face permits a very high rate of stock removal and the machine, with single or double wheelhead, can be adapted also to automatic operation with continuous part feed by mechanized work handling.

**Selection of Grinding Wheels for Surface Grinding.**—The most practical way to select a grinding wheel for surface grinding is to base the selection on the work material. [Table 2a](#) gives the grinding wheel recommendations for Types 1, 5, and 7 straight wheels used on reciprocating and rotary table surface grinders with horizontal spindles. [Table 2b](#) gives the grinding wheel recommendations for Type 2 cylinder wheels, Type 6 cup wheels, and wheel segments used on vertical spindle surface grinders.

The last letters (two or three) that may follow the bond designation V (vitrified) or B (resinoid) refer to: 1) bond modification, “BE” being especially suitable for surface grinding; 2) special structure, “P” type being distinctively porous; and 3) for segments made of 23A type abrasives, the term 12VSM implies porous structure, and the letter “P” is not needed.

The wheel markings in [Table 2a](#) and [Table 2b](#) are those used by the Norton Co., complementing the basic standard markings with Norton symbols. The complementary symbols used in these tables, that is, those preceding the letter designating A (aluminum oxide) or C (silicon carbide), indicate the special type of basic abrasive that has the friability best suited for particular work materials. Those preceding A (aluminum oxide) are

- 57—a versatile abrasive suitable for grinding steel in either a hard or soft state.
- 38—the most friable abrasive.
- 32—the abrasive suited for tool steel grinding.
- 23—an abrasive with intermediate grinding action, and
- 19—the abrasive produced for less heat-sensitive steels.

Those preceding C (silicon carbide) are

- 37—a general application abrasive, and
- 39—an abrasive for grinding hard cemented carbide.

**Table 2a. Grinding Wheel Recommendations for Surface Grinding—Using Straight Wheel Types 1, 5, and 7**

Material	Horizontal-spindle, reciprocating-table surface grinders		Horizontal-spindle, rotary-table surface grinders
	Wheels less than 16 inches diameter	Wheels 16 inches diameter and over	Wheels of any diameter
Cast iron	37C36-K8V or 23A46-I8VBE	23A36-I8VBE	37C36-K8V or 23A46-I8VBE
Nonferrous metal	37C36-K8V	37C36-K8V	37C36-K8V
Soft steel	23A46-J8VBE	23A36-J8VBE	23A46-J8VBE
Hardened steel, broad contact	32A46-H8VBE or 32A60-F12VBEP	32A36-H8VBE or 32A36-F12VBEP	32A46-I8VBE
Hardened steel, narrow contact or interrupted cut	32A46-I8VBE	32A36-J8VBE	32A46-J8VBE
General-purpose wheel	23A46-H8VBE	23A36-I8VBE	23A46-I8VBE
Cemented carbides	Diamond wheels <sup>a</sup>	Diamond wheels <sup>a</sup>	Diamond wheels <sup>a</sup>

<sup>a</sup> General diamond wheel recommendations are listed in [Table 5](#) on page 1309.

**Table 2b. Grinding Wheel Recommendations for Surface Grinding—Using Type 2 Cylinder Wheels, Type 6 Cup Wheels, and Wheel Segments**

Material	Type 2 Cylinder Wheels	Type 6 Cup Wheels	Wheel Segments
High tensile cast iron and nonferrous metals	37C24-HKV	37C24-HVK	37C24-HVK
Soft steel, malleable cast iron, steel castings, boiler plate	23A24-I8VBE or 23A30-G12VBEP	23A24-I8VBE	23A24-I8VSM or 23A30-H12VSM
Hardened steel—broad contact	32A46-G8VBE or 32A36-E12VBEP	32A46-G8VBE or 32A60-E12VBEP	32A36-G8VBE or 32A46-E12VBEP
Hardened steel—narrow contact or interrupt cut	32A46-H8VBE	32A60-H8VBE	32A46-G8VBE or 32A60-G12VBEP
General-purpose use	23A30-H8VBE or 23A30-E12VBEP	...	23A30-H8VSM or 23A30-G12VSM

**Process Data for Surface Grinding.**—In surface grinding, similarly to other metal-cutting processes, the speed and feed rates that are applied must be adjusted to the operational conditions as well as to the objectives of the process. Grinding differs, however, from other types of metal cutting methods in regard to the cutting speed of the tool; the peripheral speed of the grinding wheel is maintained within a narrow range, generally 5500 to 6500 surface feet per minute. Speed ranges different from the common one are used in particular processes which require special wheels and equipment.

**Table 3. Basic Process Data for Peripheral Surface Grinding on Reciprocating Table Surface Grinders**

Work Material	Hardness (Brinell/ Rockwell)	Material Condition	Wheel Speed, fpm	Table Speed, fpm	Downfeed, in. per pass		Crossfeed per pass, fraction of wheel width
					Rough	Finish, max.	
Plain carbon steel	52 RC max.	Annealed, cold drawn	5500-6500	50-100	0.003	0.0005	¼
	52-65 RC	Carburized and/or quenched and tempered	5500-6500	50-100	0.003	0.0005	⅓
Alloy steels	52 RC max.	Annealed or quenched and tempered	5500-6500	50-100	0.003	0.001	¼
	52-65 RC	Carburized and/or quenched and tempered	5500-6500	50-100	0.003	0.0005	⅓
Tool steels	150-275 BHN	Annealed	5500-6500	50-100	0.002	0.0005	⅓
	56-65 RC	Quenched and tempered	5500-6500	50-100	0.002	0.0005	⅓
Nitriding steels	200-350 BHN	Normalized, annealed	5500-6500	50-100	0.003	0.001	¼
	60-65 RC	Nitrided	5500-6500	50-100	0.003	0.0005	⅓
Cast steels	52 RC max.	Normalized, annealed	5500-6500	50-100	0.003	0.001	¼
	Over 52 RC	Carburized and/or quenched and tempered	5500-6500	50-100	0.003	0.0005	⅓
Gray irons	52 RC max.	As cast, annealed, and/or quenched and tempered	5000-6500	50-100	0.003	0.001	⅓
Ductile irons	52 RC max.	As cast, annealed or quenched and tempered	5500-6500	50-100	0.003	0.001	⅓
Stainless steels, martensitic	135-235 BHN	Annealed or cold drawn	5500-6500	50-100	0.002	0.0005	¼
	Over 275 BHN	Quenched and tempered	5500-6500	50-100	0.001	0.0005	⅓
Aluminum alloys	30-150 BHN	As cast, cold drawn or treated	5500-6500	50-100	0.003	0.001	⅓

In establishing the proper process values for grinding, of prime consideration are the work material, its condition, and the type of operation (roughing or finishing). *Table 3* gives basic process data for peripheral surface grinding on reciprocating table surface

grinders. For different work materials and hardness ranges data are given regarding table speeds, downfeed (infeed) rates and cross feed, the latter as a function of the wheel width.

**Common Faults and Possible Causes in Surface Grinding.**—Approaching the ideal performance with regard to both the quality of the ground surface and the efficiency of surface grinding, requires the monitoring of the process and the correction of conditions adverse to the attainment of that goal.

Defective, or just not entirely satisfactory surface grinding may have any one or more of several causes. Exploring and determining the cause for eliminating its harmful effects is facilitated by knowing the possible sources of the experienced undesirable performance. Table 4, associating the common faults with their possible causes, is intended to aid in determining the actual cause, the correction of which should restore the desired performance level.

While the table lists the more common faults in surface grinding, and points out their frequent causes, other types of improper performance and/or other causes, in addition to those indicated, are not excluded.

**Vitrified Grinding Wheels.**—The term “vitrified” denotes the type of bond used in these grinding wheels. The bond in a grinding wheel is the material which holds the abrasive grains together and supports them while they cut. With a given type of bond, it is the amount of bond that determines the “hardness” or softness” of wheels. The abrasive itself is extremely hard in all wheels, and the terms “hard” and “soft” refer to the strength of bonding; the greater the percentage of bond with respect to the abrasive, the heavier the coating of bond around the abrasive grains and the stronger the bond posts, the “harder” the wheel.

Most wheels are made with a vitrified bond composed of clays and feldspar selected for their fusibility. During the “burning” process in grinding wheel manufacture, the clays are fused into a molten glass condition. Upon cooling, a span or post of this glass connects each abrasive grain to its neighbors to make a rigid, strong, grinding wheel. These wheels are porous, free cutting and unaffected by water, acids, oils, heat, or cold. Vitrified wheels are extensively used for cylindrical grinding, surface grinding, internal grinding and cutter grinding.

**Silicate Bonding Process.**—Silicate grinding wheels derive their name from the fact that silicate of soda or water glass is the principal ingredient used in the bond. These wheels are also sometimes referred to as *semi-vitrified* wheels. Ordinarily, they cut smoothly and with comparatively little heat, and for grinding operations requiring the lowest wheel wear, compatible with cool cutting, silicate wheels are often used. Their grade is also dependable and much larger wheels can be made by this bonding process than by the vitrified process. Some of the grinding operations for which silicate wheels have been found to be especially adapted are as follows: for grinding high-speed steel machine shop tools, such as reamers, milling cutters, etc.; for hand-grinding lathe and planer tools; for surface grinding with machines of the vertical ring-wheel type; and for operations requiring dish-shaped wheels and cool cutting. These wheels are unequalled for wet grinding on hardened steel and for wet tool grinding. They are easily recognized by their light gray color.

**Oilstones.**—The natural oilstones commonly used are the *Washita* and *Arkansas*. The Washita is a coarser and more rapidly cutting stone, and is generally considered the most satisfactory for sharpening woodworkers' tools. There are various grades of Washita rock, varying from the perfect crystallized and porous whetstone grit, to vitreous flint and hard sandstone. The best whetstones are porous and uniform in texture and are composed entirely of silica crystals. The poorer grades are less porous, making them vitreous or “glassy.” They may also have hard spots or sand holes, or contain grains of sand among the crystals. For general work, a soft, free-grit, quick-cutting stone is required, although a fine-grit medium-hard stone is sometimes preferable. These are commonly furnished in three grits: fine, medium, and coarse, and in all required shapes.

**Table 4. Common Faults and Possible Causes in Surface Grinding**

CAUSES	FAULTS	WORK DIMENSION			METALLURGICAL DEFECTS		SURFACE QUALITY				WHEEL CONDITION			WORK RETAINMENT	
		Work not flat	Work not parallel	Poor size holding	Burnishing of work	Burning or checking	Feed lines	Chatter marks	Scratches on surface	Poor finish	Wheel loading	Wheel glazing	Rapid wheel wear	Not firmly seated	Work sliding on chuck

### Offhand Grinding

Offhand grinding consists of holding the wheel to the work or the work to the wheel and grinding to broad tolerances and includes such operations as certain types of tool sharpening, weld grinding, snagging castings and other rough grinding. Types of machines that are used for rough grinding in foundries are floor- and bench-stand machines. Wheels for these machines vary from 6 to 30 inches in diameter. Portable grinding machines (electric, flexible shaft, or air-driven) are used for cleaning and smoothing castings.

Many rough grinding operations on castings can be best done with shaped wheels, such as cup wheels (including plate mounted) or cone wheels, and it is advisable to have a good assortment of such wheels on hand to do the odd jobs the best way.

**Floor- and Bench-Stand Grinding.**—The most common method of rough grinding is on double-end floor and bench stands. In machine shops, welding shops, and automotive repair shops, these grinders are usually provided with a fairly coarse grit wheel on one end for miscellaneous rough grinding and a finer grit wheel on the other end for sharpening tools. The pressure exerted is a very important factor in selecting the proper grinding wheel. If grinding is to be done mostly on hard sharp fins, then durable, coarse and hard wheels are required, but if grinding is mostly on large gate and riser pads, then finer and softer wheels should be used for best cutting action.

**Portable Grinding.**—Portable grinding machines are usually classified as air grinders, flexible shaft grinders, and electric grinders. The electric grinders are of two types; namely, those driven by standard 60 cycle current and so-called high-cycle grinders. Portable grinders are used for grinding down and smoothing weld seams; cleaning metal before welding; grinding out imperfections, fins and parting lines in castings and smoothing castings; grinding punch press dies and patterns to proper size and shape; and grinding manganese steel castings.

Wheels used on portable grinders are of three bond types; namely, resinoid, rubber, and vitrified. By far the largest percentage is resinoid. Rubber bond is used for relatively thin wheels and where a good finish is required. Some of the smaller wheels such as cone and plug wheels are vitrified bonded.

Grit sizes most generally used in wheels from 4 to 8 inches (102–203 mm) in diameter are 16, 20, and 24. In the still smaller diameters, finer sizes are used, such as 30, 36, and 46.

The particular grit size to use depends chiefly on the kind of grinding to be done. If the work consists of sharp fins and the machine has ample power, a coarse grain size combined with a fairly hard grade should be used. If the job is more in the nature of smoothing or surfacing and a fairly good finish is required, then finer and softer wheels are called for.

**Swing-Frame Grinding.**—This type of grinding is employed where a considerable amount of material is to be removed as on snagging large castings. It may be possible to remove 10 times as much material from steel castings using swing-frame grinders as with portable grinders; and 3 times as much material as with high-speed floor-stand grinders.

The largest field of application for swing-frame machines is on castings which are too heavy to handle on a floor stand; but often it is found that comparatively large gates and risers on smaller castings can be ground more quickly with swing-frame grinders, even if fins and parting lines have to be ground on floor stands as a second operation.

In foundries, the swing-frame machines are usually suspended from a trolley on a jib that can be swung out of the way when placing the work on the floor with the help of an overhead crane. In steel mills when grinding billets, a number of swing-frame machines are usually suspended from trolleys on a line of beams which facilitate their use as required.

The grinding wheels used on swing-frame machines are made with coarser grit sizes and harder grades than wheels used on floor stands for the same work. The reason is that greater grinding pressures can be obtained on the swing-frame machines.

### Abrasive Belt Grinding

Abrasive belts are used in the metalworking industry for removing stock, light cleaning up of metal surfaces, grinding welds, deburring, breaking and polishing hole edges, and finish grinding of sheet steel. The types of belts that are used may be coated with aluminum oxide (the most common coating) for stock removal and finishing of all alloy steels, high-carbon steel, and tough bronzes; and silicon carbide for use on hard, brittle, and low-tensile strength metals which would include aluminum and cast irons.

Table 1 is a guide to the selection of the proper abrasive belt, lubricant, and contact wheel. This table is entered on the basis of the material used and type of operation to be done and gives the abrasive belt specifications (type of bonding and abrasive grain size and material), the range of speeds at which the belt may best be operated, the type of lubricant to use, and the type and hardness of the contact wheel to use. Table 2 serves as a guide in the selection of contact wheels. This table is entered on the basis of the type of contact wheel surface and the contact wheel material. The table gives the hardness and/or density, the type of abrasive belt grinding for which the contact wheel is intended, the character of the wheel action and such comments as the uses, and hints for best use. Both tables are intended only as guides for general shop practice; selections may be altered to suit individual requirements.

There are three types of abrasive belt grinding machines. One type employs a contact wheel behind the belt at the point of contact of the workpiece to the belt and facilitates a high rate of stock removal. Another type uses an accurate parallel ground platen over which the abrasive belt passes and facilitates the finishing of precision parts. A third type which has no platens or contact wheel is used for finishing parts having uneven surfaces or contours. In this type there is no support behind the belt at the point of contact of the belt with the workpiece. Some machines are so constructed that besides grinding against a platen or a contact wheel the workpiece may be moved and ground against an unsupported portion of the belt, thereby in effect making it a dual machine.

Although abrasive belts at the time of their introduction were used dry, since the advent of the improved waterproof abrasive belts, they have been used with coolants, oil-mists, and greases to aid the cutting action. The application of a coolant to the area of contact retards loading, resulting in a cool, free cutting action, a good finish and a long belt life.

### Abrasive Cutting

Abrasive cut-off wheels are used for cutting steel, brass and aluminum bars and tubes of all shapes and hardnesses, ceramics, plastics, insulating materials, glass and cemented carbides. Originally a tool or stock room procedure, this method has developed into a high-speed production operation. While the abrasive cut-off machine and cut-off wheel can be said to have revolutionized the practice of cutting off materials, the metal saw continues to be the more economical method for cutting off large cross sections of certain materials. However, there are innumerable materials and shapes that can be cut with much greater speed and economy by the abrasive wheel method. On conventional chop-stroke abrasive cutting machines using 16-inch (406.4 mm) diameter wheels, 2-inch (50.8 mm) diameter bar stock is the maximum size that can be cut with satisfactory wheel efficiency, but bar stock up to 6 inches (152.4 mm) in diameter can be cut efficiently on oscillating-stroke machines. Tubing up to 3½ inches (88.9 mm) in diameter can also be cut efficiently.

Abrasive wheels are commonly available in four types of bonds: Resinoid, rubber, shellac and fiber or fabric reinforced. In general, resinoid bonded cut-off wheels are used for dry cutting where burrs and some burn are not objectionable and rubber bonded wheels are used for wet cutting where cuts are to be smooth, clean and free from burrs. Shellac bonded wheels have a soft, free cutting quality which makes them particularly useful in the tool room where tool steels are to be cut without discoloration. Fiber reinforced bonded wheels are able to withstand severe flexing and side pressures and fabric reinforced bonded wheels which are highly resistant to breakage caused by extreme side pressures, are fast cutting and have a low rate of wear.

**Table 1. Guide to the Selection and Application of Abrasive Belts**

Material	Type of Operation	Abrasive Belt <sup>a</sup>	Grit	Belt Speed		Type of Grease Lubricant	Contact Wheel	
				fpm	m/min		Type	Durometer Hardness
Hot-and Cold-Rolled Steel	Roughing	R/R Al <sub>2</sub> O <sub>3</sub>	24–60	4000–6500	1219–1981	Light-body or none	Cog-tooth, serrated rubber	70–90
	Polishing	R/G or R/R Al <sub>2</sub> O <sub>3</sub>	80–150	4500–7000	1372–2134	Light-body or none	Plain or serrated rubber, sectional or finger-type cloth wheel, free belt	20–60
	Fine Polishing	R/G or electro-coated Al <sub>2</sub> O <sub>3</sub> cloth	180–500	4500–7000	1372–2134	Heavy or with abrasive compound	Smooth-faced rubber or cloth	20–40
Stainless Steel	Roughing	R/R Al <sub>2</sub> O <sub>3</sub>	50–80	3500–5000	1067–1524	Light-body or none	Cog-tooth, serrated rubber	70–90
	Polishing	R/G or R/R Al <sub>2</sub> O <sub>3</sub>	80–120	4000–5500	1219–1676	Light-body or none	Plain or serrated rubber, sectional or finger-type cloth wheel, free belt	30–60
	Fine Polishing	Closed-coat SiC	150–280	4500–5500	1372–1676	Heavy or oil mist	Smooth-faced rubber or cloth	20–40
Aluminum, Cast or Fabricated	Roughing	R/R SiC or Al <sub>2</sub> O <sub>3</sub>	24–80	5000–6500	1524–1981	Light	Cog-tooth, serrated rubber	70–90
	Polishing	R/G SiC or Al <sub>2</sub> O <sub>3</sub>	100–180	4500–6500	1372–1981	Light	Plain or serrated rubber, sectional or finger-type cloth wheel, free belt	30–50
	Fine Polishing	Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub>	220–320	4500–6500	1372–1981	Heavy or with abrasive compound	Plain faced rubber, finger-type cloth or free belt	20–50
Copper Alloys or Brass	Roughing	R/R SiC or Al <sub>2</sub> O <sub>3</sub>	36–80	2200–4500	671–1372	Light-body	Cog-tooth, serrated rubber	70–90
	Polishing	Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub> or R/G SiC or Al <sub>2</sub> O <sub>3</sub>	100–150	4000–6500	1219–1981	Light-body	Plain or serrated rubber, sectional or finger-type cloth wheel, free belt	30–50
	Fine Polishing	Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub>	180–320	4000–6500	1219–1981	Light or with abrasive compound	Same as for polishing	20–30
Nonferrous Die-Castings	Roughing	R/R SiC or Al <sub>2</sub> O <sub>3</sub>	24–80	4500–6500	1372–1981	Light-body	Hard wheel depending on application	50–70
	Polishing	R/G SiC or Al <sub>2</sub> O <sub>3</sub>	100–180	4500–6500	1372–1981	Light-body	Plain rubber, cloth or free belt	30–50
	Fine Polishing	Electro-coated Al <sub>2</sub> O <sub>3</sub> or closed-coat SiC	220–320	4500–6500	1372–1981	Heavy or with abrasive compound	Plain or finger-type cloth wheel, or free belt	20–30
Cast Iron	Roughing	R/R Al <sub>2</sub> O <sub>3</sub>	24–60	2000–4000	610–1219	None	Cog-tooth, serrated rubber	70–90
	Polishing	R/R Al <sub>2</sub> O <sub>3</sub>	80–150	4000–5500	1219–1676	None	Serrated rubber	30–70
	Fine Polishing	R/R Al <sub>2</sub> O <sub>3</sub>	120–240	4000–5500	1219–1676	Light-body	Smooth-faced rubber	30–40
Titanium	Roughing	R/R SiC or Al <sub>2</sub> O <sub>3</sub>	36–50	700–1500	213–457	Sulfur-chlorinated	Small-diameter, cog-tooth serrated rubber	70–80
	Polishing	R/R SiC	60–120	1200–2000	366–610	Light-body	Standard serrated rubber	50
	Fine Polishing	R/R SiC	120–240	1200–2000	366–610	Light-body	Smooth-faced rubber or cloth	20–40

<sup>a</sup> R/R indicates that both the making and sizing bond coats are resin. R/G indicates that the making coat is glue and the sizing coat is resin. The abbreviations Al<sub>2</sub>O<sub>3</sub> for aluminum oxide and SiC for silicon carbide are used. Almost all R/R and R/G Al<sub>2</sub>O<sub>3</sub> and SiC belts have a heavy-drill weight cloth backing. Most electro-coated Al<sub>2</sub>O<sub>3</sub> and closed-coat SiC belts have a jeans weight cloth backing.

**Table 2. Guide to the Selection and Application of Contact Wheels**

Surface	Material	Hardness and Density	Purposes	Wheel Action	Comments
Cog-tooth	Rubber	70 to 90 durometer	Roughing	Fast cutting, allows long belt life.	For cutting down projections on castings and weld beads.
Standard serrated	Rubber	40 to 50 durometer, medium density	Roughing	Leaves rough- to medium-ground surface.	For smoothing projections and face defects.
X-shaped serrations	Rubber	20 to 50 durometer	Roughing and polishing	Flexibility of rubber allows entry into contours. Medium polishing, light removal.	Same as for standard serrated wheels but preferred for soft nonferrous metals.
Plain face	Rubber	20 to 70 durometer	Roughing and polishing	Plain wheel face allows controlled penetration of abrasive grain. Softer wheels give better finishes.	For large or small flat faces.
Flat flexible	Compressed canvas	About nine densities from very hard to very soft	Roughing and polishing	Hard wheels can remove metal, but not as quickly as cog-tooth rubber wheels. Softer wheels polish well.	Good for medium-range grinding and polishing.
Flat flexible	Solid sectional canvas	Soft, medium, and hard	Polishing	Uniform polishing. Avoids abrasive pattern on work. Adjusts to contours. Can be performed for contours.	A low-cost wheel with uniform density at the face. Handles all types of polishing.
Flat flexible	Buff section canvas	Soft	Contour polishing	For fine polishing and finishing.	Can be widened or narrowed by adding or removing sections. Low cost.
Flat flexible	Sponge rubber inserts	5 to 10 durometer, soft	Polishing	Uniform polishing and finishing. Polishes and blends contours.	Has replaceable segments. Polishes and blends contours. Segments allow density changes.
Flexible	Fingers of canvas attached to hub	Soft	Polishing	Uniform polishing and finishing.	For polishing and finishing.
Flat flexible	Rubber segments	Varies in hardness	Roughing and polishing	Grinds or polishes depending on density and hardness of inserts.	For portable machines. Uses replaceable segments that save on wheel costs and allow density changes.
Flat flexible	Inflated rubber	Air pressure controls hardness	Roughing and polishing	Uniform finishing.	Adjusts to contours.

The types of abrasives available in cut-off wheels are: Aluminum oxide, for cutting steel and most other metals; silicon carbide, for cutting non-metallic materials such as carbon, tile, slate, ceramics, etc.; and diamond, for cutting cemented carbides. The method of denoting abrasive type, grain size, grade, structure and bond type by using a system of markings is the same as for grinding wheels (see page 1282). Maximum wheel speeds given in the ANSI Standard "Safety Requirements for The Use, Care, and Protection of Abrasive Wheels" (ANSI B7.1-2017) range from 9500 to 14,200 sfpm (2896–4328 m/min) for organic bonded cut-off wheels larger than 16 inches (40.6 cm) in diameter and from 9500 to 16,000 sfpm (2896–4877 m/min) for organic bonded cut-off wheels 16 inches in diameter and smaller. Maximum wheel speeds specified by the manufacturer should never be exceeded even though they may be lower than those given in the B7.1 Standard.

There are four basic types of abrasive cutting machines: Chop-stroke, oscillating stroke, horizontal stroke and work rotating. Each of these four types may be designed for dry cutting or for wet cutting (includes submerged cutting).

The accompanying table based upon information made available by The Carborundum Co. gives some of the probable causes of cutting off difficulties that might be experienced when using abrasive cut-off wheels.

**Probable Causes of Cutting-Off Difficulties**

Difficulty	Probable Cause
Angular Cuts and Wheel Breakage	(1) Inadequate clamping which allows movement of work while the wheel is in the cut. The work should be clamped on both sides of the cut. (2) Work vise higher on one side than the other causing wheel to be pinched. (3) Wheel vibration resulting from worn spindle bearings. (4) Too fast feeding into the cut when cutting wet.
Burning of Stock	(1) Insufficient power or drive allowing wheel to stall. (2) Cuts too heavy for grade of wheel being used. (3) Wheel fed through the work too slowly. This causes a heating up of the material being cut. This difficulty encountered chiefly in dry cutting.
Excessive Wheel Wear	(1) Too rapid cutting when cutting wet. (2) Grade of wheel too hard for work, resulting in excessive heating and burning out of bond. (3) Inadequate coolant supply in wet cutting. (4) Grade of wheel too soft for work. (5) Worn spindle bearings allowing wheel vibration.
Excessive Burring	(1) Feeding too slowly when cutting dry. (2) Grit size in wheel too coarse. (3) Grade of wheel too hard. (4) Wheel too thick for job.

**Honing Process**

The hone-abrading process for obtaining cylindrical forms with precise dimensions and surfaces can be applied to internal cylindrical surfaces with a wide range of diameters such as engine cylinders, bearing bores, pin holes, etc. and also to some external cylindrical surfaces. The process is used to: 1) eliminate inaccuracies resulting from previous operations by generating a true cylindrical form with respect to roundness and straightness within minimum dimensional limits; 2) generate final dimensional size accuracy within low tolerances, as may be required for interchangeability of parts; 3) provide rapid and economical stock removal consistent with accomplishment of the other results; and 4) generate surface finishes of a specified degree of surface smoothness with high surface quality.

**Amount and Rate of Stock Removal.**—Honing may be employed to increase bore diameters by as much as 0.100 inch (2.5 mm) or as little as 0.001 inch (0.25 mm). The amount of stock removed by the honing process is entirely a question of processing economy. If other operations are performed before honing then the bulk of the stock should be taken off by the operation that can do it most economically. In large diameter bores that have been distorted in heat treating, it may be necessary to remove as much as 0.030 to 0.040 inch (0.76–1.02 mm) from the diameter to make the bore round and straight. For out-of-round or tapered bores, a good “rule of thumb” is to leave twice as much stock (on the diameter) for honing as there is error in the bore. Another general rule is: For bores over 1 inch (25.4 mm) in diameter, leave 0.001 to 0.0015 inch stock per inch of diameter (0.025–0.038 mm stock/mm). For example, 0.002 to 0.003 inch (0.05–0.08 mm) of stock is left in 2-inch bores (50.8 mm) and 0.010 to 0.015 inch (0.25–0.38 mm) in 10-inch (254 mm) bores. Where parts are to be honed for finish only, the amount of metal to be left for removing tool marks may be as little as 0.0002 to 0.015 inch (0.005–0.38 mm) on the diameter.

In general, the honing process can remove stock from bore diameters at the rate of 0.009 to 0.012 inch per minute (0.23–0.30 mm/min) on cast-iron parts and from 0.005 to 0.008 inch per minute (0.13–0.20 mm/min) on steel parts having a hardness of 60 to 65 RC (Rockwell C scale). These rates are based on parts having a length equal to three or four times the diameter. Stock has been removed from long parts such as gun barrels, at the rate of 65 cubic inches per hour (17.75 cc/s). Recommended honing speeds for cast iron range from 110 to 200 surface feet per minute (34–61 m/min) of rotation and from 50 to 110 lineal feet per minute (15–34 m/min) of reciprocation. For steel, rotating surface speeds range from 50 to 110 feet per minute (15–34 m/min) and reciprocation speeds from 20 to 90 lineal feet per minute (6–27 m/min). The rotation and reciprocation speeds to be used depend on the size of the work, the amount and characteristics of the material to be removed, and the

quality of the finish desired. In general, the harder the material to be honed, the lower the speed. Interrupted bores are usually honed at faster speeds than plain bores.

**Formulas for Rotative Speeds.**—Empirical formulas for determining rotative speeds for honing have been developed by the Micromatic Hone Corp. These formulas take into consideration the type of material being honed, its hardness and its surface characteristics; the abrasive area; and the type of surface pattern and degree of surface roughness desired. Because of the wide variations in material characteristics, abrasives available, and types of finishes specified, these formulas should be considered as a guide only in determining which of the available speeds (pulley or gear combinations) should be used for any particular application.

The formula for rotative speed,  $S$ , in surface feet per minute is:  $S = \frac{K \times D}{W \times N}$

The formula for rotative speed in revolutions per minute is:  $R.P.M = \frac{R}{W \times N}$

where,  $K$  and  $R$  are factors taken from the table on the following page,  $D$  is the diameter of the bore in inches,  $W$  is the width of the abrasive stone or stock in inches, and  $N$  is the number of stones.

Although the actual speed of the abrasive is the resultant of both the rotative speed and the reciprocation speed, this latter quantity is seldom solved for or used. The reciprocation speed is not determined empirically but by testing under operating conditions. Changing the reciprocation speed affects the dressing action of the abrasive stones, therefore, the reciprocation speed is adjusted to provide for a desired surface finish which is usually a well lubricated bearing surface that will not scuff.

**Table of Factors for Use in Rotative Speed Formulas**

Character of Surface <sup>a</sup>	Material	Hardness <sup>b</sup>					
		Soft		Medium		Hard	
		Factors					
		$K$	$R$	$K$	$R$	$K$	$R$
Base Metal	Cast Iron	110	420	80	300	60	230
	Steel	80	300	60	230	50	190
Dressing Surface	Cast Iron	150	570	110	420	80	300
	Steel	110	420	80	300	60	230
Severe Dressing	Cast Iron	200	760	150	570	110	420
	Steel	150	570	110	420	80	300

<sup>a</sup> The character of the surface is classified according to its effect on the abrasive: *Base Metal* being a honed, ground or fine bored section that has little dressing action on the grit; *Dressing Surface* being a rough bored, reamed or broached surface or any surface broken by cross holes or ports; *Severe Dressing* being a surface interrupted by keyways, undercuts or burrs that dress the stones severely. If over half of the stock is to be removed after the surface is cleaned up, the speed should be computed using the *Base Metal* factors for  $K$  and  $R$ .

<sup>b</sup> Hardness designations of soft, medium, and hard cover the following ranges on the Rockwell C hardness scale, respectively: 15 to 45, 45 to 60, and 60 to 70.

**Abrasive Stones for Honing.**—Honing stones consist of aluminum oxide, silicon carbide, CBN or diamond abrasive grits, held together in stick form by a vitrified clay, resinoid or metal bond. CBN metal-bond stones are particularly suitable and widely used for honing. The grain and grade of abrasive to be used in any particular honing operation depend upon the quality of finish desired, the amount of stock to be removed, the material being honed and other factors.

The following general rules may be followed in the application of abrasive for honing: 1) Silicon-carbide abrasive is commonly used for honing cast iron, while aluminum-oxide abrasive is generally used on steel; 2) The harder the material being honed, the softer the abrasive stick used; 3) A rapid reciprocating speed will tend to make the abrasive cut

fast because the dressing action on the grits will be severe; and 4) To improve the finish, use a finer abrasive grit, incorporate more multi-direction action, allow more "run-out" time after honing to size, or increase the speed of rotation.

### Possible Adjustments for Eliminating Undesirable Honing Conditions

Undesirable Condition	Adjustment Required to Correct Condition <sup>a</sup>								
	Abrasive <sup>b</sup>				Other				
	Friability	Grain Size	Hardness	Structure	Feed Pressure	Reciprocation	R.P.M.	Runout Time	Stroke Length
Abrasive Glazing	+	--	--	+	++	++	--	-	0
Abrasive Loading	0	--	-	-	++	+	--	0	0
Too Rough Surface Finish	0	++	++	-	-	-	++	+	0
Too Smooth Surface Finish	0	--	--	+	+	+	--	-	0
Poor Stone Life	-	+	++	-	-	-	+	0	0
Slow Stock Removal	+	--	-	+	++	++	--	0	0
Taper — Large at Ends	0	0	0	0	0	0	0	0	-
Taper — Small at Ends	0	0	0	0	0	0	0	0	+

<sup>a</sup> The + and ++ symbols generally indicate that there should be an increase or addition while the - and -- symbols indicate that there should be a reduction or elimination. In each case, the double symbol indicates that the contemplated change would have the greatest effect. The 0 symbol means that a change would have no effect.

<sup>b</sup> For the abrasive adjustments the + and ++ symbols indicate a more friable grain, a finer grain, a harder grade or a more open structure and the - and -- symbols just the reverse.

Compiled by Micromatic Hone Corp.

Surface roughnesses ranging from less than 1 micro-inch rms (0.0254  $\mu\text{m}$  rms) to a relatively coarse roughness can be obtained by judicious choice of abrasive and honing time but the most common range is from 3 to 50 micro-inches rms (0.0762–1.27  $\mu\text{m}$  rms).

**Adjustments for Eliminating Undesirable Honing Conditions.**—The accompanying table indicates adjustments that may be made to correct certain undesirable conditions encountered in honing. Only one change should be made at a time and its effect noted before making other adjustments.

**Tolerances.**—For bore diameters above 4 inches (101.6 mm) the tolerance of honed surfaces with respect to roundness and straightness ranges from 0.0005 to 0.001 inch (0.0127–0.0254 mm); for bore diameters from 1 to 4 inches (25.4–101.6 mm), 0.0003 to 0.0005 inch (0.0076–0.0127 mm); and for bore diameters below 1 inch (25.4 mm), 0.00005 to 0.0003 inch (0.0013–0.0076 mm).

### Laps and Lapping

**Material for Laps.**—Laps are usually made of soft cast iron, copper, brass or lead. In general, the best material for laps to be used on very accurate work is soft, close-grained cast iron. If the grinding, prior to lapping, is of inferior quality, or an excessive allowance has been left for lapping, copper laps may be preferable. They can be charged more easily and cut more rapidly than cast iron, but do not produce as good a finish. Whatever material is used, the lap should be softer than the work, as, otherwise, the latter will become charged with the abrasive and cut the lap, the order of the operation being reversed. A common and inexpensive form of lap for holes is made of lead which is cast around a tapering steel arbor. The arbor usually has a groove or keyway extending lengthwise, into which the lead flows, thus forming a key that prevents the lap from turning. When the lap has worn slightly smaller than the hole and ceases to cut, the lead is expanded or stretched a little by the driving in of the arbor. When this expanding operation has been repeated two or three times, the lap usually must be trued or replaced with a new one, owing to distortion.

The tendency of lead laps to lose their form is an objectionable feature. They are, however, easily molded, inexpensive, and quickly charged with the cutting abrasive. A more elaborate form for holes is composed of a steel arbor and a split cast-iron or copper shell which is sometimes prevented from turning by a small dowel pin. The lap is split so that it can be expanded to accurately fit the hole being operated upon. For hardened work, some toolmakers prefer copper to either cast iron or lead. For holes varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch (6.35–12.7 mm) in diameter, copper or brass is sometimes used; cast iron is used for holes larger than  $\frac{1}{2}$  inch (12.7 mm) in diameter. The arbors for these laps should have a taper of about  $\frac{1}{4}$  or  $\frac{3}{8}$  inch per foot (20.83 or 31.25 mm/m). The length of the lap should be somewhat greater than the length of the hole, and the thickness of the shell or lap proper should be from  $\frac{1}{8}$  to  $\frac{1}{6}$  its diameter.

External laps are commonly made in the form of a ring, with an outer ring or holder and an inner shell which forms the lap proper. This inner shell is made of cast iron, copper, brass, or lead. Ordinarily the lap is split and screws are provided in the holder for adjustment. The length of an external lap should at least equal the diameter of the work, and may be longer. Large ring laps usually have a handle for moving them across the work.

**Laps for Flat Surfaces.**—Laps for producing plane surfaces are made of cast iron. In order to secure accurate results, the lapping surface must be a true plane. A flat lap that is used for roughing or “blocking down” will cut better if the surface is scored by narrow grooves. These are usually located about  $\frac{1}{2}$  inch (12.7 mm) apart and extend both lengthwise and crosswise, thus forming a series of squares similar to those on a checker-board. An abrasive of No. 100 or 120 emery and lard oil can be used for charging the roughing lap. For finer work, a lap having an unscored surface is used, and the lap is charged with a finer abrasive. After a lap is charged, all loose abrasive should be washed off with gasoline, for fine work, and when lapping, the surface should be kept moist, preferably with kerosene. Gasoline will cause the lap to cut a little faster, but it evaporates so rapidly that the lap soon becomes dry and the surface caked and glossy in spots. Loose emery should not be applied while lapping, for if the lap is well charged with abrasive in the beginning, is kept well moistened and not crowded too hard, it will cut for a considerable time. The pressure upon the work should be just enough to insure constant contact. The lap can be made to cut only so fast, and if excessive pressure is applied it will become “stripped” in places. The causes of scratches are: Loose abrasive on the lap; too much pressure on the work, and poorly graded abrasive. To produce a perfectly smooth surface free from scratches, the lap should be charged with a very fine abrasive.

**Grading Abrasives for Lapping.**—For high-grade lapping, abrasives can be evenly graded as follows: A quantity of flour-emery or other abrasive is placed in a heavy cloth bag, which is gently tapped, causing very fine particles to be sifted through. When a sufficient quantity has been obtained in this way, it is placed in a dish of lard or sperm oil. The largest particles will then sink to the bottom and in about one hour the oil should be poured into another dish, care being taken not to disturb the sediment at the bottom. The oil is then allowed to stand for several hours, after which it is poured again, and so on, until the desired grade is obtained.

**Charging Laps.**—To charge a flat cast-iron lap, spread a very thin coating of the prepared abrasive over the surface and press the small cutting particles into the lap with a hard steel block. There should be as little rubbing as possible. When the entire surface is apparently charged, clean and examine for bright spots; if any are visible, continue charging until the entire surface has a uniform gray appearance. When the lap is once charged, it should be used without applying more abrasive until it ceases to cut. If a lap is over-charged and an excessive amount of abrasive is used, there is a rolling action between the work and lap which results in inaccuracy. The surface of a flat lap is usually finished true, prior to charging, by scraping and testing with a standard surface-plate, or by the well-known method of scraping-in three plates together, in order to secure a plane surface. In any case, the bearing marks or spots should be uniform and close together. These spots can be blended by covering the plates evenly with a fine abrasive and rubbing them together. While the

plates are being ground in, they should be carefully tested and any high spots which may form should be reduced by rubbing them down with a smaller block.

To charge cylindrical laps for internal work, spread a thin coating of prepared abrasive over the surface of a hard steel block, preferably by rubbing lightly with a cast-iron or copper block; then insert an arbor through the lap and roll the latter over the steel block, pressing it down firmly to embed the abrasive into the surface of the lap. For external cylindrical laps, the inner surface can be charged by rolling-in the abrasive with a hard steel roller that is smaller in diameter than the lap. The taper cast-iron blocks sometimes used for lapping taper holes can also be charged by rolling-in the abrasive, as described; there is usually one roughing and one finishing lap, and when charging the former, it may be necessary to vary the charge according to any error that might exist in the taper.

**Rotary Diamond Lap.**—This style of lap is used for accurately finishing very small holes, which, because of their size, cannot be ground. While the operation is referred to as lapping, it is, in reality, a grinding process, the lap being used the same as a grinding wheel. Laps employed for this work are made of mild steel, soft material being desirable because it can be charged readily. Charging is usually done by rolling the lap between two hardened steel plates. The diamond dust and a little oil is placed on the lower plate, and as the lap revolves, the diamond is forced into its surface. After charging, the lap should be washed in benzine. The rolling plates should also be cleaned before charging with dust of a finer grade. It is very important not to force the lap when in use, especially if it is a small size. The lap should just make contact with the high spots and gradually grind them off. If a diamond lap is lubricated with kerosene, it will cut freer and faster. These small laps are run at very high speeds, the rate depending upon the lap diameter. Soft work should never be ground with diamond dust because the dust will leave the lap and charge the work.

When using a diamond lap, it should be remembered that such a lap will not produce sparks like a regular grinding wheel; hence, it is easy to crowd the lap and "strip" some of the diamond dust. To prevent this, a sound intensifier or "harker" should be used. This is placed against some stationary part of the grinder spindle, and indicates when the lap touches the work, the sound produced by the slightest contact being intensified.

**Grading Diamond Dust.**—The grades of diamond dust used for charging laps are designated by numbers, the fineness of the dust increasing as the numbers increase. The diamond, after being crushed to powder in a mortar, is thoroughly mixed with high-grade olive oil. This mixture is allowed to stand 5 minutes and then the oil is poured into another receptacle. The coarse sediment is left is removed and labeled No. 0, according to one system. The oil poured from No. 0 is again stirred and allowed to stand 10 minutes, after which it is poured into another receptacle and the sediment remaining is labeled No. 1. This operation is repeated until practically all of the dust has been recovered from the oil, the time the oil is allowed to stand being increased as shown by the following table. This is done to obtain the smaller particles that require a longer time for precipitation:

To obtain No. 1 — 10 minutes	To obtain No. 4 — 2 hours
To obtain No. 2 — 30 minutes	To obtain No. 5 — 10 hours
To obtain No. 3 — 1 hour	To obtain No. 6 — until oil is clear

The No. 0 or coarse diamond which is obtained from the first settling is usually washed in benzine, and re-crushed unless very coarse dust is required. This No. 0 grade is sometimes known as "ungraded" dust. In some places the time for settling, in order to obtain the various numbers, is greater than that given in the table.

**Cutting Properties of Laps and Abrasives.**—In order to determine the cutting properties of abrasives when used with different lapping materials and lubricants, a series of tests was conducted, the results of which were given in a paper by W. A. Knight and A. A. Case, presented before the American Society of Mechanical Engineers. In connection with these tests, a special machine was used, the construction being such that quantitative results could be obtained with various combinations of abrasive, lubricant, and lap material. These tests were confined to surface lapping.

It was not the intention to test a large variety of abrasives, three being selected as representative; namely, Naxos emery, carborundum, and alundum. Abrasive No. 150 was used in each case, and seven different lubricants, five different pressures, and three different lap materials were employed. The lubricants were lard oil, machine oil, kerosene, gasoline, turpentine, alcohol, and soda water.

These tests indicated throughout that there is, for each combination of lap and lubricant, a definite size of grain that will give the maximum amount of cutting. With all the tests, except when using the two heavier lubricants, some reduction in the size of the grain below that used in the tests (No. 150) seemed necessary before the maximum cutting rate was reached. This reduction was continuous and soon passed below that which gave the maximum cutting rate.

**Cutting Qualities with Different Laps.**—The surfaces of the steel and cast-iron laps were finished by grinding. The hardness of the different laps, as determined by the scleroscope was, for cast-iron, 28; steel, 18; copper, 5. The total amount ground from the test-pieces with each of the three laps showed that, taking the whole number of tests as a standard, there is scarcely any difference between the steel and cast iron, but that copper has somewhat better cutting qualities, although, when comparing the laps on the basis of the highest and lowest values obtained with each lap, steel and cast iron are as good for all practical purposes as copper, when the proper abrasive and lubricant are used.

**Wear of Laps.**—The wear of laps depends upon the material from which they are made and the abrasive used. The wear on all laps was about twice as fast with carborundum as with emery; with alundum the wear was about one and one-fourth times that with emery. On an average, the wear of the copper lap was about three times that of the cast-iron lap. This is not absolute wear, but wear in proportion to the amount ground from the test-pieces.

**Lapping Abrasives.**—As to the qualities of the three abrasives tested, it was found that carborundum usually began at a lower rate than the other abrasives, but, when once started, its rate was better maintained. The performance gave a curve that was more nearly a straight line. The charge or residue as the grinding proceeded remained cleaner and sharper and did not tend to become pasty or mucklike, as is so frequently the case with emery. When using a copper lap, carborundum shows but little gain over the cast-iron and steel laps, whereas, with emery and alundum, the gain is considerable.

**Effect of Different Lapping Lubricants.**—The action of the different lubricants, when tested, was found to depend upon the kind of abrasive and the lap material.

*Lard and Machine Oil:* The test showed that lard oil, without exception, gave the higher rate of cutting, and that, in general, the initial rate of cutting is higher with the lighter lubricants, but falls off more rapidly as the test continues. The lowest results were obtained with machine oil, when using an emery-charged, cast-iron lap. When using lard oil and a carborundum-charged steel lap, the highest results were obtained.

*Gasoline and Kerosene:* On the cast-iron lap, gasoline was superior to any of the lubricants tested. Considering all three abrasives, the relative value of gasoline, when applied to the different laps, is as follows: Cast iron, 127; copper, 115; steel, 106. Kerosene, like gasoline, gives the best results on cast iron and the poorest on steel. The values obtained by carborundum were invariably higher than those obtained with emery, except when using gasoline and kerosene on a copper lap.

*Turpentine and Alcohol:* Turpentine was found to do good work with carborundum on any lap. With emery, turpentine did fair work on the copper lap, but, with the emery on cast-iron and steel laps, it was distinctly inferior. Alcohol gives the lowest results with emery on the cast-iron and steel laps.

*Soda Water:* Soda water gives medium results with almost any combination of lap and abrasives, the best work being on the copper lap and the poorest on the steel lap. On the cast-iron lap, soda water is better than machine or lard oil, but not so good as gasoline or

kerosene. Soda water when used with alundum on the copper lap, gave the highest results of any of the lubricants used with that particular combination.

**Lapping Pressures.**—Within the limits of the pressures used, that is, up to 25 pounds per square inch (172 kPa), the rate of cutting was found to be practically proportional to the pressure. The higher pressures of 20 and 25 pounds per square inch (138 and 172 kPa) are not so effective on the copper lap as on the other materials.

**Wet and Dry Lapping.**—With the “wet method” of using a surface lap, there is a surplus of oil and abrasive on the surface of the lap. As the specimen being lapped is moved over it, there is more or less movement or shifting of the abrasive particles. With the “dry method,” the lap is first charged by rubbing or rolling the abrasive into its surface. All surplus oil and abrasive are then washed off, leaving a clean surface, but one that has embedded uniformly over it small particles of the abrasive. It is then like the surface of a very fine oilstone and will cut away hardened steel that is rubbed over it. While this has been termed the dry method, in practice, the lap surface is kept moistened with kerosene or gasoline.

Experiments on dry lapping were carried out on the cast-iron, steel, and copper laps used in the previous tests, and on one of tin made expressly for the purpose. Carborundum alone was used as the abrasive and a uniform pressure of 15 pounds per square inch (103 kPa) was applied to the specimen throughout the tests. In dry lapping, much depends upon the manner of charging the lap. The rate of cutting decreased more rapidly after the first 100 revolutions than with the wet method. Considering the amounts ground off during the first 100 revolutions, and the best result obtained with each lap taken for comparison, it was found that with a tin lap, charged by rolling No. 150 carborundum into the surface, the rate of cutting, when dry, approached that obtained with the wet method. With the other lap materials, the rate with the dry method was about one-half that of the wet method.

**Summary of Lapping Tests.**—The initial rate of cutting does not greatly differ for different abrasives. There is no advantage in using an abrasive coarser than No. 150. The rate of cutting is practically proportional to the pressure. The wear of the laps is in the following proportions: cast iron, 1.00; steel, 1.27; copper, 2.62. In general, copper and steel cut faster than cast iron, but, where permanence of form is a consideration, cast iron is the superior metal. Gasoline and kerosene are the best lubricants to use with a cast-iron lap. Machine and lard oil are the best lubricants to use with copper or steel laps. They are, however, least effective on a cast-iron lap. In general, wet lapping is from 1.2 to 6 times as fast as dry lapping, depending upon the material of the lap and the manner of charging.

## NONTRADITIONAL MACHINING AND CUTTING

**Introduction.**—Manufacturers are constantly pursuing new methods to machine complex features faster, with more accuracy, and without imposing significant cutting forces on sensitive or thin parts. In addition, use of advanced composites and harder and brittle materials is increasing. These challenges create a growing need for nontraditional machining processes, which can be categorized by material removal processes: chemical, electrochemical, mechanical erosion, and electro-thermal. Such modern methods tend to be automated, with sophisticated systems and software often used to control process variables.

Shown in [Table 1](#) are characteristics of some of the most commonly used nontraditional machining methods discussed in this section. Equipment improvements are ongoing and capabilities vary, so values given are representative rather than absolute. [Table 2](#) contains some examples of cutting speeds for metals from industry literature. Actual speeds will vary, depending on equipment, setup, materials processed, and other factors.

**Table 1. Typical Characteristics of Some Nontraditional Machining Methods**

	<b>Water Jet (WJM/AWJM)</b>	<b>Laser (LBM)</b>	<b>Plasma (PAM)</b>	<b>Electrical Discharge (EDM/WEDM)</b>
<b>Process Used</b>	Erosion	Melting/Vaporization	Melting	Vaporization/Erosion
<b>Materials Processed</b>	Most	Many	Conductive	Conductive
<b>Materials Not Processed</b>	Diamond	Some Reflective	Non-Conductive	Non-Conductive
	Tempered Glass	Non-Homogeneous	Non-Homogeneous	Non-Homogeneous
<b>Feature Detail Level</b>	High	Very High	Medium	Very High
<b>Maximum Part Thickness (Rough Cut)</b>	12 in. (305 mm)	1.5 in. (38.1 mm)	6 in. (152.4 mm)	12 in. (305 mm)
<b>Maximum Part Thickness (High-Quality Cut)</b>	2 in. (50.8 mm)	1 in. (25.4 mm)	2 in. (50.8 mm)	12 in. (305 mm)
<b>Typical Accuracy (Thin Stock)</b>	±0.001 in. (0.03 mm)	±0.001 in. (0.03 mm)	±0.01 in. (0.25 mm)	±0.001 in. (0.03 mm)
<b>Typical Accuracy (Thick Stock)</b>	±0.005 in. (0.13 mm)	±0.005 in. (0.13 mm)	±0.03 in. (0.76 mm)	±0.001 in. (0.03 mm)

### Mechanical Erosion Processes

Many conductive and non-conductive materials can be machined or cut using mechanical erosion processes that exert relatively low force on the workpiece or part and do not introduce thermal effects. Currently, the most prevalent of these processes are water jet machining (WJM) and abrasive water jet machining (AWJM). Other mechanical erosion processes include ultrasonic machining (USM), abrasive jet machining (AJM), abrasive flow machining (AFM), and magnetic abrasive finishing (MAF).

**Water Jet Machining (WJM).**—Conductive, non-conductive, reflective, thin, and very thick materials can be cut using water jet machining technology, also known as hydrodynamic machining, which includes both abrasive water jet machining and pure water jet machining. In both processes, a pump or intensifier pressurizes water and drives it through a small orifice to form a supersonic jet that exerts force on the workpiece. A typical system pressure is 60 ksi (414 MPa); some systems are capable of up to 90 ksi (620 MPa); and with some pump and orifice combinations, jet velocity can be as high as three times the speed of sound, or 2952 fps (900 m/s). The jet orifice normally is made of jewel, often sapphire or ruby; as the orifice can crack or chip from use, diamond may be used to extend tool life.

One limitation of water jet cutting is its inability to cut into hollow sections without special precautions. Upon cutting through the first wall of the section, the jet will spread rapidly and either just gouge or cut a wide path through the far wall. A sacrificial part can be placed inside the hollow to absorb the jet force, but if the inserted part does not completely fill the space, some blasting damage will occur inside the hollow due to ricochet.

**Water Jet Cut Quality:** Water jet systems can create relatively smooth cuts that require no secondary finishing. Cut quality typically decreases with decreasing speed. Subjective cut quality designations typically used in industry range from Q1 to Q5 and refer to surface quality. Q1 cuts, suitable for rapid separations or roughing, have a heavily striated surface, with curved striations, due to stream lag induced by head travel. Q2 is appropriate for general-purpose through cuts, often producing heavy striations toward the bottom. Q3 cuts are commonly used for general-purpose clean cuts, while Q4 cuts produce a finer surface finish. Q5 cuts have the best surface finish, often targeting a roughness average (Ra) of 80  $\mu\text{in.}$  (2  $\mu\text{m.}$ )

Additional cut characteristics, such as accuracy, kerf width, taper (bevel), entrance rounding, and exit burr, are managed through process and maintenance. (Refer to [Table 1](#) and [Table 2](#) for some typical performance characteristics of precision water jet systems.) Obtaining a straight cut edge may require optimizing process parameters or employing a tilting head to compensate. Head component wear affects accuracy and is of particular concern in abrasive water jet processes.

Kerf width, or the width of material removed in cutting, is a function of jet diameter, standoff distance, cutting speed, and taper. With increased standoff distance, kerf width and taper increase. Standoff distance between the nozzle and workpiece typically ranges from 0.063 in. (1.6 mm) to 0.125 in. (3.2 mm). Excessive rounding of the entrance often occurs at standoff distances beyond this range.

Taper angle grows with increasing cutting speed; it is possible to produce a cut with negligible taper, but the process is likely to be slow. High speeds also will produce a tapered cut that is wider at the entrance than it is at the exit. Taper tends to increase in workpieces less than 0.125 in. (3.2 mm) thick, so stacking parts may be used to decrease taper.

Very slow speeds or very soft workpieces can result in a reverse tapered cut that is narrower at the entrance than it is at the exit; minimizing standoff distance can reduce this taper. When the workpiece is very thick, cuts may exhibit barrel taper, where the kerf is widest halfway through the cut, and narrowest at both entrance and exit. When cutting through ductile materials, the presence of a small burr at the cut exit is likely, but can be minimized through speed and standoff reduction.

**Abrasive Water Jet Machining (AWJM):** This process is appropriate for cutting hard and/or thick materials, including certain metals, ceramics, and stone. Metal workpieces less than 2 in. (50.8 mm) thick are well suited for abrasive water jet machining, and even

thicker metals in excess of 12 in. (305 mm) thick can be cut slowly. Supersonic water jets pull in metered, abrasive particles just after the orifice, and this solution travels down the mixing tube to the nozzle outlet.

The abrasive material often is garnet or similar material, with a particle size selected according to the nozzle opening, workpiece, and process. Grit sizes commonly used range from 50 mesh to 220 mesh (higher numbers indicate finer particles) in the Tyler Mesh Sizes (see *Meshes, Sieves, and Screens*, beginning on page 1068). An 80-mesh sieve size (0.007 in. or 0.177 mm) is most commonly used. The orifice and mixing tube combination determines the abrasive water jet stream diameter, which can be as small as 0.015 in. (0.38 mm), though 0.03–0.04 in. (0.76–1 mm) is more common. Nozzle mixing tubes wear rapidly with use; this can affect jet size and location.

**Pure Water Jet Machining:** Use of this process is limited to low-strength materials such as foam, fabric, and some plastics. The food industry often uses pure water jet cutting because it can be run as a sanitary process. As the jet contains no particles, very small jet sizes are possible. Typical orifices range from 0.003 in. to 0.015 in. (0.08 mm to 0.38 mm).

**Ultrasonic Machining (USM).**—Also referred to as ultrasonic vibration machining, this abrasive method makes cuts in material or changes its surface texture using a transducer that vibrates a tool at low amplitude (25 to 100 microns) and high frequency (15 to 30 kHz) and in a slurry containing fine abrasive particles. The vibrations force the particles against the material surface, removing material to the desired depth. For further information, see page 1260.

**Abrasive Flow Machining (AFM).**—Often used for deburring, smoothing, or polishing an interior part surface, but also applicable to final shaping, breakthrough, and drilling holes, this process forces a viscous fluid, containing abrasive material, through a workpiece.

**Magnetic Abrasive Finishing (MAF).**—This finishing process can be used to create a high surface quality, even on freeform parts. It involves adding micron-sized iron particulates to a flexible magnetic abrasive brush that can easily deform, based on the magnetic field strength, matching and honing a part, regardless of the complexity of the shape.

### Electro-Thermal Processes

These processes use melting, burning, or vaporization to remove material from a workpiece. Included are electrical discharge machining (EDM), laser beam machining (LBM), plasma arc cutting (PAM), and electron beam machining (EBM). The heat of these cutting methods can cause distortion, discoloration, changes in surface hardness or composition, and introduction of residual stresses in the workpiece.

To specify and evaluate quality and tolerances of cuts made with oxyfuel flame systems, plasma arc systems, and laser cutting systems, refer to ISO 9013, "Classification of thermal cuts – Geometrical product specification and quality tolerances." Below are the most commonly used electro-thermal processes. Additional information on some of these processes is included in the *ELECTRICAL DISCHARGE MACHINING* on page 1469 and the *WELDING* section, starting on page 1575.

**Electrical Discharge Machining (EDM).**—This process vaporizes conductive materials in contact with an electrode in a dielectric fluid bath. Both through-cutting wire systems and three-dimensional die-sinking systems are widely available and highly accurate. Refer to Table 1 for some typical performance characteristics of EDM processes. For detailed information, see page 1471.

**Laser Beam Machining (LBM).**—Lasers can cut both metals and non-metals through a process of vaporization, fusion (melt and blow), burning, or thermal stress cracking. Shallow engraving, blind features, and through cuts are all possible. Lasers can cut delicate parts, since there is no contact; however, laser processes generally use gas jets to create a reactive environment or eject material, and that may produce some pressure on the part in the area of the cut.

Material, geometry, and type of cut determine the best type of laser to use. CO<sub>2</sub> (gas) laser systems and Nd:YAG (rod crystal, solid state) laser systems have been used in

industry for many years. Fiber lasers are a newer solid-state technology that uses an Yb-doped optical fiber to amplify, contain, and direct a diode-generated laser beam; when the amplified light exits the fiber, a lens system collimates and focuses the beam. Thin disk (Yb:YAG) lasers are another new solid-state technology that provides power and beam quality comparable to fiber lasers. Most laser cutting systems in industry today use either fiber lasers or CO<sub>2</sub> lasers, and thin disk lasers are gaining in popularity.

Fiber and disk laser systems have the advantage of providing efficiency typically around 30 percent, while CO<sub>2</sub> lasers typically operate at 6 to 8 percent efficiency. Additional advantages of fiber and disk lasers are that they are made of solid-state components and do not require the high-speed turbines used in CO<sub>2</sub> laser systems, reducing periodic maintenance costs. However, CO<sub>2</sub> lasers often are preferred for cutting non-metals, such as ceramics, plastics, and various composites, due to their longer wavelength.

Most laser systems operate within an interlocked enclosure capable of blocking harmful light emissions, enclosing moving parts, and managing cutting fumes. Unlike CO<sub>2</sub> systems, fiber and disk laser light is delivered through an optical fiber, eliminating the need for periodic cleaning and alignment of the delivery system.

Wavelengths for common industrial lasers are as follows: CO<sub>2</sub> = 10.6 μm, Nd:YAG = 1.06 μm, thin disk Yb:YAG = 1.03 μm, and fiber = 1.07 μm. Due to increased absorptivity of the laser beam at shorter wavelengths, high cutting speeds are possible when cutting steel less than 0.2 in. (5 mm) thick with solid state lasers. For example, fiber-delivered systems can cut up to three times faster than CO<sub>2</sub> systems at the same power level.

*Laser Cutting Reflective Materials:* Laser cutters, CO<sub>2</sub> systems in particular, are vulnerable to damage due to back-reflection when processing reflective workpieces. Back-reflections that reach the laser cavity can cause instabilities in laser output or even destroy laser components. Most high-power CO<sub>2</sub> laser manufacturers do not warrant their equipment for processing highly reflective metals, and devices available to protect CO<sub>2</sub> lasers from unwanted back-reflection are bulky, expensive, and impractical for high-powered industrial uses.

For fiber-delivered lasers, both the forward- and backward-traveling light is confined to the optical fiber. So back-reflection isolators designed to protect the laser can be compact fiber components, incorporated either near the output of the delivery fiber or at the output of the laser.

When the workpiece is reflective, some portion of laser light is reflected instead of being absorbed to supply cutting energy. Metals reflect laser light at increasing percentages with increasing laser wavelength. Increasing laser power or using a shorter wavelength can help overcome reflectivity problems.

*Laser Cutting Assist Gas:* A gas jet emitting from the laser head is used to eject molten material from the cut, protect the cutting head from splatter, and either react with the material or shield it. Oxygen assist gas reacts with the workpiece material and leaves an oxidized cut edge. The exothermic reaction adds energy to the cutting process and can enhance the depth or cutting speed; however, secondary operations may be necessary to remove an oxide layer if the laser-cut metal part is to be welded or painted.

Low-pressure oxygen assist gas can be used when cutting carbon steel. It performs this function economically due to the low flow rates and increased thickness capability afforded by the exothermic reaction. Oxygen assist can make cuts in stainless steel or aluminum possible with power levels that would be inadequate without oxygen. This facilitated initial development of industrial laser cutting, when laser power was limited and very expensive. However, use of oxygen assist to cut stainless steel has some disadvantages: cut edge discoloration (which may be unacceptable for cosmetic reasons), reduced corrosion resistance (due to the formation of chromium oxides), and dross formation (due to the higher melting point and surface tension of chromium oxide). For these reasons, and with the increased viability of higher laser power, the use of oxygen in laser cutting of stainless steel is no longer common.

In current practice, high-pressure nitrogen is the most commonly used assist gas for cutting stainless steels and aluminum with high-power lasers. This inert gas's shielding

effect results in a higher-quality cut than can be obtained with oxygen. Nitrogen-assisted cut edges suffer no discoloration and are oxide-free, so they are ready for subsequent welding or painting. Since the assist gas is inert, there is no addition of energy to the process, and achievable cutting speeds are lower than with oxygen. The high viscosity of molten steel (compared to that of iron oxide) can lead to dross adhesion at the bottom of the cut. This can be addressed by using very high assist gas pressures, resulting in high consumption of pure nitrogen and increased operating costs.

Air-assisted cutting is often used with aluminum, but the air must meet high cleanliness and pressure requirements. The presence of reactive oxygen in air can enhance cutting speed, while still producing a clean cut edge in aluminum; however, this technique can require high investment costs for a setup that delivers clean air at elevated pressure and high flow rates. Instead, laser cutting with shop air, which is both inexpensive and commonly available in industrial settings, can be used to cut relatively thin steel (both carbon and stainless steel) far more economically than using pure oxygen or nitrogen.

Assist gas flow, pressure, purity, and delivery (standoff distance and jet shape) all affect cut characteristics, necessitating careful selection and monitoring of gas pressure, nozzle size, feed rate, laser power, and material thickness. For nitrogen-assisted cutting, high gas volumes and pressures are needed to successfully cut narrow kerfs, and selection of the gas nozzle size will directly affect volume capability. In many cases, a larger nozzle diameter is needed to cut a narrower kerf. For oxygen-assisted cutting, gas pressure plays a key role in determining cut quality: low pressure can result in incomplete cuts, while high pressure can lead to uncontrolled burning and a rough cut edge.

Laser cutting equipment manufacturers provide a variety of nozzle types designed to provide assist gas flow characteristics tailored for optimal performance. Performance requirements and user preferences determine system priorities, such as cut edge quality (roughness, angle), cutting speed, gas consumption, and so on. Fig. 1 shows a laser cutting head with a commonly used double-nozzle design, which can accommodate two assist gas streams: an inner, primary assist gas stream and an outer, shield gas stream. These two streams could be fed by different gases, or by different supply pressures of the same assist gas to produce the desired outcome.

Fig. 1. Laser Cutting Nozzle with Two Assist Gas Pathways

**Laser Cutting Heat Effects:** Laser cutting and machining normally exposes workpieces to high thermal energy for a brief period. This leads to formation of a narrow heat-affected zone (HAZ) and minor heat effects in the part. Plastics and composites generally are much more vulnerable to heat effects than metals; some materials, such as PVC, will give off hazardous fumes, and others may discolor, warp, or char.

The thickness of the HAZ for a laser cut in thin material is small, often under 0.005 in. (0.13 mm), and is based on beam focus, assist gas, speed, and part material and thickness. The HAZ will be thicker around a cut in thicker material than in a thinner piece. Pulsing the laser can help to reduce HAZ thickness and other heat effects. Ultra-short pulse laser systems, sometimes called femtosecond lasers, are available that create no HAZ in applicable materials.

Efficiency loss during laser cutting occurs primarily due to heat conduction in the workpiece. In thermally conductive materials, a portion of the absorbed laser energy is

conducted away from the cut zone. This diverted energy performs no useful work and only serves to heat the material. As a result, efficiency may dictate reduced cutting speeds and cut depths for highly thermally conductive metals, such as aluminum, brass, and copper.

**Laser Cutting Performance Characteristics:** Modern laser systems in the 6–8 kW range can cut through 1.5 in. (38 mm) steel, 0.75 in. (19 mm) aluminum, or 0.38 in. (9.6 mm) copper. The depth of cut is proportional to laser power and inversely proportional to speed. While fiber lasers are much more efficient and usually faster for cutting thin materials, CO<sub>2</sub> lasers usually are as fast as fiber systems when oxygen (flame) cutting materials over 0.2 in. (5 mm) thick. The cutting tolerance of a typical system on 0.5 in. (12.7 mm) thick carbon steel is  $\pm 0.005$  in. (0.13 mm). Higher precision is possible in some cases. [Table 1](#), [Table 2](#), and [Fig. 2](#) provide some examples of expected performance characteristics.

In thin workpieces, laser systems can create extremely small holes and fine features with a great deal of precision. Cut patterns can be as close as one beam diameter apart, if the cutting process is accurate and material thin. Kerf width will depend on wavelength, setup (spot size), process, and workpiece characteristics. A fiber laser has a wavelength ten times smaller than that of a CO<sub>2</sub> laser. As a result, a fiber laser can focus on a much smaller spot size, and kerf widths of 0.001 in. (0.025 mm) are achievable. Deeper cuts require a larger beam and wider kerf.

Beam shape is not cylindrical, so cuts will tend to have a wider entrance than exit. A 2 degree taper angle is typical. Reduction of this taper angle is possible by changing head angle, process parameters, standoff distance, or material thickness. Zero taper can be achieved in some cases.

Fig. 2. Characteristics of Laser Cuts

**Laser Hole Cutting and Drilling:** Laser drilling can create holes that are blind or pierce through. The holes will tend to have taper, with the entrance being larger than the exit. When drilling, molten material rapidly expands in the hole and ejects upward. Some of this material can cling to the sides of the hole and form a recast layer.

In some cases, a single-shot direct drilling process can rapidly create a shallow drilled hole with minimal recast. A low-power pulsed beam can create holes of greater depth, smaller holes, and higher precision holes. Called percussion drilling, this method is slower than direct drilling and more prone to form a recast layer.

Helical drilling and trepanning can produce large diameter holes with high precision, minimal recast, and controllable taper. These methods require more sophisticated equipment and take longer than direct or percussion drilling. Helical drilling involves moving a pulsing laser along the circumference of the desired hole, while increasing the cut depth on each pass. Trepanning starts with percussion drilling a pilot hole, and then moving the pulsing laser in a spiral pattern, until it reaches the target diameter. Unlike the other drilling methods, trepanning begins with a through hole, allowing downward ejection of molten material.

**Plasma Arc Machining (PAM).**—Conductive metals, including expanded metal, cast iron, and rusted or painted parts, can be plasma cut. In this electro-thermal process, an

electric arc is generated between the plasma torch and workpiece. The plasma arc melts the material and a high velocity gas jet removes the molten material.

A plasma cutting torch consists of an electrode that serves as an attachment point of the arc and a nozzle used to confine the plasma arc and direct the high velocity gas jet toward the workpiece. This gas jet further confines or constricts the arc and protects the nozzle from the high temperature plasma. The core of the plasma arc is made of ionized gas atoms and electrons, which exit the torch nozzle at temperatures near 40,000°F (22,000°C). The plasma arc transfers energy via electrons re-entering the conductive workpiece, thermal conduction, and recombination of the plasma ions.

Some plasma torches may use a secondary or shield gas flow to protect the nozzle from spatter, electrically isolate the nozzle from the workpiece, and improve the cutting process. Other plasma torch enhancements include liquid cooling of torch components, high-precision nozzles to enhance confinement of the plasma jet via additional gases or nozzle geometry, or use of magnetic fields and the resulting Lorentz forces to constrict the arc. Efforts to constrict the arc as much as possible are meant to narrow the plasma jet to produce a narrow kerf, as well as increase the energy density of the plasma to allow a higher range of cutting speeds.

Some plasma torch components wear out and need to be replaced periodically to maintain cut quality and reliable operation. Such consumable items include the electrode, nozzle and shield.

*Plasma Cutting Performance Characteristics:* Plasma cutting is a highly flexible method of cutting metal. Small portable systems are available for large or difficult-to-access workpieces. Some plasma cutting processes can operate on materials submerged in water to reduce noise, fumes, and light emission. Plasma torches also can be used in multiple orientations, enabling three-dimensional cutting.

Plasma systems can make both through cuts and non-through gouges. It is possible to cut some materials up to 6 in. (152 mm) thick, but cut quality tends to suffer for thicknesses beyond 2 in. (50.8 mm). Since this is a thermal process, an HAZ will surround each cut. Depending on material and process parameters, an HAZ less than 0.01 in. (0.25 mm) thick is possible with little edge hardening. Cut quality characteristics, including cut smoothness, bevel angle, kerf width, and the presence of slag or dross on the bottom of the cut, are highly dependent on material and process parameters. Smoothness of the cut is generally good but can deteriorate at very high speeds or for thicknesses above 2 in. (50.8 mm).

A plasma cut usually has a positive bevel angle, where the entrance to the cut is larger than the cut exit. Plasma cuts also have two different bevel angles on the two sides of the cut kerf. This difference is a result of the plasma gas flow swirl component relative to the direction of torch motion. As a result, the plasma torch produces a “good” cut side, with a typical bevel angle of 2 degrees, and a “bad” cut side, with an angle close to 5 degrees. Cutting speed and standoff are the most direct ways to influence bevel angle. High cutting speed and standoff distances increase bevel angle, while lower speed and standoff lower the angle. Other factors include type and pressure of the gas, arc current, and nozzle characteristics. Precision systems with the right process settings can improve on this, in some cases, providing a straight cut (0 degree bevel).

While kerf width is process and workpiece dependent, it often is estimated as 1.5 times the nozzle orifice diameter. Kerf width is typically larger than 0.02 in. (0.5 mm) and often near 0.1 in. (2.5 mm). High standoff, low speed, and high amperage will widen the kerf.

Holes cut with a standard plasma torch should be larger in diameter than 1.5 times the material thickness, and larger than 3/16 in. (4.8 mm). State-of-the-art automated plasma systems can produce holes that are cylindrical and accurate enough to rival drilled holes, with a diameter to thickness ratio as low as 1:1. Some automated table systems also can tilt the torch relative to the workpiece, allowing additional control of the cut bevel angle or produce angled cuts.

Dross formation depends primarily on cutting speed. Speeds that are too slow will produce thick dross on the bottom of the cut; speeds that are too fast will produce a fine, beady

dross. For a given application, there usually is a speed range for dross-free cutting, though there may be no dross-free speed for very thick workpieces.

Gouges are made with plasma systems by tilting the torch relative to the workpiece, so the molten material is blown away on the top of the plate. This technique may be used to remove material in preparation for repair or re-work.

*Plasma Cutting Assist Gas:* Plasma cutting gas selection for best cut quality depends on material type and thickness. Oxygen is the best gas for cutting mild steel, because it allows the highest cutting speed for a high-quality cut. Air also can be used to cut mild steel, but nitriding can occur and should be considered if the cut edge is to be welded.

Stainless steel can be cut with good speed and bevel angle using air, but the cut edges will be rough and black because of oxidation and may require secondary cleanup operations. Using nitrogen plasma gas on stainless steel reduces oxidation and gives a smooth cut surface but still adds dark color, especially with material thicker than 0.25 in. (6 mm). Adding a water shield flow when using nitrogen plasma gas can give an edge color that is close to the base material color and improve the taper and rounding of the cut edge.

Plasma gases containing hydrogen provide a further improvement in the appearance of the cut edge. F5 plasma gas (95 percent nitrogen, 5 percent hydrogen) can give bright silver cut edges in stainless steel up to 0.375 in. (9.5 mm) thick, while H35 (65 percent argon, 35 percent hydrogen) improves the edge color for thicknesses greater than 0.5 in. (12.7 mm). Nitrogen is the most common shield gas when cutting with hydrogen-containing plasma gases. Aluminum cutting can be done with air, nitrogen, or hydrogen-containing gases. Edge quality is often rougher with the oxygen-containing gases and smoother with the hydrogen gas processes. Some modern systems can mix gases, such as argon, hydrogen and/or nitrogen to improve results on both stainless steel and aluminum.

**Electron Beam Machining (EBM).**—This non-contact machining method employs a beam of high-velocity electrons, usually applied in a vacuum, to make cuts and gouges. As the electrons collide with the workpiece, their kinetic energy produces heat and vaporization of material. This process is often chosen to perforate thin materials at high speeds. Almost any material up to 0.4 in. (10mm) can be machined with this method, usually without burr, and with relatively minor thermal effects. Tapered holes and cuts occur when part thickness exceeds 0.005 in. (0.13 mm). The finish and speed of electron beam hole drilling are superior to most other methods, but the capital equipment cost is high. Electron beams also are used in hardening, diffusion bonding, powder bed fusion, and welding processes.

## CNC NUMERICAL CONTROL PROGRAMMING

Numerical control programming—better known as CNC programming—is an integral part of technology known as Numerical Control (NC), or its modern equivalent—Computerized Numerical Control (CNC). This technology can be defined as an operation of machine tools by means of specifically coded sequential instructions to be processed by the control system. These instructions are combinations of letters of the English alphabet “A-Z”, all ten digits “0–9”, and a few selected symbols, such as a decimal point “.”, negative sign “-”, parentheses “()”, forward slash “/”, and several others. The main purpose of a CNC program is to provide detailed instructions necessary to machine a part (also called a workpiece) for a given machine setup—with minimal human interaction. All instructions to the control system must be written in a logical order and in a specified format called the program structure. The resulting CNC Program or a Part Program can be stored on various media for the future and used repeatedly to achieve identical machining results at any time.

A completed part program is processed by the CNC unit—commonly called the control system—and individual program instructions are carried out to complete desired actions of the CNC machine. These actions include all required machine activities, such as motion control, spindle speed, cutting feed rates, coolant functions, program flow control, various adjustments, etc. In order to develop a CNC program, a qualified person—typically called a CNC Programmer—is assigned to the task.

As a key person in the production environment, the CNC programmer has the responsibility for developing safe, efficient, and error free programs for CNC machines installed in the machine shop. Many CNC programmers have machining skills and hands-on experience as machine operators working on manual or CNC machines. Typical skills of a CNC programmer include the ability to interpret drawings, mathematical aptitude, knowledge of setup and tooling, and the very important understanding of “*how to machine a part*”. The programmer has to be able to visualize all tool motions and recognize any restricting factors that may be involved. The programmer collects, analyzes, processes, and logically integrates all data into a single, production ready, part program. Equally important skills include knowledge of mathematics, particularly the ability to solve equations and trigonometry. The knowledge of manual programming is absolutely essential even in the age of computers and computer based programming software. Another important quality of a professional CNC programmer is his or her ability to listen to and work with other people such as engineers, operators, customers, and managers.

### CNC Coordinate Geometry

A basic step in understanding CNC principles is to understand the geometry of machine tools. This term covers the relationship between the machine data, part data, and tool data, which includes setup.

As with all CAD/CAM systems (see *CAD/CAM* on page 1390), CNC is based on the same principles of a system of coordinates that define the location of a point in three dimensional space (3-D). A system of coordinates is founded on the concept of two perpendicular lines (named axes “X” and “Y”), intersecting at a point called *origin*, where both coordinates have a value of zero (X0, Y0). Both lines are divided into equal units of measurement.

A point can be defined in a plane (any two axes = 2D) or in space (three axes = 3D). For CNC work, the *rectangular coordinate system*—also known as the *Cartesian coordinate system*—is the most commonly used system. It is based on three standard axes: X,Y,Z. *Points* are defined as locations with a distance from the origin defined by projecting a line at 90 degrees to each axis, forming a visual rectangle. For example, in Fig. 2, P1 is defined as X3.0, Y2.0, P2 is defined as X-4.0, Y1.0, P3 as X-2.0, Y-3.0, and P4 as X2.0, Y-2.0.

Fig. 1. Rectangular Coordinate System.

Fig. 2. Absolute Coordinates.

Once the point locations are established, the programmer can use them as points representing the center of individual holes to be machined or as endpoints for a continuous contour. The points can also be connected by providing specific motion instructions, as a toolpath between given points. Fig. 3 shows a linear motion from P1 to P2 to P3 to P4 and back to P1.

Fig. 3. Incremental Motions.

### CNC Programming Process

CNC program (also called *part program*) development starts with an engineering drawing and material stock. Initial decisions include tasks to be done and goals to be achieved. The part program has to provide a safe and efficient method of machining a part, it should have a consistent structure (method of data entry), and be as portable as possible. Program portability allows the same program to run on machines that have similar characteristics. Typical logical process of program development can be summarized in a short, general list shown below. In actual use, specific steps will vary:

#### Program Development List

- a) Evaluation of initial drawing and material.
- b) Sequence of machining operations.
- c) Tooling selection and arrangement of cutting tools.
- d) Part setup method.
- e) Technological data selection (speeds, feed rates, depths, etc.)
- f) Toolpath determination.
- g) Mathematical calculations.
- h) Program writing and preparation for transfer to CNC.
- i) Program testing.
- j) Program documentation.

**Word Address Format.**—Writing any data to be processed by a computer requires a certain input format called a program. CNC program instructions are written in a special coded form obeying strict rules required by the programming language. These alphanumerical instructions are called *words*. Where a single letter is followed by one or more digits—the letter must always be first. Special symbols, such as a decimal point or a negative sign may also be used, if required. Each letter, digit, or symbol represents one program character as well as one character in the control memory. A *character* is the basic unit of a CNC program. CNC programs only use characters that are readily available on a standard computer keyboard, without any multi-key combinations. A *word* in CNC program consists of two or more characters and is a single instruction to the control system. It can be used individually or it can be grouped into a series of combined instructions (words), to be performed at the same time. A program word is the *unit of instruction* to the control system. Instructions performed simultaneously are called a *block*, which is always represented by one line of the program. Individual instructions (blocks) are written in sequential order. Some typical words used in a block are:

M08 D14 X7.875 H03 /M01 Y0 G01 S850 Z-2.5 N49 T0707 T05 F10.0

Within a word, there cannot be any spaces, but spaces are allowed in a block, between words only. The numeric value that immediately follows the address (letter) has to be entered in a format specific for that address. Using some of the words above, a meaningful block can be constructed:

N49 G01 Z- 2.5 F10.0 M08

where:

N49 = Block number (sequence number)

G01 = Linear motion selected

Z-2.5 = Z-axis motion only

F10.0 = Feed rate specification

M08 = Coolant ON function

An early standard of *Electronic Industry Association* (EIA) RS-274 from the 1960's defines various commands and functions for part programming. It was last updated in February 1980 to RS-274D but has never fully succeeded in its attempt to provide a uniform CNC programming environment for different control systems, mainly because of competitive forces in industry. However, many features of this standard have become common practice in programming and are used to this day.

**Program Development.**—There are several methods of programming CNC equipment that will generate a working part program:

- a) Manual programming (also known as G-code programming)
- b) Computer based programming (also known as CAM programming)
- c) Shop-floor programming (also known as Conversational programming)
- d) Macro programming

*Manual (G-code) Programming* requires the most effort, is time consuming, and prone to errors. The programmer writes every instruction separately, typically using a text editor on a computer to enter programming instructions. All calculations are done with the use of a pocket calculator. In spite of its disadvantages, manual programming has two major advantages—it offers complete human control over every detailed aspect of toolpath development and all related activities. Also, it provides important learning ground for part programming using computer methods.

Originally, all manual programming was done all by hand and written on paper. Now, any computer can be used to write the program using a keyboard, several software based calculators can be used instead of hand-held devices, and simulation software can verify the toolpath graphically, on a computer screen.

*Computer Based Programming:* Computer generated programs are based on graphical input, and typically require development of part geometry (point, lines, arcs, etc.). The final edited geometry serves as the toolpath geometry and can be assigned machining parameters. Specifying tool definition, spindle speeds and cutting feeds, and various cutting conditions is part of the programming process. A good knowledge of manual programming provides may necessary skills for computer based part programming.

Computer based programming is sometimes called (incorrectly) “CAM programming”, because of the multitude of CNC software that uses the “cam” in the product title. It has nothing to do with a mechanical motion control device of the same name.

Any CAD/CAM system that provides CNC capabilities also has to provide precise formatting of the final program output. This output is always based on a particular machine tool and control system combination. Software vendors offering program development software are very much aware of this need, yet face the extremely difficult task to cover every machine tool design with every control system available. When the toolpath is initially processed, it is generic—it has no connection to any particular control or machine specifications. The same toolpath has to be processed again (post processed) for a

specific type of formatting, unique to a particular machine and control. The majority of post processors are customizable by the users who have thorough knowledge of manual programming methods, as well as a various machine and control systems.

The major advantage of computer based program generation is elimination of tedious calculations, minimizing errors, and providing a program in much shorter time than using the manual approach. Graphical interfaces quickly allow obvious errors to be detected visually. For more on this topic, see *CAD/CAM* on page 1390.

*Shop-floor Programming:* Shop-floor programming, sometimes called conversational programming, is performed at the machine by the CNC operator using programming software built into the control system. Using the keyboard and control display screen, the programmer/operator interactively defines tools, material, setup, toolpath, cutting conditions, etc. Virtually all work is completed at the display screen. The resulting program can be stored externally, to be used at another time. Although relatively fast, visual, and easy to edit, the built-in programming software adds to the overall cost of the machine. If not managed efficiently, it does not offer the same flexibility in toolpath control as other methods. It also tie up the machine from production and is not as portable as some alternatives.

Depending on the control system, conversational programming software ranges from some software having only minimum basic features to others with very advanced features. In addition to defining points, lines, and arcs, typical features include various patterns of holes, pocketing cycles, automatic roughing, corner rounding and chamfering, threading, and other operations.

Typically, the programming method selected is also the most convenient programming method available. Type and complexity of the job is always a major factor. The choice between manual and computer based programming has become rather narrow. Complex parts always benefit from a computer generated programs, while simple parts will typically benefit from a manual program.

*Macro Programming:* Macro programming is the highest level of manual programming. It requires thorough knowledge of manual programming concepts at all levels. In principle, the single purpose of a macro program is to develop a generic toolpath or other activity for a particular purpose. Once the macro program is stored in the control memory, it can be used many times in the future—with variable data supplied for a specific job. Typical examples include a bolt circle or a rectangular pocket—in both cases the basic input features remain the same, but the actual dimensions change from part to part. All basic shapes of a bolt circle or pocket are retained while their sizes change—the macro itself does not change. See page 1377 for detailed information on macro programming.

**Control System.**—The control system, the actual computer controlling a CNC machine, is the main core of any CNC machine activity. It has many features that are important not only to the machine operator, but to the programmer as well. Some features are unique to a particular type of control system (mill, lathe, wire, etc.), while others are optional and may not be available on all controls.

Typical features of various CNC systems include:

*ON/OFF switch:* Power switch for the main power and the control unit.

*Cycle start:* Starts program execution or an MDI command.

*Emergency stop:* Stops all machine activity and turns off power to the control unit.

*Feedhold:* Temporarily stops motion of all axes.

*Single block:* Allows program to run one block at a time.

*Optional stop:* Temporarily stops the program execution (requires M01).

*Block skip:* Ignores blocks preceded with a forward slash (/) in the program.

*Dry run:* Enables program testing at fast feed rates (without a mounted part).

*Spindle override:* Overrides programmed spindle speed within 50–120% range.

*Feed rate override:* Overrides the programmed feed rate, within 0–200% range.

*Chuck clamp:* Displays current status of chuck clamping (Outside / Inside).

- Table clamp:* Shows current status of table clamping.
- Coolant switch:* Coolant control ON / OFF / AUTO.
- Gear selection:* Shows current status of working gear range selection.
- Spindle rotation:* Spindle rotation direction indicator (CW or CCW).
- Spindle orientation:* Manual spindle orientation.
- Tool change:* Switch allowing a manual tool change.
- Reference position:* Switches and lights relating to machine zero position (HOME).
- Tailstock switch:* Tailstock and/or quill switch to manually position tailstock.
- Index table switch:* Manually indexes machine table during setup.
- M-S-T lock:* Disables machine, spindle, and tool functions in the program.
- Machine lock:* Disables all machine motions.
- Manual absolute:* Coordinate system update on/off.
- Z-axis neglect:* Milling Z-axis can be turned off during program verification.
- MDI mode:* Manual Data Input mode.
- AUTO mode:* Allows automatic operations.
- MEMORY mode:* Allows program execution from memory of the CNC unit.
- DNC mode:* Allows program execution from an external device.
- EDIT mode:* Allows changes to programs stored in the CNC memory.
- MANUAL mode:* Allows manual operations during setup.
- HOME mode:* Allows manual return to machine zero.
- HANDLE mode:* Manual Pulse Generator (MPG) for manual axis movement.
- JOG mode:* Selects the jog mode for setup (manual feed rate motion).
- RAPID mode:* Selects the rapid mode for setup.
- Memory access:* Key (switch) to allow program editing.
- Lube light:* Indicates low level of slide lubrication.
- Error lights:* Red light indicating an error.
- Optional stop and block skip:* Switches function only if the part program supports their use. For optional stop, part program must contain M01 function, and for block skip, the slash (/) symbol.

*Manual Data Input (MDI):* This is a feature of the control panel that allows quick entry of program data. An operating mode can be selected as MDI, which allows program data to be entered by the machine operator. MDI is not intended to enter complete machining programs, but allows the operator a great deal of flexibility during setup. Typical applications include position data for setup, tool motion to a given location, machine functions control, even some special settings of machine parameters. Knowledge of basic programming principles is necessary, as MDI requires the use of normal programming methods.

### CNC Program Data

The program data is a collection of all the program entries that will be accepted by the CNC system. Although the basic program principles are the same, the actual methods of inputting will always vary to a certain extent with different control models.

**Program Structure.**—A CNC program structure is a method of developing a part program that is well designed and written. This means that the program should be easy to read on paper or computer screen and written in a consistent manner. Program initialization should be logical; repetition of any tool should be made easy (without manual interaction); it should include important comments; and be as short as possible. A part program should always be designed with the machine operator in mind.

*Comments and Messages:* Various comments and other messages can be included in the program, provided they are enclosed with a single set of matching parentheses. An abundance of comments may strain the CNC memory, but when used in moderation,

comments are an excellent way to inform the machine operator about key issues relating to the job at hand.

Typical comments should be in capital letters (for best compatibility between programs) and contain a short message, description, or caution. Comments may be used as separate blocks or at the end of a block—for example, both the following comments are valid:

Comment as a whole block: (CHECK HOLE DEPTH)

Comment as part of a block: N55 M00 (CHECK HOLE DEPTH)

**Program Number (O-address):** In most cases, a program number can be assigned at the machine, by the CNC operator. Only special program numbers can be selected by the programmer, typically, for subprograms. Program number requires the letter “O” to be followed by four or five numeric digits (O1 to O9999 or O99999), depending on the control.

**Block Number (N-address):** One or more instructions can be programmed in a single program sequence (block). A typical program may only require a very small number of blocks for a simple machining job, but—literally—hundreds or thousands of blocks for complex work. To distinguish one instruction (one block) from another, a simple numbering system can be used for each block sequence. Depending on the control system, the block numbers can be ascending, descending, or even mixed. Most control systems offer all these options, and it is up to the programmer to choose the most advantageous ones.

The address “N” is used for block numbering. The smallest block number is N1 (N0 is usually not allowed), the largest is either N9999 or N99999, depending on the control system. Block numbers can be used for each program sequence, or they can be used selectively, to enable more efficient search.

A forward slash symbol “/” placed in front of the N-address identifies a block that can be selectively skipped during processing. This block skip function is activated or deactivated from the operation panel of the CNC machine.

**Preparatory Commands (G-address, G-codes):** Preparatory commands are commonly known as G-codes. The address “G” identifies a preparatory command, which has one and only objective—to preset or to prepare the control system for a certain desired condition, or to a certain mode or a state of operation. For example, the address G00 presets (prepares or selects) a rapid motion mode, G01 selects a linear motion, G81 selects the drilling cycle, etc. The term *preparatory command* indicates its meaning—a G-code will prepare the control to correctly interpret the programming instructions following the G-code in a specific way.

Standard G-codes are programmed in the range of G00 to G99, although not all numbers are available. G-codes with three digits usually apply to special machine functions provided by the control manufacturers. Most—but not all—of G-codes are standard for various controls, and most—but not all—are *modal*. A modal G-code in one that is programmed only once and remains in effect until changed or canceled. Non-modal G-codes have to be repeated anytime they are used. On the majority of controls, one or more G-codes can be programmed in a single block, providing there is no conflict between them. It is customary to program a G-code or G-codes at the beginning of the block, after the sequence number.

**Table 1. Typical Turning G-Codes**

G-Code	Description	G-Code	Description
G00	Rapid positioning	G57	Work coordinate offset 4
G01	Linear interpolation	G58	Work coordinate offset 5
G02	Circular interpolation clockwise	G59	Work coordinate offset 6
G03	Circular interpolation counterclockwise	G61	Exact stop mode
G04	Dwell (as a separate block)	G62	Automatic corner override mode
G09	Exact stop check—one block only	G64	Cutting mode
G10	Programmable data input (Data setting)	G65	Custom macro call
G11	Data setting mode—cancel	G66	Custom macro modal call

**Table 1. (Continued) Typical Turning G-Codes**

G-Code	Description	G-Code	Description
G20	US customary units of input	G67	Custom macro modal call—cancel
G21	Metric units of input	G68	Mirror image for double turrets
G22	Stored stroke check ON	G69	Mirror image for double turrets—cancel
G23	Stored stroke check OFF	G70	Profile finishing cycle
G25	Spindle speed fluctuation detection ON	G71	Profile roughing cycle—Z axis direction
G26	Spindle speed fluctuation detection OFF	G72	Profile roughing cycle—X axis direction
G27	Machine zero position check	G73	Pattern repetition cycle
G28	Machine zero return (reference point 1)	G74	Drilling cycle
G29	Return from machine zero	G75	Grooving cycle
G30	Machine zero return (reference point 2)	G76	Threading cycle
G31	Skip function	G90	Cutting cycle A (Group type A)
G32	Threading—constant lead	G90	Absolute command (Group type B)
G35	Circular threading CW	G91	Incremental command (Group type B)
G36	Circular threading CCW	G92	Thread cutting cycle (Group type A)
G40	Cutter radius—cancel (Tool nose radius offset cancel)	G92	Tool position register (Group type B)
G41	Cutter radius—left (Tool nose radius offset left)	G94	Cutting cycle B (Group type A)
G42	Cutter radius—right (Tool nose radius compensation right)	G94	Feed rate per minute (Group type B)
G50	Tool position register (obsolete) / Maximum r/min preset	G95	Feed rate per revolution (Group type B)
G52	Local coordinate system setting	G96	Constant surface speed
G53	Machine coordinate system setting	G97	Constant spindle speed (r/min)
G54	Work coordinate offset 1	G98	Feed rate per minute (Group type A)
G55	Work coordinate offset 2	G99	Feed rate per revolution (Group type A)
G56	Work coordinate offset 3		

Note that some G-codes are optional and some will vary from one control system to another.

Typical list includes Group type A and Group type B—where some G-codes are different. For example, Group A uses addresses U and W to identify incremental motion, while Group B uses G91 and G92. There are other differences as well. Group A is the most common.

**Table 2. Typical Milling G-Codes**

G-Code	Description	G-Code	Description
G00	Rapid positioning	G52	Local coordinate system setting
G01	Linear interpolation	G53	Machine coordinate system
G02	Circular interpolation clockwise	G54	Work coordinate offset 1
G03	Circular interpolation counterclockwise	G55	Work coordinate offset 2
G04	Dwell (as a separate block)	G56	Work coordinate offset 3
G09	Exact stop check—one block only	G57	Work coordinate offset 4
G10	Programmable data input (Data setting)	G58	Work coordinate offset 5
G11	Data setting mode—cancel	G59	Work coordinate offset 6
G15	Polar coordinate command—cancel	G60	Single direction positioning
G16	Polar coordinate command	G61	Exact stop mode
G17	XY plane designation	G62	Automatic corner override mode
G18	ZX plane designation	G63	Tapping mode
G19	YZ plane designation	G64	Cutting mode

**Table 2.** (Continued) **Typical Milling G-Codes**

G-Code	Description	G-Code	Description
G20	US customary units of input (G70 on some controls)	G65	Custom macro call
G21	Metric units of input (G71 on some controls)	G66	Custom macro modal call
G22	Stored stroke check ON	G67	Custom macro modal call—cancel
G23	Stored stroke check OFF	G68	Coordinate system rotation
G25	Spindle speed fluctuation detection ON	G69	Coordinate system rotation—cancel
G26	Spindle speed fluctuation detection OFF	G73	High speed peck drilling cycle (deep hole)
G27	Machine zero position check	G74	Left hand threading cycle
G28	Machine zero return (reference point 1)	G76	Fine boring cycle
G29	Return from machine zero	G80	Fixed cycle—cancel
G30	Machine zero return (reference point 2)	G81	Drilling cycle
G31	Skip function	G82	Spot-drilling cycle
G40	Cutter radius offset—cancel	G83	Peck-drilling cycle (deep hole drilling cycle)
G41	Cutter radius offset—left	G84	Right hand threading cycle
G42	Cutter radius offset—right	G85	Boring cycle
G43	Tool length offset—positive	G86	Boring cycle
G44	Tool length offset—negative	G87	Back boring cycle
G45	Position compensation—single increase (obsolete)	G88	Boring cycle
G46	Position compensation—single decrease (obsolete)	G89	Boring cycle
G47	Position compensation—double increase (obsolete)	G90	Absolute dimensioning mode
G48	Position compensation—double decrease (obsolete)	G91	Incremental dimensioning mode
G49	Tool length offset cancel	G92	Tool position register
G50	Scaling function cancel	G98	Return to initial level in a fixed cycle
G51	Scaling function	G99	Return to R level in a fixed cycle

Note that some G-codes are optional and some will vary from one control system to another.

A typical example of using G-codes is a simple program entry, such as X18.0. X-address is mainly used as a dimension, but not exclusively. The amount of 18.0 could be in millimeters or inches, it can be an absolute location from part zero or an incremental distance and direction from current point. In addition, the same address can be a dwell time in seconds (a pause). Using one or more G-codes will narrow down the options to only those required by the program. Here are some examples:

G21 G90 G00 X18.0 ... rapid to absolute location of 18 mm

G20 G91 G01 X18.0 F10.0 ... feed by the distance of 18 inches in positive direction

G04 X18.0 ... dwell for 18 seconds

**Miscellaneous Function (M-Codes).**—Along with G-codes (preparatory commands), a CNC program requires a number of miscellaneous functions, called M-codes or M-functions. These auxiliary functions fall into two groups—those that control various machine functions and those that control program flow. Miscellaneous functions are the least standard words in CNC applications and vary greatly between control systems. Those that are typical to most controls are:

Three-digit M-codes are normally specific to a particular machine and various functions associated with it.

Table 3. M-codes

M-Code	Description	M-Code	Description
M00	Program stop	M09	Coolant OFF
M01	Optional program stop	M19	Spindle orientation
M03	Spindle rotation normal (clockwise)	M30	Program end
M04	Spindle rotation reverse (counterclockwise)	M60	Automatic Pallet Change (APC)
M05	Spindle stop	M98	Subprogram call
M06	Automatic Tool Change (ATC)	M99	Subprogram end
M08	Coolant ON		

**Units of Measurement (G20, G21).**—Dimension words in CNC programming are data that contain a location, distance, radius or feed rate. In all cases, such data is dependent on the active units of measurement. For CNC work, either metric or US customary units can be selected by the program or by manual setting. US customary units can be set by G20 (G70 for older controls) command, metric units by G21 (G71 for older controls) command, and each command cancels the other. US customary mode is specified in inches, metric mode in millimeters. In some cases, feet/min or m/min are also used.

Dimensions measured along an axis can be programmed up to four decimal places in inches, and three decimal places in millimeters. Minimum increment (i.e., amount of motion) possible is 0.0001 inch or 0.001 mm. Maximum programmable motion amount is typically 9999.9999 inches or 99999.999 mm. Note that there is no actual unit conversion involved, just a shift in decimal point position.

**Absolute and Incremental Programming (G90, G91).**—A motion dimension along X, Y, Z axes (as well as any parallel or rotary axis) can be programmed in two ways—as an absolute location measured from part zero (origin) or as an incremental distance and direction measured from the current tool position.

The *absolute* method of programming is selected by the G90 command, the *incremental* method by the G91 command. One command cancels the other. The benefit of the absolute programming method is that one change of a point location requires only one change in the program. The same change in incremental program will require two changes. The main benefit of incremental programming method is that it can be used for a toolpath repetition, typically in the form of subprograms or macros.

**Spindle Function (S-Address).**—The *spindle* function programmed with the S-address causes the machine spindle to rotate at a defined rate in revolutions per minute (r/min). Its programmable range is set by the machine manufacturer in increments of one revolution. The major difference between machining centers and some lathe operations defines the meaning of the S-address used in the program:

- 1) Milling—direct spindle speed in r/min (all operations)
- 2) Turning, Boring, Facing, and Grooving—cutting speed in ft/min or m/min
- 3) Threading and Centerline Operations—direct spindle speed in r/min

In all three application groups, spindle rotation direction must also be specified, using M03 or M04 miscellaneous functions.

*Example:* For milling, the programming is straightforward:

S800 M03—normal spindle rotation (CW) at 800 revolutions per minute  
 S750 M04—reverse spindle rotation (CCW) at 750 revolutions per minute

*CNC Lathes:* For CNC lathes, the situation is somewhat different, because the part itself is rotating and cutting diameters change constantly, particularly during turning and boring operations. To select the required spindle speed mode, two G-codes are available:

G96—constant cutting speed—programmed in ft/min or m/min  
 G97—constant spindle speed—programmed in r/min

*Example:* G96 S300 M03 is 300 ft/min in G20 mode, or 300 m/min in G21 mode.  
 G97 S1200 M03 is 1200 r/min, regardless of the measuring units selected.

**Cutting Speed:** The purpose of cutting speed, (CS), also known as peripheral speed or surface speed, is to increase or decrease the spindle speed with each change in cutting diameter. The speed will be slowed down for increasing diameters, and speeded up for decreasing diameters. These changes are automatically adjusted by the control system in very fine increments.

In order to limit the spindle speed from increasing to potentially dangerous levels at very small diameters, the programmer can limit the maximum spindle speed by using the G50 command.

*Example:* G50 S2500 limit r/min to 2500 in cutting speed mode

*Example:* (G96) G96 S300 M03 cutting speed of 300 ft/min or 300 m/min.

G50 is only applicable in G96 mode and has no effect in G97 mode. Its setting should always be less than the maximum spindle speed of the machine.

Cutting speed, "CS", can be converted to spindle speed using the following formulas:

US customary units:  $r/\text{min} = (\text{ft}/\text{min} \times 12) / (3.14 \times \text{diameter in inches})$

**Metric units:**  $r/\text{min} = (\text{m}/\text{min} \times 1000) / (3.14 \times \text{diameter in mm})$

The mathematical constant of 3.14 represents mathematical function  $\pi$  ( $\pi$ ), rounded to two decimal places, is more than suitable for such calculations. An even shorter formula can be used for US customary units, also suitable for most applications, particularly without a calculator:

$$r/\text{min} = (\text{ft}/\text{min} \times 4) / \text{Diameter in inches}$$

**Spindle Override:** Spindle override is a feature of CNC machines that allows temporary adjustments to the programmed spindle speed during program execution, without changing the program itself. For this purpose, a spindle override switch is provided at the operation panel. Usually a rotary switch, it is graduated in 10 percent increments, typically between 50 and 120 percent. Permanent changes to the speed must be made in the program itself.

**Feed Rate Function (F-Address).**—Cutting motions are defined as motions of a cutter that is in contact with the material, including clearances. Non-cutting motions are typically rapid motions without a physical contact with the material. Programming the feed rate address depends on the type of machine and the units of measurement. Milling machines and machining centers generally use feed rate per minute (inch/min or mm/min), while lathes and turning centers use feed rate per revolution (inch/rev or mm/rev). For lathes, preparatory commands G94 and G95 determine whether feed rate per minute is selected (G94) or feed rate per revolution is selected (G95). G94 mode—feed rate per revolution—is the default for lathe work. Feed rate specification is always modal, and remains in effect until a different feed rate is selected.

Feed rate per revolution (feed/rev) can be converted to feed rate per minute (feed/min) by multiplying spindle speed in revolutions per minute (r/min) by the feed rate per revolution:

$$\text{Feed}/\text{min} = r/\text{min} \times \text{feed}/\text{rev}$$

For multi-edge cutters, feed rate is also given as "per tooth" or "per flute." This feed rate per edge is also generally called "chipload," specified in inches or millimeters. Feed per tooth (fpt) can be converted to cutting feed rate:

$$\text{Feed}/\text{rev} = \text{feed per tooth} \times \text{number of teeth}$$

Once the feed/rev is known, feed rate per minute can be calculated, if desired.

**Inverse Time Feed Rate.**—One type of feed rate that may be required in some special applications is the *inverse time* feed rate. This feed rate represents the reciprocal of the time in minutes required to complete a programmed motion. The feed command is indicated by a G93 command followed by an F-address value found by dividing the feed rate, in inches (millimeters) or degrees per minute, by the distance moved in the block:

$$\text{Inverse time feed command} = \text{feed rate} / \text{distance} = (\text{distance} / \text{time}) / \text{distance} = 1 / \text{time}$$

The inverse time feed rate has been used in some rotary and multi-axis applications.

**Feed Rate Override.**—The *feed rate override* is a feature of CNC machines that allows temporary adjustments to the programmed cutting feed rate during program execution, without changing the program itself. For this purpose, a feed rate override switch is provided at the operation panel. Usually a rotary switch, it is graduated in 10 percent increments, typically with a range of 0 to 150 or 200 percent. Permanent changes to the feed rate must be made in the program itself.

**Tool Function (T-Address).**—Both CNC milling and turning machine groups use automatic tool change (ATC). In the program, each tool has to be numbered using the T-address. On machining centers, tools are stored in a special tool magazine, located on a side of the machine. On lathes, tools are stored in an indexing turret, located within the machining area. There is a difference in programming each group. In both groups, the T-address indicates the tool number of the next tool. For example, on a machining center, T06 is tool number six. Tools can be stored in any magazine position, but must be registered in the control system prior to use. On lathes, the four-digit tool number is determined by the turret station number, followed by a wear offset number. The turret station number is also equivalent to the geometry offset for the stored tool. Wear offset is used for fine-tuning. For example T0313 calls a tool located in turret station three, activates geometry offset three as well as work offset thirteen.

Tool offset screens (geometry and wear) are special tables visible on the control display panel that show the setting information about each tool. Such information includes the XZ setting, tool nose radius (R), and the tool tip number (T) which should not be confused with tool number.

**Tool Nose Radius Compensation.**—A typical manually generated program uses both coordinate points read directly from drawings and calculated on the basis of drawing dimensions. In both cases, these calculated coordinate points represent a toolpath along the part edge suitable only for a cutter that has a radius of zero. Since a zero tool radius is not practical, the tool's actual radius has to be considered. This is achieved by using a powerful control feature called cutter radius offset (compensation) or—for lathe terms—tool nose radius compensation.

During program development, the programmer ignores the cutter radius, and uses drawing based dimensions. In order to allow for radius compensation at the machine, two preparatory commands are used—G41 for the compensation to left, and G42 for the compensation to the right. In both cases, the direction is determined by viewing along the cutter path direction.

At the control, the operator sets not only the XZ geometry and wear offsets, but also enters the tool nose radius (R-column) and the tool tip number (T-column). The purpose of the tool tip number is to establish the location of the tool nose radius center point.

Fig. 4. Tool Tip Numbers—Rear Lathe.

**Rapid Motion (G00).**—In basic terms, machine motions are divided into two groups, non-cutting motions (unproductive) and cutting motions (productive). Rapid motion is the only

non-cutting and non-productive motion available to the CNC programmer. Its single purpose is to move the cutter from one location to another at the highest speed possible, typically between actual cuts. CNC manufacturers determine the maximum rapid motion rate.

Fig. 5. Rapid Motion G00.

Fig. 5 shows the effect of programmed and actual rapid motion applied on a machining center. As both X and Y axes have the same rapid rate—and the actual toolpath is not important—the resulting motion starts at 45 degrees. When one axis reaches its destination, the other axis continues as a single axis motion. Some machines can produce rapid motion as programmed.

**Linear Interpolation (G01).**—In *linear interpolation mode* (programmed in G01 mode with a cutting feed rate in effect), the tool moves along a linear path, directly from one point to the next (traversing the shortest distance). This is a major departure from the rapid motion mode (programmed in G00 mode), where the shortest distance is disregarded and the result is the fastest motion available. The word *interpolation* defines a mathematical process that translates into synchronized feed rate for all programmed axes. This is done by the control system automatically.

The programming command for linear interpolation is G01 (modal), which cancels any other active motion command. Feed Rate is required with G01 and its selection is based on cutting conditions.

**Circular Interpolation (G02, G03).**—*Circular interpolation* applies to a cutting tool-path moving along an arc or a circle. An arc (circle) can be programmed directly, without linear approximation. The cutting motion along an arc is two-dimensional and always takes place in a single plane. No arc or circle exists as a three-dimensional entity (it becomes a helix). Depending on the required outcome, the desired plane can be defined using one of three specific G-codes (Fig. 6- Fig. 8):

G17 = XY plane — arc/circle uses XY coordinates at a given Z-depth

G18 = ZX plane — arc/circle uses ZX coordinates at a given Y-depth

G19 = YZ plane — arc/circle uses YZ coordinates at a given X-depth

Fig. 6. Planes on a CNC Vertical Machining Center.

Fig. 7. Circular Interpolation.

Fig. 8. Circular Interpolation in Planes.

It is very important to understand that the G18 mathematical plane does not correspond to the machine axes orientation and that the arc direction appears to be incorrect. Programming an arc requires a direction of motion in the plane (G02 = CW, G03 = CCW), a start point (typically the current block), an end point (typically the target point, the end of motion), as well as the arc radius. The arc radius can be specified directly (for example R1.5), or it can be defined by special vectors, using IJK addresses.

When using direct radius R, there are some limitations. Radius R (positive) can only be programmed for arcs up to and including 180 degree arc sweep angle. If the sweep angle exceeds 180 degrees but is less than 360 degrees, R- (negative) must be used. For a full circle (360 degrees arc sweep angle), the address R cannot be used at all and a two-vector combination must be used. There is no need to break arc motion at the quadrants.

The definition of IJK vectors is the same for all three axes, where X and I, Y and J, Z and K are related (paired): The I-J-K vector is the distance and direction from the start point of the arc to the arc center, measured along X-Y-Z axis respectively.

A typical milling application in the XY plane is shown in Fig. 9. Current plane selection determines the arc vectors. Some controls use I-J-K as an absolute location. The start point of the arc is defined as the endpoint of the previous motion.

Fig. 9. Arc Vectors.

**Helical and Other Interpolation Methods.**—Most milling controls offer another motion—helical interpolation (either as a standard feature or as an option), but only very few specialized controls offer parabolic or hyperbolic interpolation. Helical interpolation produces a helix. Two axes (typically XY) form the circle while the third axis (typically Z-axis) provides synchronized linear motion. The selected plane (G17, G18, or G19) determines the circular axes, while the remaining axis is linear motion. Helical interpolation is most commonly used for thread milling—a method of thread development that offers many advantages over tapping.

### Offsets for Milling

In CNC terms, the word *offset* means an adjustment. The primary purpose of offsets is to provide a link between the known information at the time of programming and the unknown situation at the time of setup and machining. The single most important purpose of offsets is to provide adjustments necessary to keep precise part dimensions. Such adjustments allow corrections for tool wear, cutter length, or radius at the machine. Offsets can also be used for machining applications, for example, to use the same program for a roughing contour and a finishing contour, or to use a tool with a different diameter or length. Offsets allow the programmer to virtually ignore tool dimensions. There are three groups of offsets for milling applications:

*Work Offset* = Offset to link machine zero and part zero.

*Tool Length Offset* = Offset to link tool tip and part zero.

*Cutter Radius Offset* = Offset to link tool radius and drawing dimensions.

**Work Offset (G54 through G59).**—Every CNC machine has a built-in location called the machine reference point (also known as machine zero or home position). By default, this location has coordinates of X0Y0Z0. The purpose of *work offset* is to establish the difference between machine zero and part zero. All machine axes can be set, although only X and Y axes are normally used.

Fig. 10. Work Offset Using G54.

Work offset allows the programmer to use the dimensions from the drawing without considering the actual position of the part on the machine table. There are six standard work offsets defined by G54 through G59 commands, with additional sets available optionally. Fig. 10 shows the most commonly used work offset, G54. Note the direction is from machine zero to part zero, along an axis. A typical program entry combines the work offset with other data, for example:

```
N3 G90 G54 G00 X__ Y__ S__ M03 T__
```

**Tool Length Offset (G43, G44).**—The *tool length offset* is a setting that specifies the distance between the tool reference point and part zero, along the Z-axis. Two methods are available—the *preset method* and the *touch-off method*. The preset method requires additional equipment and is used off-machine. The touch-off method is much simpler, and is done at the CNC machine. Each tool used in the program normally requires one tool length offset. A specific offset number is necessary to include with the G43 command. For example,

```
N5 G43 Z0.1 H01 M08
```

G44 is used by only a very few programmers, for specific applications only. Fig. 11 shows typical tool length offset measurement using the touch-off method with G43 command.

Fig. 11. Tool Length of Offset.

**Cutter Radius Offset (G41, G42).**—The *cutter radius offset* is an adjustment of the contour toolpath from the part edge to the cutter center. It is also known as *cutter radius compensation* or *tool nose radius compensation for lathes* (see page 1361).

Point calculations based on the drawing dimensions are far more convenient and practical than programming coordinates to the center of a cutter. Fig. 12 illustrates a toolpath offset by the cutter radius. The toolpath generated on the basis of drawing dimensions may only be suitable for holes where the spindle centerline and hole centerline match. Such a toolpath cannot be used on a contour because the cutter centerline must be shifted—offset—away from the contour by the cutter radius. The purpose of the cutter radius offset is to provide automatic adjustment for the toolpath. This toolpath shifts the cutter center in such a way that the cutter edge is in constant contact with the programmed contour. This control generated toolpath is called an *equidistant toolpath*.

Fig. 12. Cutter Radius Offset.

Fig. 13. Manually Calculated Radius Offset.

Programming to the center of the cutter requires tedious calculations for every point on the contour. Fig. 13 shows such a typical calculation. In addition, manually calculated center toolpaths cannot be adjusted at the machine.

To activate a cutter radius offset, two preparatory commands are available—G41 (offset to the left) and G42 (offset to the right)—both left and right offsets are determined by the cutting direction. As more than one tool can use cutter radius offset, G41 or G42 has to be programmed together with corresponding offset number, using the D-address. Many control systems use only a single offset registry for both tool length offset and cutter radius offset. In such cases, the D-address must have a distinct number from the tool length offset, even if the addresses are different.

*Example:* Tool 1 will be programmed as T01, using G43 H01 as the tool length offset, and G41 D51 as the cutter radius offset. G40 command cancels the cutter radius offset.

Programming the cutter radius offset is relatively simple, but several rules have to be observed. The most important rule requires the G41/G42 command to be applied after completing the Z-depth motion and in G00 or G01 mode only (not on an arc).

*Example:* N44 G01 Z-0.5 F15.0; N45 G41 X0.25 D51 F20.0; N46 Y\_\_

Cutter radius offset uses a so called look-ahead type of radius compensation. During program execution, the control stores the next motion block in the buffer—it “looks ahead” in the program in order to compensate correctly and consistently.

### Machining Holes

Virtually all applications of CNC machining include machining holes. Regardless of what type of machining takes place at a single hole location, there are similarities important to CNC programming, particularly for CNC milling machines and machining centers. In the majority of applications, machining holes is not a complicated procedure. The only cutting tool motion that takes place is along the Z axis, after a required XY location has been applied. This type of machining is commonly known as point-to-point machining and is applied to operations such as drilling, spot drilling, spot facing, counter-boring, counter-sinking, tapping, boring, and reaming.

Each toolpath step relating to a particular machining operation on a hole is always consistent and can be preset within the control system software (built-in software routine). This is the basis for shortening programming holes by using fixed cycles. As the name suggests, these cycles contain an internal set order of tool motions and cannot be changed. Table 4 shows symbols and abbreviations used in the following cycle descriptions.

**Table 4. Fixed Cycle Descriptions**

Symbol	Description
	Rapid Motion and Direction
	Cutting Motion and Direction
	Manual Motion and Direction
	Boring Bar Shift and Direction
	Programmed Coordinate (XY)
Q	Depth of Peck / Shift Amount
d	Clearance Value (built in)
CW / CCW	Spindle Rotation Direction
OSS	Oriented Spindle Stop
DWELL	Dwell Function Executed

**Fixed Cycles.**—“Fixed cycles” sometimes called canned cycles, are series of preset sequences of toolpath motions, allowing consecutive motions to be performed with a single block of program. Typical fixed cycles are:

**Table 5. Fixed Cycle Codes**

G-Code	Description	G-Code	Description
G81	Drilling cycle	G86	Boring cycle
G82	Drilling cycle with dwell (spot drilling cycle)	G76	Fine boring cycle
G83	Deep hole drilling cycle (peck drilling cycle)	G87	Back boring cycle
G73	Chip-breaking cycle	G88	Boring cycle (with manual action)
G84	Right hand tapping cycle	G89	Boring cycle
G74	Left hand tapping cycle	G80	Fixed cycle cancel
G85	Boring cycle		
In addition, two preparatory commands are also used with fixed cycles see Fig. 14:			
G98	Retract to initial level	G99	Retract to R-level

Fig. 14. Initial Level and R-level.

All cycles are modal and are typically canceled by G80. Between the cycle call and the cycle cancel block, only the data that changed is programmed, usually the XY position, occasionally the R-level, or the Z-depth. The general and most commonly used format for all fixed cycles is:

$$N\_G98(G99)G\_X\_Y\_R\_Z\_P\_Q\_F\_$$

where:

$N\_$  = block number,

$G\_$  = cycle number,

$X\_Y\_$  = hole location,

$R\_$  = start position from where feed rate mode starts,

$Z\_$  = final depth,

$P\_$  = amount time delay (dwell) for G82 and G89,

$Q\_$  = either the depth of each peck for G83 and G73, or the shift amount for G76 and G87,

$F\_$  = cutting feed rate in feed per minute mode.

**Fixed Cycle (G81):** The G81 code is used mainly for drilling, and has the following format see Fig. 15:

$$N\_G99(G98)G81X\_Y\_R\_Z\_F\_$$

In the G81 cycle, the tool rapids to XY location first, than to the R-level (feed plane). From that position it feeds to the depth, followed by a rapid retract to the R-level in G99 mode or the initial level, in G98 mode.

Fig. 15. G81 Fixed Cycle.

Fig. 16. G82 Fixed Cycle.

**Spot Drilling, Facing, Counterboring-sinking (G82):** The G82 fixed cycle is used for spot drilling, spot facing, counterboring, countersinking, and any other operation where a dwell at the bottom of the hole is required. It has the following format Fig. 16:

$$N\_G99(G98)G82X\_Y\_R\_Z\_P\_F\_$$

All tool motions are identical to G81 cycle, with the added pause  $P\_$  (dwell). Pause is programmed in milliseconds (ms), without decimal a point. Its purpose is to smooth out

the bottom of the hole. The dwell period should be a minimum of two spindle revolutions to allow for a full clean-up in case 50 percent spindle speed override is in effect. To calculate minimum dwell, divide 60 by the spindle revolutions (r/min):

$$\text{Minimum Dwell (seconds)} = \frac{60}{r/min}$$

To convert to milliseconds, multiply the result by 1000.

*Example:* For 750 r/min, the minimum dwell will be  $60 / 750 \times 1000 = 80$  ms.

**Deep Hole Drilling (G83):** The G83 fixed cycle is used mainly for deep hole drilling using the following format:

N\_\_G99(G98)G83 X\_\_Y\_\_R\_\_Z\_\_Q\_\_F\_\_

From the R-level, the drill will cut by the amount of Q\_\_, which specifies the depth of each peck. When the peck depth Q\_\_ is completed, the drill retract to R-level, then rapids back to cut another depth—there is small non-programmable clearance between the cuts, that is part of the cycle (See Fig. 17).

A general rule of peck drilling is that the greater the Q\_\_ amount is, the fewer pecks will be generated and vice versa. Some controls allow programming of the actual number of pecks required. No peck motion will ever exceed the final Z\_\_ depth.

Fig. 17. G83 Fixed Cycle.

**Chip Breaking (G73):** The G73 fixed cycle is used mainly for chip breaking and has the following format

N\_\_G99(G98)G73 X\_\_Y\_\_R\_\_Z\_\_Q\_\_F\_\_

Its basic function is the same as for G83, but the drill does not retract after each peck, only after the last peck. In both cases, the G98 or G99 retract method will be applied for the last peck only (see Fig. 18).

Fig. 18. G73 Fixed Cycle.

**Right Hand Thread (G84):** The G84 fixed cycle is used for cutting a right hand thread and has the following format

N\_\_G99(G98)G84 X\_\_Y\_\_R\_\_Z\_\_F\_\_

The cycle will start feeding from the R-level to the Z-depth, where the tap stops, reverses its rotation and feeds back to the R-level, where it stops again and resumes normal spindle rotation (see Fig. 19).

G84 cycle must be programmed with spindle rotation CW (normal), typical in M03 mode.

Fig. 19. G84 Fixed Cycle.

Fig. 20. G74 Fixed Cycle.

**Left Hand Thread (G74):** The G74 fixed cycle is used for cutting a left hand thread and has the following format

$$N\_G99(G98)G74X\_Y\_R\_Z\_F\_$$

G74 cycle must be programmed with spindle rotation CCW (reverse), typical in M04 mode. In all other respects, G74 is identical to G84 (see Fig. 20).

**Boring Cycle (G85):** The G85 fixed cycle is used for boring and has the following format

$$N\_G99(G98)G85X\_Y\_R\_Z\_F\_$$

From the R-level, the boring bar will feed to the Z-depth, then feeds back to R-level, both at the programmed feed rate  $F\_$ . A similar cycle G89 has a dwell at the bottom of the hole. Either one of these cycles is commonly used for reaming (see Fig. 21).

Fig. 21. G85 Fixed Cycle.

Fig. 22. G86 Fixed Cycle.

**Boring Cycle (G86):** The G86 fixed cycle is used for boring and has the following format:

$$N\_G99(G98)G86X\_Y\_R\_Z\_F\_$$

In G86 mode, the boring bar will feed from the R-level to the Z-depth, where the spindle stops rotating and the tool is retracted at a rapid rate. Note that a straight line (tool mark) will be generated on the bored hole (see Fig. 22).

**Boring Cycle (G76):** The G76 fixed cycle is used for fine boring and has the following format:

$$N\_G99(G98)G76X\_Y\_R\_Z\_Q\_F\_$$

This cycle is called a "fine" boring cycle, because it does not leave any tool marks on the bored hole. The  $Q\_$  in the block is the amount of shift away from the hole centerline that

takes place before tool retraction. Typically, the amount of  $Q_{\_\_}$  is very small, usually in the range of 0.005-0.010 inches or 0.125-0.250 mm.

In this internally complex cycle, the tool starts at the R-level and feeds to the Z-depth. When the depth is reached, the spindle stops and orients (so called OSS—oriented spindle stop). When oriented, the tool moves away by the  $Q_{\_\_}$  amount, then retracts to the R-level. Once outside of the hole, it moves back by the  $Q_{\_\_}$  amount and the spindle resumes normal rotation (see Fig. 23).

When setting a boring bar used with G76 at the machine, the operator has to align the cutting tip in such a way that it is aimed in the opposite direction of the shift motion. This is done in oriented spindle mode, using the M19 command in MDI.

Fig. 23. G76 Fixed Cycle.

Fig. 24. G87 Fixed Cycle.

**Back Boring (G87):** The G87 fixed cycle is used for *back boring* and has the following format:

$$N_{\_\_} G98 G87 X_{\_\_} Y_{\_\_} R_{\_\_} Z_{\_\_} Q_{\_\_} F_{\_\_}$$

As the name suggests, this cycle is used to bore upwards, starting at the bottom of an existing hole. The R-level is below the part, and only G98 retract method can be used with this cycle. The  $Q_{\_\_}$  amount is also the amount of shift away from the centerline.

When the tool reaches  $X_{\_\_} Y_{\_\_}$  hole location at the initial level, the spindle stops, tool orients and shifts away from hole centerline by the amount of  $Q_{\_\_}$ . Then, it rapids to the R-level, shifts back, and feeds to the Z-depth. When the depth is reached, the tool stops again, orients, and shifts by the  $Q_{\_\_}$  amount. The following retract will be to the initial level, where the tool shifts back, and the spindle resumes normal rotation (see Fig. 24).

This cycle can only be used if the boring bar can move clearly through the existing hole. The shift amount  $Q_{\_\_}$  must be greater than one half of the difference between the back bore diameter and the existing hole diameter. Note that G99 retract mode cannot be used.

**Manual Boring (G88):** The G88 fixed cycle is used for boring with manual intervention and has the following format:

$$N_{\_\_} G99 (G98) G88 X_{\_\_} Y_{\_\_} R_{\_\_} Z_{\_\_} P_{\_\_} F_{\_\_}$$

The G88 fixed cycle is rather rare. Its use is limited to boring operations with special tools that require manual interference at the bottom of a hole. When such a operation is completed, the tool is moved out of the hole for safety reasons. This cycle may be used by some tool manufactures for certain special operations (see Fig. 25).

Fig. 25. G88 Fixed Cycle.

Fig. 26. G89 Fixed Cycle.

**Boring with Dwell (G89):** The G89 fixed cycle is used for boring with dwell and has the following format:

$$N\_G99(G98)G89X\_Y\_R\_Z\_P\_F\_$$

From the R-level, the boring bar will feed to the Z-depth, dwells for the number of milliseconds specified by P\_\_, then feeds back to R-level, both at the programmed feed rate F\_\_. G85, a similar cycle, does not have a dwell. Either one of these cycles is commonly used for reaming (see Fig. 26).

**Fixed Cycle Cancellation (G80):** The G80 fixed cycle cancel is used to cancel any fixed cycle and has the following format:

$$N\_G80$$

G80 is the recommended method for fixed cycle cancellation, although programming any motion command (G00, G01, G02, G03) will also cancel any active cycle.

**General Notes on Fixed Cycles:** Except G87, all fixed cycles can retract to either the R-level (using G99) or the initial level (using G98). The R-level is often called the feed plane and is the Z-position from where the feed rate mode begins. In the cycle, the Z-address is used for depth and the R-address is used for the feed plane to avoid a conflict of two identical addresses. The initial level is the last Z-address programmed before a fixed cycle is called. Although the initial level can be equivalent of the R-level, it usually is higher. Its purpose is to provide means for special clearance setting to bypass obstacles between holes.

Fixed cycles for boring can be applied to either single point or double point boring bars, with the exception of G76 and G87 cycles, which require a shift. In all cases, boring bars must be preset to the diameter of the hole machined.

**Contouring.**—Contouring is the most common semi-finishing and finishing toolpath for both machining centers and lathes. The programmer has to calculate every single point of the part in the order of machining. Using a cutter radius offset, the toolpath is based on the drawing dimensions. Not every point is identified in the drawing and its coordinates have to be calculated manually. For vertical and horizontal lines the calculations are quite simple, but for angular lines and partial arcs trigonometric calculations are necessary.

Fig. 27 shows typical calculations for start and end points of an arc tangent to two lines, a common situation in programming. As in any calculations, certain features must be known. For the calculations shown, point P, radius R, and angle A (as shown) must be known.

Fig. 27. Calculation of Tangent Points.

**Turning and Boring.**—With the advancement of computer technology, control manufacturers have developed cutting cycles capable of complex lathe operations and made them an integral part of the lathe control systems. These special cycles are called *Multiple Repetitive Cycles*. Their main attraction is their excellent flexibility. Some of these advanced cycles cover turning and boring, others grooving and threading. These cycles are only complex in the mathematical sense and even then, only within the control system. In practice, these advanced machining cycles are easy to program. Their other benefit is that they can be easily changed at the control terminal to be optimized for best performance.

The most common multiple repetitive cycles are:

Table 6. Multiple Repetitive Cycles

G-Code	Description	G-Code	Description
G70	Contour finishing cycle (used after G71, G72, and G73)	G74	Peck drilling cycle—along the Z-axis
G71	Roughing cycle—horizontal direction	G75	Peck grooving cycle—along the X-axis
G72	Roughing cycle—vertical direction	G76	Single point threading cycle (straight or tapered)
G73	Pattern repeating roughing cycle		

For turning and boring operations, G71 cycle is the most common, along with G76 cycle for threading (described separately).

**Roughing Cycle (G71):** The most common roughing cycle is G71. Its purpose is to remove stock by horizontal cutting, primarily along the Z axis, typically from the right to the left. It is used for roughing out material out of a solid cylinder. It is available in two formats—a one-block and a two-block format, depending on the control system.

Older controls use a one-block format:

N\_G71P\_Q\_I\_K\_U\_W\_D\_F\_S\_

where:

$P_$  = first block number of the finishing profile,

$Q_$  = last block number of the finishing profile,

$I_$  = distance and direction of rough semi finishing in the X axis—per side,

$K_$  = distance and direction of rough semi finishing in the Z axis,

$U_$  = stock amount for finishing on the X axis diameter,

$W_$  = stock left for finishing on the Z axis,

$D_$  = depth of roughing cut,

$F_$  = cutting feed rate per revolution,

$S_$  = spindle speed in ft/min or m/min (cutting speed).

The I and K parameters are not available on all machines. They control the amount of cut for semi finishing, the last continuous cut before final roughing motions.

Newer controls require a two-block data entry for the G71 cycle, and the programming format is:

$$G71 U\_R\_; G71 P\_Q\_U\_W\_F\_S\_$$

where the parameters in the first block are:

$U\_$  = depth of roughing cut,

$R\_$  = amount of retract from each cut.

where the parameters in the second block are:

$P\_$  = first block number of the finishing profile,

$Q\_$  = last block number of the finishing profile,

$U\_$  = stock amount for finishing on the X axis diameter,

$W\_$  = stock left for finishing on the Z axis,

$F\_$  = cutting feed rate per revolution,

$S\_$  = spindle speed in ft/min or m/min (cutting speed).

The U-address in the first block is independent of the U-address in the second block. The I and K parameters may be used only on some controls and the retract amount R is set by a system parameter.

G71 cycle can be used for external roughing (turning) as well as for internal roughing (boring). The control system determines the type of machining by comparing the start point SP with the point P.

Fig. 28. G71 Roughing Cycle.

A typical program segment will have the following structure (tool 01 used):

N1 G20 T0100; N2 G96 S\_\_ M03;

N3 G00 X\_\_ Z\_\_ T0101 M08 (START POINT SP); N4 G71 U0.15 R0.04;

N5 G71 P6 Q11 U0.06 W0.005 F0.015; N6 G00 X\_\_ (POINT P BLOCK); N7 ..;

N8 ...

N9 ...

N10 ...

N11 U0.2 (POINT Q BLOCK); N12 G28 U0 W0; N13 M30; %;

G72 Roughing cycle is similar, but applies for vertical direction of cut.

There are two types of G71 and G72—Type I and Type II. Type I does not allow for a change of direction, whereby Type II allows for a change in one axis only.

*Repeated Finish Counting (G73):* G73 pattern repeating cycle is used to machine a finishing contour repeatedly, by a given distance, in specified number of steps.

*Finish Cycle (G70):* G70 is programmed after G71, G72, and G73 as a finishing cycle, and has a simple format:

$$N\_ G70 P\_ Q\_ F\_ S\_$$

where:

$P\_ =$  the first block number of the finishing profile,

$Q\_ =$  the last block number of the finishing profile,

$F\_ =$  the cutting feed rate per revolution,

$S\_ =$  the spindle speed in ft/min or m/min (cutting speed).

In all the examples, the spindle speed or feed rate can be omitted in the cycle, if already active (declared previously). The program example for G70 will use the data from the roughing operation:

N\_ G70 P6 Q11 F0.01 S400

*Basic Rules for G71, G73 Cycles:* It is important to observe some general rules, in order to make the multiple repetitive safe and efficient. Here are some more important rules:

- a) Apply a tool nose radius offset before the stock removal cycle is called.
- b) Cancel the tool nose radius offset after the stock removal cycle is completed.
- c) Return motion to the start point is automatic and must not be programmed.
- d) The P block in G71 should not include the Z-axis value for cycle Type I.
- e) Change of direction is allowed only for Type II G71 cycle and along one axis only.
- f) Stock amount U is programmed on a diameter (U+ for turning, U- for boring.)
- g) The Feed Rate programmed between the P and Q points will be ignored during roughing.
- h) Multiple repetitive cycles can be optimized at the machine by changing one or more settings. G72 and G73 are programmed in a similar way. G74 and G75 are used much less frequently and have a simpler format.

### Thread Cutting on CNC Lathes

The method of thread cutting on CNC lathes is called *single point threading* using an indexable threading insert. As a threading operation is both a cutting and a forming operation, the shape and size of the threading insert must correspond to the shape and size of the finished thread. By definition, a single point threading is a machining process of cutting a helical groove of a specific shape with a uniform advancement per spindle revolution. The uniformity of the thread is controlled by the programmed feed rate in feed rate per revolution. Feed rate for threading is always the lead of the thread, never the pitch. For single start threads, the lead and the pitch are identical. As single point threading is a multi-pass operation, the CNC system provides spindle synchronization for each threading pass.

**Depth of Thread Calculations.**—Regardless of the threading method used, the depth of a thread will be required for various calculations. It can be calculated from these common formulas ( $TPI$  is the number of threads per inch):

External V-threads (60-degrees for metric or US customary units):

$$\text{Depth of Thread} = \frac{0.61343}{TPI} = 0.61343 \times \text{Pitch} \quad (1)$$

Internal V-threads (60-degrees for metric or US customary units):

$$\text{Depth of Thread} = \frac{0.54127}{TPI} = 0.54127 \times \text{Pitch} \quad (2)$$

*Thread Pitch* = the distance between two corresponding points of adjacent threads.

$$\text{Pitch} = \frac{1}{TPI} \quad (3)$$

In metric drawings, the pitch is specified as part of the thread designation.

*Thread Lead* = the distance the threading tool will advance along an axis in one revolution of the spindle

$$\text{Feed Rate} = \text{Lead} = \frac{\text{Number of Starts}}{\text{TPH}} = \text{Number of Starts} \times \text{Pitch} \quad (4)$$

Spindle speed is always programmed in direct r/min mode (G97) not in the constant surface speed mode G96.

**Infeed Methods.**—The way a threading tool enters into the material can be programmed in several ways, using two infeed methods available. Infeed is the type of motion from one pass to the next. Three basic thread infeed methods are shown in Fig. 29:

Fig. 29. Thread Infeed Methods.

- 1) Plunge method—also known as the radial infeed
- 2) Angular method—also known as the compound or flank infeed
- 3) Modified angular method—also known as the modified compound (flank) infeed

Specified infeed is typically selected to achieve the best cutting conditions for the insert edge in a given material. With the exception of some very fine leads and soft material, the majority of threading cuts will benefit from a compound infeed or modified compound infeed (angular method), providing the thread geometry allows this method. For example, a square thread will require a radial infeed, while an Acme thread will benefit from compound infeed. Four methods can be applied for compound infeed threading:

- 1) Constant cutting amount
- 2) Constant cutting depth
- 3) One edge cutting
- 4) Both edges cutting

**Radial Infeed.**—Radial infeed is one of the more common threading methods, if the conditions are suitable. It is applied to a cutting motion that is perpendicular to the diameter being cut. Each threading pass diameter is specified as the X-axis, while the Z-axis start point remains unchanged. This infeed method is suitable for soft materials, such as brass, certain aluminum grades, etc. In harder materials it could damage the thread integrity and is not recommended.

The inevitable outcome of a radial infeed motion is that both insert edges are working simultaneously. Since the insert edges are opposite of each other, the chips are formed at both edges at the same time, causing problems that can be traced to high temperatures, lack of coolant access, and tool wear problems. If the radial infeed results in a poor quality thread, a compound infeed method will usually solve the problem.

**Compound Infeed.**—Compound infeed method—also known as a flank infeed method—works on a different principle. Instead of feeding the threading tool perpendicularly towards the part diameter, the position for each pass is shifted by trigonometric calculation to a new Z-position. This approach results in a threading pass where most of the cutting takes place at one edge. As only one insert edge does most of the work, the generated heat can dissipate away from the tool edge while the cutting chips curl away, which extends the tool life.

Using the compound threading method, a heavier pass depth with fewer passes can be used for majority of threads. Compound infeed can be modified by providing 1 to 2 degrees of clearance on one edge to prevent rubbing. The angle of the thread will be maintained by the angle of the threading insert.

**Threading Operations.**—There are many threading operations that can be programmed for a typical CNC lathe. Several operations require a special type of threading insert and some operations can only be programmed if the control system is equipped with special (optional) features:

- a) Constant lead single start threads (typically using G32 or G76)
- b) Variable lead threads—increasing or decreasing (special option) (G34 and G35)
- c) External and internal threading
- d) Tapered threads (conical threads)
- e) Right hand (R/H) and left hand (L/H) threads
- f) Face threads (scroll threads)
- g) Multi-start threads
- h) Circular threads (special option)
- i) Multi-block threads (so called long-hand threading, block-by-block) (G32)

The most common threading modes use either G32 (G33 on some controls) and G76.

**Threading Cycle (G32).**—The G32 command is sometimes called “long-hand threading,” because each tool motion is programmed as one block. Programs using G32 can be quite long and virtually impossible to edit without major reprogramming. On the other hand, G32 method offers great flexibility and often is the only method that can be used, particularly for special threads. The programming format for G32 requires at least four blocks of input for a single thread pass from a start position:

N_ G00 X_ Z_	Current threading pass diameter
N_ G32 Z_ F_	Actual thread cutting (X_ Z_ for taper threads)
N_ G00 X_	Retract to X-start position
N_ Z_	Return to Z-start position

**Threading Cycle (G76).**—G76 is a multiple repetitive cycle for threading, and is the most common method used to generate most of thread forms. Similar to roughing cycles, G76 is programmed in two versions, depending on the control system used. For older controls, a one-block format is used, for newer controls a two-block format is used. The two-block format offers additional settings that are not available in the one-block method.

The G76 threading cycle requires information about the thread and the cutting method.

*One-Block Cycle:* For a one-block G76 cycle, the format is:

N\_ G76 X\_ Z\_ I\_ K\_ D\_ A\_ (P\_) F\_

Where:

- X = the diameter of the last threading pass
- Z = the end of thread along the Z axis
- I = the amount of taper over the total length (per side)
- K = the single depth of the thread
- D = the depth of the first threading pass
- A = the included insert angle (only A0, A29, A30, A55, A60, and A80 allowed)
- P = the infeed method adjustment—positive (not available on all controls)
- F = the feed rate (thread lead)

*Two-Block Cycle:* The two-block G76 format includes several additional programmable features that make the cycle more flexible. For a two-block G76 cycle, the format is:

N\_ G76 P\_ Q\_ R\_  
N\_ G76 X\_ Z\_ R\_ P\_ Q\_ F\_

Where the first block:

$P$  = a six-digit data entry in three pairs:

Digits 1 and 2—number of finishing cuts (01–99)

Digits 3 and 4—number of leads for gradual pull-out (0.0–9.9 times lead), no decimal point used (00–99)

Digits 5 and 6—angle of thread (00, 29, 30, 55, 60, 80 degrees only)

$Q$  = the minimum cutting depth (positive radial value—no decimal point)

$R$  = the fixed amount for finish allowance (decimal point allowed)

Where the second block:

$X$  = the diameter of the last threading pass

$Z$  = the end of thread along the Z axis

$R$  = the amount of taper over the total length (per side)

$P$  = the single depth of the thread (positive radial value—no decimal point)

$Q$  = the depth of the first threading pass (positive radial value—no decimal point)

$F$  = the feed rate (thread lead)

The P/Q/R addresses of the first block are not related to the P/Q/R addresses of the second block. They have their own meaning, applied within each block only.

The G76 threading cycle is used to program the majority of CNC thread cutting operations. Several of parameters of the G76 cycle can be changed at the machine to optimize the threading operation.

*Example:* The code block for cutting an external thread on 2 inch diameter, 12 threads per inch, using tool number 6 to the length of 1.5 inches (thread ends in a recess) would be:

```
N31 T0600; N32 G97 S800 M03; N33 G00 X2.2 Z0.3 T0606 M08 (START POINT FOR THE THREAD); N34 G76 P010060 Q0040 R0.002; N35 G76 X1.8978 Z-1.5 R0 P0511 Q0100 F0.083333; N36 G00 X8.0 Z5.0 T0600; N37 M01;
```

**Multi-Start Threads.**—Threads with more than one start can be programmed using either G32 or G76 threading commands. The lead (and feed rate) for multi-start threads is always the number of starts times the pitch. For example, a triple start thread with the pitch of 0.0625 (16 TPI) will be 0.1875 (F0.1875). In order to achieve proper distribution of each start around the cylinder, each thread has to start at an equal angle, determined by the following calculation:

$$\text{Thread cylindrical spacing angle} = 360 / \text{Number of starts}$$

To achieve this angular spacing, the Z-axis point for each start must be one pitch further than the previous start:

$$\text{Shift amount} = \text{Pitch}$$

$$\text{Number of shifts} = \text{Number of starts} - 1$$

### Subprograms, Macros and Parametric Programming

CNC programs use several techniques to allow the programmer to create complex pieces of code using CNC code building blocks.

**Subprograms.**—*Subprograms* (also known as subroutines), are specially designed programs that can be called on demand by another program and repeated as desired. Such repetition can take place in one program or in several programs. The content of standard subprograms is fixed and can be used only for the intended, specific purpose. For variable type subprograms—called macros—a special control option is required (see page 1378).

The main advantages of subprograms include transportability between programs (even machines), shorter programs, and easier editing. Any repetitive toolpath or machine activity is suitable to be developed as a subprogram.

Any subprogram has to have a number (for example O6001), in the same format as the main program (or other program of origin). The end of subprogram uses the M99 function, which transfers the processing put of the subprogram back to the program of origin. Another miscellaneous function—M98—is used to call a previously stored subprogram, for example M98 P6001. The address O is used for storing the subprogram, address P is used for calling the subprogram.

If required, a subprogram can be repeated, up to 9999 times. That is achieved in three ways, depending on the control system:

Method 1: M98 P6001 L5 will repeat subprogram O6001 five times

Method 2: M98 P6001 K5 will repeat subprogram O6001 five times

Method 3: M98 P00056001 will repeat subprogram O6001 five times

Subprograms can be nested. Nesting is a feature that allows one subprogram to call another subprogram up to four levels deep.

In the example of a simple subprogram application Fig. 30, a complete toolpath is developed for one pocket, stored as a subprogram, and called at the equivalent location of the three remaining pockets. Typical programming methods will use an incremental method of dimensioning.

Fig. 30. Typical Subprogram Application.

**Macros and Parametric Programming.**—In this general introduction to the subject of macros and parametric programming, the most common development tool is known as Fanuc Custom Macros B. In spite of the great advancement of CAD/CAM software, macros still have their special place. In addition to manual or computer assisted programming, macros are used to provide a special solution to a special requirement. Macro programming is a method using variable data in a special subprogram (now called a macro), with actual values defined in the main program. This method provides a single 'master' program that can be used many times with different numerical values. A typical example is a bolt circle, where only a few values change. The main purpose of a macro program is to save programming time.

**Basic Macro Skills.**—Depending on the complexity of the macro to be developed, some basic knowledge and skills are required. The following list identifies the most important items:

- a) Understanding various methods of data settings
- b) CNC machines and controls—operation and programming
- c) Machining skills—how to machine a part
- d) Basic mathematics skills—calculations, formulas
- e) Program structure development skills—convenience and consistency
- f) Offsets and compensations applications skills—various adjustments
- g) Fixed cycles in depth—how they work, in detail
- h) Subprograms in depth, including multi nesting applications
- i) System parameters, their purpose and functions

In addition, if a macro is written for a particular function of the machine, knowledge of that function as it relates to the machine is also very important. If the macro is developed for probing or in-process gauging, the programmer has to understand the full process as well as the objective of the macro development.

**Confirming Macro Capability.**—A macro is a control option, and may not be automatically available to the user. There is a simple way to find out if a macro is active. Set the control to MDI mode (Manual Data Input) and enter this command:

```
#1=1
```

After pressing the “Cycle Start” button, the control will either accept the statement or reject it. The # symbol identifies the subsequent number as a variable number 1 with an assigned value of 1. A statement using the # symbol is unique to macros. If the control rejects it, or it is impossible to enter the symbols, that means the control does not support macro functions.

**Common Features and Applications.**—Typical features found in macros are:

- 1) Arithmetic and algebraic calculations
- 2) Trigonometric calculations
- 3) Variable data storage
- 4) Logical operations
- 5) Branching
- 6) Looping
- 7) Error detection
- 8) Alarm generation
- 9) Input and Output
- 10) Miscellaneous features

A macro program looks like a regular CNC program, but includes many other features. A macro program is structured as a subprogram—it is stored under its own program number (O-), and it is usually called by the main program, using the G65 preparatory command. In a simple form, macro features can be used in the main program, without the macro call. The following list highlights some of the most common applications of macros:

- 1) Groups of similar parts (parametric programming)
- 2) Offset control
- 3) Custom cycles
- 4) Non-standard tool motions (simulating curves)
- 5) Special G-codes and M-codes
- 6) Alarm and message generation
- 7) Hiding and protecting macro programs
- 8) Probing and gauging
- 9) Various shortcuts and utilities

**Macro Structure.**—There are three basic areas to understand for successful macro development. These three areas offer many special functions that are used within the macro.

*Variables* are the key element of all macros. They provide flexibility by easily storing changeable data. When a value is assigned to a variable, it is stored for future use. Stored values are called *Defined Variables*.

*Functions and Constants* are also an important part of macros. Functions calculate something—they solve a mathematical calculation or a formula. For example, a “+” (plus) function will sum two or more values together. In addition to functions, constants can be defined in a macro as well, for example the pi ( $\pi$ ) with the value of 3.14159265359

*Logical Functions* are used for branching and looping purposes. Looping and branching provide a change in the program flow that is based on a certain condition that has been previously defined. The given condition may be tested (evaluated), using the comparison functions, such as ‘greater than’ (>), ‘equal to’, ‘less than or equal to’, and several others, used together with the IF function. They are called Boolean or logical operators. The given condition can be tested only once, using the IF checking function or it may be evaluated repeatedly, using the loop function WHILE—while the given condition is true, the loop is repeated. The result of the evaluation will determine further flow of the program.

**Macro Definition and Call.**—Macros are defined in a similar way as subprograms, but they are called or invoked by the G65 command:

```
O7001 (MACRO)
...
...
M99
%
```

**Variable Definition (G65).**—The G65 macro command accepts variable definitions, called arguments. Arguments are actual program values required for a particular macro only. They are passed to the macro. Variable data in the macro is then replaced with the supplied arguments. A typical program sample of a G65 macro using three arguments may have the following format: G65 P7001 A6.0 B8.5 F10.0

```
G65... Macro call command
P7001... Program number containing the macro—stored as O7001
A6.0... Assignment of local variable A (#1) argument to be passed to macro
B8.5... Assignment of local variable B (#2) argument to be passed to macro F10.0...
Assignment of a local variable F (#9) argument to be passed to macro
```

The illustration Fig. 31 shows graphically the flow between the main program and a macro, as well as the definition and use of the three variables (defined as arguments). In the example, a macro linear motion command will be replaced with the defined amounts:

G01 X#1 Y#2 F#9 = G01 X6.0 Y8.5 F10.0

Fig. 31. Macro Call From Main Program.

Assignment of macro variables as arguments is one of the most important parts of developing any macro. Macro B has an arbitrary list of variables (called *Argument List 1*) and their meaning, shown in the following table:

**Table 7. Macro B Argument List**

Argument List 1	Macro Local Variable	Argument List 1	Macro Local Variable	Argument List 1	Macro Local Variable	Argument List 1	Macro Local Variable
A	1	H	11	O	Not assigned	V	22
B	2	I	4	P	Not assigned	W	23
C	3	J	5	Q	17	X	24
D	7	K	6	R	18	Y	25
E	8	L	Not assigned	S	19	Z	26
F	9	M	13	T	20		
G	Not assigned	N	Not assigned	U	21		

The above variables are LOCAL variables and can be used in arguments or in the macro.

Note that there are five letters missing (not assigned)—they are G N O P L. These letters are reserved and cannot be used as arguments. The letter L is used for the number of macro repetitions.

Variables #10, #12, #14, #15, #16, #27, #28, #29, #30, #31, #32 and #33 can only be used in a macro, not as an argument.

**Types of Variables.**—There are four types of variables available for macros:

*Null Variable:* Variable identified as #0 is a null variable. A null variable has no value—it is an empty variable, often called a vacant variable. This variable can be read by the macro program, but it cannot be assigned a value, which means data cannot be assigned to it.

*Local Variables:* Local variables are temporary only—they are used in macro body and hold certain data. When the macro is called, the local variables are set to their assigned values. When the macro is completed and exits (using the miscellaneous function M99), or the control power is turned off, all local variables are set to null values—they will no longer exist.

*Common Variables:* Common—or global—variables are still stored in the control memory when macro is completed. These variables are maintained by the system and they can be shared by several other macro programs. This group of variables is normally cleared by a specially designed macro program.

*System Variables:* System variables are used for setting and/or changing default conditions and can read and write different CNC data, for example, a current status of a G-code mode, the current work offset, etc. Their numbers are assigned by the control system manufacturer.

**Variable Declarations and Expressions.**—Variable data is not only defined in the argument section of the G65 macro call, variables can also be defined—or declared—in the macro body itself. Compare the two following declarations:

#19 = 800	A value of 800 is assigned to variable number 19—it can be spindle speed (r/min)
#9 = 15.0	A value of 15.0 is assigned to variable number 9—it can be a feed rate (mm/min, m/min, ft/min, in/min, etc.)

Both declarations store values—the value of “800” is stored into the variable #19 and the value of “15.0” into the variable #9. Both values shown in the example are numbers, but they are two different types of a number. 800 is an integer, 15.0 is a real number. In macros, this distinction is important. Variables may also use special expressions. For example, the variable definition #9 = 15.0 can be redefined later, as #9 = #9 \* 1.1, which returns 16.5. If #9 defines the cutting feed rate, the new feed rate will be F16.5. Expressions can also be nested, following the standard mathematical hierarchy of the order of calculations:

```
#1 = 5.0
#2 = 8.5
#3 = 10.0
#4 = [#3 * #2] / #1; which returns 17.0
```

Note that brackets are used for nesting, not parentheses. Parentheses indicate a program comment or a message:

#19 = 800(SPINDLE SPEED DEFINED)

#9 = 15.0(CUTTING FEEDRATE DEFINED)

If a macro feature is available, variables can be defined and used in the main program directly, for example:

#19 = 800

N4 G90 G54 G00 X24.0 Y13.5 S#19 M03

Many variations and applications are possible.

**Macro Functions.**—The available macro functions can be divided into six groups:

- 1) ARITHMETIC functions
- 2) TRIGONOMETRIC functions
- 3) ROUNDING functions
- 4) MISCELLANEOUS functions
- 5) LOGICAL functions and operations
- 6) CONVERSION functions

*Macro Arithmetic Functions:* There are four arithmetic functions:

+	Addition	*	Multiplication
-	Subtraction	/	Division

*Example:*

#1 = 3.5	3.5	Returned value of variable #1 is 3.5
#2 = 4.25	4.25	Returned value of variable #2 is 4.25
#3 = 2.0 + 5.0	7.0	Returned value of variable #3 is a sum of 2+5
#4 = #3 + 1	8.0	Add 1 to the result of variable #3
#5 = #2 - 0.8	3.45	Subtract 0.8 from the current value of variable #2
#6 = #1 - #3	-3.5	Subtract contents of #3 from the contents of #1
#7 = #2 * 6	25.5	Multiply contents of #2 by 6
#8 = 7.0 / 8.0	0.875	Divide 7 by 8 as real numbers
#9 = 7 / 8	0.875	Divide 7 by 8 as integer numbers

*Trigonometric Functions:* The following trigonometric functions are generally available for macros:

SIN	Sine	COS	Cosine	TAN	Tangent
ASIN	arcsine	ACOS	arccosine	ATAN	arctangent

All inputs for SIN, COS, and TAN are in degrees and the output of the inverse functions ATAN, ASIN and ACOS is also in degrees. Inverse functions are usually marked as  $\tan^{-1}$ ,  $\sin^{-1}$ , and  $\cos^{-1}$  on the calculator.

*Example:*

#1 = SIN[38]	0.6156615	Actual value must be in brackets
#2 = 23.7	23.7	
#3 = COS[#2]	0.9156626	Reference to a variable must be in brackets
#4 = TAN[12.86]	0.2282959	

The inverse trigonometric functions accept the length of two sides of a triangle, both enclosed in brackets, "[ ]", and separated by the slash symbol, "/", standing alone between them. The acceptable range is within  $0 \leq \text{RESULT} < 360$ :

*Example:*

#5 = ATAN[0.25]/[0.5]	26.5650512	Position of the slash symbol is important
-----------------------	------------	---

ASIN and ACOS functions are not available on all controls.

*Rounding Functions:* Rounding functions control how decimal places are handled. There are three rounding functions:

- 1) ROUND
- 2) FIX
- 3) UP

(1) *ROUND:* The ROUND function rounds off a value to the nearest whole number. The function disregards fractions that are less than 0.5. For fractions that are equal to or greater than 0.5, the next whole number is the rounded value:

ROUND[0.00001]	Returns 0.0
ROUND[0.5]	Returns 1.0
ROUND[0.99999]	Returns 1.0
ROUND[1.0]	Returns 1.0

There is one very important difference between using the ROUND function directly in a program statement or in a variable definition. Consider the following two blocks:

```
#I01 = 27/32
G91 G00 X[ROUND[#I01]]
```

The incremental motion will be X0.8438 (US customary) or X0.844 (metric). However, if the ROUND function is used in a variable definition, the result will be different:

```
#I01 = [ROUND[27/32]]Returns 1.0
G91 G00 X[#I01]
```

The incremental motion will be X1.0

Rounding can also be performed to a given number of decimal places, but it is a two step process. In the first step, the given value must be multiplied by the factor of:

- 10... to round off to one decimal place
- 100... to round off to two decimal places
- 1000... to round off to three decimal places (typical for metric system)
- 10000... to round off to four decimal places (typical for US customary system)

The second step is to use the ROUND function together with the multiplier. For example, to round 123.56789 to three decimal places:

```
#I01 = 123.456789
#I01 = #I01*1000Returns 123456.789
#I01 = ROUND[#I01]Returns 123457.0 (nearest whole number)
#I01 = #I01/1000Returns 123.457
```

Note that only a single variable has been used for all four calculations. If the original value is not required later, this is a very efficient method of defining variables in the macro body.

The remaining two rounding functions FIX and FUP are used to round a given value up or down only, regardless of whether the decimal portion is over or under 0.5. The FIX and FUP functions are commonly used for counting rather than calculations.

(2) *FIX:* The FIX function is designed to round down the given value (discard fractions less than 1.0) i.e., strip all values after decimal point.

ROUND[0.00001]	Returns 0.0
ROUND[0.5]	Returns 0.0
ROUND[0.99999]	Returns 0.0
ROUND[1.0]	Returns 1.0

(3) *FUP:* The FUP function is designed to round up the given value (raise fractions less than 1.0).

ROUND[0.00001]	Returns 1.0
ROUND[0.5]	Returns 1.0
ROUND[0.99999]	Returns 1.0
ROUND[1.0]	Returns 1.0

*Miscellaneous Functions:* There are two common miscellaneous functions, SQRT and ABS. Several others exist but are not available on all control models.

(1) *SQRT:* The SQRT function calculates the square root of a number supplied between brackets:

SQRT[25.0]                      Returns 5.0

(2) *ABS:* The ABS function (absolute function) always returns a positive value of a given number:

ABS[-1.3]                      Returns 1.3

ABS[1.3]                      Returns 1.3

Using the ABS function is very useful in many applications, for example, to guarantee a positive or a negative value:

#26 = 1.3                      Positive input  
 G01 Z-[ABS[#26]]              The motion will be equivalent to Z-1.3  
 #26 = -1.3                      Negative input  
 G01 Z-[ABS[#26]]              The motion will be equivalent to Z-1.3

*Logical Functions:* Logical functions consist of Boolean operators and bitwise or binary functions:

Boolean functions (operators) compare two values and return a true or false condition:

EQ	Equal to	GT	Greater than	GE	Greater than or equal to
NE	Not equal to	LT	Less than	LE	Less than or equal to

Bitwise functions provide a means of combining comparisons.

AND	And	OR	Or	XOR	Exclusive Or
-----	-----	----	----	-----	--------------

The AND, OR, and XOR functions compare two defined conditions simultaneously. The compared conditions are evaluated, and return either a TRUE value or a FALSE value. In English language, it is easy to understand the difference between the AND and the OR functions, because they follow the basic logic of everyday language. Function XOR is not used with the same frequency in machining macros. Examples of usage:

*Example 1, (OR) #33 = [#1 EQ #2] OR [#3 EQ #4]*

Variable #33 returns true (return value is 1) if #1 equals #2 OR #3 equals #4—otherwise it returns zero (false).

*Example 2, (AND) : #33 = [#1 EQ 1] AND [#2 EQ 2]*

Variable #33 returns 1 (true) if #1 equals 1 AND #2 equals 2—otherwise it returns 0 (false).

*Example 3, (XOR) #33 = [#1 EQ 1] XOR [#2 EQ 2]*

Variable #33 returns 0 (false) if both expressions are true or both expressions are false. If only one expression is true and the other is expression false, #33 returns 1 (true). XOR function is also known as the “exclusive or” function.

**Branching and Looping.**—Both branches and loops (iterations) are based on the return value of an evaluated condition. There are three macro functions available: “IF”, “GOTOn”, and WHILE (also IF-THEN on some controls).

*IF function:* The “IF” function evaluates a given condition and branches to a specified block number providing the condition is true. If the condition is false, the macro processing continues in the next block. This function is commonly used when choosing between two alternatives. Effectively, the IF function bypasses one or more blocks if a certain condition is true. The programming format is:

IF [<this condition is true>] GOTOn

**GOTO $n$  Function:** The “GOTO $n$ ” function is an unconditional branch and is programmed by itself in the block; the “ $n$ ” is replaced by the block number to branch to. For example, GOTO901 will branch to block N901. The programming format is:

GOTO901

**WHILE function:** The “WHILE” function is for looping—it also requires a specified condition to be true for the loop to be processed. The word “while” can be interpreted as meaning “as long as”. Its programming format is:

WHILE [*<this condition is true>*] DOn

The “END $n$ ” is the end of loop identification. There can be up to three levels of loop nesting. Each nested loop will have its own WHILE-END $n$ . For a single loop, the END $n$  is END1.

Note—there is also IF-THEN method available on some control systems. If available, the programming is much more streamlined. The programming format is:

IF [*<this condition is true>*] THEN [*<argument>*]

The ‘THEN’ argument is a statement, normally a definition based on the condition being true:

*Example:* IF [#1 EQ 1] THEN #33 = 0

All branching and looping functions are extremely powerful and are a fundamental part of effective use of macros.

**Macro Example.**—A classic example of macro development is an equally spaced arrangement of holes along a circle—a bolt circle pattern, see Fig. 32. Many versions can be developed, depending on the actual needs

Fig. 32. Bolt Circle Macro Sample

(MAIN PROGRAM—CALLS MACRO **O7051**)

```

M99
%
```

The macro call in block N5 includes six arguments that will be passed to the macro:

X = #24 = Bolt circle center distance from X0 (X3.0)  
 Y = #25 = Bolt circle center distance from Y0 (Y6.5)  
 D = #7 = Bolt circle diameter (D4.5)  
 H = #11 = Number of EQSP holes (H6)  
 A = #1 = Bolt circle angular orientation (default is 0) (A5.0)  
 S = #19 = Start hole number (default is 1) (S1)

### Axis Nomenclature

To distinguish among the different motions, or axes, of a machine tool, a system of letter addresses has been developed. A letter is assigned, for example, to the table of the machine, another to the saddle, and still another to the spindle head. These letter addresses, or axis designations, are necessary for the electronic control system to assign movement instructions to the proper machine element. The assignment of these letter addresses has been standardized on a worldwide basis and is contained in three standards, all of which are in agreement. These standards are EIA RS-267-B, issued by the Electronics Industries Association; AIA NAS-938, issued by the Aerospace Industries Association; and ISO/R 841, issued by the International Organization for Standardization.

The standards are based on a “right-hand rule,” which describes the orientation of the motions as well as whether the motions are positive or negative. If a right hand is laid palm up on the table of a vertical milling machine, as shown in Fig. 1, for example, the thumb will point in the positive *X*-direction, the forefinger in the positive *Y*-direction, and the erect middle finger in the positive *Z*-direction, or up. The direction signs are based on the motion of the cutter relative to the workpiece. The movement of the table shown in Fig. 2 is therefore positive, even though the table is moving to the left, because the motion of the cutter relative to the workpiece is to the right, or in the positive direction. The motions are considered from the part programmer’s viewpoint, which assumes that the cutter always moves around the part, regardless of whether the cutter or the part moves. The right-hand

rule also holds with a horizontal-spindle machine and a vertical table, or angle plate, as shown in Fig. 3. Here, spindle movement back and away from the angle plate, or workpiece, is a positive Z-motion, and movement toward the angle plate is a negative Z-motion.

Fig. 1.

Fig. 2.

Rotary motions also are governed by a right-hand rule, but the fingers are joined and the thumb is pointed in the positive direction of the axis. Fig. 4 shows the designations of the rotary motions about the three linear axes, X, Y, and Z. Rotary motion about the X-axis is designated as A; rotary motion about the Y-axis is B; and rotary motion about the Z-axis is C. The fingers point in the positive rotary directions. Movement of the rotary table around the Y-axis shown in Fig. 4 is a B motion and is common with horizontal machining centers. Here, the view is from the spindle face looking toward the rotary table. Referring, again, to linear motions, if the spindle is withdrawn axially from the work, the motion is a positive Z. A move toward the work is a negative Z.

When a second linear motion is parallel to another linear motion, as with the horizontal boring mill seen in Fig. 5, the horizontal motion of the spindle, or quill, is designated as Z and a parallel motion of the angle plate is W. A movement parallel to the X-axis is U and a movement parallel to the Y-axis is V. Corresponding motions are summarized as follows:

Linear	Rotary	Linear and Parallel
X	A	U
Y	B	V
Z	C	W

Fig. 3.

Fig. 4.

Axis designations for a lathe are shown in Fig. 6. Movement of the cross-slide away from the workpiece, or the centerline of the spindle, is noted as a plus X. Movement toward the workpiece is a minus X. The middle finger points in the positive Z-direction; therefore,

movement away from the headstock is positive and movement toward the headstock is negative. Generally, there is no  $Y$ -movement.

Fig. 5.

Fig. 6.

The machine shown in Fig. 6 is of conventional design, but most NC lathes look more like that shown in Fig. 7. The same right-hand rule applies to this four-axis lathe, on which each turret moves along its own two independent axes. Movement of the outside-diameter or upper turret, up and away from the workpiece, or spindle centerline, is a positive  $X$ -motion, and movement toward the workpiece is a negative  $X$ -motion. The same rules apply to the  $U$ -movement of the inside-diameter, or boring, turret. Movement of the lower turret parallel to the  $Z$ -motion of the outside-diameter turret is called the  $W$ -motion. A popular lathe configuration is to have both turrets on one slide, giving a two-axis system rather than the four-axis system shown.  $X$ - and  $Z$ -motions may be addressed for either of the two heads. Upward movement of the boring head therefore is a positive  $X$ -motion.

Fig. 7.

Axis nomenclature for other machine configurations is shown in Fig. 8. The letters with the prime notation (e.g.,  $X'$ ,  $Y'$ ,  $Z'$ ,  $W'$ ,  $A'$ , and  $B'$ ) mean that the motion shown is positive, because the movement of the cutter with respect to the work is in a positive direction. In these instances, the workpiece is moving rather than the cutter.

Fig. 8.

**Total Indicator Reading (TIR).**—Total indicator reading is used as a measure of the range of machine tool error. TIR is particularly useful for describing the error in a machine tool spindle, referred to as runout. As shown in Fig. 9, there are two types of runout: axial and radial, which can be measured with a dial indicator. Axial runout refers to the wobble of a spindle and is measured at the spindle face. Radial runout is the range of movement of the spindle centerline and is measured on the side of the spindle or quill.

Fig. 9.

### CAD/CAM

CAD in engineering means *computer-aided design* using a computer graphics system to develop mechanical, electrical/electronic, and architectural designs. A second D (CADD) is sometimes added for *computer-aided drafting and design* to indicate use of a computerized drafting or drawing program. CAD technology is the foundation for a wide variety of engineering, design, drafting, analysis, and manufacturing activities. Often a set of drawings initially developed in the design phase of a project is also used for analyzing and optimizing the design, creating mechanical drawings of parts and assemblies and for generating NC/CNC part programs that control machining operations.

Formerly, after a component had been designed with CAD, the design was passed to a part programmer, who developed a program for machining the components, either manually or directly on a computer (graphic) screen, but the process often required redefining and reentering part geometry. This procedure is often regarded as the CAM part of CAD/CAM, although CAM (for computer-aided manufacturing) has a much broader meaning and involves the computer in many other manufacturing activities, such as factory simulation and planning analyses. Improvements in the speed and capability of computers, operating systems, and programs have simplified the process of integrating the manufacturing process and passing drawings (revised, modified, and translated, as necessary) through the design, analysis, simulation, and manufacturing stages.

A CAD drawing is a graphic representation of part geometry data stored in a drawing database file. The drawing database generally contains the complete list of entity (line, arc, etc.) and coordinate information required to build the item drawn. This may include additional information required to define solid surfaces and other model characteristics.

**Types of CAD Drawings.**—The simplest CAD drawings are two-dimensional (2D) and conform to normal engineering drafting practice showing orthographic (front, top, and side views, for example), exploded, isometric, or other views of a component. Depending on the complexity of the part and machining requirements, 2D drawings are often sufficient for use in developing NC/CNC part programs.

Fig. 1. Simple Wireframe Cube with Hidden Lines Removed

Fig. 2. Simple Wireframe Cube with Hidden Lines Shown

*Wireframes* are the simplest two- and three-dimensional forms of drawing images and are created by defining all edges of a part, with, where required, lines defining surfaces. Wireframe drawing elements consist primarily of lines and arcs that can be used in practically any combination. Hidden lines can be shown dashed or can be omitted from the view; hidden-line removal can be used to indicate relative elevations of the elements.

A wireframe drawing of a cube, as in Fig. 1, consists of twelve lines of equal length (some are hidden and thus not shown), each perpendicular to the others. Fig. 2 shows the same wireframe drawing of a cube but with the hidden lines shown. Information about the interior of the cube and the character of the surfaces is not included in the drawing. With such a system, if a 1-inch cube is drawn and a 0.5-inch cylinder is required to intersect the cube's surface at the center of one of its faces, the intersection points cannot be determined, because nothing is known about the area between the edges. A wireframe model of this type is ambiguous if the edges overlap or do not meet where they should.

Two-dimensional drawing elements, such as lines, arcs, and circles, are constructed by specifying point coordinates, usually  $x$  and  $y$ , to identify the location, size, and orientation of these elements. Three-dimensional (3D) drawings are also made up of a collection of lines, arcs, circles, and other drawing elements and are stored in a similar manner. A third point coordinate,  $z$ , indicates the elevation of a point in 3D drawings. On the drawing screen, working in the  $x$ - $y$  plane, the elevation is commonly thought of as the distance of a point or object into the viewing screen (away from the observer) or out of the viewing screen (toward the observer). Coordinate axes are orientated according to the right-hand rule; if the fingers of the right hand point in the direction from the positive  $x$  axis to the positive  $y$  axis, the thumb of the right hand points in the direction of the positive  $z$  axis.

Assigning a thickness (or extruding) to objects drawn in two dimensions gives some 3D characteristics to an object and can be used to create simple prismatic 3D shapes, such as cubes and cylinders. Usually, the greatest difficulty in creating 3D drawings is in picking and visualizing the 3D points in a 2D workspace (the computer display screen). To assist in the selection of 3D points, many CAD programs use a split or windowed screen drawing area that can simultaneously show different views of a drawing. Changes made in the current or active window are reflected in the other windows. A typical window setup might show three orthogonal (mutually perpendicular) views of the drawing and a perspective or 3D view. Usually, the views can be changed as required to suit the needs of the operator.

*Surface Images:* A surface image defines not only the edges of the part, but also the "skin" of each face or surface. Surface models are necessary for designing free-form objects such as automotive body panels and plastics injection moldings used in consumer goods. For a surface model, the computer must be provided with the  $x$ ,  $y$ ,  $z$  coordinates defining each point, as in a wireframe drawing, plus much more information about the part. This may include tangent vectors, surface, and weighting information that determines how much influence one point has on another, twists, and other mathematical data that define abstract curves. For instance, Fig. 3 shows a typical 3D surface patch.

Fig. 3. A 3D Surface Patch

Fig. 4. Isometric Drawing Showing Orientation of Principle Drawing Axis

**Solid Images:** A solid image is the ultimate electronic representation of a part, containing all the necessary information about edges, surfaces, and the interior. Most solid-imaging programs can calculate volume, center of mass, centroid, and moment of inertia. Solid images may be sliced or sectioned on the screen to provide a view of the interior. This type of image is also useful for checking fit and assembly of parts.

One method for building a solid model is to perform Boolean operations on simple shapes such as cylinders, cones, cubes, and blocks. Boolean operations are used to union (join), difference (subtract one from another), and intersect (find the common volume between two objects). Thus, making a hole in a part requires subtracting a cylinder from a rectangular block, in a process called constructive solid geometry (CSG). The boundary representation type of imaging program uses profiles of 2D shapes that it extrudes, rotates, and otherwise translates in 3D space to create the required solid.

Solid images provide complete, unambiguous representation of a part, but the programs require large amounts of computer memory. Each time a Boolean operation is performed, the list of calculations to define the model becomes longer, so computation time increases. The greater the precision, the more time is needed for calculations, so compromises may be required to maintain reasonable productivity. Sometimes, combinations of different programs are used to attain a blend of flexibility, accuracy, and performance.

**Drawing Projections.**—Different techniques are used to display objects to give an accurate 3D appearance. Several methods are commonly used in CAD drawings.

*Isometric drawings*, as in Fig. 4, can be used to good effect for visualizing a part, because they give the impression of a 3D view and are often much faster to create. Isometric drawings are created in 2D space, with the  $x$  and  $y$  axes being inclined at 30 degrees to the horizontal, as shown in Fig. 4, and the  $z$  axis as vertical. Holes and cylinders in isometric drawings become elliptical. Because of the orientation of the  $x$ ,  $y$ , and  $z$  axes, the true length of lines may not be accurately represented in isometric drawings, so dimensions should not be taken directly from a print. Some CAD programs have a special set of predefined drawing axes to facilitate creating isometric drawings.

In *parallel projections*, lines that are parallel in an object, assembly, or part being portrayed remain parallel in the drawing. Parallel projections show 3D objects in a dimensionally correct manner. Though the resulting drawing may not appear as realistic as an isometric or perspective view, it can be used for accurate relative and scaled dimensions.

A characteristic of *perspective drawings* is that parallel lines converge (see Fig. 5) so that objects that are farther away from the observer appear smaller. Perspective drawing techniques are used in some 3D drawings to convey the true look of an object, or group of objects. Because objects are not drawn to scale, dimensional information cannot be extracted from a perspective drawings. Some 3D drawing packages have a true perspective drawing capability; others use a simulation technique to portray a 3D perspective.

Fig. 5. Perspective Drawing of Three Equal-Size Cubes and Construction Lines

An *axonometric projection* is a 3D perpendicular projection of an object onto a surface, such that the object is tilted relative to its normal orientation. An axonometric projection of a cube, as in Fig. 1, shows three faces of the cube. Today's CAD systems are adept at using this type of view, making it easy to see an object from any angle.

**Drawing Tips and Traps.**—Exact decimal values should be used when entering point coordinates from the keyboard, if possible. Fractional sizes should be entered as fractions, not truncated decimals. For example,  $\frac{5}{16}$  should be entered as 0.3125 or  $\frac{5}{16}$ , not 0.313. Accumulated rounding errors and surprises later on when parts do not fit are thus reduced. However, drawing dimensions should not have more significant digits or be more precise than necessary. Unnecessary precision in dimensioning leads to increased difficulty in production, because the part has to be made according to the accuracy level of the drawing.

*Snap* and *object snap* commands make selecting lines, arcs, circles, or other drawing entities faster, easier, and more accurate when picking and placing objects on the screen. Snap permits only points that are even multiples of the snap increment to be selected by the pointer. A  $\frac{1}{8}$ -inch snap setting, for example, will allow points to be picked at exactly  $\frac{1}{8}$ -inch intervals. It is important to set the *snap increment* to the smallest distance increment ( $\frac{1}{4}$  inch, 1 foot, etc.) being used in the area of the drawing under construction. It also is useful to reset the snap increment frequently. The snap feature can be turned off during a command to override the setting or to select points at a smaller interval than the snap increment allows. Some systems permit setting a different snap value for each coordinate axis.

The *object snap* selection mode is designed to select points on a drawing entity according to predefined characteristics of the entity. For example, if end-point snap is in effect, picking a point anywhere along a line will select the end point of the line nearest the point picked. Other object snap modes include point, intersection, midpoint, center and quadrants of circles, tangency point (allows picking a point on an arc or circle that creates a tangent to a line), and perpendicular point (picks a point that makes a perpendicular from the base point to the object selected). When two or more object snap modes are used together, the nearest point that meets the selection criteria will be chosen.

*Create Blocks of Frequently Used Objects:* Once created, complete drawings or parts of drawings can be saved and later recalled into another drawing. Such objects can be scaled, copied, stretched, mirrored, rotated, or otherwise modified without changing the original. When shapes are initially drawn in unit size (i.e., fitting within a  $1 \times 1$  square) and saved, they can be inserted into any drawing and easily scaled. One or more drawing elements can be saved as a group element, or *block*. Block properties vary, depending on the drawing program, but are among the most powerful features of CAD.

Typically, blocks are uniquely named and, as with simple objects, may be saved in a file. (Blocks are ideal for creating libraries of frequently used drawing symbols.) Blocks can be copied, moved, scaled, rotated, arrayed, and inserted as many times as is required in a drawing and manipulated in a drawing as one element. When scaled, each object within the block is scaled to the same degree.

Once blocked, the individual components of a block (lines, arcs, circles, surfaces, and text, for example) cannot be changed or edited. To edit them, a copy (instance) of the block must be *exploded* (unblocked) to divide it into its original components. Once exploded, all of the elements of the block (except other blocks) can be edited. When the required changes have been made, the block must be redefined (redeclared as a block by giving it a name and identifying its components). If the block is redefined using the same name, previous references to the block in the drawing will be updated to match the redefined block.

For example, an assembly drawing is needed that shows a mechanical frame with 24 similar control panels attached to it. Once one of the panels is drawn and defined as a block (using the name *PANEL*, for instance), the block can be inserted (or copied) into the drawing 24 times. Later, if changes need to be made to the panel design, one instance of the block *PANEL* can be exploded, modified, and redefined with the name *PANEL*. When *PANEL* is redefined, every other copy of the *PANEL* block in the drawing is also redefined, so every copy of *PANEL* in the drawing is updated. On the other hand, if the block was redefined with a different name, say, *PANEL1*, existing copies of *PANEL* would remain unchanged. When redefining a block that already exists in the drawing, be sure to use the same insertion point that was used for the original definition of the block; otherwise, the positions of existing blocks with the same name also will be changed.

It is worth noting that many manufacturers distribute drawings of their products in libraries of CAD drawings, usually as DWG or DXF files that can be incorporated into existing drawings. The suitability of such drawings depends on the CAD program, drawing format being used, skill of the technician who created the drawings, and accuracy of the drawings. An example, Fig. 6, shows a sewage pump assembly drawing. Libraries of frequently used drawing symbols and blocks are also available from commercial sources.

Fig. 6. Available CAD Drawing of a Sewage Pump Assembly

*Use of Text Attributes to Request Drawing Information Automatically:* Text attributes are a useful method for attaching textual information to a particular part or feature of a drawing. An attribute is basically a text variable that has a name and can be assigned a value. Attributes are created by defining attribute characteristics such as a name, location in the drawing, text size and style, and default value.

Fig. 7 shows two views of a title block for size A, B, C, and G drawing sheets. The top view includes the title block dimensions per ASME Y14.1-2012, with the names and locations of the attributes (COMPANY, TITLE1, TITLE2, etc.). The first step for creating this title block is to draw the frame of the title block and define the attributes (name, location, and default value for: company name and address, drawing titles [2 lines], drawing size, drawing number, revision number, scale, and sheet number). Then the block must be created and named with the title frame and the attribute definitions.

When the block is inserted into a drawing, the operator is asked to enter the attribute values (company name, drawing title, etc.). The bottom view in Fig. 7 shows a completed title block as it might appear in a drawing. A complete drawing sheet could include several

blocks: a sheet frame, a revision block, a parts list block, and any others needed. Some might be combined into a single block for insertion into a drawing at one time.

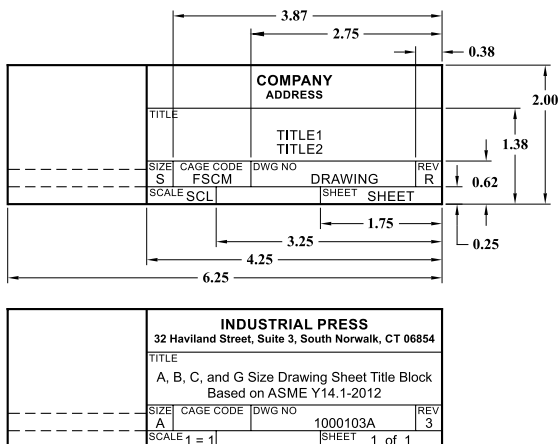

Fig. 7. Top: Title Block for A, B, C and G Drawing Sheets Showing Placement of Text Attributes with ASME Standard Dimensions for Creating this Block. Bottom: Completed Title Block

**Define a Default Drawing Configuration:** Drawing features used in a particular type of drawing can be set up in a template file so that default settings, such as text and dimension styles, text size, drawing limits, and initial view, are set up when a new drawing is started. Different configurations can be defined for each drawing type, such as assembly, parts, or circuit drawings. When creating a new drawing, you can use a template file as a pattern or open a template file and use it to create the new drawing.

**Use Appropriate Detail:** Excessive detail may reduce the effectiveness of the drawing, increase the drawing time on individual commands and the overall time spent on a drawing, and reduce performance and speed of the CAD program. Wherever possible, symbolic drawing elements should be used to represent more complicated parts of a drawing unless the appearance of that particular component is essential to the drawing.

**Scaling Text on Drawing Sheets:** It is usually desirable that text, dimensions, and a few other features on drawings stay a consistent size on each sheet, even when the drawing size is different. The following procedure ensures that text and dimensions (other features as well, if desired) will be the same size from drawing to drawing, without resorting to scaling the drawing to fit onto the drawing sheet.

**Example:** Create a drawing sheet having the dimensions of the actual sheet to be output (A, B, C, D, or E size, for example). Use text attributes, such as the title block illustrated in Fig. 7, to include text that needs to be entered each time the drawing sheet is used. Create a block of the drawing sheet, including the text attributes, and save the block to disk. Repeat for each size drawing sheet required. Establish the text and dimension size requirements for the drawing sheet when it is plotted full size (1:1 scale). Use Table 1 as a guide to recommended text sizes. Test the sheet by placing text and dimensions on the drawing sheet. Plot a copy of the sheet to check that text and dimensions are the expected size.

**Table 1. Standard Sizes of Mechanical Drawing Lettering ANSI/ASME Y14.2-2014**

Use For	Inch		Metric	
	Min. Letter Heights, (in.)	Drawing Size	Min. Letter Heights, (mm)	Drawing Size
Drawing title, drawing size, CAGE Code, drawing number, and revision letter <sup>a</sup>	0.24	D, E, F, H, J, K	6	A0, A1
	0.12	A, B, C, G	3	A2, A3, A4
Section and view letters	0.24	All	6	All
Zone letters and numerals in borders	0.24	All	6	All
Drawing block headings	0.10	All	2.5	All
All other characters	0.12	All	3	All

<sup>a</sup> When used within the title block.

**Drawing Exchange Standards.**—The ability to transfer working data between different CAD, CAD/CAM, design analysis, and NC/CNC programs is one of the most important requirements of engineering drawing programs. Once an engineer, designer, draftsman, or machinist enters relevant product data into his or her machine (computer or machine tool), the information defining the characteristics of the product should be available to the others involved in the project without recreating or reentering it. In view of manufacturing goals of reducing lead time and increasing productivity, concurrent engineering, and improved product performance, interchangeable data are a critical component in a CAD/CAM program.

*DXF* stands for *Drawing Exchange Format* and is a pseudo-standard file format used for exchanging drawings and associated information between different CAD and design analysis programs. Nearly all 2D and 3D CAD programs support some sort of drawing exchange through the use of DXF files, and most can read and export DXF files. There are, however, differences in the drawing features supported and the manner the DXF files are handled by each program. For example, if a 3D drawing is exported in the DXF format and imported into a 2D CAD program, some loss of information results, because all the 3D features are not supported by the 2D program. Most common drawing entities (lines, arcs, etc.) will transfer, although other problems may occur. For example, entities treated as a single object (such as blocks, hatch patterns, and symbols) may be divided into hundreds of components when converted into a DXF file, making the drawing more difficult to edit.

*IGES* stands for *Initial Graphics Exchange Specification* and is a means of exchanging or converting drawings and CAD file for use in a different computer graphics system. Normally, a drawing prepared on the computer graphics system used by company A would have to be redrawn before it would operate on a different computer graphics system used by company B. However, with IGES, the drawing can be passed through a software package called a pre-processor, which converts it into a standardized IGES format that can be saved on a storage device, such as a portable hard drive or memory stick. A postprocessor at company B is then used to convert the standard IGES format to that required for their graphics system. Most graphics software companies have or can assist with IGES programs for file conversion.

*STEP* stands for *Standard for the Exchange of Product Model Data* and is a series of existing and proposed ISO standards written to allow access to all the data surrounding a product. It extends the IGES idea of providing a geometric data transfer to include all the other data that would need to be communicated about a product over its lifetime, and facilitates the use and accessibility of the product data. Although STEP is a new standard, software tools have been developed for converting data between IGES and STEP formats.

*STL*, an abbreviation for *standard tessellation language*, is the format primarily used to send CAD drawings to additive manufacturing machines. Many full-featured CAD systems support translation of drawing files into STL format. CAD programs without STL file format capability can use the IGES or DXF file format, but this process can be time-consuming and expensive, because added steps may be needed to recreate features lost in conversion; also unwanted changes may occur. The safest route, reducing unexpected errors, is to create a CAD model and export it directly into the STL format. Reverse STL generators are available to display a file saved in STL format or convert it into a form that can be imported into a CAD program. For more on this topic, see *Metal Additive Manufacturing* on page 1555.

## SHEET METAL WORKING AND PRESSES

## Basic Theory of Metal Working

Metal working theory provides a background from which reasonable evaluations may be made of the deformations obtainable without instability and fracture. The fundamental principles, rules, and laws of metal working theory are used to describe the plastic flow or deformation of solid materials when subjected to external loads. For this purpose, such materials are considered as homogeneous, continuous, isotropic media. Understanding the theory underlying metal working is important for both the design and production engineer.

Solid materials may be subjected to forces that may be classified as either volume forces or surface forces. In this discussion, only surface forces acting on the surface as external forces are considered.

In analyzing design situations for either dimensioning purposes or forming processes, it is most appropriate to use force per unit area as a measure of the load rather than the total force distributed over the area.

The force per unit area is called the *stress* ( $\sigma$ ) and is described as follows:

$$\sigma = \frac{\text{force}}{\text{area}} \quad (1)$$

Common ways of loading solid bodies include compression, tension, shear, torsion, or a combination of these stresses, such as fatigue. Fig. 1 shows a tensile specimen loaded with force  $F$ . The stress on a cross section  $A$  perpendicular to the longitudinal axis is defined

$$\sigma = \frac{F}{A} \quad (2)$$

where  $F$  = force (lb) and  $A$  = cross-sectional area (in<sup>2</sup>).

If a cross section is inclined at an angle to the longitudinal axis, the mean oblique stress may be defined by

$$\sigma_m = \frac{F}{A_\theta} = \frac{F}{A} \sin \theta \quad (3)$$

where  $A_\theta$  = inclined cross-sectional area of specimen (in<sup>2</sup>); and,  $\theta$  = inclined angle cross-sectional area of specimen ( $^\circ$ ).

The mean oblique stress lies in the direction of the longitudinal axis of the specimen. Force  $F$  can be divided into components  $F_n$ , which is perpendicular to cross section  $A_\theta$  and  $F_t$ , which is parallel to cross section  $A_\theta$ , so that the state of the stresses can be defined by

$$\begin{aligned} \sigma_\theta &= \frac{F_n}{A_\theta} = \frac{F}{A} \sin^2 \theta \\ \tau_\theta &= \frac{F_t}{A_\theta} = \frac{F}{2A} \sin 2\theta \end{aligned} \quad (4)$$

where  $\sigma_\theta$  = normal stress—stress normal to cross section  $A_\theta$  (lb/in<sup>2</sup>); and  $\tau_\theta$  = shear stress—stress parallel to cross section  $A_\theta$  (lb/in<sup>2</sup>).

Fig. 1. A Tensile Specimen with Cross-Sectional Area  $A$  Subjected to the Load  $F$

**Stress-Strain Relationship.**—When solid materials are subjected to stress, they usually respond in an elastic fashion; that is, the strain produced by the stress is reversible (the strain goes back to zero when the stress is removed), and the magnitude of the strain is directly proportional to the magnitude of the stress. This relationship between stress and strain is usually referred to as *Hooke's Law* and can be written

$$\frac{\text{stress}}{\text{strain}} = E = \text{constant} \quad (5)$$

where  $E$  = modulus of elasticity (lb/in<sup>2</sup>).

The most common procedure for describing the various relationships between stress and strain is the tensile test, which is used to determine the modulus of elasticity, the elastic limit, the elongation, the proportional limit, the reduction area, the tensile strength, the yield point, the yield strength, and other tensile properties. The stress ( $\sigma$ ), calculated from the load, and the strain ( $\epsilon$ ), calculated from the extension, can either be plotted as

- 1) nominal (engineering) stress-strain, or
- 2) true stress-strain

The first is more important in design, and the second is more important in manufacturing. The graphs used in each case will be different.

**Nominal Stress-Strain:** Nominal stress, also called engineering stress, is defined as the ratio of the applied load  $F$  to the original cross-sectional area  $A$  of the specimen:

$$\sigma_n = \frac{F}{A_0} \quad (6)$$

where  $\sigma_n$  = nominal stress (lb/in<sup>2</sup>);  $F$  = applied load in the test (lb); and,  $A_0$  = original cross-section area of specimen (in<sup>2</sup>).

**Nominal strain** is defined as

$$\epsilon_n = \frac{l - l_0}{l_0} = \frac{\Delta l}{l_0} \quad (7)$$

where  $\epsilon_n$  = nominal strain (in./in.);  $l_0$  = original gauge length (in.); and  $l$  = instantaneous length of the specimen (in.).

**True Stress-Strain:** A nominal stress-strain curve does not give a true indication of the deformation characteristic of a solid because it is based on the original cross-sectional area  $A_0$  of the specimen, and this dimension changes continuously during the test. In the solution of technical problems in metalworking, true stress and true strain are much more important.

**True stress**  $\sigma$  is defined as the ratio of the load  $F$  to the actual stress-section area  $A$  of the specimen:

$$\sigma = \frac{F}{A} \quad (8)$$

where  $\sigma$  = true stress (lb/in<sup>2</sup>);  $F$  = applied load in the test (lb);  $A$  = actual area (instantaneous) area resisting the load (in<sup>2</sup>).

*True strain* in a tensile test can be defined by dividing the total elongation into small increments of actual change in length. Then, using calculus, it can be shown that true strain is defined by the equation

$$\epsilon = \ln\left(\frac{l}{l_0}\right) \quad (9)$$

where  $\epsilon$  = true strain (in./in.); and  $l$  = instantaneous length at any moment during elongation (in.).

If the true stress, based on the actual (instantaneous) cross section area of the specimen, is used, it is found that the stress-strain curve increases continuously up to fracture. If the strain measurement is also based on instantaneous measurements, the curve obtained is known as a true stress-strain curve (Fig. 2).

The stress-strain curve in Fig. 2(a) can be represented by the equation

$$\sigma = K\epsilon^n \quad (10)$$

where  $K$  = the strength coefficient (lb/in<sup>2</sup>), and  $n$  = strain-hardening (work-hardening) exponent.

This equation is called the *flow curve*, and it represents the behavior of metals in the plastic zone, including their capacity for cold strain hardening.

When the curve shown in Fig. 2(a) is plotted on a logarithmic graph as in Fig. 2(b), it is found that the curve is a straight line, and the slope of the line is equal to the exponent  $n$ . The value of constant  $K$  equals the value of true stress at a true strain value to 1.

The strain-hardening exponent may have a value from  $n = 0$  (perfectly plastic solid) to  $n = 1$  (elastic solid). For most metals,  $n$  has values between 0.10 and 0.50.

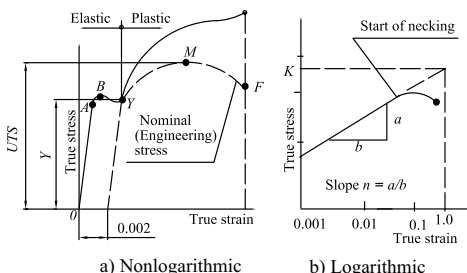

Fig. 2. True Stress-Strain Curve for Medium Steel

*Ductility* is most commonly defined as the ability of a metal to plastically deform easily upon application of a tensile force without breaking or fracturing. Ductility may be expressed as either percentage of elongation or percentage of area reduction in the specimen.

Elongation can be defined as

$$\delta = \frac{l_f - l_0}{l_0} \times 100 \quad (11)$$

Reduction can be defined as

$$\Psi = \frac{A_0 - A_f}{A_0} \times 100 \quad (12)$$

where  $l_f$  = length at the fracture (in.);  $l_0$  = the original specimen's gauge length (in.);  $A_0$  = original specimen's gauge cross-sectional area, (in<sup>2</sup>);  $A_f$  = cross-sectional area of the specimen at the fracture, (in<sup>2</sup>). *Note:*  $l_f$  length is measured between the original gauge marks after the pieces of the broken specimen are placed together.

Elongation ranges between about 8 and 60 percent for most metals, and typical measurements for reduction of area range from about 20 to 90 percent. Ductile materials such as thermoplastic and superplastic materials show large deformation before fracture, and of course, exhibit much higher ductility, but brittle materials have little or no ductility.

### Designing Sheet Metal Parts for Production

#### Sheet metal parts should be designed to satisfy the following criteria:

The parts should allow high productivity rates.

They should make highly efficient use of the materials involved.

The production machines should be easy to service.

Machines should be usable by workers with relatively basic skills.

Unfortunately, very few product designers concern themselves with suitability of production; their prime concern is usually the function of the part.

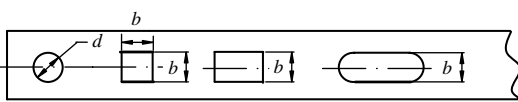

#### Design rules for parts to be produced by blanking and punching:

Avoid part design with complex configurations.

Use minimum dimensions of punched openings relative to material thickness given in Table 1.

Use minimum distances between punched opening and rounded radius relative to material thickness given in Table 2.

**Table 1. Minimal Dimensions of Punched Openings**

Material	Form of opening			
	Circle $d_{min} =$	Square $b_{min} =$	Rectangular $b_{min} =$	Oval $b_{min} =$
Stainless steel	1.50 $T$	1.40 $T$	1.20 $T$	1.10 $T$
High-carbon steel	1.20 $T$	1.10 $T$	0.90 $T$	0.80 $T$
Medium-carbon steel	1.00 $T$	0.90 $T$	0.70 $T$	0.60 $T$
Low-carbon steel	0.90 $T$	0.80 $T$	0.60 $T$	0.55 $T$
Brass and copper	0.80 $T$	0.70 $T$	0.60 $T$	0.55 $T$
Magnesium alloy at 500° F	0.25 $T$	0.45 $T$	0.35 $T$	0.30 $T$

Note: With fine punching process, minimal diameter of punched hole is (0.50 - 0.70)  $T$ .

**Table 2. Minimum Distance between Punched Opening and Edges and Rounded Radius**

Part is	Form of opening	Minimum Distance	Sketch
Blanked	Circle	$c \geq T$ $r \geq 0.5T$	
	Rectangle	$c \geq 1.2T$ $r \geq 0.5T$	
Bent	Circle	$c \geq 2T$ $r \geq (0.5 - 1.0)T$ <sup>a</sup> $r \geq (1.0 - 2.0)T$ <sup>b</sup> $r \geq (2.0 - 3.0)T$ <sup>c</sup>	
Drawn	Circle	$d \leq (d_1 - 2r)$ $D_1 \geq (d_1 - 2r)$ $D \geq (D_1 + 3T + d_2)$ $c \geq r + 0.5T$	

<sup>a</sup> Al and brass

<sup>b</sup> Steel

<sup>c</sup> Al-alloy 6000 series

**Design rules for parts produced by bending:**

Minimum bend radius should be used only if it is necessary for correct function of part.

The bend radius should be larger than the thickness of the material.

Use minimum distances between punched opening and bend radius given in Table 2.

Flange length as shown in Table 2 needs to be  $h \geq 2T$ .

If a part has more than one bend, it is necessary to define technological data.

**Design rules of parts produced by drawing:**

Avoid very complicated parts.

Make diameter of flange  $D$  less than three times the diameter of shell ( $D < 3d$ ), if height  $h$  of shell is greater than twice the diameter of shell ( $h > 2d$ ) as shown in Table 2.

Avoid design of rectangular and square shells with bottom radii less than the corner radius in the junction area.

The shortest distance between corner radii should be no less than the depth of shell.

**Shearing**

Shearing involves the cutting of flat material such as metal sheets, plates, or strips. To be classified as shearing, the cutting action must be along a straight line. The piece of sheet metal sheared off may or may not be called a blank. Shearing is performed in a special machine with different types of blades or cutters. The machines may be foot-, hand-, or power-operated. The shear is equipped with long or rotary blades for cutting. The upper blade of power shears is often inclined to reduce the required cutting force.

During shearing operations, three phases (Fig. 3) may be noted:

*Phase I - Plastic Deformation:* As the upper blade begins to push into the work material, plastic deformation occurs in the surfaces of the sheet, and the stress on the material is lower than the yield stress.

*Phase II - Penetration:* As the blade moves downward, penetration occurs, in which the blade compresses the work material and cuts into the metal. In this phase, the stress on the material is higher than the yield stress but lower than the ultimate tensile strength (UTS).

*Phase III - Fracture:* As the blade continues to travel into the work material, fracture begins in the material at the two cutting edges. The stress on the work material is equal to the shearing stress. If the clearance between the blades is correct, the two fracture lines meet, resulting in a separation of the work material into two parts.

Fig. 3. Schematic Illustration of the Phases of Shearing

Shearing is the preferred way to cut blanks whenever the blank shape permits its use. In most cases, however, the limitation of straight lines in the shape of the blank eliminates the use of shears. Shearing is economical because no expensive dies have to be made for cutting out the blanks. Shearing is used for the following purposes:

- 1) To cut strip or coiled stock into blanks
- 2) To cut strip or coiled stock into smaller strips to feed into a blanking or drawing die
- 3) To trim large sheets, squaring the edges of the sheet.

**Shearing Forces.**—Calculating the force and power involved in shearing operations varies according to the types of blades. There are three types of blades:

a) straight parallel blades; b) straight inclined blades; and c) rotary cutters.

*Shearing with Straight Parallel Blades:* The shearing force with straight parallel cutters can be calculated approximately as

$$F = \tau A \quad (13)$$

where  $F$  = shearing force (lb);  $\tau$  = shear strength of the material (lb/in<sup>2</sup>); and  $A$  = cutting area (in<sup>2</sup>). The cutting area is calculated as

$$A = bT \quad (13a)$$

where  $b$  = length of the cutting material (in.), and  $T$  = thickness of material (in.).

This calculated shearing force needs to be increased by 20 to 40 percent, depending on whether the following conditions exist: an enlarged clearance between the blades, variations in the thickness of the material, the obtuseness of the cutting edge angles, and other unpredictable factors.

The real force of the shearing machine is

$$F_M = 1.3F \quad (14)$$

*Shearing with Straight Inclined Blades:* Shears with straight inclined blades are used for cutting material of relatively small thickness compared with the width of cutting. Using inclined blades reduces the shearing force and increases the range of movement necessary to disjoin the material. The penetration of the upper blade into the material is gradual and as a result, the shearing force is lower.

The shearing force can be calculated as

$$F = n \cdot k \cdot UTS \cdot \lambda \frac{T^2}{\tan \phi} \quad (15)$$

where  $n$  = 0.75 to 0.85 (for most materials);  $k$  = 0.7 to 0.8 (ratio  $UTS/\tau$ );  $\lambda$  = the relative amount of penetration of the upper blade into material (Table 3); and,  $\phi$  = angle of inclination of the upper blade.

**Table 3. Relative Amount of Penetration of the Blade into the Material**

Material	Thickness of material $T$ , inch (mm)			
	<0.04 in. (< 1.0 mm)	0.04–0.08 in. (1.0–2.0 mm)	0.08–0.16 in. (2–4 mm)	>0.16 in. (> 4 mm)
Plain carbon steel	0.75 to 0.70	0.70 to 0.65	0.65 to 0.55	0.50 to 0.40
Medium steel	0.65 to 0.60	0.60 to 0.55	0.55 to 0.48	0.45 to 0.35
Hard steel	0.50 to 0.47	0.47 to 0.45	0.44 to 0.38	0.35 to 0.25
Aluminum and copper (annealed)	0.80 to 0.75	0.75 to 0.70	0.70 to 0.60	0.60 to 0.50

The real force of the shearing machine is

$$F_M = 1.3F \quad (16)$$

*Shearing with Rotary Cutters:* The rotary shearing operation is much like shearing with straight inclined blades because the straight blade may be thought of as a rotary cutter with an endless radius. It is possible to make straight line cuts as well as to produce circular blanks and irregular shapes by this method. Fig. 4 illustrates the conventional arrangement of the cutters in a rotary shearing machine for the production of a perpendicular edge. Only the upper cutter is rotated by the power drive system. The upper cutter pinches the material and causes it to rotate between the two cutters.

Fig. 4. Schematic Illustration of Shearing with Rotary Cutters

Shearing force with rotary cutters can be calculated approximately as

$$F = n \cdot k \cdot UTS \cdot \lambda \cdot \frac{T^2}{2 \tan \phi} \quad (17)$$

where  $\phi = \arccos \left[ 1 - \frac{\mu + T}{D} \right]$ ;  $\mu$  = lap of cutters (in.);  $T$  = thickness of material (in.);  $D$  = diameter of cutter (in.);  $n = 0.75$  to  $0.85$  (for most materials);  $k = 0.7$  to  $0.8$  (ratio  $UTS/\tau$ ); and,  $\lambda$  = relative amount of penetration of the cutters (Table 3).

The real force of a shearing machine with rotary cutter is

$$F_M = 1.3F \quad (18)$$

Rotary shearing machines are equipped with special holding fixtures that rotate the work material to generate the desired circle.

**Clearance.**— Clearance is defined as the space between the upper and lower blades. Without proper clearance, the cutting action no longer progresses. With too little clearance, a defect known as “secondary shear” is produced. If too much clearance is used, extreme plastic deformation will occur. Proper clearance may be defined as that clearance which causes no secondary shear and a minimum of plastic deformation.

The clearance between straight blades (parallel and inclined) is:  $c = (0.02 \text{ to } 0.05)$ , mm.

The clearance between rotary cutters with parallel inclined axes is

$$c = (0.1 \text{ to } 0.2)T \quad (19)$$

where  $T$  = material thickness (in.).

### Cutoff and Parting

**Cutoff.**— Cutoff is a shearing operation in which the shearing action must be along a line. The pieces of sheet metal cutoff are the blanks. Fig. 5 shows several types of cutoff operations. As seen in the illustration, a cutoff is made by one or more single line cuts. The line of cutting may be straight, curved, or angular. The blanks need to be nested on the strip in such a way that scrap is avoided. Some scrap may be produced at the start of a new strip or coil of sheet metal in certain cases. This small amount is usually negligible.

The use of cutoff operations is limited by the shape of a blank. Only blanks that nest perfectly may be produced by this operation. Cutoff is performed in a die and therefore may be classified as a stamping operation. With each cut, a new part is produced. More blanks may be produced per stroke of the press ram by adding more single-line cutting edges.

Fig. 5. Types of Cutoff

**Parting.**—Parting is a cutting operation of a sheet metal strip by a die with cutting edges on two opposite sides. During parting, some amount of scrap is produced, as shown in Fig. 6. This might be required when the blank outline is not a regular shape and is precluded from perfectly nesting on the strip. Thus, parting is not as efficient an operation as cutoff.

Fig. 6. Types of Parting

### Blanking and Punching

Blanking and punching are fabricating processes used to cut materials into forms by the use of a die. Major variables in these processes are as follows: the punch force, the speed of the punch, the surface condition and materials of the punch and die, the condition of the blade edge of the punch and die, the lubricant, and the amount of clearance.

In blanking, a workpiece is removed from the primary material strip or sheet when it is punched. The material that is removed is the new workpiece or blank. Punching is a fabricating process that removes a scrap slug from the workpiece each time a punch enters the punching die. This process leaves a hole in the workpiece (Fig. 7).

Fig. 7. Blanking and Punching

**Characteristics of the blanking process include:**

- 1) Ability to produce workpieces in both strip and sheet material during medium and mass production.
- 2) Removal of the workpiece from the primary material stock as a punch enters a die.
- 3) Control of the quality by the punch and die clearance.
- 4) Ability to produce holes of varying shapes quickly.

**Characteristics of the punching process include:**

- 1) Ability to produce holes in both strip and sheet material during medium and mass production.
- 2) Ability to produce holes of varying shapes quickly.

There are three phases in the process of shearing during blanking and punching as illustrated in Fig. 8.

Fig. 8. Phases in the Process of Shearing

In Phase I, work material is compressed across and slightly deformed between the punch and die, but the stress and deformation in the material does not exceed the plastic limit. This phase is known as the elastic phase.

In Phase II, the work material is pushed farther into the die opening by the punch; at this point in the operation the material has been obviously deformed at the rim, between the cutting edges of the punch and the die. The concentration of outside forces causes plastic deformation at the rim of the material. At the end of this phase, the stress in the work material close to the cutting edges reaches a value corresponding to the material shear strength, but the material resists fracture. This phase is called the plastic phase.

During Phase III, the strain in the work material reaches the fracture limit, and microcracks appear, which turn into macro-cracks, followed by separation of the parts of the workpiece. The cracks in the material start at the cutting edge of the punch on the upper side of the work material, and at the die edge on the lower side of the material; the crack propagates along the slip planes until complete separation of the part from the sheet occurs. A slight burr is generally left at the bottom of the hole and at the top of the slug. The slug is then pushed farther into the die opening. The slug burnish zone expands and is held in the die opening. The whole burnish zone contracts and clings to the punch.

**Blanking and Punching Clearance.**—*Clearance, c*, is the space (per side) between the punch and the die opening shown in Fig. 9, such that:  $c = \frac{D_d - d_p}{2}$

Ideally, proper clearance between the cutting edges enables the fractures to start at the cutting edge of the punch and the die. The fractures will proceed toward each other until they meet. The fractured portion of the sheared edge then has a clean appearance. For optimum finish of a cut edge, correct clearance is necessary. This clearance is a function of the type, thickness, and temper of the material.

When clearance is not sufficient, additional layers of the material must be cut before complete separation is accomplished. With correct clearance, the angle of the fracture will permit a clean break below the burnish zone because the upper and lower fractures will extend toward one another. Excessive clearance will result in a tapered cut edge, because for any cutting operation, the opposite side of the material that the punch enters after cutting will be the same size as the die opening.

Fig. 9. Punch and Die Clearance

Where Clearance is Applied: Whether clearance is deducted from the dimensions of the punch or added to the dimensions of the die opening depends upon the nature of the work-piece. In the blanking process (a blank of given size is required), the die opening is made to that size and the punch is made smaller. Conversely, in the punching process (when holes of a given size are required), the punch is made to the dimensions and the die opening is made larger. Therefore, for blanking, the clearance is deducted from the size of the punch, and for piercing the clearance is added to the size of the die opening.

Value for Clearance: Clearance is generally expressed as a percentage of the material thickness, although an absolute value is sometimes specified.

Table 4 shows the value of the shear clearance in percentages, depending on the type and thickness of the material.

Table 4. Values for Clearance as a Percentage of the Thickness of the Material

Material	Material Thickness, $T$				
	<0.040 in. (< 1.0 mm)	0.040-0.080 in. (1.0-2.0 mm)	0.082-0.118 in. (2.1-3.0 mm)	0.122-0.197 in. (3.1-5.0 mm)	0.200-0.275 in. (5.1-7.0 mm)
Low carbon steel	5.0	6.0	7.0	8.0	9.0
Copper and soft brass	5.0	6.0	7.0	8.0	9.0
Medium carbon steel 0.20% to 0.25% carbon	6.0	7.0	8.0	9.0	10.0
Hard brass	6.0	7.0	8.0	9.0	10.0
Hard steel, 0.40% to 0.60% carbon	7.0	8.0	9.0	10.0	12.0

Table 5 shows absolute values for the blanking and punching clearance for high-carbon steel (0.60% to 1.0% carbon) depending on the thickness of the work material.

Table 5. Absolute Values of Clearance for Blanking and Punching High-Carbon Steel

Effect of Clearance: Manufacturers have performed many studies on the effect of clearance on punching and blanking. Clearance affects not only the smoothness of the fracture, but also the deformation force and work. A tighter blanking and punching clearance generates more heat on the cutting edge and the bulging area tightens around the punch. These effects produce a faster breakdown of the cutting edge. If the clearance increases, the

bulging area disappears and the roll-over surface is stretched and will retract after the slug breaks free. Less heat is generated with increases in the blanking and punching clearance, and the edge breakdown rate is reduced. The deformation force is greatest when the punch diameter is small compared to the thickness of the work material. In one example, a punching force of about 142 kN was required to punch 19 mm holes into 8 mm mild steel when the clearance was about 10 percent. With a clearance of about 4.5 percent, the punching force increased to 147 kN, and a clearance of 2.75 percent resulted in a force of 153.5 kN.

**Die Opening Profile.**—Die opening profiles depend on the purpose and required tolerance of the workpiece. Two opening profiles are shown in Fig. 10a and Fig. 10b.

Fig. 10a. Opening Profile for High Quality Part

Fig. 10b. Opening for Low Accuracy Part

The profile in Fig. 10a gives the highest quality workpiece. To allow a die block to be sharpened more times, the height  $h$  of the block needs to be greater than the thickness of the workpiece. The value of  $h$  is given in Table 6. The die opening profile in Fig. 10b is used for making a small part with low accuracy from very soft material, such as soft thin brass. The angle of the cone  $\alpha = 15'$  to  $45'$ .

**Table 6. Value of Dimension  $h$  Based on Material Thickness**

	Work material thickness, $T$		
	< 0.04 in. ( < 1 mm )	> 0.04 to 0.2 in. ( > 1 to 5 mm )	> 0.2 to 0.4 in. ( > 5 to 10 mm )
Height $h$	0.14 in (3.5 mm)	0.26 in (6.5 mm)	0.45 in (11.5 mm)

Angle  $\alpha = 3^\circ$  to  $5^\circ$

**Deformation Force, Deformation Work, and Force of Press.**—Deformation force  $F$  for punching and blanking with flat face of punch is defined by the following equation:

$$F = LT\tau_m = 0.8LT(UTS) \quad (20)$$

where  $F$  = deformation force, lb (N)

$L$  = the total length of cutting, in. (mm)

$T$  = thickness of the material, in. (mm)

$\tau_m$  = shear stress, lb/in<sup>2</sup> (MPa)

$UTS$  = the ultimate tensile strength of the work material, lb/in<sup>2</sup> (MPa)

*Force of Press:* Such variables as unequal thickness of the material, friction between the punch and workpiece, or dull cutting edges, can increase the necessary force by up to 30 percent, so these variables must be considered in selecting the power requirements of the press. That is, the force requirement of the press,  $F_p$  is

$$F_p = 1.3F \quad (21)$$

The blanking and punching force can be reduced if the punch or die has bevel-cut edges. In blanking operations, bevel shear angles should be used on the die to ensure workpiece remains flat. In punching operations, bevel shear angles should be used on the punch.

*Deformation Work  $W$*  for punching and blanking with flat face of punch is defined by the following equation:

$$W = kFT \quad (22)$$

where  $k$  = a coefficient that depends on the shear strength of the material and the thickness of the material

$F$  = deformation force (lb)

$T$  = material thickness (in.)

**Table 7. Values for Coefficient  $k$  for Some Materials**

Material	Shear Strength lb/in <sup>2</sup> (MPa)	Material Thickness, inch (mm)			
		< 0.040 in. < (1.0 mm)	0.040–0.078 in. (1.0–2.0 mm)	0.078–0.157 in. (2.0–4.0 mm)	> 0.157 in. > 4.0 mm
Low carbon steel	35,000–50,000 (240–345)	0.70–0.65	0.64–0.60	0.58–0.50	0.45–0.35
Medium carbon steel 0.20 to 0.25% carbon	50,000–70,000 (345–483)	0.60–0.55	0.54–0.50	0.49–0.42	0.40–0.30
Hard steel 0.40 to 0.60% carbon	70,000–95,000 (483–655)	0.45–0.42	0.41–0.38	0.36–0.32	0.30–0.20
Copper, annealed	21,000 (145)	0.75–0.69	0.70–0.65	0.64–0.55	0.50–0.40

**Stripper Force.**—*Elastic Stripper:* When spring strippers are used, it is necessary to calculate the amount of force required to effect stripping. This force may be calculated by the following equation:

$$F_s = \frac{1}{0.00117} PT = 855PT \quad (23a)$$

where  $F_s$  = stripping force (lb)

$P$  = sum of the perimeters of all the  
punching or blanking faces (in.)

$T$  = thickness of material (in.)

$$F_s = 5.9PT \quad (23b)$$

where  $F_s$  = stripping force (N)

$P$  = sum of the perimeters of all the  
punching or blanking faces  
(mm)

$T$  = thickness of material (mm)

This formula has been used for many years by a number of manufacturers and has been found to be satisfactory for most punching and blanking operations.

After the total stripping force has been determined, the stripping force per spring must be found in order to establish the number and dimensions of springs required. Maximum force per spring is usually listed in the manufacturer's catalog.

The correct determined force per spring must satisfy the following relationship:

$$F_{max} > F_{so} > \frac{F_s}{n} \quad (24)$$

where  $F_{max}$  = maximum force per spring, lb (newton)

$F_{so}$  = stripping force per spring, lb (newton)

$F_s$  = total stripping force, lb (newton)

$n$  = number of springs

**Blanking Pressure.**—When designing parts that are to be blanked in a press, it is often necessary to work out the pressure required. A press of sufficient tonnage, providing the necessary blanking force, must be used. Otherwise, the press is likely to stall. To calculate the pressure required in tons for blanking various materials, use the following formula:

$$P = A \times T \times S$$

where  $P$  = pressure required (tons)

$A$  = perimeter of blank (in.)

$T$  = thickness of material (in.)

$S$  = shear strength of material (tons per in<sup>2</sup>)

*Example:* Calculate the pressure required in tons for the blank illustrated by Fig. 11. Soft sheet brass is to be used with a thickness of 0.125 inch and a shear strength of 17 tons per square inch.

## BLANKING PRESSURE

Fig. 11. Dimensioned Drawing of Part to be Blanked

Perimeter of blank =  $4 + 2.45 + 3.5 + 0.8 + 0.5 + 0.85 + 1 + 0.8 = 13.9$  in.

Circumference of holes =  $2(\pi \times 0.8) = 5.026$  in.

Total perimeter =  $13.9 + 5.026 = 18.926$  in.

Pressure required =  $P = A \times T \times S = 18.926 \times 0.125 \times 17 = 40.22$  tons

When metric dimensions are used, the same formula applies:

where  $P$  = pressure required (kg)  
 $A$  = perimeter of blank (mm)  
 $T$  = thickness of material (mm)  
 $S$  = shear strength of material (kg per mm<sup>2</sup>)

Note: The general rule for punches that have a shear, where the cutting faces are ground at an angle, is to halve the tonnage for material thicknesses of up to 0.25 inch or 6 mm. For material thicknesses over 0.25 inch or 6 mm, two-thirds of the tonnage should be used.

**Fine Blanking.**—This process uses special presses and tooling to produce flat components from sheet metal or plate, with high dimensional accuracy. According to Hydrel A. G., Romanshorn, Switzerland, fine-blanking presses can be powered hydraulically or mechanically, or by a combination of these methods, but they must have three separate and distinct movements. These movements clamp the work material, perform the blanking operation, and eject the finished part from the tool. Forces of 1.5–2.5 times those used in conventional stamping are needed for fine blanking, so machines and tools must be designed accordingly. In mechanical fine-blanking presses, clamping and ejection forces are exerted hydraulically. Such presses generally are of toggle-type design and are limited to total forces of up to about 280 tons. Higher forces usually require all-hydraulic designs. These presses are also suited to embossing, coining, and impact extrusion work.

Cutting elements of tooling for fine blanking generally are made from 12 percent chromium steel, although high-speed steel and tungsten carbide also are used for long runs or improved quality. Cutting clearances between the punch and die as a percentage of the thickness of material are given in Table 8.

**Table 8. Values for Clearances Used in Fine-Blanking Tools as a Percentage of the Thickness of the Material**

Material Thickness		Clearance, %	
(in.)	(mm)	Inside Contour	Outside Contour
<0.040	<1.016	2.0	1.0
0.040–0.063	1.016–1.600	1.5	
0.063–0.098	1.600–2.489	1.25	
0.098–0.125	2.489–3.175	1.0	
0.125–0.197	3.175–5.004	0.8	0.5
0.197–0.315	5.004–8.001	0.7	
0.315–0.630	8.001–16.002	0.5	

The clamping elements are sharp projections of 90-degree V-section that follow the outline of the workpiece and are incorporated into each tool as part of the stripper plate with thin material and also as part of the die plate when material thicker than 0.15 inch (3.81 mm) is to be blanked. Pressure applied to the elements containing the V-projections prior to the blanking operation causes the sharp edges to enter the material surface, preventing sideways movement of the blank. The pressure applied as the projections bite into the work surface near the contour edges also squeezes the material, causing it to flow toward the cutting edges, reducing the usual rounding effect at the cut edge. When small details such as gear teeth are to be produced, V-projections are often used on both sides of the work, even with thin materials, to enhance the flow effect. With suitable tooling, workpieces can be produced with edges that are perpendicular to top and bottom surfaces within 0.004 inch (0.1mm) on thicknesses of 0.2 inch (5.0 mm), for instance. V-projection dimensions for various material thicknesses are shown in Table 9.

**Table 9. Dimensions for V-projections Used in Fine-Blanking Tools**

V-Projections on Stripper Plate Only		V-Projections on Both Stripper and Die Plate			
Material Thickness	A	h	r	H	R
V-Projections on Stripper Plate Only					
0.040–0.063	0.040	0.012	0.008	...	...
0.063–0.098	0.055	0.015	0.008	...	...
0.098–0.125	0.083	0.024	0.012	...	...
0.125–0.157	0.098	0.028	0.012	...	...
0.157–0.197	0.110	0.032	0.012	...	...
V-Projections on Both Stripper and Die Plate					
0.157–0.197	0.098	0.020	0.008	0.032	0.032
0.197–0.248	0.118	0.028	0.008	0.040	0.040
0.248–0.315	0.138	0.032	0.008	0.047	0.047
0.315–0.394	0.177	0.040	0.020	0.060	0.060
0.394–0.492	0.217	0.047	0.020	0.070	0.080
0.492–0.630	0.276	0.063	0.020	0.087	0.118

All units are in inches.

Fine-blanked edges are free from the fractures that result from conventional tooling and can have surface finishes down to 80  $\mu\text{in.}$  (2.0  $\mu\text{m}$ ) Ra with suitable tooling. Close tolerances can be held on inner and outer forms and on hole center distances. Flatness of fine-blanked components is better than that of parts made by conventional methods but distortion may occur with thin materials due to release of internal stresses. Widths must be slightly greater than are required for conventional press working. Generally, the strip width must be 2–3 times the thickness, plus the width of the part measured transverse to the feed direction. Other factors are shape, material quality, size and shape of the V-projection

in relation to the die outline, and spacing between adjacent blanked parts. Holes and slots can be produced with ratios of width to material thickness down to 0.7, compared with the 1:1 ratio normally specified for conventional tooling. Operations such as countersinking, coining, and bending up to 60 degrees can be incorporated in fine-blanking tooling.

The cutting force in pounds, lb (Newton, N) exerted in fine blanking is 0.9 times the length of the cut in inches (mm) times the material thickness in inches (mm), times the tensile strength in  $\text{lb}_f/\text{in}^2$  (MPa). Pressure in lb (N) exerted by the clamping element(s) carrying the V-projections is calculated by multiplying the length of the V-projection, which depends on its shape, in inches (mm) by its height ( $h$ ), times the material tensile strength in  $\text{lb}_f/\text{in}^2$  (MPa), times an empirical factor  $f$ . Factor  $f$  has been determined to be 2.4–4.4 for a tensile strength of 28,000–113,000  $\text{lb}_f/\text{in}^2$  (193–779 MPa). The clamping pressure is about 30 percent of the cutting force, as calculated. Dimensions and positioning of the V-projection(s) are related to the material thickness, quality, and tensile strength. A small V-projection close to the line of cut has about the same effect as a large V-projection spaced away from the cut. But if the V-projection is too close to the cut, it may move out of the material at the start of the cutting process, reducing its effectiveness. Positioning the V-projection at a distance from the line of cut increases both material and blanking force requirements; its location relative to the line of cut also affects tool life.

**Shaving.**—The edges of punched and blanked parts are generally rough and uneven. Shaving is the process of removing a thin layer of material, from the inside or outside contour of a workpiece or from both sides with a sharp punch and die, to achieve precise, clean parts.

*Shaving a Punched Workpiece:* It is necessary to provide a small amount of stock on the punched or blanked workpiece for subsequent shaving. This amount,  $\delta$ , is the difference between diameters of the hole after shaving and before shaving.

$$\delta = d - d_o \quad (25)$$

where  $d$  = diameter of hole after shaving (inch or mm) and,  $d_o$  = diameter of hole before shaving (inch or mm).

The value of  $\delta$  is 0.006 to 0.0098 inch (0.15 to 0.25 mm) for a previously-punched hole, and 0.004 to 0.006 inch (0.10 to 0.15 mm) for a previously-drilled hole.

The diameter of punch  $d_p$  can be calculated from the formula:

$$d_p = d + \epsilon + i \quad (26)$$

where  $d$  = diameter of hole after shaving (inch or mm)

$\epsilon$  = production tolerance of the hole (inch or mm)

$i$  = amount of compensation for tightening of the hole after shaving (inch or mm)  
( $i = 0.0002$  to  $0.00067$  in. or  $0.005$ – $0.017$  mm)

The diameter of the die  $D_d$  is

$$D_d = (1.20 \text{ to } 1.30) d_p \quad (27)$$

*Shaving a Blanked Workpiece:* Thin layers of material can be removed from a blanked surface by a process similar to punching. If the workpiece after shaving needs to have a diameter  $D$ , the punch diameter for the blanking operation is

$$d_p = D + \delta \quad (28)$$

The die diameter for the blanking operation is

$$d_d = d_p + 2c = D + \delta + 2c \quad (29)$$

where  $D$  = diameter of final piece (inch or mm)

$c$  = clearance between die and punch (inch or mm)

$\delta$  = amount of material for shaving (inch or mm)

### Bending

One of the most common processes for sheet metal forming is bending, which is used to form pieces such as L, U, or V-profiles, and also to improve the stiffness of a piece by increasing its moment of inertia. Bending metal is a uniform straining process that plastically deforms the material and changes its shape. The material is stressed above the yield strength but below the ultimate tensile strength. The surface area of the material changes only in the bending zone. "Bending" usually refers to linear deformation about one axis. Bending may be performed by air bending, bottoming bending, or coining.

**Air Bending:** Air bending is done with the punch touching the workpiece but not bottoming it in the lower die. The profile of a die for air bending can have a right angle or an acute angle. The edges of the die with which the workpiece is in contact are rounded, and the radius of the punch will always be smaller than the bending radius.

**Bottoming Bending and Coining:** Bottoming or coining bending is the process by which the punch and the workpiece bottom on the die. It is necessary to flatten the bottom bend area of the workpiece between the tip of the punch and bottom on the die in order to avoid springback. The tonnage required on this type of press is higher than in air bending.

**Inside Bend Radius.**—Fig. 12 shows the terminology used in the bending process.

Fig. 12. Schematic Illustration of Terminology Used in the Bending Process

One of the most important factors influencing the quality of bent workpieces is the inside bend radius which must be within defined limits.

**Minimum Bend Radius:** If the bend radius is less than  $R_{min}$  given in Equation (30), particularly in harder materials, the material at the outside of the bend will tend to "orange peel." If this orange peeling, or opening of the grain, is severe enough, the metal will fracture or crack off completely in extreme cases.

The minimum bend radius,  $R_{min}$  is given by the following formula:

$$R_{min} = T \left( \frac{50}{r} - 1 \right) \quad (30)$$

where  $T$  = material thickness (inch or mm) and,  $r$  = percentage reduction in a tensile test for a given material (%).

**Maximum Bend Radius:** If the bend radius is greater than  $R_{max}$  given in Equation (31), the bend will be very hard to control and will spring back erratically. The amount of springback will worsen on thinner materials. When large bends are required, an allowance should always be made for this in the tolerance of the part.

To achieve permanent plastic deformation in the outer fibers of the bent workpiece the maximum bend radius must be

$$R_{max} \leq \frac{TE}{2(YS)} \quad (31)$$

where  $E$  = modulus of elasticity, lb/in<sup>2</sup> (N/mm<sup>2</sup>);  $YS$  = yield strength, lb/in<sup>2</sup> (N/mm<sup>2</sup>); and,  $T$  = thickness of material, inches (mm).

**Neutral Axis:** When material is formed, the deformation in the inside fibers of the material will compress during forming and the fibers of the material on the outside of the bend will expand. The material between these two regions remains neutral during forming and is referred to as the neutral axis of the material. The length of fibers along the neutral axis of the bend does not change during forming. This neutral axis is used when figuring the bend allowance for flat blank layouts.

Table 10. Lengths of Straight Stock Required for 90-Degree Bends in Soft Copper and Soft Brass

Radius R of Bend, Inches	Thickness T of Material, Inch

*Allowances for Bending Sheet Metal:* In bending steel, brass, bronze, or other metals, the problem is to find the length of straight stock required for each bend; these lengths are added to the straight section lengths to obtain the total length of material before bending.

If  $L$  = length (inch or mm) of straight stock required before bending;  $T$  = thickness (inch or mm); and  $R$  = inside radius of bend (inch or mm):

For 90° bends in soft brass and soft copper see Table 10 or:

$$L = (0.55 \times T) + (1.57 \times R) \quad (32)$$

For 90° bends in half-hard copper and brass, soft steel, and aluminum see Table 11 or:

$$L = (0.64 \times T) + (1.57 \times R) \quad (33)$$

For 90° bends in bronze, hard copper, cold-rolled steel, and spring steel see Table 12 or:

$$L = (0.71 \times T) + (1.57 \times R) \quad (34)$$

*Example, Showing Application of Formulas 32–34:* Find the length before bending of the part illustrated by Fig. 13. Soft steel is to be used.

Fig. 13.

For bend at left-hand end (180-degree bend):

$$L = [(0.64 \times 0.125) + (1.57 \times 0.375)] \times \frac{180}{90} = 1.338$$

For bend at right-hand end (60-degree bend):

$$L = [(0.64 \times 0.125) + (1.57 \times 0.625)] \times \frac{60}{90} = 0.707$$

Total length before bending = 3.5 + 1.338 + 0.707 = 5.545 inches

*Angle of Bend Other Than 90 Degrees:* For angles other than 90 degrees, find length  $L$ , using tables or formulas, and multiply  $L$  by angle of bend, in degrees, divided by 90 to find length of stock before bending. In using this rule, note that *angle of bend* is the angle through which the material has actually been bent; hence, it is not always the angle as given on a drawing. To illustrate, in Fig. 14, the angle on the drawing is 60 degrees, but the angle of bend  $A$  is 120 degrees ( $180 - 60 = 120$ ); in Fig. 15, the angle of bend  $A$  is 60 degrees; in Fig. 16, angle  $A$  is  $90 - 30 = 60$  degrees. Formulas (32), (33), and (34) apply to parts bent with simple tools or on the bench, where limits of  $\pm 1/64$  inch are specified. If a part has two or more bends of the same radius, it is, of course, only necessary to obtain the length required for one of the bends and then multiply by the number of bends, to obtain the total allowance for the bent sections.

Fig. 14.

Fig. 15.

Fig. 16.

*Springback:* Every plastic deformation is followed by elastic recovery. As a consequence of this phenomenon, which occurs when a flat-rolled metal or alloy is cold-worked, upon release of the forming force, the material has a tendency to partially return to its original shape. This effect is called springback and is influenced not only by the tensile and yield strengths, but also by the thickness, bend radius, and bend angle. To estimate springback, an approximate formula in terms of the bend radius before springback  $R_i$  and bend radius after springback  $R_f$  is as follows

$$\frac{R_i}{R_f} = 4 \left( \frac{R_i (YS)}{ET} \right)^3 - 3 \left( \frac{R_i (YS)}{ET} \right) + 1 \quad (35)$$

where  $R_i$  = bend radius before springback, inch (mm);  $R_f$  = bend radius after springback, inch (mm);  $YS$  = yield strength of the material, lb/in<sup>2</sup> (MPa);  $E$  = modulus of elasticity of the material lb/in<sup>2</sup> (MPa); and,  $T$  = material thickness, inch (mm).

**Other Bending Allowance Formulas:** When bending sheet steel or brass, add from  $\frac{1}{3}$  to  $\frac{1}{2}$  the thickness of the stock, for each bend, to the sum of the inside dimensions of the finished piece, to get the length of the straight blank. The harder the material the greater the allowance ( $\frac{1}{3}$  of the thickness is added for soft stock and  $\frac{1}{2}$  of the thickness for hard material). The data given in Table 13 refer to the bending of sheet metal for counters, bank fittings, and general office fixtures, for which purpose it is not essential to have the sections of the bends within very close limits. Absolutely accurate data for this work cannot be deduced as the hardness and other mechanical properties vary considerably. The values given in the table apply to sheet steel, aluminum, brass and bronze. Experience has demonstrated that for semi-square corners, such as those formed in a V-die, the amount to be deducted from the sum of the outside bend dimensions, shown in Fig. 17 as the sum of the letters from  $a$  to  $e$ , is as follows:  $X = 1.67 BG$ , where  $X$  = the amount to be deducted;  $B$  = the number of bends; and  $G$  = the decimal equivalent of the gage thickness of the stock. The values of  $X$  for different gages and numbers of bends are given in the table.

Fig. 17.

**Table 13. Allowances for Square Bends in Sheet Metal**

Square Bends	Gage	Thickness Inches	Amount to be deducted from the sum of the outside bend dimensions, (in.)						
			1	2	3	4	5	6	7
			Bend	Bends	Bends	Bends	Bends	Bends	Bends

Approximate values for sheet steel, aluminum, brass, and bronze.

The lower part of the table applies to square bends that are either drawn through a block of steel made to the required shape, or are drawn through rollers in a drawbench. The pressure applied not only gives a much sharper corner, but it also elongates the material more than in the V-die process. In this example, the deduction is  $X = 1.33 BG$ .

**Example:** The following further illustrates this type of calculation. A strip having two bends is to have outside dimensions of 2,  $1\frac{1}{2}$  and 2 inches, and is made of stock 0.125 inch thick. The sum of the outside dimensions is thus  $5\frac{1}{2}$  inches, and from Table 13 the amount to be deducted is found to be 0.416; hence, the blank will be  $5.5 - 0.416 = 5.084$  inches long.

**Bending Force:** The bending force is a function of the strength of the material, the length of the workpiece, and the die opening. A good approximation of the required force  $F$  is

$$F = \frac{LT^2(UTS)}{W} \quad (36)$$

where  $F$  = bending force (lb or N)  
 $L$  = length of the workpiece (inch or mm)  
 $T$  = material thickness (inch or mm)  
 $UTS$  = ultimate tensile strength of the material (lb/in<sup>2</sup> or MPa)  
 $W$  = die opening (inch or mm)

**Three-Roll Bending.**—Many curved sheet metal parts, such as rings, cylinders, truncated cones, or segments of these shapes, are impractical to produce by press forming. Such parts are best produced by a process called roll bending. In this process, the workpiece is produced from a flat blank by passing it between three staggered rolls. Depending upon such variables as the composition of the work material, machine capability, or workpiece size, the shape may be formed in a single pass or a series of passes, with roll adjustments needed after each pass. Fig. 18 illustrates the basic setup for three-roll bending on pyramid-type machines.

Fig. 18. Three-Roll Bending

To achieve permanent deformation in the outside and inside fibers of the material, the following relationship must apply:

$$\frac{D}{T} < \frac{E}{YS} + 1 \quad (37)$$

where  $D$  = outer diameter of the workpiece, inch (mm)  
 $T$  = material thickness, inch (mm)  
 $E$  = modulus of elasticity, lb/in<sup>2</sup> (MPa)  
 $YS$  = yield stress, lb/in<sup>2</sup> (MPa)

Three-roll bending is one of the bending operations most used in industrial manufacturing. With only one set of rolls and by setting only one axis, it is possible to achieve different radii or a distribution of radii along the profile length within the bending plane. In addition to the high flexibility and thus economy of this process, it can achieve high quality standards, too, if suitable measures are used.

**Two-Roll Bending.**—Traditionally, roll-bending machines have used three rolls to form the curve. As shown in Fig. 18, the blank passes between or is supported by a third roll, whose position can be adjusted to control the bend. The two-roll bending process shown in Fig. 19 is an alternate method that often is the best choice for high-volume production. Soft to hard materials can be used, thin-gauge material can be rolled to reasonably small diameters, and round workpieces can be made even if the blank has cutouts or holes.

Two-roll bending machines have two basic frame designs: vertical and horizontal. Major parts of both designs include one urethane-covered roll, another steel roll, and an overarm that can be opened and closed to facilitate removal of a finished workpieces. On horizontal machines, the lower urethane-covered roll deforms under the pressure of the upper steel roll to impact the desired shape and size to the blank in a single pass. The diameter of the rolled workpiece is controlled by the diameter of the upper steel roll; a slip-on tube is used to change the desired diameter. The operation of vertical roll-bending machines is basically the same as that of the horizontal one, except that workpieces are loaded and unloaded vertically.

Fig. 19. Two-Roll Bending

When sheet metal is inserted between the two rolls, the urethane roll wraps the blank tightly against the steel roll. The urethane transmits applied force in all directions, as does hydraulic fluid in a hydroforming presses, exerting high pressure; since the urethane roll is driven, true curvature of the sheet metal is obtained. This radius remains uniform, whether the shape being formed is a complete circle or only a segment. Variations in diameter of the final workpiece are due to variations in and natural spring-back of the material.

Since the workpiece is completely controlled, flattening and kinking are eliminated. In most applications, there is no need for pre-forming or cutting off blank ends; flat spots on leading and trailing edges are minimal: one to four material thicknesses, depending on the material.

### Drawing

The drawing of metal, or deep drawing, is the process by which a punch is used to force sheet metal to flow between the surfaces of a punch and a die. Many products made from sheet metals are given the required shape by using a drawing operation. A blank is first cut from flat stock, and then a shell of cylindrical, conical or special shape is produced from this flat blank by means of one or more drawing dies. Most drawn parts are of cylindrical shape, but rectangular, square, and specialized shapes are sometimes produced. With this process, it is possible to get a final part, using minimal operations and generating minimal scrap, that can be assembled without further operations.

**Mechanics of Deep Drawing.**—As the material is drawn into the die by the punch, it flows into a three-dimensional shape. The blank is held in place with a blank holder using a fixed force. High compressive stresses act upon the metal, which without the offsetting effect of a blank holder, would result in a severely wrinkled workpiece.

Wrinkling is one of the major defects in deep drawing; it can damage the dies and adversely affect part assembly and function. The prediction and prevention of wrinkling is very important. There are a number of different analytical and experimental methods that can help to predict and prevent flange wrinkling, including finite element modeling (FEM).

There are many important variables in the deep drawing process, but they can be classified as either material and friction factors, or tooling and equipment factors.

Important material properties such as the strain-hardening coefficient ( $n$ ) and normal anisotropy ( $R$ ) affect deep-drawing operations. Friction and lubrication at the punch, die, and workpiece interfaces are very important in a successful deep drawing process.

Unlike bending operations, in which metal is plastically deformed in a relatively small area, drawing operations impose plastic deformation over large areas, and stress states are different in different regions of the part. As a starting point, consider what appear to be three zones undergoing types of deformation:

- 1) The flat portion of the blank that has not yet entered the die cavity (the flange)
- 2) The portion of the blank that is in the die cavity (the wall)
- 3) The zone of contact between the punch and the blank (bottom)

The radial tensile stress is due to the blank being pulled into the female die, and the compressive stress, normal in the blank sheet, is due to the blank holder pressure. The punch transmits force  $F$  to the bottom of the cup, so the part of the blank that is formed into the

bottom of the cup is subjected to radial and tangential tensile stress. From the bottom, the punch transmits the force through the walls of the cup to the flange. In this stressed state, the walls tend to elongate in a longitudinal direction. Elongation causes the cup wall to become thinner, which can cause the workpiece to tear.

If a drawing die radius in a deep drawing operation is too small, it will cause fracture of the cup in the zone between the wall and the flange. If a punch corner radius is too small, it may cause fracture in the zone between a wall and the bottom of a cup. Fracture can also result from high longitudinal tensile stresses in the bottom cup, due to a high ratio between the blank diameter and the punch diameter. Parts made by deep drawing usually require several successive draws. One or more annealing operations may be required to reduce work hardening by restoring the ductile grain structure.

**Number of Draws:** The number of successive draws  $n$  required is a function of the ratio of the part height  $h$  to the part diameter  $d$ , and is given by this formula:

$$n = \frac{h}{d} \quad (38)$$

where  $n$  = number of draws;  $h$  = part height; and,  $d$  = part diameter.

The value of  $n$  for the cylindrical cup draw is given in Table 14.

**Table 14. Number of Draws ( $n$ ) for a Cylindrical Cup Draw**

$h/d$	<0.6	0.6 to 1.4	1.4 to 2.5	2.5 to 4.0	4.0 to 7.0	7.0 to 12.0
$n$	1	2	3	4	5	6

**Deep Drawability :** Deep drawability is the ability of a sheet metal to be formed, or drawn, into a cupped or cavity shape without cracking or otherwise failing. The depth to which metal can be drawn in one operation depends upon the quality and kind of material, its thickness, and the amount that the work material is thinned in drawing.

**Drawing a Cylindrical Cup Without a Flange:** A general rule for determining the depth to which a cylindrical cup without a flange can be drawn in one operation is defined as the ratio of the mean diameter  $d_m$  of the drawn cup to the blank diameter  $D$ . This relation is known as the drawing ratio  $m$ . The value of the drawing ratio for the first and succeeding operations is given by:

$$m_1 = \frac{d_{m1}}{D} \quad m_2 = \frac{d_{m2}}{D_{m1}} \quad m_3 = \frac{d_{m3}}{D_{m2}} \quad \dots \quad m_n = \frac{d_{mn}}{D_{m_{n-1}}}$$

The magnitude of these ratios determines the following parameters:

- 1) the stresses and forces of the deep drawing processes
- 2) the number of successive draws
- 3) the blank holder force
- 4) the quality of the final drawn parts.

Table 15 shows optimal drawing ratios for cylindrical cups of sheet steel and brass with a flange.

**Table 15. Optimal Ratios  $M$  for Drawing a Cylindrical Cup Without Flanges**

Drawing ratio $m$	Relative Thickness of the Material $T_r = \frac{T}{D} 100$ (%)					
	2.0–1.5	1.5–1.0	1.0–0.6	0.6–0.3	0.3–0.15	0.15–0.08
$m_1$	0.48–0.50	0.50–0.53	0.53–0.55	0.55–0.58	0.58–0.60	0.60–0.63
$m_2$	0.73–0.75	0.75–0.76	0.76–0.78	0.78–0.79	0.79–0.80	0.80–0.82
$m_3$	0.76–0.78	0.78–0.79	0.79–0.80	0.81–0.82	0.81–0.82	0.82–0.84
$m_4$	0.78–0.80	0.80–0.81	0.81–0.82	0.82–0.83	0.83–0.85	0.85–0.86
$m_5$	0.80–0.82	0.82–0.84	0.84–0.85	0.85–0.86	0.86–0.87	0.78–0.90

Diameters of drawing workpieces for the first and succeeding operations are given by:

$$d_1 = m_1 D \quad d_2 = m_2 d_1 \quad \dots \quad d_i = m_i d_{i-1}$$

**Drawing a Cylindrical Cup With a Flange:** Table 16 gives values of the drawing ratio  $m$  for the first and succeeding operations for drawing a cylindrical cup with flange.

Diameters of drawing workpiece for the first and succeeding operations are given by

$$d_1 = m_1 D \quad d_2 = m_2 d_1 \quad \dots \quad d_i = m_i d_{i-1}$$

However, diameter  $D_f$  needs to be accomplished in the first drawing operation if possible.

**Diameters of Shell Blanks:** The diameters of blanks for drawing plain cylindrical shells can be obtained from Table 17, which gives a very close approximation for thin stock. The blank diameters given in this table are for sharp-cornered shells and are found by the following formula

$$D = \sqrt{d^2 + 4dh} \quad (39)$$

where  $D$  = diameter of flat blank (inch or mm);  $d$  = diameter of finished shell (inch or mm); and,  $h$  = height of finished shell (inch or mm).

**Example 1:** If the diameter of the finished shell  $d$ , is to be 1.5 inches (mm), and the height  $h$ , 2 inches (mm), the trial diameter of the blank  $D$ , would be found as follows:

**Table 16. Values of Ratio  $m$  for Drawing a Cylindrical Cup With Flange**

Drawing ratio $m$	$\frac{D_f}{d}$	Relative thickness of the material $T_r = \frac{T}{D} 100$ (%)				
		2.0-1.5	1.5-1.0	1.0-0.6	0.6-0.3	0.3-0.15
$m_1$	1.1	0.51	0.53	0.55	0.57	0.59
	1.3	0.49	0.51	0.53	0.54	0.55
	1.5	0.47	0.49	0.50	0.51	0.52
	1.8	0.45	0.46	0.47	0.48	0.48
	2.0	0.42	0.43	0.44	0.45	0.45
	2.5	0.37	0.38	0.38	0.38	0.38
	3.0	0.32	0.33	0.33	0.33	0.33
$m_2$	...	0.73	0.75	0.76	0.78	0.80
$m_3$	...	0.75	0.78	0.79	0.80	0.82
$m_4$	...	0.78	0.80	0.82	0.83	0.84
$m_5$	...	0.80	0.82	0.84	0.85	0.86

$$D = \sqrt{1.5^2 + 4 \times 1.5 \times 2} = \sqrt{14.25} = 3.78 \text{ inches (mm)}$$

For a round-cornered cup, the following formula, in which  $r$  equals the radius of the corner, will give fairly accurate diameters, provided the radius does not exceed, say,  $\frac{1}{4}$  the height of the shell:

$$D = \sqrt{d^2 + 4dh} - r \quad (40)$$

These formulas are based on the assumption that the thickness of the drawn shell is to be the same as the original thickness of the stock and that the blank is so proportioned that its area will equal the area of the drawn shell. This method of calculating the blank diameter is quite accurate for thin material, when there is only a slight reduction in the thickness of the metal incident to drawing; but when heavy stock is drawn and the thickness of the finished shell is much less than the original thickness of the stock, the blank diameter obtained from Formulas (39) or (40) will be too large, because when the stock is drawn thinner, there is an increase in area. When an appreciable reduction in thickness is to be made, the blank diameter can be obtained by first determining the "mean height" of the drawn shell by the following formula, which is only approximately correct, but will give results sufficiently accurate for most work:

$$M = \frac{ht}{T} \quad (41)$$

**Table 17. Diameters of Blanks for Drawn Cylindrical Shells**

where  $M$  = approximate mean height of drawn shell (inch or mm);  $h$  = height of drawn shell (inch or mm);  $t$  = thickness of shell (inch or mm); and  $T$  = thickness of metal (inch or mm) before drawing.

After determining the mean height, the blank diameter for the required shell diameter is obtained from Table 16, the mean height being used instead of the actual height.

**Example 2:** Suppose a shell 2 inches (mm) in diameter and  $3\frac{3}{4}$  inches (mm) high is to be drawn, and that the original thickness of the stock is 0.050 inch (mm) and the thickness of the drawn shell, 0.040 inch (mm). To what diameter should the blank be cut? Obtain the mean height from Formula (41):

$$M = \frac{ht}{T} = \frac{3.75 \times 0.040}{0.050} = 3 \text{ inches (mm)}$$

According to Table 16, the blank diameter for a shell 2 inches (mm) in diameter and 3 inches (mm) high is 5.29 inches (mm). Formula (41) is accurate enough for all practical purposes, unless the reduction in the thickness of the metal is greater than about one-fifth of the original thickness. When there is considerable reduction, a blank calculated by this formula produces a shell that is too long. However, the error is in the right direction, as the edges of drawn shells are ordinarily trimmed.

If the shell has a rounded corner, the radius of the corner should be deducted from the figures given in the table. For example, if the shell referred to in Example 2 had a corner of  $\frac{1}{4}$ -inch (mm) radius, the blank diameter would equal  $5.29 - 0.25 = 5.04$  inches (mm).

Another formula sometimes used for obtaining blank diameters for shells, when there is a reduction in the thickness of the stock, is as follows:

$$D = \sqrt{a^2 + (a^2 - b^2)\frac{h}{t}} \quad (42)$$

where  $D$  = blank diameter (inch or mm);  $a$  = outside diameter (inch or mm);  $b$  = inside diameter (inch or mm);  $t$  = thickness of shell at bottom (inch or mm); and,  $h$  = depth of shell (inch or mm).

Equation (42) is based on the volume of metal in the drawn shell. It is assumed that the shells are cylindrical, and no allowance is made for a rounded corner at the bottom, or for trimming the shell after drawing. To allow for trimming, add required amount to depth  $h$ .

When a shell is of irregular cross section, if its weight is known, the blank diameter ( $D$ ) can be determined by the following formula:

$$D = 1.1284\sqrt{\frac{W}{wt}} \quad (43)$$

where  $D$  = blank diameter, inches (mm)

$W$  = weight of shell, lbs (kg)

$w$  = weight of metal, lb/in<sup>3</sup> (kg/mm<sup>3</sup>)

$t$  = thickness of the shell, inch (mm)

In the construction of dies for producing shells, especially of irregular form, a common method to be used is to make the drawing tool first. The required blank diameter then can be determined by trial. One method is to cut a trial blank as near to size and shape as can be estimated. The outline of this blank is then scribed on a flat sheet, after which the blank is drawn. If the finished shell shows that the blank is not of the right diameter or shape, a new trial blank is cut either larger or smaller than the size indicated by the line previously scribed, this line acting as a guide. If a model shell is available, the blank diameter can also be determined as follows:

First, cut a blank somewhat large and from the same material used for making the model; then, reduce the size of the blank until its weight equals the weight of the model.

**Forces:** The punch force for drawing a cylindrical shell needs to supply the various types of work required in deep drawing, such as the work of deformation, redundant work, friction work, and the work required for ironing (if required).

*Force for the First Drawing Operation:* The calculation of the punch force for the first drawing operation (neglecting friction) is given by the following formula:

$$F_1 = \pi d_{m1} T (UTS) \quad (44)$$

where  $d_{m1}$  = mean diameter of shell after the first operation, (inch or mm)

$T$  = material thickness, (inch or mm)

$UTS$  = ultimate tensile strength of the material, (lb/in<sup>2</sup> or N/mm<sup>2</sup>)

*Force for Subsequent Drawing Operations:* Subsequent drawing operations are different from the first operation: as in the deep-drawing process, the flange diameter decreases but the zone of the plastic deformation does not change. The punch force for the next drawing operation can be calculated by the approximate empirical formula as follows:

$$F_i = \pi d_p T (UTS) \cdot \left( \frac{D}{d_p} - 0.7 \right) \quad (45)$$

where  $d_p$  = punch diameter (inch or mm)

$D$  = blank diameter (inch or mm)

$T$  = material thickness (inch or mm)

$UTS$  = ultimate tensile strength of the material (lb/in<sup>2</sup> or MPa)

*Shapes of Blanks for Rectangular Shells:* There is no formula for determining the shape of the blank for rectangular drawing that will produce the part as drawn to print. All corner contours must be developed. However, the following conservative procedure will get the die in the final design ballpark with a minimum of trials. When laying out a blank by this method, first draw a plan view of the finished shell or lines representing the shape of the part at the bottom, the corners being given the required radius, as shown in Fig. 20. Next, insert the sides and ends, making the length  $L$  and the width  $W$  equal to the length and width of the drawn part minus twice the radius  $r$  at the corners. To provide just the right amount of material for the corners, the first step is to find what blank diameter will be required to draw a cylindrical shell having a radius  $r$ . This diameter can be calculated by the formula for the blank diameter ( $D$ ) of the cylindrical shell:

$$D = \sqrt{d^2 - 4dh} \quad (46)$$

where  $D$  = blank diameter (inch or mm)

$d$  = diameter of drawn shell (inch or mm)

$h$  = height of shell (inch or mm)

After determining the diameter  $D$ , scribe arcs at each corner having radius  $R$  equal to one-half of diameter  $D$ . The outline of the blank for the rectangular part is then obtained by drawing curved lines between the ends and the sides, as shown in Fig. 20. These curves should touch the arcs  $R$ .

Fig. 20. Layout Design for Deep Drawn Rectangular Shell

When laying out the blank it is usually advisable to plan for a form that will produce corners a little higher than the sides. The wear of the die is at the corners, and when it occurs, the material will thicken and the drawn part will be low at the corners if no allowance for this wear has been made on the blank.

**Blank for Rectangular Flanged Shells:** The shape of the blank for a rectangular flanged shell may be determined in practically the same way as described in the foregoing, except that the width of the flange must be considered. Referring to Fig. 20, the dimension  $h$  in the flat blank is made equal to the height of the drawn part plus the width of the flange; however, the blank diameter  $D$  for a cylindrical shell having a flange can be determined by the formula

$$D = \sqrt{d^2 + 4dh} \quad (47)$$

where  $D$  = blank diameter (inch or mm)

$d$  = diameter of drawn shell (inch or mm)

$d_1$  = diameter measured across the flange (inch or mm)

$h$  = height of shell (inch or mm)

After determining diameter  $D$  and the corresponding radius  $R$ , the outline of the blank is drawn the same as for a rectangular shell without the flange.

**Ironing Process.**—The ironing process is the reduction in thickness of drawn shell walls by pulling them through tight dies. Ironing is a very useful process when employed in combination with deep drawing to produce a uniform wall thickness and to increase the wall height. It is done to obtain a wall that is thin compared with the shell bottom or merely to correct natural wall thickening toward the top edge of a drawn shell.

Basically, in the ironing processes, a previously deep-drawn shell is placed on a punch and pushed through one or more ironing die rings that have a smaller inside diameter than the outside diameter of the shell (Fig. 21). Hence, the clearance between the ironing rings and the punch is less than the shell's wall thickness, so the shell after ironing has a constant wall thickness equal to the clearance. The theoretical maximum reduction in wall thickness per operation due to ironing is approximately 60 percent.

Fig. 21. Ironing of Drawn Cup: a) Cup Before Ironing; b) Cup After Ironing.

**Ironing Force:** Ironing involves the compression and additional work hardening of the metal. The stress on the sidewall can be quite severe, creating the additional possibility of cup failure.

The force required to iron a cylindrical workpiece can be calculated as

$$F_{ir} = S_c \pi d_0 (T - c) \quad (48)$$

where  $F_{ir}$  = ironing force (lb);  $d_0$  = outside diameter of cylindrical cup (in.);  $S_c$  = compressive strength of metal (lb/in<sup>2</sup>);  $T$  = thickness of material (in.); and,  $c$  = clearance between punch and die (in.).

### Stretch Forming

Stretch forming is a metal forming process in which a blank of sheet metal is formed by the simultaneous application of tensile loads to the material over a die in order to form large contoured parts in the required shape.

During stretch forming, the sheet blank is subjected to both *elastic* and *plastic deformation*. The most appropriate measure of formability for stretch forming is the strain-hardening exponent, or  $n$  value:

$$c = k\epsilon^n \quad (49)$$

where  $k$  = a constant.

A high value of  $n$  is desired if the sheet is to show good stretch formability. In assessing the formability of sheet metals while forming a workpiece, a technique called circle grade analysis (CGA) is used to construct a forming limit diagram of the sheet metal to be used.

Two methods are used in stretch forming: simple stretch forming, also called the *block method*, and stretch-wrap forming, also called *tangential stretch forming*.

**Simple Stretch Forming.**—In the simple stretch forming process, the sheet blank to be formed is clamped between two gripping jaws located on opposite ends, and the tool moves into the clamped sheet blank as shown in Fig. 22.

Fig. 22. Simple Stretch Forming.

The most common stretch presses are oriented vertically; the form die rests on a press table that can be raised to the sheet by a hydraulic ram. As the form die is driven into the sheet, the tensile forces increase and the sheet plastically deforms into a new shape.

At the beginning of the process, the sheet blank first drapes itself around the form block, following its contours. Due to the large contact area between form block and blank, the frictional forces prevent a deformation of the sheet in this region.

**Stretch-Wrap Forming.**—In this method also, a sheet blank is gripped from two opposite ends and stretched into the plastic region before being wrapped over a punch, so that the whole cross section of the material undergoes a uniform plastic deformation; then the die is brought down to complete the operation. The main difference from the simple stretch forming process is that both the form block and the gripping jaws are movable (Fig. 23).

Stretch formed parts are typically large and possess large radial bends. The shapes that can be produced range from a simple curved surface to complex non-uniform cross sections. Stretch forming is capable of shaping parts with very high accuracy and smooth surfaces. Ductile materials are preferable, the most commonly used being aluminum, steel, and titanium. Typical stretch formed parts are large curved panels such as door panels in cars or wing panels on aircraft.

## STRETCH FORMING

Fig. 23. Stretch Draw Forming.

The advantages of this process are the following:

- a) The tensile forces applied always act tangentially to the body of the blank
- b) The lack of springback in the finished part
- c) Flexible low-cost tooling
- d) Increase of yield stress up to 10 percent
- e) Less forming pressure required
- f) The die can be made of inexpensive material

The disadvantages are these:

- a) More material required for gripping
- b) Difficulty of adaptation to modern high-speed automated lines
- c) Reduction of material thickness by 5 to 7 percent

### Spinning

Metal spinning is the process of forming various seamless and axially symmetrical parts from flat circles of sheet metal (blanks) or from a length of tubing over a mandrel with tools or rollers. There are three types of metal spinning processes: conventional spinning, shear spinning, and tube spinning.

**Conventional Spinning.**—In conventional metal spinning, a disc of metal is rotated at controlled speeds on a specialized machine similar in design to a machine lathe. Instead of the clamping chuck common on a machine lathe, a wood or metal spinning mandrel is used, the form of which corresponds with the internal contour of the part to be produced. The blank is clamped between the spinning mandrel and a follower on the tailstock spindle, as shown in Fig. 24.

The mandrel, blank, and holder are then set in rotation. Spinning tools or spinning rollers are forced against the rotating blank by hand or by a computer controlled hydraulic mechanism. The process requires a series of crossing steps, as indicated in Fig. 24, to complete the shaping of the workpiece. With this forming technique, a material's thickness generally does not change from the blank to the finished component. If the spinning forces applied with the hydraulic mechanism are higher in comparison to hand spinning, mandrels made of a harder material have to be used, e.g., boiler plate, chilled cast iron, or hardened tool steel.

Fig. 24. Conventional Spinning

**Shear Spinning.**—Shear spinning is the process of forming complex shapes such as cones with tapering walls or symmetrical-axis curvilinear shapes such as the nose cones of missiles. This process achieves a deliberate and controlled reduction in blank thickness (Fig. 25), as opposed to a limited reduction of blank thickness in conventional spinning.

The shear forming roller or rollers achieve local metal flow, which applies a pressure on the blank against the support from the steel mandrel. Special shear forming rollers control the material's flow, and they move the free material parallel to the axis of the mandrel. The remaining portion of the blank, which does not take part in the actual deformation, remains always at right angles with respect to the axis of rotation and does not change its external diameter. The material flow takes place in the axial direction. The wall of the workpiece is produced from the reduction in blank thickness, but the diameter of the blank stays constant, as shown in Fig. 25. The thickness of the initial blank depends on the angle of the final part and the finished wall requirements and can be calculated by the formula:

$$T = \frac{T_w}{\sin \alpha} \quad (50)$$

where  $T$  = thickness of the initial blank (inch or mm);  $T_w$  = wall thickness of the spun part (inch or mm); and  $\alpha$  = half angle of cone.

The bottom and the flange maintain their original thickness. A particular advantage is that the surface finishes achieved are comparable to those achieved with grinding or fine turning. The accuracy of the shape and the dimensional repeatability are excellent.

Fig. 25. Shear Spinning

**Tube Spinning.**—Tube spinning is used to reduce the wall thickness of a hollow cylindrical blank while it is spinning on a cylindrical mandrel using spinning tools (Fig. 26). Applying the spinning tool to the cylindrical blank internally or externally achieves reduction of the workpiece wall, and this reduction in turn results in an increase in the workpiece's length. Workpieces may be spun either forward or backward.

The ideal tangential force in forward tube spinning may be calculated by the following formula:

$$F_t = \sigma_{f(m)}(T - T_w)f \quad (51)$$

where  $F_t$  = ideal tangential force (lb or N);  $\sigma_{f(m)}$  = average flow stress of the material (lb/in<sup>2</sup> or MPa);  $T$  = thickness of the initial blank (inch or mm);  $T_w$  = wall thickness of the spun part (inch or mm); and  $f$  = feed (inch or mm).

Because of friction and other influencing factors, the force exerted is about twice that of the ideal force.

Fig. 26. Tube Spinning

### Rubber Pad and Hydroforming Processes

In the rubber pad forming process, one of the dies in a set (punch or die) is replaced with a flexible material such as rubber or polyurethane. Polyurethane is widely used because of its resistance to abrasion and its long fatigue life. Several processes utilize rubber pad forming techniques. Fig. 27 schematically illustrates the Verson-Wheelon, Marform, and hydroforming processes.

Fig. 27. Rubber Pad Forming Processes: a) Verson-Wheelon; b) Marform; c) Hydroforming

**Guerin Process.**—Fig. 28 shows the Guerin process, synonymous with the term “rubber pad forming,” in which a rigid forming block is placed on the lower bed of the press; on top of this block, the blank is positioned and a soft die of rubber or polyurethane (hardness 50 to 70 Shore) is forced over the rigid block and blank into its required shape. The thickness of the rubber pad, which is held in a sturdy cast-iron or steel container, is usually three times the height of the formed block, but it must be a minimum of 1.5 times thicker than the

height of a rigid form block. During the process cycle, the rubber pad deforms elastically over the form block and the blank, applying a strong pressure. The pressure that the soft die exerts on the blank is uniform, so that the forming process creates no thinning of the material, but the radii are more shallow than those produced in conventional dies.

The following formula can be used to determine total pad forming pressure:

$$p = \frac{F}{A} \times 2000$$

where  $p$  = total rubber pad pressure (psi);  $F$  = capacity of press (tons); and  $A$  = area of pad (in<sup>2</sup>).

Fig. 28. Guerin Forming Process

An improvement over the Guerin process is the Marform process (see Fig. 27), which features the addition of a blankholder and die cushion to make this process suitable for deeper draws and to alleviate the wrinkling problems common to the Guerin process.

The advantages of the rubber pad forming processes compared to conventional forming processes are the following:

- a) For forming a workpiece, only one part of the tool (punch or die) is necessary.
- b) One rubber pad or diaphragm takes the place of many different shapes, thicknesses, and kinds of tools, returning to its original shape when the pressure is released.
- c) Tool material is low cost and easy to machine.
- d) No tool marks are created during forming, so parts with very fine surfaces can be formed.
- e) Set-up time is usually shorter than in conventional forming operations.

However, these processes also have some disadvantages:

- a) The rubber pad and diaphragm have limited lifetimes.
- b) The production rate is relatively slow.
- c) Rubber pads or diaphragms exert less pressure than conventional die, resulting in less sharply formed workpieces that usually need some hand finishing.

### Superplastic Forming and Diffusion Bonding

Conventional metals and alloys will extend in tension no more than 120 percent, regardless of the temperature or speed with which the metal is pulled. However, it has been known since the 1920s that some materials could endure enormous tensile strains without necking. This phenomenon, called "superplasticity," has been scientifically investigated. In the beginning, activities were primarily concentrated in research laboratories and were entirely directed towards the exploration of basic material science. The materials investigated appeared not to be sufficiently attractive for real production. But this changed with the development of supersonic aircraft with high requirements for power density and skin temperature.

A general definition of the term "superplasticity" was formulated for the first time in 1991 during the International World Conference on Superplasticity of Advanced Materials: "Superplasticity is the ability of a polycrystalline material to exhibit, in a generally isotropic manner, very high tensile elongations prior to failure."

Some materials developed for superplastic forming include

- titanium (Ti-6Al-N)
- aluminum (2004, 2419, 7475)
- aluminum-lithium (2090, 2091, 8090)
- stainless steel (2205 series).

In general, the alloys chosen for superplastic forming should have a grain size below 10 microns in diameter. The grain size must not increase if it is kept at temperatures 90 percent of melting for a few hours, and the alloys must have strain rate sensitivity parameters of  $0.35 < m \leq 0.85$ .

High strain rate sensitivity is necessary for reducing the rate of flow localization, i.e., necking. A low rate of damage accumulation, e.g., cavitation, is necessary to allow large plastic strains to be reached.

**Superplastic Forming.**—Superplastic forming (SPF) is a metal forming process that takes advantage of the high extendability of certain materials in order to form components whose shapes might be otherwise very difficult to obtain. Today, superplastic forming of titanium and aluminum alloys is a standard industrial practice accepted worldwide. Due to the high temperatures and simultaneously relatively low gas pressure (typically less than 200 psi), superplastic forming has found widespread application. Because of titanium's (and some other alloys') high affinity with oxygen and hydrogen, inert gases are exclusively used as the pressure medium. Fig. 29 schematically illustrates the SPF process in four steps.

Typically, the closed die and the blank with created seal are heated to the same temperature in a special hydraulic hot-press (Step 1). Inert gas pressure is introduced at a controlled rate using a sophisticated gas management system until the sheet is fully formed against the die surface (Steps 2 and 3). Each workpiece's geometry is unique and requires a unique pressure/time profile to maintain the appropriate strain rate. As the sheet thins, it requires less forming pressure. However, as the workpiece radius decreases, more pressure is required.

Fig. 29. Schematic Illustration of Superplastic Forming Process

The advantages of the superplastic process are the following:

- Using one of the alloys with superplastic capabilities means getting to the finished product in fewer steps, which means lower costs.

- b) Products that are usually formed in several parts separately can be integrally formed as a single part through superplastic forming. The single piece forming minimizes the number of parts and joints, and thus leads to weight savings.
- c) Since the forming needs only the female die, the investment cost for the die is reduced.
- d) Little or no residual stress develops in the formed parts.
- e) Superior transferability of the die surface to the workpiece is provided.
- f) Material waste is minimized.

Disadvantages are these:

- a) There is low productivity because of low strain rates, typically  $10^{-4}$  to  $10^{-2}/s$
- b) Material costs are high.

Although the process is increasingly being applied in the aerospace and automotive industries as a way of manufacturing very complex geometries at a fraction of the cost of conventional stamping, some practical problems are still of concern, the main ones being predicting the final thickness distribution of the formed parts, determining the optimum pressure cycles, and learning more about the microstructure of superplastic material and how it changes during such dramatic elongation.

**Diffusion Bonding.**—The International Institute of Welding (IIW) has accepted the definition of solid state diffusion bonding proposed by Kazakov. This definition is: “Diffusion bonding of materials in the solid state is a process for making a monolithic joint through the formation of bonds at atomic level, as a result of closure of plastic deformation at elevated temperature, which aids interdiffusion at the surface layers of the materials being joined.”

The process is dependent on a number of parameters, such as time, applied pressure, bonding temperature, and the method of heat application. The process allows bonding of homogeneous or heterogeneous materials. Hence, structures can be manufactured from two or three metal sheets. Diffusion bonding generally occurs in three stages:

- a) The deformation process results in the surfaces to be joined coming into intimate contact, but not enough to produce gross deformation.
- b) Bonds are formed by diffusion-controlled mechanisms where the diffusion grain boundary predominates. At this stage, pores are eliminated and the grain boundary arrangement finally ensues.
- c) In the third stage, volume diffusion dominates and the joining process is completed.

The mechanism of diffusion bonding involves holding together sheet metal components under moderate pressure, about 10 MPa (1450 psi), at an elevated temperature of  $(0.5-0.8) T_m$  (where  $T_m$  is the melting temperature in K), usually in a protective atmosphere or vacuum to protect oxidation during bonding. The length of time the materials are held at this temperature depends upon the materials being bonded, the joint properties required, and the remaining bonding parameters.

The aim in diffusion bonding is to bring the surfaces of two or more pieces being joined sufficiently close so that interdiffusion can result in bond formation. To form a high quality bond, surface roughness must be limited to minimum values ( $R_a < 4$  microns); cleanliness must be absolute; and flat surfaces' waviness must be held to less than 400 microns.

A minimum of deformation and an almost complete lack of residual stresses are characteristics of the process, except possibly when two different metals being diffusion-bonded together have large differences in their coefficients of thermal expansion (CTE). This can cause strains to develop at the interface, which can cause premature failure of the bond.

The process is most commonly used for titanium in the aerospace industry, and sometimes it is combined with superplastic forming. Titanium is the easiest of all common engineering materials to join by diffusion bonding, due to its ability to dissolve its own oxide at bonding temperatures (bonding of Ti alloys takes place at  $925^\circ\text{C}$ ).

The more conventional form of diffusion bonding usually takes place in a uniaxial loading press. Pressure and heat can be applied by different means. More complex geometries than are possible by the uniaxial process can be handled by hot isocratic pressing, which

involves the application of high-temperature, high-pressure argon gas to components. A hot isostatic press consists of a furnace within a gas pressure vessel. The components must be encapsulated in a sealed can to prevent the gas from entering the site of the bond.

The advantages of diffusion bonding include the following:

- a) Limited microstructural changes.
- b) The ability to join dissimilar alloys.
- c) The ability to fabricate very complex shapes, especially using superplastic forming.
- d) Minimal deformation.
- e) A highly automated process that does not require highly skilled workers
- f) The ability to produce high quality joints so that neither metallurgical discontinuities nor porosity exist across the interface.
- g) Diffusion bonding is free from ultraviolet radiation and gas emission, so there is no direct detrimental effect on the environment and health and safety standards are maintained.

Disadvantages:

- a) Slowness of the process.
- b) Protective atmosphere required.
- c) Expensive equipment.
- d) Smooth surface finish requirements.
- e) Need for exceptional cleanliness.

*Electron beam diffusion bonding* is a variant of diffusion bonding in which only the interface region is heated, resulting in considerable energy savings. The heating source is an electron beam that is swept over the area of the joint at such a speed that fusion of the titanium or aluminum alloy is prevented. A force is applied across the joint. As the heated area is very limited, higher forces can be used without the risk of plastic collapse of the components being bonded, resulting in a significant reduction of bonding time.

**Combined DB/SPF.**—Diffusion bonding (DB) is often combined with superplastic forming (SPF) in the manufacture of complex structures in aerospace industry. This process is probably the most spectacular near-net shape process that has been developed specifically within the aerospace industry, and its industrial importance is such that it should be considered separately. The process is used commercially for titanium and its alloys.

The most common DB/SPF approaches are 2-sheet (hat-stiffened structures), 3-sheet (truss-core structures) and 4-sheet (rib-stiffed structures).

The processing conditions for superplastic forming and diffusion bonding are similar, both requiring an elevated temperature and benefiting from the fine grain size. Therefore, these two processes have been combined into one manufacturing process known as DB/SPF, which produces parts of greater complexity than sheet forming alone can. Fig. 30 schematically illustrates how combining diffusion bonding with superplastic forming creates a more complicated part shape in the same die.

The combined DB/SPF process generally occurs in two steps:

*Step 1:* The sheets have a stop-off material, such as boron nitride, placed on them in locations where no bonding is to occur in order to prevent diffusion bonding. Sheets are put down in layers, with stop-off areas into the die, heated together at an elevated temperature, and then bonded together by the use of pressure.

*Step 2:* In the same die, the SPF process is used to shape the outside of the laminated sheets. Pressure is applied by blowing gas between the sheets, usually in two phases. In the first phase, gas pressure is applied to cause a plastic stretching of the sheets, which eventually contact the die cavity and take a shape like that of the membrane. In the second phase, the pressure is increased to make the final shape of the part. This process generates a part that is very well bonded in the required locations.

Fig. 30. Schematic Illustration of DB/SPF Process

However, this process also has its challenges. One of these involves how to apply the stop-off material in the proper location using the most cost-effective process. Historically, silk screening has been used to define the required pattern for the stop-off material. This process requires several pieces of equipment, including a wash booth, since the screen needs to be cleaned after each part. A masking paper and laser scribing process has also been developed for defining the stop-off pattern.

There are a number of commercial applications of superplastic forming and diffusion bonding, including aerospace, ground transportation, and numerous miscellaneous other uses. Examples are wing access panels in the Airbus A310 and A320; bathroom sinks in the Boeing 737; turbo fan engine-cooling duct components in the B-1, the T-38, the C-17, and the F-15E; and external window frames in the space shuttle.

### High-Energy Rate Metal Forming Processes

The term “high-energy rate forming processes” (HERF) refers to dynamic metal forming processes that form workpieces at very high velocities and extremely high pressure. HERF processes involve a short, sharp forming energy input usually of microsecond duration that is transmitted to the workpiece surface through a medium such as air or water. The resulting shockwave accelerates the workpiece to high velocity and, with its significant kinetic energy, impacts the die, which has the desired shape of the finished part.

High-energy rate metal forming was studied fairly extensively as early as the 1950s. Several processes have been developed, including explosive forming and two-capacitor, discharge-based forming methods; they are *electrohydraulic* and *electromagnetic forming*.

**Explosive Forming.**—Explosive forming is a manufacturing process that uses explosions to force sheet metal into dies. In this method, the explosive charge is located at some predetermined distance from the workpiece, and the energy is transmitted through an intervening medium such as air, oil, or water. The maximum pressure at the workpiece may range from a few thousand psi to several hundred thousand psi, depending on the parameters of the operation. Fig. 31 shows a typical explosive forming operation.

The workpiece is clamped and sealed over the die cavity. A vacuum is then created in the die cavity. The die assembly is put together at the bottom of the tank. The explosive charge is placed in the intervening medium at a certain distance above the workpiece. After the detonation of the charge, the liquid buffer is instantaneously converted from a fluid of low density, low temperature, and low pressure to a fluid of high density, high temperature, and high pressure, causing the rapid forming of the blank into the cavity die. The extremely high forming velocity of explosive forming minimizes material springback, but it does not completely eliminate it. If the relative elongation of material is more than 10 percent, it can be formed without the chance of fracturing.

The distance between the charge and the blank is called the "standoff distance." The standoff distance and the amount of charge determine the amount of pressure transmitted to the workpiece. Other factors, such as the explosive type, the explosive's shape, and the type of buffer medium, also affect the pressure.

An understanding of the compression waves and rarefactions developed in detonation is extremely important in predicting the forming metal's reaction. In the aviation and aerospace industries, the explosive method of forming has been used since the 1980s.

**Explosive:** Explosives are substances that undergo rapid chemical reaction, during which heat and large quantities of gaseous products are evolved. Explosives can be solid (TNT-trinitro toluene), liquid (nitroglycerine), or gaseous (oxygen-acetylene mixtures).

**Die Material:** Different materials are used for the explosive forming process. For instance: kirkite and fiberglass are used for low pressure and few parts; epoxy and concrete are used for low pressure and larger numbers of parts; and ductile iron, tool steel, and cast steel are used for high pressure and many parts.

Fig. 31. Explosive Forming Set-Up

Explosive forming has the following characteristic features: a) very large sheets with relatively complex shapes, although usually axisymmetric; b) low tooling costs, but high labor costs; c) long cycle times; d) suitability for low-quantity production; e) maintenance of precise tolerances; and controllable smoothness of contours.

An exceptionally interesting development in the field of explosive method forming is the fabrication of spherical pressure vessels with diameters up to 13 ft, and thickness from 0.12 to 0.79 in. of high strength steel designed for water or oil storage in the chemical industry, and other uses.

**Electromagnetic Forming.**—Electromagnetic metal forming (EMF) is a high-energy rate cold forming process that can deform metal workpieces without contact. This process uses ultrastrong pulsed magnetic fields to form metal parts rapidly. A capacitor bank is suddenly discharged by means of a switch through a coil in which the workpiece is placed.

Basically, whenever an electrical current is rapidly sent through an electrical conductor, it will develop a magnetic field. This change in magnetic field will induce eddy currents in the workpiece that generally run in a direction opposite to the current in the coil (Lenz's

law). The two antiparallel currents repel each other, supplying energy to the workpiece in the form of kinetic energy, which accelerates in the workpiece up to a certain velocity, such as 650 to 1000 ft/s. This kinetic energy drives the material into the die, causing forming on impact. This method is quite useful for general applications and suitable for any workpiece made from a good conductor, provided the current pulse is of a sufficiently high frequency.

There are two very broad ways in which this technique can be employed:

**Radial forming**, in which a round part such as a tube or ring is compressed or expanded. The forming can be done either inward or outward onto a die to give the tube a more complex shape (Fig. 32). One of the most common applications of electromagnetic forming is the compression crimp sealing and assembly of axis-symmetric components such as automotive oil filter canisters.

Fig. 32. Schematic Illustration of Electromagnetic Radial Forming of Tube

**Sheet metal forming**, in which using the flat coil configuration shown in Fig. 33 forms a sheet metal. The velocity of the workpiece is sufficient to cause its impact against a die to give it a more complex shape. The workpiece material should have an electrical resistance of less than  $38 \mu\Omega/\text{in}$ . The die needs to be made of either nonmetallic materials or of poor electric conductors.

Advantages of electromagnetic metal forming include: a) reduced number of operations needed; b) narrow tolerances; c) improved strain distribution; d) high repeatability; e) high productivity; f) less reliance on lubricants; and g) lower energy cost.

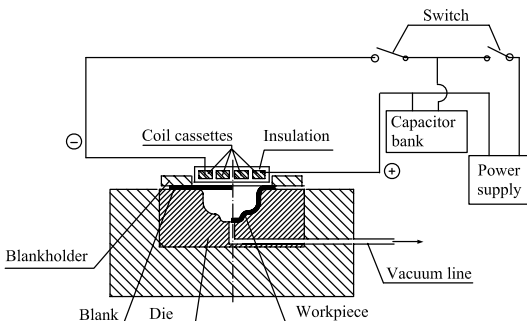

Fig. 33. Schematic Illustration of Electromagnetic Sheet Metal Forming

**Electrohydraulic Forming.**—Electrohydraulic forming is also known as electric spark forming or electric discharge forming. In this process an electric arc's discharge is used to convert electrical energy to mechanical energy. Electrical energy is stored in large capacitors, and then a pulse of high current is delivered across two electrodes positioned a short distance apart while submerged in a transfer medium (water or oil). Capacitor banks have typically stored 55 to 58 BTU at a charged voltage of 20 kV. This creates a sudden release of steam, which, along with ionization, causes the development of a high pressure shock wave within the transfer medium. The die cavity containing the blank to be formed

is immersed in the tank as well. When exposed to the shock wave, the blank is forced to take on the shape of the die. A schematic illustration of the process is shown in Fig. 34.

Electrohydraulic forming is a hybrid between explosive forming and electromagnetic forming. The liquid-based shock is very similar to what would be produced by the explosive method. However, this method uses essentially the same equipment (capacitor banks) that produces the current in electromagnetic forming. Electrohydraulic forming methods are adapted for use in the production of smaller part sizes. On the other hand, these methods are more favorable for automation because of the fine control of energy discharges and the compactness of the system.

Fig. 34. Electrohydraulic Forming Set-Up

### Lubricants and Their Effects on Press Work

Most sheet metal forming operations use lubricants to protect the die and part from excessive wear caused by scratching, scoring, welding, and galling. The physical characteristics of the lubricant and metal-forming operation involved determine the application method to be used.

Methods for applying lubricant to sheet metal include dips, swabs, brushes, wipers, rollers, or recirculation. Of these, the three most common are the following: 1) manually wiping lubricant onto a surface with a rag; 2) roll coating, during which metal blanks pass through rollers that apply the compound; and 3) flooding, during which tooling and metal sheets are drenched with lubricant and the excess liquid is recovered via a filtration and recirculation system.

**Lubricants for Blanking Operations.**—Blanking dies used for carbon and low-alloy steels are often run with only mill lubricant, but will last longer if lightly oiled. Higher alloy steels and stainless steels require thicker lubricants. Kerosene is usually used with aluminum. Lubricant thickness needs to be about 0.0001 inch (0.0025 mm). During successive strokes, metal debris adheres to the punch and may accelerate wear, but damage may be reduced by application of the lubricant to the sheet or strip. High-speed blanking may require heavier applications of lubrication. For sheets thicker than 1/8 inch (3.18 mm) and for stainless steel, high-pressure lubricants containing sulfurs and chlorines are often used.

**Lubricants for Drawing Operations.**—Shallow drawing and forming of steel can be done with low-viscosity oils and soap solutions, but during deep drawing, different lubrication requirements exist, from hydrodynamic lubrication in the blank holder to boundary lubrication at the drawing radius, where breakdown of the film very often occurs. Characteristic of deep drawing is the high pressure involved in the operation, on the order of 100,000 pounds per square inch (690 MPa). To deal with such force, the choice of

lubricant is critical to the success of the operation. Under such pressure, the drawing lubricant should cool the die and the workpiece, provide boundary lubrication between the die and the workpiece, prevent metal-to-metal adhesion or welding, and cushion the die during the drawing operation.

Lubricants work by forming lubricating films between two sliding surfaces in contact with each other. When these metal surfaces are viewed under magnification, peaks and valleys become apparent, even on finely-ground surfaces.

The lubricating film needs to prevent the asperities (peaks) on the two surfaces in sliding contact with each other from damaging the mating surface. Under hydrodynamic or full-film lubrication, two surfaces are completely separated by a fluid film, with no contact between the asperities. This condition could change as speeds vary during start-and-stop modes or if the pressure and temperature increase beyond the lubricant's film strength. Boundary lubricants work up to a certain temperature and pressure, and then the boundary additive breaks down and metal contacts metal. The working temperature varies with the type and amount of additive used and its interaction with other additives.

Three types of drawing lubricants are used: 1) drawing oils; 2) emulsions; and 3) lubricants containing both oil and solid substances.

Drawing oils become an absorbed film, and they take the form of light or soluble oils such as straight mineral oil or emulsions of soluble oil and soap, or of heavy oils, fats, and greases such as tallow or lard oil. Aqueous solutions of non-oily lubricants containing some suspended solids are called emulsions. These lubricants are not widely used in deep drawing because they contain little or no oil.

Lubricants containing both oil and solid substances are used in applications involving severe drawing; these lubricants contain oily components that reduce friction and heat. The combination of the oil and the solids produces enough lubrication for severe drawing applications such as deep drawing. Deep drawing often involves ironing or thinning the wall by up to 35 percent, and lubricant containing high proportions of chemically-active components. Dry soaps and polymer films are frequently used for these purposes. Aluminum can be shallow drawn with oils of low to medium viscosity, and for deep drawing, tallow may be added, as well as wax or soap suspensions for very large reductions.

**Lubricant Removal.**—Removing lubricant from a formed part after the deep drawing operation is important because any lubricant left behind can interfere with subsequent steps in the manufacturing of the part. Mineral oils, animal fat, and vegetable oils can be removed with an organic solvent by emulsification or saponification, or with an aqueous alkaline cleaner. Greases can also be removed from sheet metal with an organic solvent or an alkaline cleaner. Solids are more difficult to remove because they are not readily soluble. The presence of solids often requires that additional cleaning methods be used. Petroleum oils can raise special issues from removal through disposal. These oils require the use of alkaline cleaners for removal, which can then contaminate cleaner tanks with oil, leading to potential disposal challenges. Vegetable oils can be removed with hot water if the parts are cleaned immediately, and with mildly to moderately alkaline cleaners if the parts have been left standing for a few days.

### Joining and Edging

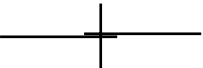

A duct system is an assembly whose main function is to convey air. Elements of the duct system are sheets, transverse joints, longitudinal seams, and reinforcements. The sheets must be able to withstand deflection caused by both internal pressure and vibration due to turbulent air flow. Transverse joints must be able to withstand 1.5 times the maximum operating pressure without failure. Transverse joint designs should be consistent with the static pressure class, sealing requirements, materials involved, and support interval distances. Notching, bending, folding, and fit up tolerances shall be appropriate for the proper class. Longitudinal seams also must be able to withstand 1.5 times the operating pressure without deformation. Seams must be formed and assembled with proper dimension and proportion for tight and secure fit up. Seams may be a butt, corner, plug, or spot

weld design. Seam types must be selected based on material and pressure. A duct section between adjacent hangers must be able to carry its own weight and to resist the external loads for which it is constructed. Reinforcing members must be able to resist the external deflection of the sheet and their own deflection.

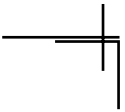

There is a relationship between duct width, reinforcement spacing, reinforcement size, pressure, and sheet thickness. For constant pressure and constant duct size, the thicker sheet allows more distance between reinforcements. The higher the pressure the shorter the spacing between reinforcements. Joints and intermediate reinforcements are labor-intensive and may be more costly than the savings gained by a reduction in wall thickness. Thicker duct wall and stronger joints are more cost-effective than using more reinforcement. The following material illustrates various joint designs, used both in duct work and other sheet metal assemblies.

### Sheet Metal Joints

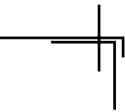

#### Plain Lap and Flush Lap:

 <p>Fig. 35. Plain Lap</p>  <p>Fig. 36. Flush Lap</p>	<p>The <i>plain lap</i> (Fig. 35) and <i>flush lap</i> (Fig. 36) are both used for various materials such as galvanized or black iron, copper, stainless steel, aluminum, or other metals, and may be soldered, and/or riveted, as well as spot, tack, or solid-welded. Lap dimensions vary with the particular application, and since it is the duty of the drafter to specify straight joints in lengths that use full-sheet sizes, transverse lap dimensions must be known.</p>
---	--

#### Raw and Flange Corner:

 <p>Fig. 37. Raw and Flange Corner</p>	<p>The <i>raw and flange corner</i> (Fig. 37) is generally spot-welded, but may be riveted or soldered. For heavy gages it is tack-welded or solid-welded.</p>
---	--

#### Flange and Flange Corner:

 <p>Fig. 38. Flange and Flange Corner</p>	<p>The <i>flange and flange corner</i> (Fig. 38) is a refinement of the raw and flange corner. It is particularly useful for heavy-gage duct sections that require flush outside corners and must be field-erected.</p>
--	---

#### Standing Seam:

 <p>Fig. 39. Standing Seam</p>	<p>The <i>standing seam</i> (Fig. 39) is often used for large plenums, or casings. Before the drafter is able to lay out a casing drawing, the seam allowance measurements are needed, so that panel sizes can be detailed for economical use of standard sheets. Considering velocity levels, standing seams are considered for duct interiors: 1-inch (25.4 mm) seam is normally applied for duct widths up to 42-inch (1067 mm) and 1½-inch (38 mm) for bigger ducts.</p>
---	--

*Groove Seam:*

Fig. 40. Groove Seam

The *groove seam* (Fig. 40) is often used for rectangular or round duct straight joints, or to join some sheets for fittings that are too large to be cut out from standard sheets. It is also known as the *pipeline*, or *flat lock* seam.

*Corner Standing Seam:*

Fig. 41. Corner Standing Seam

The *corner standing seam* (Fig. 41) has applications similar to the standing seam, and also can be used for straight-duct sections. This type of seam is mostly applied at the ends at 8 inches (203 mm) intervals.

*Double Seam:*

Fig. 42. Double Corner Seam

The *double corner seam* (Fig. 42) at one time was the most commonly used method for duct fabrication. However, although it is seldom used because of the hand operations required for assembly, the double seam can be used advantageously for duct fittings with compound curves. It is called the *slide lock seam*. Machines are available to automatically close this seam.

*Slide-Corner:*

Fig. 43. Slide Corner

The *slide-corner* (Fig. 43) is a large version of the double seam. It is often used for field assembly of straight joints, such as in an existing ceiling space, or other restricted working area where ducts must be built in place. To assemble the duct segments, opposite ends of each seam are merely "entered" and then pushed into position. Ducts are sent to job sites "knocked-down" for more efficient use of shipping space.

*Button Punch Snap Lock:*

Fig. 44. Button Punch Snap Lock

The *button punch snap lock* (Fig. 44) is a flush-type seam that may be soldered or caulked. This seam can be modified slightly for use as a "snap lock". This type of seam is not applicable for aluminum or other soft metals. This seam may be used up to 4" (10.2 cm) w.g. by using screws at the ends. The pocket depth should not be smaller than  $\frac{3}{8}$  inch (15.88 mm) for 20-, 22- and 26-gage material (0.91-0.45 mm).

*Pittsburg:*

Fig. 45. Pittsburg

The *Pittsburgh* (Fig. 45) is the most commonly used seam for standard-gage duct construction. The common pocket depths are  $\frac{3}{16}$  inch (7.94 mm) and  $\frac{5}{8}$  inch (15.88 mm) depending on the thickness of the sheet.

*Flange:*

Fig. 46. Flange

The *flange* (Fig. 46) is an end edge stiffener. The drafter must indicate size of flange, direction of bend, degree of bend (if other than 90°) and when full corners are desired. Full corners are generally advisable for collar connections to concrete or masonry wall openings at louvers.

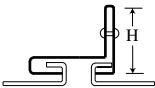

*Hem:*

 <p>Fig. 47. Hem</p>	<p>The <i>hem edge</i> (Fig. 47) is a flat, finished edge. As with the flange, this hem must be designated by the drafter. For example, drawing should show: <math>\frac{3}{4}</math> inch (19 mm) hem out.</p>
---	---

*Flat Drive Slip:*

 <p>Fig. 48. Drive Slip</p>	<p>The drive slip is one of the simplest transverse joints. It is applicable where pressure is less than 2 inches (50.8 mm) w.g. This is a slide-type connection generally used on small ducts in combination with "S" slips, but should not be used above 2 inches w.g.</p>
--	--

*Standing Drive Slip:*

 <p>Fig. 49. Standing Drive Slip</p>	<p>This slip is also a slide type connection. It is made by elongating the flat drive slip and fastening standing portions 2 inches (50.8 mm) from each end. The design is applicable for any length in 2 inches w.g., 36 inches (914 mm) for 3 inches w.g., and 30 inches (762 mm) at 4 inches w.g. service.</p>
---	---

*Flat Drive Slip Reinforced:*

 <p>Fig. 50. Drive Slip Reinforced</p>	<p>This reinforcement on the flat drive slip is made by adding a transverse angle section after a fixed interval.</p>
---	---

*Double "S" Slip Reinforced:*

 <p>Fig. 51. Double "S" Slip</p>	<p>The double "S" slip is used to eliminate the problem of notching and bending, especially for large ducts. Use 24 gage sheet for 30 inches (762 mm) width or less, and 22 gage sheet over 30 inches-width. (22 gage = 0.76 mm, 24 gage = 0.60 mm)</p>
---	---

*Flat "S" Slip:*

 <p>Fig. 52. Plain "S" Slip</p>	<p>Normally the "S" slip is used for small ducts. However, it is also useful if the connection of a large duct is tight to a beam, column or other object, and an "S" slip is substituted for the shop standard slip. Service above 2 inches w.g. is not applicable. Gage shall not be less than 24, and shall not be less than the duct gage. When it is applied on all four edges, fasten within 2 inches of the corners and at 12-inch (305 mm) maximum intervals.</p>
--	---

*Hemmed "S" Slip:*

 <p>Fig. 53. Hemmed "S" Slip</p>	<p>This modified "S" slip is made by adding hem and an angle for reinforcing. The hem edge is a flat and finished edge. Hemmed "S" slip is mostly applied with angle. The drive is generally 16 gage (0.76 mm), forming a 1 inch height slip pocket and screws at the end. Notching and bending operations on "S" slip joints can be cumbersome and costly, especially for large sizes. Tie each section of the duct within 2 inches (50 mm) from the corner at maximum 6-inch (152.4 mm) intervals.</p>
---	--

**Other Types of Duct Connections***Clinch-bar Slip and Flange:*

 <p>Fig. 54. Clinch-bar Slip and Flange</p>	<p>The <i>clinch-bar slip and flange</i> (Fig. 54) uses the principle of the standing seam, but with a duct lap in the direction of airflow. These slips are generally assembled as a framed unit with full corners either riveted or spot-welded, which adds to the duct cross section rigidity. Reinforcement may be accomplished by spot welding the flat-bar to the flange of the large end. Accessibility to all four sides of the duct is required because the flange of the slip must be folded over the flange on the large end after the ducts are connected.</p>
--	--

*Clinch-bar Slip and Angle :*

Fig. 55. Clinch-bar Slip and Angle

The *clinch-bar slip and angle* (Fig. 55), is similar to clinch bar slip (Fig. 54), but it has a riveted or spot-welded angle on the large end. This connection can also have a raw large end that is inserted into the space between the angle and the shop-fabricated slip. Matched angles, minimum of 16-gage (1.52 mm), are riveted or spot-welded to the smaller sides of the ducts to pull the connection "home."

**Flanged Duct Connections***Angle Frame, or Ring:*Fig. 56. Raw Ends and Matched  $\angle$ s

Any of the following flanged connections may have gaskets. The drafter should not allow for gasket thicknesses in calculations for running length dimensions, nor indicate angle sizes, bolt centers, etc., as these items are established in job specifications and approved shop standards. Generally, angles are fastened to duct sections in the shop. If conditions at the job site require consideration for length contingencies, the drafter should specify "loose angles" such as at a connection to equipment that may be located later. The most common matched angle connection is the *angle frame, or ring* (Fig. 56). The angles are fastened flush to the end of the duct.

*Flanged End and Angle:*Fig. 57. Flanged Ends and Matched  $\angle$ s

The *flanged end and angle* (Fig. 57), is often used for ducts 16 gage or lighter, as the flange provides a metal-to-metal gasket and holds the angle frame or ring on the duct without additional fastening. The drafter may indicate in a field note that a round-duct fitting is to be "rotated as required". This type of angle-ring-connection is convenient for such a condition.

*Formed Flanges:*

Fig. 58. Formed Flanges

*Double flanges* (Fig. 58), are similar to Fig. 46, except that the connecting flange has a series of matched bolt holes. This connection, caulked airtight, is ideal for single-wall apparatus casings or plenums. The flanges are formed at the ends of the duct; after assembly they will form a T shape. Mating flanges shall be locked together by long clips. In order to form an effective seal, gaskets with suitable density and resiliency are used. At the corners 16 gage (1.5 mm) thickness steel corners are used with  $\frac{3}{8}$  inch (9.5 mm) diameter bolts.

*Double Flanges and Cleat:*

Fig. 59. Double Flanges and Cleat

*Double Flanges and Cleat* (Fig. 59) is identical to (Fig. 58), but has an air seal cleat. The reinforcements are attached to the duct wall on both sides of the joint.

*Clinch-type Flanged Connections:*

Fig. 60. Bead Clinch and Z Rings

*Clinch-type flanged connections* for round ducts, 16 gage or lighter, are shown in Fig. 60. The angles or rings can be loose, as explained in *Flanged End and Angle*, (Fig. 57). The drafter should indicate flange sizes, bend direction, and type of assembly. An example such as the flange lap for a field assembly of a 10 gage (3.4 mm) casing corner would be written:  $1\frac{1}{2}$  inches (38 mm) flange out square on side with  $\frac{1}{2}$  inch (7 mm)  $\varnothing$  bolt holes 12 inches (30 cm) CC. At the beginning and ending, angles are connected by rivets or welding. The bolt will be  $\frac{3}{16}$  inch (8 mm)  $\varnothing$  at 6 inch (152 mm) maximum spacing.

### Sheet Metal Mill Finishes

Mill finish is the natural surface texture of sheet metal after it exits a rolling mill, with no external mechanical or chemical finishing. This surface can be rough and lack sheen. It also may show oxidation or contamination with mill oil. Most mill finish surfaces are treated with polishing, industrial etching, or some other surface finishing process before being considered complete. Typical sheet metal mill finishes can be identified as:

*Unspecified:* This is the natural finish provided by hot-rolling or cold-rolling using unpolished rolls. Ranging from dull to bright, the finished surface may retain stains or a light film of oil.

*Specular as Fabricated:* Produced on one or both sides of a sheet by passing it through highly polished cold rolls, this is a mirror-like finish.

*Non-Specular as Fabricated:* Refers to a finish that is more uniform than the “unspecified” process but without the reflective properties of a “specular as fabricated” finish.

The quality and characteristics of various mill finishing processes can vary widely from one mill to another and even between lots (sets of similar parts, processed consecutively or in a short time). Hot-rolled sheets usually have dark, dull surfaces, oxidized from being hot-worked. But it is possible for a mill to influence the finish of produced stock. Carefully maintained and polished rollers can increase surface smoothness and luster; some mills will follow rolling with an annealing process to give stock a matte finish.

**Surface Finishes of Aluminum Sheets.**—A light metal, aluminum has good tensile strength over a wide range of temperatures and excellent corrosion resistance. These properties and aluminum’s appearance can be improved by alloying it with other metals.

Mill finish is the natural state of the aluminum sheet as it comes from the rolling mill, with no additional finishing. When aluminum is exposed to air, a thin, glass-hard oxidized film forms on the surface. This film clings tenaciously, presenting an effective surface barrier against the elements. Generally, a rolled sheet develops a thinner oxide film than hot extruded aluminum.

With little care, aluminum sheets in mill finish state will maintain their original appearance for a long time. Surface coating can increase the effectiveness of aluminum’s corrosion resistance. Types of aluminum surface treatment are shown in [Table 18](#).

**Table 18. Types of Surface Treatment**

Type of Treatment	Technique	Characteristics
Mechanical	Grinding/brushing	Produces a flat, even surface with a silk or matte appearance. Leaves fine lines in direction of grinding.
	Polishing and buffing	Reduces or removes grinding lines, die lines, tool marks, surface blemishes, and “stress risers.”
	Vibration polishing	Yields a matte-to-shiny surface. Suited to small batches and mass-produced parts.
	High-finish polishing	Creates a mirror-like finish. Usually followed by bright anodizing.
Chemical	Milling	Removes surface to desired depth. Can be selectively applied for sign writing and other etched products.
	Etching	Leaves a matte or silky appearance. Usually a pretreatment for other finishing processes. Different etchants leave different textures that may show in anodizing sheen.
	Brightening	Removes surface texture for a mirror-like finish. Residual film is usually less than 0.000591 in. or 15 $\mu\text{m}$ .
	Chromating/phosphating	Pretreatment applied prior to powder coating or other coating processes.
	Electrochemically plating with copper, tin, nickel, or silver	Improves corrosion resistance. Can provide a good soldering surface, conductivity, and reflectivity.

**Table 18. (Continued) Types of Surface Treatment**

Electrochemical	Decorative anodizing	Deposits a hard, natural, or colored oxide layer up to 0.0009842 in. or 25 $\mu\text{m}$ . Mainly for decoration, resists pitting and corrosion, while adding wear resistance and electrical insulation.
	Hard anodizing	Adds a gray to brown hard oxide layer of 0.0029528 to 0.0049213 in. or 75 to 125 $\mu\text{m}$ . Mainly used for engineering purposes to resist abrasion and wear.
	Electrolytic polishing	Creates a smooth surface with high reflectivity.
Organic surface coating	Powder coating	Provides various degrees of protective and decorative finishes that can withstand heavy chemical attack (if surface coating remains unbroken).
	Screen printing	Used for printing text, decorative patterns, and so on.
	Coating with protective foils	Added for decoration, protection, or other properties.
	Wet coating	Used in capital-intensive operations for coil coating. Effective, efficient, and common in the building industry.

**Mechanical Finishes:** Mechanical finishing is done before chemical finishing or anodizing to remove surface defects and irregularities and/or add desired texture. While the resulting surface appearance can vary, most mechanical processes result in a directional or nondirectional sanded finish, uniform matte finish, or a specular (mirror-like) finish. The mechanical finish will show through anodic oxides, because uncolored anodic oxides are transparent or translucent; anodized finishes also conform to surface textures.

Grinding requires a rotary grinder with a bonded adhesive cup wheel or canvas wheel, faced with suitable abrasives. Low-speed grinding at 59 in/min (1,500 mm/min) using aluminum oxide is preferred to avoid overheating the surface.

Machine polishing involves wheels or belts with abrasives either bonded to them or sprayed on at regular intervals. Methods include both contact and mush polishing (where only the polishing compound touches the metal surface), the latter being more common. Polishing can include final buffing to remove emery marks.

**Chemical Finishes:** Many types of chemical treatment are used on aluminum sheets as finishing processes, but few are final finishes. Most are intermediate steps in an overall finishing process, requiring subsequent application of some form of protective coating.

There are numerous methods of providing intermediate process finishes on sheet metals that involve washing or dipping fabricated product in chemical solutions; many are proprietary processes. Such treatments have various purposes but in general are used to: a) clean the surface, without otherwise affecting it; b) create a clean, matte, textured surface for applying a smooth, bright finish; or c) chemically add a film to provide a substrate for organic coatings.

**Conversion Coatings:** Although chemical conversion coatings generally are used on aluminum to prepare surfaces for painting, some can be used as a final finish. Since the natural oxide film present on aluminum surfaces does not always provide a good bond for paints, other organic coatings, and laminates, the chemical nature of the film is often converted to improve adhesion and undercoating protection. Such conversion films or coatings usually are applied using phosphate or chromate solutions, many of which are proprietary in nature.

One of the simplest methods for improving adhesion of organic coatings is etching surfaces with a phosphoric acid solution to provide a good mechanical bond. Finishes of this type, such as acid-chromate fluoride treatments, usually are governed by ASTM B449, "Specifications for Chromates on Aluminum."

**Anodic Coatings:** These economical, electrolytically formed oxides in sulfuric or phosphoric acid coatings impart excellent, comparatively thick 0.0003 to 0.002 in. (8 to 50  $\mu\text{m}$ ), transparent, durable, protective coatings to aluminum surfaces. Color anodic coatings are formed by: impregnating the coating with organic dyes or pigments; using alloys and processes that produce integral color; or electrolytically depositing pigments in the anodic film.

Quality control tests after anodizing are performed on representative samples taken at random from rack loads to determine whether the coating meets the specified thickness and weight and is properly sealed. Test methods for checking thickness and weight are specified in: 1) ASTM B244, "Test Method for Measurement of Thickness of Anodic

Coatings on Aluminum and of Other Nonconductive Coatings on Nonmagnetic Basis Metals with Eddy Current Instruments”: This nondestructive method determines coating thickness using the lift-off effect of a probe coil, which contacts the coating and generates measurable eddy currents in the aluminum substrate; 2) ASTM B137, “Test Method for Measurement of Weight of Coating Mass per Unit Area on Anodically Coated Aluminum”: This test involves weighing a small sample of known surface area on an analytical balance, dissolving the coating in a solution that does not attack aluminum, and then reweighing the specimen and comparing weights.

**Surface Finishes of Stainless Steel Sheet.**—Finishes for stainless steel include standard mill and polished, proprietary, electropolished, blasted, rolled, textured, colored, or etched, or any combination of these.

Specific finishes for stainless steel sheet and strip products are defined in ASTM A480/ASTM A480M, “Standard Specification for General Requirements for Flat-Rolled Stainless and Heat-Resisting Steel Plate, Sheet, and Strip” (see Table 19). These finishes are identified by a system of numbers and letters: unpolished or “mill” finishes are No. 1, No. 2D, and BA for bright annealed (usually 2BA); polished finishes are No. 3, No. 4, No. 6, No. 7, and No. 8. Temper-rolled (TR) finishes are used when strong mechanical properties are needed. Also specified are additional architectural finishes, which may be described as No. 5 and form a separate category, as there are numerous techniques and finish variations available worldwide. Other finishes, such as embossing, coining, and special rolled finishes, also are applied mechanically; non-mechanical options include coloring and etching.

**Table 19. Standard Mechanical Finishes for  
Stainless Steel Sheet, ASTM A480/A480M**

Finish Designation	DEFINITION	NOTES
		<b>Unpolished Finishes (Mill Finishes)</b>
No. 1	Hot-rolled, annealed and pickled, and descaled	This is a dull, nonreflective finish.
No. 2D	Cold-rolled, dull finish	A smooth, nonreflective, cold-rolled, annealed, and pickled or descaled finish. This nondirectional finish is effective in retaining lubricants in deep drawing applications.
No. 2B	Cold-rolled, bright finish	A smooth, moderately reflective, cold-rolled and annealed and pickled or descaled finish typically produced with a final, light, cold-rolled pass using polished rolls. This general-purpose finish is more readily polished than No. 1 or No. 2D. Product with No. 2B finish is normally supplied in annealed plus lightly cold-rolled condition, unless a tensile-rolled product is specified.
BA (bright annealed)	Bright, cold-rolled finish, retained by final annealing in a controlled atmosphere furnace	This smooth, bright, reflective finish is usually produced by cold-rolling, followed by annealing in a protective atmosphere to prevent oxidation and scaling during annealing.
<b>Polished Finishes</b>		
No. 3	Intermediate polished finish, one or both sides	A linearly textured finish, produced by either mechanical polishing or rolling, with surface roughness average generally up to 40 $\mu\text{in.}$ or 1.016 $\mu\text{m Ra}$ . Surface roughness differs with various instruments, laboratories, and skilled operators, who may blend this finish. There can be overlap in surface roughness measurements for No. 3 and No. 4 finishes.
No. 4	General purpose polished finish, one or both sides	A linearly textured finish produced by either mechanical polishing or rolling, with surface roughness average generally up to 25 $\mu\text{in.}$ or 0.635 $\mu\text{m Ra}$ . Surface roughness differs with various instruments, laboratories, and skilled operators, who may blend this finish. There can be overlap in surface roughness measurements for No. 3 and No. 4 finishes.
No. 6	Dull, satin finish, Tampico brushed, one or both sides	Has a soft, satin appearance, typically produced by Tampico brushing a No. 4 finished sheet.
No. 7	High-luster finish	Has a high degree of reflectivity, produced by buffing a finely ground surface, but grit lines are not removed. Chiefly used for architectural or ornamental purposes.

**Table 19. (Continued) Standard Mechanical Finishes for Stainless Steel Sheet, ASTM A480/A480M**

No. 8	Mirror-like finish	A highly reflective, smooth finish typically produced by polishing with successively finer grit abrasives, then buffing. Faint polish lines may be visible on the final product. Blending after part assembly can be done with buffing.
TR (temper-rolled)	Cold-worked to obtain specified properties	Results from the cold-rolling of an annealed and descaled or bright annealed product to obtain mechanical properties higher than that seen in the annealed condition. Appearance will vary, depending on the alloy, starting finish, and amount of cold work.

**Standard Rolled Mill Finishes:** Standard rolled mill finishes are created when a stainless steel coil is passed through a set of rolls, and the finish on the rolls is transferred to the surface of the coil.

No. 1 is the standard rolled mill finish and least expensive. Produced by hot-rolling, annealing, and descaling by pickling, it is dull with uneven color and texture. Grinding marks and similar blemishes are common. Heavy sheet and plate for structural applications are supplied with this finish. When components will be visible, it is common to apply a secondary finish, such as polishing or abrasive blasting, for a uniform appearance.

No. 2D, No. 2B, and 2BA are standard mill sheet and strip finishes. They start with a cold-rolled coil that is annealed and pickled.

No. 2D is a uniform, dull, low-reflectivity sheet and strip finish. The dull appearance is produced by pickling or descaling. This is the preferred finish for deep drawing applications, as it holds lubricants well.

No. 2B finish is more reflective, resembling a smooth, cloudy mirror. The final finish is produced by a light pass through polished rolls. Heavier passes can be used if higher tensile strengths are required. This is a common starting finish for polishing and embossing.

A 2BA finish is a bright, reflective, mirror-like surface, ranging from hazy to clear. It is used as a lower cost alternative to highly polished stainless for architectural trim, panels, and fascia, though it is less uniform. When the final annealing is done in a furnace with a controlled atmosphere, it is referred to as bright annealing (BA); to produce a 2BA finish, the bright-annealed coil is given a light pass through highly polished rolls to flatten the coil and enhance finish uniformity. Buffing can produce a consistent mirror finish; it is not unusual for buffed BA to be specified for aesthetic applications where consistency is important. 2BA also can be the starting finish for embossing, coining, selective polishing, or etching. It is slightly more expensive than a No. 2D or No. 2B finish.

For all of these finishes, the rolling direction should be marked on the back of cut panels to facilitate installing them in the same direction. Or a protective strippable film can be applied to the front, with printed arrows indicating the rolling direction. As there can be differences in appearance from one end of the coil to the other, due to roller wear, numbering panels as they are cut from the coil enables adjacent installation of consecutive panels, optimizing uniformity. If more than one coil is needed for a project, ideally all coils should come from the same producer off the same line.

**Polished Finishes:** These finishes for stainless steel are produced by using successively finer polishing belts or by passing a stainless steel coil through special rollers that simulate a No. 3 or No. 4 polish. No common stainless steel specification requires that a finish meet specific surface roughness requirements, but surface roughness influences appearance and corrosion performance. Therefore, it can be important to specify a range or maximum for surface roughness. No. 7 and No. 8 finishes are produced by polishing with successively finer belts and then buffing, with cost based on the number of operations involved and degree of smoothness desired. These finishes can be applied to sheet, strip, tube, pipe, and any of the other stainless steel shapes.

No. 3 and No. 4 polished finishes are produced by belt or wheel polishing with fine grit abrasives or by rolling, and they are characterized by very fine parallel "grit lines." When a piece is mechanically finished, No. 3 involves abrasives between 80 and 150 grit; applied to sheets or strips, this finish typically produces an average surface roughness of up to 40  $\mu\text{in.}$  or 1.016  $\mu\text{m Ra.}$  No. 4 is commonly used as an architectural finish and can be

produced by mechanical polishing or rolling. If mechanical polishing is used, the final pass can be between 120 and 320 grit; average surface roughness on sheets or strips is typically up to 25  $\mu\text{in.}$  or 0.635  $\mu\text{m Ra.}$  There may be overlap between the surface roughness measurements and grit ranges for the No. 3 and No. 4 finishes. Either finish can be polished wet or dry. Wet polishing produces a smoother, finer finish.

A soft, satin, directional finish, No. 6 was used for the columnar features on the exterior walls of the Empire State Building and other early stainless steel projects. It is typically produced by Tampico brushing a No. 4 finish with an oil and abrasive mixture, for a silver-white appearance; however, the high wear rate of Tampico brushes makes it difficult for workers to obtain a uniform appearance, and this finish is known for having fingerprint problems. ASTM A480/A480M allows other polishing methods to be substituted if they produce a finish with the same surface roughness, reflectivity, and an appearance that a stainless steel surface finish expert considers visually identical. Polishing lines should be soft and the resultant finish much less reflective than a No. 4. A finished surface sample that acts as a visual standard is particularly important when specifying this finish, because a wide range of visually different finishes may be called a No. 6.

Still smoother and more reflective sheet finishes are obtained by buffing polished surfaces. The semi-bright No. 7 is polished to a finely ground surface and buffed to a mirror-like finish, with residual grit lines still visible. The highly reflective, mirror-like No. 8 is progressively polished and buffed so only faint polishing grit lines show on final products.

**Surface Finishes of Stainless Steel Strips.**—Five mill finishes are defined by ASTM A480/A480M for stainless steel strips. Within each of these finish categories, some variation is expected, due to the characteristics of different alloys and differences in metal thickness and methods of processing.

No. 1 strip finish is similar to a No. 2D sheet finish, which is produced by cold-rolling to the specified thickness, followed by annealing and pickling. It varies in appearance from dull gray matte to fairly reflective.

No. 2 strip finish is produced the same way as a No. 1 finish, except that it is followed by a final cold roll pass, often on highly polished rolls. It is a smoother, more reflective finish than a No. 1 strip finish. If the rolls are highly polished, it is equivalent to a No. 2B sheet finish.

BA (bright-annealed), TR (temper-rolled), and No. 3 and No. 4 polished finishes also can be used on stainless steel strips and follow the requirements for sheet finishes. No. 5 is a separate category and may be negotiated between buyer and seller.

**Surface Films.**—When stainless steel arrives from the mill or processor, it generally has a protective passive film on the surface. As long as the surface is clean and exposed to oxygen, the passive film automatically forms when the surface is abraded or machined. If the surface is protected from contamination and scratching during fabrication, transit, and installation, and there is no welding, then chemical passivation of the surface after fabrication is not required. Washing with a mild, chloride-free detergent and water solution or an ammonia and water solution still may be necessary.

*Protective Plastic Films:* These can be applied by the producer, processor, fabricator, or finisher to protect stainless steel surfaces. The use of strippable protective plastic film during forming operations that do not require heat helps protect surfaces from contamination by other metals and light scratching and also acts as a lubricant. Film also can help prevent damage from light scratching during shipping, storage, or installation. If an appropriate protective film is specified, it can be left in place until just prior to turnover, eliminating or reducing the need for final cleaning.

Commonly used protective films are porous and do not prevent corrosion from saltwater, water containing deicing salt, swimming pool atmospheres, corrosive acids, and other substances that can be corrosive to some stainless steels. Where there is exposure to such elements, a film can even accelerate corrosion by acting as a crevice, so protective strippable films should be removed immediately after installation.

If film is applied to a component that will be stored or installed in an exterior location, a UV-rated film should be specified. Film life takes into consideration the total time a film is to be used, including potential project delays. Film left in place past its warranted life

or exposed to conditions for which it was not designed can be difficult to remove, leave residual adhesive, or be a factor in corrosion.

If an improper film type is selected or if film is left in place too long, the film supplier should be contacted to identify an appropriate water-based cleaner or solvent for removal of residual adhesive, based on the type of adhesive. If a solvent is needed, rubbing alcohol or citric cleaners often are tried before resorting to more aggressive solutions.

### Sheet Metal Gauge Sizes

Gauge sizes are numbers that indicate the thickness of a piece of sheet metal. The larger the gauge number, the thinner the sheet metal specification. Gauge differs between ferrous (iron-based) metals and nonferrous metals, such as aluminum or copper. Sheet metal thickness conversion for various metals is shown in [Table 20](#).

**Table 20. Sheet Metal Gauge Conversion Chart**

Gauge Number	Nominal Thickness					
	Stainless Steel		Mild Steel		Aluminum	
	Inches	Millimeters	Inches	Millimeters	Inches	Millimeters

**Classification of Dies**

Dies may be classified according to a variety of elements and in keeping with the diversity of die design. According to the number of stations involved, dies for sheet metal working may be classified as: a) single-station dies (either compound dies or combination dies) or b) multiple-station dies (progressive dies and transfer dies).

**Single-Station Dies.**—Single-station dies may be compound dies or combination dies.

**Compound Die:** This is a die in which two or more cutting operations are performed to produce a part in a single press stroke. A die that produces washers is a good example of a compound die (Fig. 61).

Fig. 61. Compound Die

**Combination Die:** This is a die in which both cutting and noncutting operations are performed to produce a part at one stroke of the press. A combination die is economical, and a more accurate part is obtained because it eliminates the problem of relocating the workpiece. However, a combination die is not always desirable; for example, when the punching hole is too close to the edge of the blank, the cutting edge would be so weak that failure would result. A die that produces cups with flanges is a good example of the suitable use of combination dies (Fig. 62).

Fig. 62. Combination Die

**Multiple-Station Dies.**—Multiple-station dies are arranged so that a series of sequential operations is performed with each press stroke. Two die types are used:

**Progressive Die:** A progressive die (Fig. 63) is used to transform coil stock or strips into a finished part. This transformation is performed progressively by a series of stations aligned in a row; the workpiece is fed from station to station with each stroke, by being attached to the scrap skeleton. Force for the movement is applied to the incoming sheet metal strip or coil and outgoing scrap skeleton by means of rolls.

Fig. 63. Progressive Die

The cost of a progressive die is high, so it is best used for high-volume production.

**Transfer Die:** In transfer die operations, individual stock blanks are mechanically moved from die station to die station within a single die set. Large workpieces are done with tandem press lines, in which the stock is moved from press to press where specific operations are performed.

**Steel Rule Dies.**—Steel rule dies (or knife dies) were patented by Robert Gair in 1879, and, as the name implies, have cutting edges made from steel strips of about the same proportions as the steel strips used in making graduated rules for measuring purposes. According to J. A. Richards, Sr., of the J. A. Richards Co., Kalamazoo, MI, a pioneer in the field, these dies were first used in the printing and shoemaking industries for cutting out shapes in paper, cardboard, leather, rubber, cork, felt, and similar soft materials. Steel rule dies were later adopted for cutting upholstery material for the automotive and other industries, and for cutting out simple to intricate shapes in sheet metal, including copper, brass, and aluminum. A typical steel rule die, partially cut away to show the construction, is shown in Fig. 64, and is designed for cutting a simple circular shape. Such dies generally cost 25 to 35 percent of the cost of conventional blanking dies, and can be produced in much less time. The die shown also cuts a rectangular opening in the workpiece, and pierces four holes, all in one press stroke.

The die blocks that hold the steel strips on edge on the press platen or in the die set may be made from plaster, hot lead or type metal, or epoxy resin, all of which can be poured to shape. However, the material most widely used for light work is  $\frac{3}{4}$ -in. (19.05 mm) thick, five- or seven-ply maple or birch wood. Narrow slots are cut in this wood with a jig saw to hold the strips vertically. Where greater forces are involved, as with operations on metal sheets, the blocks usually are made from Lignostone densified wood or from metal. In the  $\frac{3}{4}$ -in. thickness mostly used, medium- and high-density grades of Lignostone are available. The  $\frac{3}{4}$ -in. thickness is made from about 35 plies of highly compressed lignite wood, bonded with phenolformaldehyde resin, which imparts great density and strength. The material is made in thicknesses up to 6 in. (15.24 cm), and in various widths and lengths.

Fig. 64. Steel Rule Die for Cutting a Circular Shape, Sectioned to Show the Construction

Steel rule die blocks can carry punches of various shapes to pierce holes in the stock, also projections designed to form strengthening ribs and other shapes in material such as aluminum, at the same time as the die cuts the component to shape. Several dies can be combined or nested, and operated together in a large press, to produce various shapes simultaneously from one sheet of material.

As shown in Fig. 64, the die steel is held in the die block slot on its edge, usually against the flat platen of a die set attached to the moving slide of the press. The sharp, free end of the rule faces toward the workpiece, which is supported by the face of the other die half. This other die half may be flat or may have a punch attached to it, and it withstands the pressure exerted in the cutting or forming action when the press is operated. The closed height of the die is adjusted to permit the cutting edge to penetrate into the material to the extent needed, or, if there is a punch, to carry the cutting edges just past the punch edges for the cutting operation. After the sharp edge has penetrated it, the material often clings to the sides of the knife. Ejector inserts made from rubber, combinations of cork and rubber, and specially compounded plastics material, or purpose-made ejectors, either spring- or positively actuated, are installed in various positions alongside the steel rules and the punch. These ejectors are compressed as the dies close, and when the dies open, they expand, pushing the material clear of the knives or the punch.

The cutting edges of the steel rules can be of several shapes, as shown in profile in Fig. 65, to suit the material to be cut, or the type of cutting operation. Shape *A* is used for shearing in the punch in making tools for blanking and piercing operations, the sharp edge later being modified to a flat, producing a 90° cutting edge. *B*. The other shapes in Fig. 65 are used for cutting various soft materials that are pressed against a flat surface for cutting. The shape at *C* is used for thin, and the shape at *D* for thicker materials.

Steel rule die steel is supplied in lengths of 30 and 50 in., or in coils of any length, with the edges ground to the desired shape, and heat treated, ready for use. The rule material width is usually referred to as the height, and material can be obtained in heights of 0.95, 1, 1½, 1¼, and 1½ in. Rules are available in thicknesses of 0.055, 0.083, 0.11, 0.138, 0.166, and 0.25 in. (4 to 18 points in printers' measure of 72 points = 1 in.). Generally, stock thicknesses of 0.138 or 0.166 in. (10 and 12 points) are preferred, the thinner rules being used mainly for dies requiring intricate outlines. The stock can be obtained in soft or hard temper. The standard edge bevel is 46°, but bevels of 40 to 50° can be used. Thinner rule stock is easiest to form to shape and is often used for short runs of 50 pieces or thereabouts.

Fig. 65. Cutting Edges for Steel Rule Dies

The thickness and hardness of the material to be blanked also must be considered when choosing rule thickness.

*Making of Steel Rule Dies:* Die making begins with a drawing of the shape required. Saw cutting lines may be marked directly on the face of the die block in a conventional layout procedure using a height gage, or a paper drawing may be pasted to or drawn on the die board. Because paper stretches and shrinks, Mylar or other nonshrink plastics sheets may be preferred for the drawing. A hole is drilled off the line to allow a jig saw to be inserted, and jig saw or circular saw cuts are then made under manual control along the drawing lines to produce the slots for the rules. Jig saw blades are available in a range of sizes to suit various thicknesses of rule and for sawing medium-density Lignostone, a speed of 300 strokes/min is recommended, the saw having a stroke of about 2 inch (50.8 mm). To make sure the rule thickness to be used will be a tight fit in the slot, trials are usually carried out on scrap pieces of die block before cuts are made on a new block.

During slot cutting, the saw blade must always be maintained vertical to the board being cut, and magnifying lenses are often used to keep the blade close to the line. Carbide or carbide-tipped saw blades are recommended for clean cuts as well as for long life. To keep any "islands" (such as the center of a circle) in position, various places in the sawn line are cut to less than full depth for lengths of  $\frac{1}{4}$ – $\frac{1}{2}$  in. (6.4–12.7 mm), and to heights of  $\frac{5}{8}$  to  $\frac{3}{4}$  in. (16–19 mm) to bridge the gaps. Slots of suitable proportions must be provided in the steel rules, on sides away from cutting edges, to accommodate these die block bridges.

Rules for steel rule dies are bent to shape to fit the contours called for on the drawing by means of small, purpose-built bending machines, fitted with suitable tooling. For bends of small radius, the tooling on these machines is arranged to perform a peening or hammering action to force the steel rule into close contact with the radius-forming component of the machine so that quite small radii, as required for jig saw puzzles, for instance, can be produced with good accuracy. Some forms are best made in two or more pieces, then joined by welding or brazing. The edges to be joined are mitered for a perfect fit, and are clamped securely in place for joining. Electrical resistance or a gas heating torch is used to heat the joint. Wet rags are applied to the steel at each side of the joint to keep the material cool and the hardness at the preset level, as long as possible.

When shapes are to be blanked from sheet metal, the steel rule die is arranged with flat, 90° edges (B, in Fig. 65), which cut by pushing the work past a close-fitting counter-punch. This counterpunch, shown in Fig. 64, may be simply a pad of steel or other material, and has an outline corresponding to the shape of the part to be cut. Sometimes the pad may be given a gradual, slight reduction in height to provide a shearing action as the moving tool pushes the work material past the pad edges. As shown in Fig. 64, punches can be incorporated in the die to pierce holes, cut slots, or form ribs and other details during the blanking operation. These punches are preferably made from high-carbon, high-vanadium, alloy steel, heat treated to 61 to 63 RC (Rockwell C scale), with the head tempered to 45 to 50 RC.

Heat treatment of the high-carbon-steel rules is designed to produce a hardness suited to the application. Rules in dies for cutting cartons and similar purposes, with mostly straight cuts, are hardened to 51 to 58 RC. For dies requiring many intricate bends, lower-carbon material is used, and is hardened to 38 to 45 RC. And for dies to cut very intricate shapes, a steel in dead-soft condition with hardness of about 95 RB is recommended. After the intricate bends are made, this steel must be carburized before it is hardened and tempered. For this material, heat treatment uses an automatic cycle furnace, and consists of carburizing in a liquid compound heated to 1500°F (816°C) and quenching in oil, followed by "tough" tempering at 550°F (288°C) and cooling in the furnace.

After the hardened rule has been reinstalled in the die block, the tool is loaded into the press and the sharp die is used with care to shear the sides of the pad to match the die contours exactly. A close fit, with clearances of about half those used in conventional blanking dies, is thus ensured between the steel rule and the punch. Adjustments to the clearances can be made at this point by grinding the die steel or the punch. After the adjustment work is done, the sharp edges of the rule steel are ground flat to produce a land of about  $\frac{1}{64}$  in. (0.40 mm) wide ( $B$  in Fig. 65), for the working edges of the die. Clearances for piercing punches should be similar to those used on conventional piercing dies.

### Pipe and Tube Bending

The difference between a pipe and a tube is how they are measured, and ultimately what they are used for. A pipe is a vessel; a tube is structural. A pipe is measured by the inner diameter; a tube is measured by the outer diameter.

Generally, a tube will have a consistent outer diameter and its inner diameter may have varying wall thicknesses to increase its strength. However, a pipe will have a consistent inner diameter and its outer diameter may have varying wall thicknesses.

The terms used in tube bending are defined in Fig. 66a, and those used in pipe bending are defined in Fig. 66b.

Fig. 66a. Dimension and Terms: Tube

Fig. 66b. Dimension and Terms: Pipe

The radius of the bend  $R$  is defined with respect to the centerline of the tube or pipe. When the tube or pipe is bent, fibers at the outside wall are in tension and fibers at the wall on the inside bend are in compression. This condition of tensile stress causes thinning and elongation of the wall at the outside, and the compression stress causes thickening and shortening of the inner wall. As a result, the cross section of pipe of the bent section of the tube is flattened. The oval distortions grow stronger if thinner tube/pipe walls and smaller bending radii of the workpiece have been selected. Ovality can be calculated by the following formula:

$$u = \frac{D_{max} - D_{min}}{D} 100\% \quad (52)$$

where  $u$  = percent ovality of tube

$D_{max}$  = maximum outer tube diameter after bending (inch or mm)

$D_{min}$  = minimum outer tube diameter after bending (inch or mm)

$D$  = initial outside tube diameter (inch or mm)

When the ratio of the tube diameter to the wall thickness is small enough, the tube can be bent on a relatively small radius. The material-specific diagram in Fig. 67 may be used for a first proposition to determine whether a tube or pipe with defined dimensions (outer diameter and wall thickness) can be bent at all.

Fig. 67. Technical Limits of the Tube/Pipe Bending Process

Bending without workpiece failure is impossible below the bending limit determined by stretching. The bending limit due to wrinkling separates the range where bending with mandrel and wiper shoe is possible from the range in which the tubes/pipes can also be bent without a mandrel.

Due to the elastic-plastic behavior of metallic materials, the tube/pipe will spring back by a certain angle after every bending attempt because of the phenomenon of elasticity. While in the valid range of Hooke's law (elastic line), the shaping energy is completely given back as work of elastic strain in the form of resiliency. But after the external strain has been removed, it is partly dissipated as work of plasticity when performing the elastic-plastic shaping. In this case, the extent of springback is only caused by the elastic (reversible) part of the shaping workpiece that is stored in the tube/pipe as potential energy during the bending process. Springback is an inevitable phenomenon of bending and can only be compensated for by overbending the workpiece.

Different methods can be used for bending tubes/pipes, depending on the material in use and the required finishing precision. The most common processes for bending tubes or pipes include press bending (ram tube bending), rotary draw bending (round bending), compression bending, and 3-roll bending.

**Press Bending.**—Press bending, also called *ram tube bending*, was probably the first tube/pipe bending method used to cold-form materials. When press bending is applied, the bending tool with the inwrought bending radius is pressed against two counter rollers, either manually or by means of hydraulics. This motion forces the tube/pipe inserted between the radius block (die) and the counter-rollers to bend around the die (Fig. 68). The tube/pipe cannot be supported by the mandrel. This tube-bending method creates some cross-sectional ovality; therefore, this method is suitable for thick-walled pipes and large bending radii where high levels of cross-sectional ovality are acceptable, such as in furniture tubing and handrails. Large sweeping curves can be bent in small increments, moving the tube/pipe for each bend.

Fig. 68. Press Bending

**Rotary Draw Bending.**—Today, rotary draw bending is the most widely used method of bending tube and pipe, particularly for tight radii, good finishes, and thin-walled tubes. When rotary draw bending is used, the tube/pipe is inserted in the bending machine and fastened between the bend die and the clamp die. The rotation of both tools (the bending die and the clamp) around the bending axis bend the tube/pipe according to the radius of the bend die (Fig. 69).

Fig. 69. Rotary Draw Bending.

The pressure bar serves the purpose of receiving the radial stress generated during the forming process, and in addition it supports the straight tube/pipe end from outside. If a mandrel and a wiper shoe are applied additionally (mandrel bending), high workpiece quality can be achieved even in thin-walled pipes and tight-bending radii.

The steel plug, or mandrel, fits inside the tube during rotary draw bending. The plug or mandrel supports the tube internally to reduce the amount of tube cross-sectional flattening during tube bending. After the tube has been bent, the operator extracts the mandrel from the tube, releases the clamp, and then removes the workpiece from the machine.

With modern mandrel bending machines, almost any kind of cold formable tube/pipe, depending on the material, can be safely bent to bending radii of approximately  $1.5D$  with the desired precision. The forming possibilities are not at all limited to bending only round pipes. Oval pipes and flat and mono-block material can be formed just as well by bending as square or other open profiles. Depending on the shape of the workpiece, the required forming tools are adapted accordingly.

This method of bending tube/pipe is used in the manufacture of exhaust pipes, custom exhaust pipes, turbocharger exhaust and intake tubing, dairy tubing and process tubing, heat exchanger tubing, and all stainless and aluminum tubing where a nondeformed diameter finish is critical.

The main differences among rotary-draw-bending machines are the maximum workable outside pipe diameter and the degree of automation of the various functions. Only the bending function of the so-called "1-axis controlled bending machines" is automatic; in them, feeding and contortion are carried out manually. For the user of CNC

or bending machines with fully automatic control, however, all functions are available automatically. These bending machines can be supplemented with automatic feeding and unloading systems for the production of large series without any problems.

**Compression Bending.**—Compression bending is a process whereby pipe or tube is bent to a reasonably tight radius, usually without the use of mandrel or precision tooling. It is accomplished by clamping the tube/pipe behind the rear tangent point and then by a wiper shoe on a rotary arm rolling or compressing the material around and onto a bending die (Fig. 70).

Fig. 70. Compression Bending

**Roll Bending.**—Roll bending is used for bending tube/pipe to a large radius (i.e., to a large circumference). Pipe and tube roll benders comprise three rolls on separate shafts; the tube or pipe is rolled through the rolls while the top roller exerts downward pressure on the top roll to deform the tube or pipe (Fig. 71). Roll pipe and tube benders are available in 2- or 3-driven roll machines, with either manual or hydraulic adjustment of the top roll.

This tube/pipe bending process is ideal for forming helical pipe coils for heat transfer applications, as well as for making long sweeping sections such as those used in steel construction—curved trusses and roof components for structures requiring large open spaces. Pipe cross sections are defined very little when such sweeping sections are formed.

The oldest method of bending a tube/pipe consists of first packing it with loose particles (usually sand) and then bending it into a suitable tool. The filler functions to prevent the tube from buckling inward. After the tube has been bent, the sand is shaken out.

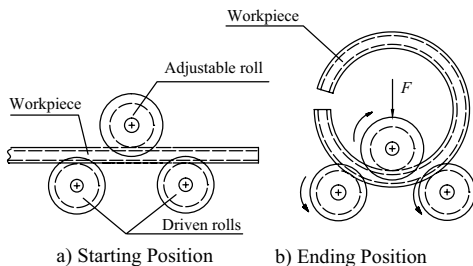

Fig. 71. Roll Bending

**Use of Filling Material in Bending.**—A simple method of preventing distortion consists of using filling material inside the pipe, supporting the walls to prevent flattening at the bend. Dry sand is often used. Materials such as resin, tar, or lead are also sometimes employed. The pipe is first filled with the molten resin, lead, or low-melting-point alloy, and then after bending, the pipe is heated to melt and remove the filling material. Resin has often been used for bending small brass and copper pipes, and lead or other alloys for

small iron and steel pipes. Before bending copper or brass pipe or tubing, the latter should be annealed.

*Alloy of Low Melting Point Used as Filler:* Filling tubes with lead may result in satisfactory bends, but the comparatively high melting point of lead often negatively effects the physical properties of the tube. Commercial alloys such as "Cerrobend" and "Bendalloy" have melting points of about 160 degrees F. They are composed of bismuth, lead, tin, and cadmium. With these materials, tubes having a wall as thin as 0.007 inch have been bent to small radii. The metal filler conforms to the inside of the tube so closely that the tube can be bent just as though it were a solid rod.

This method has been applied to the bending of copper, brass, duralumin, plain steel, and stainless steel tubes with uniform success. Tubes plated with chromium or nickel can be bent without danger of the plate flaking off. The practice usually is economical for tubes up to 2 inches in diameter. The method is considered ideal when the number of tubes of a given size or kind is more or less limited or when the bend is especially severe.

When a tube-bending operation has been completed, removal of the metal filler is accomplished by heating the tube in steam, in a bath of boiling water, or in air of about the same temperature. The metal can then be drained out and used again and again.

### Presses for Sheet Metal Working

A stamping press is a metal working machine tool that utilizes the force and speed of a moving ram to transmit force, or an amount of tonnage, to a specific die in order to achieve a workpiece's final shape, often with little or no scrap, and whenever possible, with minimal operator intervention. There are two major types of press brakes, which are classified by the nature of their drive systems: mechanical and hydraulic. Mechanical and hydraulic sheet metal working presses are available in several basic designs and a wide range of sizes, tonnage capacities, and operating speeds. The moving forces of the presses are generated by either mechanical or hydraulic mechanisms that are mounted in the frame. The two most common types of frames are the gap-frame (C-frame) and the straight side frame. Each has its advantages and disadvantages. Frames may be fabricated by casting or by welding heavy rolled steel plates. Both mechanical and hydraulic sheet metal stamping presses are classified by the following main characteristics: frame, drive, action, tonnage, stroke, and strokes per minute.

**Mechanical Presses.**—Mechanical presses are manufacturing devices designed and built to operate all types of dies. Mechanical presses typically store energy in a rotating flywheel driven by an electric motor. The flywheel revolves around a crankshaft until engaged by a clutch device. The energy of the rotating flywheel is transmitted to the vertical movement of the ram by the use of a press drive mechanism.

*Drive:* The press drive refers to the style of mechanism used to obtain the ram movement. The most common press drive mechanisms for mechanical presses are the crankshaft, the eccentric, the screw, and the knuckle.

The *crankshaft* is a mechanical element for translating the rotational motion of the electrical drive motor to the linear motion of the ram assembly in an up-and-down motion. In the press, each revolution of the crankshaft drives the ram through one complete up-and-down cycle of the machine. In a flywheel press, the flywheel is connected directly to the crankshaft, and each revolution of the flywheel completes one ram movement. The function of the flywheel is to store the necessary energy to carry out a pressing operation.

*Eccentric*—many of the newer presses are made using an eccentric for translating the rotational motion of the electric drive motor to the linear motion of the ram. The main disadvantage of the eccentric press drive is the limitation of press strokes. To obtain more press strokes, the eccentric offset must be increased in diameter.

The *screw* drive press is not as widely used, but the unique characteristics of the screw press have driven an increase in its use. As the name suggests, this type of press drive

uses a mechanical screw to translate rotational motion into the linear motion of the ram. Briefly, the ram acts as the nut on a rotating screw shaft, moving up or down depending on the screw rotation. Energy is either delivered from a flywheel, which is usually coupled with a torque-limiting (slipping) clutch, or by a direct drive reversing electric motor.

The *knuckle*—the knuckle press is a modified version of the crankshaft style. The crankshaft is behind the press frame in this type of press. The knuckle crankshaft runs from left to right in relation to the press frame. The knuckle is a group of three levers, one lever or connector of which joins the crankshaft throw to the other two levers. The upper lever or knuckle is fixed to a pivot point in the press crown at one end. The lower knuckle is fixed to a pivot point on the press ram at one end. The knuckle press is used for dies that coin, or when heavy sheet metal is drawn or formed. Because of the knuckle, the stroke of the press is limited. Fig. 72 schematically illustrates a knuckle drive mechanism.

Fig. 72. Knuckle Drive Mechanism

Fig. 73. Available Tonnage Curve for a Mechanical Press

**Tonnage:** The tonnage of a press is the force that a press ram is able to exert. In actual practice, press rams can and do exert forces greater than the rated tonnage. A safety factor is designed into the frame and drive mechanism. The tonnage of a mechanical press is calculated when the ram is near the bottom of its stroke. Thus, the tonnage of a mechanical press is constant and cannot be varied as in the hydraulic press.

The tonnage of a mechanical press when the ram is not near the bottom of its stroke is greatly reduced. Most press manufacturers will supply curves showing the tonnage available for each inch of stroke. Fig. 73 illustrates the available tonnage curve for a mechanical press. Mechanical presses have forces that typically range from 20 to 5,000 tons. A few specially designed large capacity presses with ratings up to 6,000 tons are in operation.

**Stroke:** The stroke of a press is the distance of ram movement from its up position to its down position. The offset on a crankshaft determines the press stroke. The stroke is constant for the crankshaft and eccentric drives. Strokes on mechanical presses range from 0.2 to 45 inches.

**Strokes per Minute:** Strokes per minute (press speed) is a self-explanatory term. The C-frame low tonnage presses (15 to 30 tons) have the highest stroke per minute of all press types. They run at up to 1,800 strokes per minute and typically involve light forming, such as electrical connectors; when cutting dies are operated, the speeds usually range from around 20 to 800 strokes per minute.

**Action:** The term “action” simply means the number of rams on the press. Types of press actions include the following:

*Single action:* One ram operated by a mechanism located in the crown or bed of a press. These presses are used for blanking, bending, forming, and other operations. They perform a single action with each cycle of the press.

*Double action:* One inner ram and one outer ram are operated by a mechanism located in the crown or bed on the press. The rams move from the crown towards the bed on the downstroke. They are used for severe forming and drawing operations.

*Triple action:* Same as double action with the addition of a third ram located in the bed of the press. The third ram moves upward in the bed soon after the other two rams lower.

Large presses (like those used in the automotive industry) have a die cushion integrated in the bolster plate to apply the blank holder force. This is necessary when a single acting press is used for deep drawing.

Fig. 74 schematically illustrates a mechanical press with its basic components.

Fig. 74. Schematic Illustration of Mechanical Drive Presses with Basic Components

**Gap-Frame Presses.**—The most noticeable characteristic of a press is the frame's style of construction. The frame is the supporting element of a press. All of the shafts and bearings, as well as the ram and gearing, are mounted in the frame. Frames may be fabricated by casting or by welding heavy rolled steel plates.

The cast frame has excellent rigidity but is expensive. The welded frame is lower in cost in most cases. Due to the greater toughness of rolled steel, welded frames have more resistance to shock loading.

The C-frame press gets its name from its shape. The most common types of C-frame are the inclinable or open-back inclinable (OBI), the solid frame or open-back stationary (OBS), the open-end press, and the adjustable bed or knee frame press.

*Inclinable-frame press:* The frame of an inclinable press can be tilted backward to an angle of around 30°. This inclination permits finished parts, slugs, or both, to slide to the rear of the machine upon completion. As the name implies, a fixed-position, or noninclinable machine does not tilt, and parts and/or slugs must either drop vertically or be removed by some other means.

*Solid-frame press:* Because of the more rigid base and solid construction, solid frame presses or OBS presses are built in higher tonnages than inclinable presses. These presses have larger beds and frame openings than inclinable presses and can handle larger dies.

*Adjustable-bed press:* The third type of C-frame press is the adjustable table or bed, and thus a wide range of shut heights may be obtained. Because of possible lack of rigidity, only smaller tonnages are made with this style of frame. The adjustable bed press is one of the most versatile presses.

*Open-end press:* This press has the unusual feature of having the driveshaft located from front to back. Most presses of the C-frame type have the driveshaft from right to left. The

advantage gained in the open-end press is great accessibility. All of the large gears and flywheel are at the back and out of the way. Only smaller tonnage presses are made in this style, however.

**Straight Side Presses.**—Straight side presses are so named because of the vertical columns on either side of the machine. This design eliminates the problem of angular deflection. Also, die life and part accuracy are enhanced. Straight side presses have frames consisting of a crown member, two upright side members, a bed or fundament of the press, and the bolster, which mounts on the press bed and accommodates the die while strengthening the bed. These components are often secured in a preloaded position by four tie rods. They may also be bolted and keyed together or welded into one piece. As a result, straight side presses are stiffer vertically than gap frame units, and any deflection under load tends to be symmetrical.

Straight side presses are suitable for progressive die and transfer die applications and cover an enormous range of types, sizes, and speeds.

**Hydraulic Presses.**—Hydraulic presses are manufacturing devices designed and built to operate dies using hydraulic drive systems to deliver a controlled force.

*Drive System:* These systems are relatively less complex, and are comprised of a motor, a pump, a valving system, and a hydraulic cylinder with the piston connected to the ram. The cylinder is usually double-acting so that hydraulic fluid (oil or water) is pumped under pressure into the top, above the piston, to make the ram move down; to make it come up, fluid is pumped into the bottom, under the piston. The pressure of the fluid under the piston is generally held between 10 to 15 percent of the pressure of the fluid above the piston. This is done to keep the ram from dropping by force of gravity, and also to help control the ram throughout the stroke.

*Valving System:* The valving system ensures the desired control and direction of flow either into or out of the cylinder. Fig. 75 schematically illustrates a hydraulic press drive system with its basic components.

Fig. 75. Schematic Illustration of Hydraulic Press Drive System

*Frame:* Hydraulic presses have various frame types, including C-frames, straight-sided frames, H-frames, four-column frames, and other shapes depending on the application.

*Tonnage:* The tonnage of a hydraulic press is easily calculated: the piston area times the hydraulic pressure in the cylinder. By changing the pressure, the tonnage may be varied. The tonnage of a hydraulic press ranges from about 50 tons to 50,000 tons.

*Stroke:* The stroke is variable on the hydraulic press and can vary from 0.4 in. to 48 in.

*Strokes per Minute:* Hydraulic presses are faster and more reliable than ever. The technology has undergone constant change. Improvements in seals, more efficient pumps, and stronger hoses and couplings have virtually eliminated leaks and minimized

maintenance. So, for operations requiring very short strokes, such as punching and blanking, a hydraulic press can achieve speeds that compare favorably with those of mechanical presses, especially when the material is hand fed. Because drawing and forming operations must be run more slowly to allow time for the metal to flow, press speeds usually range from around 5 to 100 strokes per minute, depending on the part size and the severity of the operation being performed.

**Mechanical and Hydraulic Presses, Advantages and Disadvantages.**—The mechanical press has been the first choice of many press users for years. Training of tool and die makers and tool designers has been oriented toward applying mechanical presses to sheet metal pressworking. However, modern hydraulic presses also offer good performance and reliability. Factors that may favor the use of hydraulic presses over their mechanical counterparts may include the following:

- a) Full power during the stroke: Maximum power is maintained during the entire stroke of a hydraulic press. This allows for rapid movement to a position just above the part, when the stroke is slowed for the working stroke and an adjustable slowdown speed during forming. The result is more strokes per minute.
- b) Overload protection: Because the pressure is pre-adjusted, if the pressure exceeds a limit, such as might occur when a part is not properly ejected, the machine shuts down, eliminating catastrophic results to tooling or to the machine.
- c) Cost: Depending on the application, a hydraulic press may cost less than an equivalent mechanical press.
- d) Lower operating costs: Hydraulic presses have fewer operating parts; therefore, there are fewer things to break. Automatic lubrication of moving parts helps eliminate maintenance problems.
- e) Flexibility: Owing primarily to electronic controls and robotics, hydraulic presses fit well into such areas as flexible manufacturing systems (FMS) and factory automation.
- f) No design limitations: The principles of hydraulic force allow for creative engineering. Presses can be designed for traditional down-acting, up-acting, side-acting and multi-action operation. Power systems can be placed above, below, or away from the press and force actuators. Large bed presses can be designed for low tonnage applications and small bed presses can be designed for high tonnage requirements.
- g) Unlimited control options: The hydraulic press can be controlled in a variety of ways, ranging from basic relays to more sophisticated PLC or PC control systems. Operator interfaces can be added to press systems to facilitate ease of job set by storing individual job parameters for each die. Presses can be controlled for precise pressure and position, including pressure holding, speed control, and dynamic adjustments to real-time operating variances. Ram force and speed can be controlled in any direction with various levels of precision.
- h) Small footprint: Hydraulics allow for generation of high pressure over a small surface area. This reduces the overall structure required for support of the force actuators. When compared to mechanical presses, hydraulic presses consume almost 50 percent less space for the same tonnage capability. This size advantage results in lower manufacturing costs and a faster return on investment by requiring less long-term overhead expense.
- i) Hydroforming: Hydroforming is one of the areas in which hydraulic presses have no competition. The hydraulic press ram moves down to close the die and the hydroforming high-pressure fluid fills and acts onto the inside tubular parts and expands it to fill the die. The mechanical presses are not capable of carrying out the hydroforming operation, as they do not have the speed control or the ability to stay on the bottom for performing high-pressure-forming operations.

Although hydraulic presses have many advantages, they also suffer from some disadvantages when compared to mechanical presses. Some of these include:

- a) **Tolerances:** While some hydraulic presses do maintain high tolerances, most of them are limited to approximately 0.020 inch. When closer tolerances are required on these machines, they are usually accounted for in the tooling, which increases the cost of the die or other tooling.
- b) **Speed:** Although high speed is attainable in hydraulic presses, generally, a mechanical press will produce parts faster. This is especially true when short strokes are used.
- c) **Automatic feeding:** Because of fewer moving parts, there is less equipment on which to attach automatic feed mechanisms. Therefore, most automatic feed equipment must be integrated into the process via electronic components, which increases cost.

Factors that favor the use of mechanical presses over their hydraulic counterparts may include these:

- The mechanical press is faster than the hydraulic press.
- The mechanical press is by far the most suitable for blanking and punching.
- Mechanical presses do not require as large a motor as hydraulic presses because they can store energy in the flywheel and then dissipate the energy throughout the press stroke.
- Mechanical presses can be easily adapted to use different rolls and transfer feeds for progressive dies.
- Mechanical presses with short strokes are more economical than hydraulic presses.

**Lubrication System.**—The lubrication systems of mechanical and hydraulic presses are very important. If the lubricating system should fail, not only will the press stop, but also many of the parts are likely to be damaged beyond repair. Therefore, when lubrication failure occurs, the press can seldom be run again without a major overhaul.

The lubricating system delivers oil to the moving parts of the press to reduce friction and to assist in keeping the parts cool. Most newer and more modern presses are equipped with a pressure re-circulating lubricating system that delivers the oil under pressure to the bearings and bushings, and other lubricant points.

After selection of the correct lubricant, the next most critical factors to long machine and lubricant life are keeping the lubricant clean and dry. Details such as machine criticality, operating environment, and component clearances as well as lubricant type, viscosity, flow rate, and economic issues must be carefully considered for optimum lubricant contamination control.

In any press application, the most important aspect for insuring maximum press and lubricant life is the selection of the correct lubricant. This process includes choosing the correct base oil, the correct oil viscosity, and the correct additives for the application. Next in importance is keeping the oil clean and dry. Particulate and water contamination can have devastating effects on machine and lubricant life. The primary source of particulate contamination in lubricants is ambient dust and dirt. While the composition can vary, in general, dust and dirt will contain materials such as silicon oxides and aluminum oxides. Elemental indicators of dirt ingress would be silicon (Si), aluminum (Al), and in some cases calcium (Ca) and magnesium (Mg). If a contaminant particle is larger than the clearance between two slide surfaces, the particle will grind against them, removing metal from the slide surfaces in a process called abrasive wear. The resultant wear particles can cause a chain reaction by increasing the total number of particulates in the lubricant. Additionally, this newly generated abrasive wear material can get broken into smaller particles and become harder due to the process of work hardening. These more numerous and harder particles combine with the original solid contaminants to increase the amount of abrasive material in the lubricant. Under conditions of high velocity or high pressure or both, small particles can impinge on a press surface and result in erosive wear. In this case, particles can be much smaller than the machine clearances and still cause extensive damage due to the velocities and pressures involved. Particles generated during erosive wear also add to the overall contamination of the system and further increase machine

wear. Erosive wear most commonly occurs in hydraulic systems that contain servo or proportional devices. Two of the most commonly used lubricant systems are:

*Lost Lubricant Systems:* Lost lubricant systems are used on smaller gap presses. Older presses are usually lubricated by grease, and newer ones by oil. A hand pump is often used in lost lubricant systems. The major disadvantages of this system are that used lubricant must be cleaned periodically, and if a hand pump is used, lubrication of the machine depends on the reliability of the operator.

*Re-circulating Lubricant Systems:* In these, oil is pumped from a reservoir, filtered, and then distributed to all lubrication points. The pump is powered by an electric motor or by a press-driven mechanical device. The circulating oil lubricates, cools, and flushes small particles from the bearing and friction surfaces.

If the failure of the lubrication system is not detected early, serious damage to the machine will occur. Thermo-chromatic indicators are often used for early detection of lubrication system failure. By the use of thermo-chromatic indicators, mechanical or electrical problems can be detected immediately by the operator or maintenance person. The machine can then be inspected and repaired before serious damage occurs. A few dollars invested in thermo-chromatic indicators can save thousands of dollars on expensive repairs and production losses.

Another sign of lubrication system failure is the presence of bronze particles around the bearing. In this case, it is usually too late for inexpensive repairs because serious damage of the bearing or friction surfaces has already occurred.

**Press Selection.**—When selecting a press, compromises must be made if more than just one type of stamping operation is desired; there is not a single universal type of press that provides productive and efficient operation. Such compromises include consideration of the following primary factors: tonnage; energy capacity; press size and frame design; speed; and control system for press.

Other factors can be considered as well, such as the number of operations to be performed, quantities and production rates, size, geometry and accuracy of workpieces, and equipment costs.

A press-rated tonnage for mechanical presses is the maximum force that should be exerted by the slide against the workpiece at a given distance above the bottom of the stroke. The higher the rating, the greater the torque capacity of its drive members and its capability of delivering more flywheel energy. Presses with flywheel-type drives are basically used for light blanking and piercing operations. The energy requirements of these machines are small and the machines operate at relatively high speeds. Single-gear presses are mostly used for shallow drawn workpieces and require more energy than fly-wheel types. Double-gear presses are used for deeper draw operations when a larger amount of energy is needed.

As stamping operations become more automated, the use of CNC system and various electro-mechanical systems to feed material to the press must also be factored in. There are mechanical blank handing systems where manual handling is not practical due to speed and size. High volume feeding is done with coil stock, which also requires an investment in additional feeding equipment.

## ELECTRICAL DISCHARGE MACHINING

Generally called EDM, electrical discharge machining uses an electrode to remove metal from a workpiece by generating electric sparks between conducting surfaces. The two main types of EDM are termed sinker or plunge, used for making mold or die cavities, and wire, used to cut shapes such as are needed for stamping dies. For die sinking, the electrode usually is made from copper or graphite and is shaped as a positive replica of the shape to be formed on or in the workpiece. A typical EDM sinker machine, shown diagrammatically in Fig. 1, resembles a vertical milling machine, with the electrode attached to the vertical slide. The slide is moved down and up by an electronic, servo-controlled drive unit that controls the spacing between the electrode and the workpiece on the table. The table can be adjusted in three directions, often under numerical control, to positions that bring a workpiece surface to within 0.0005–0.030 inch (0.013–0.76 mm) from the electrode surface, where a spark is generated.

Fig. 1. Sinker or Plunge Type EDM Machines are Used to Sink Cavities in Molds and Dies.

Fig. 2. Wire Type EDM Machines are Used to Cut Stamping Die Profiles.

Wire EDM, shown diagrammatically in Fig. 2, are numerically controlled and somewhat resemble a bandsaw with the saw blade replaced by a fine brass or copper wire, which forms the electrode. This wire is wound off one reel, passed through tensioning and guide rollers, then through the workpiece and through lower guide rollers before being wound onto another reel for storage and eventual recycling. One set of guide rollers, usually the lower, can be moved on two axes at 90 degrees apart under numerical control to adjust the angle of the wire when profiles of varying angles are to be produced. The table also is movable in two directions under numerical control to adjust the position of the workpiece relative to the wire. Provision must be made for the cut-out part to be supported when it is freed from the workpiece so that it does not pinch and break the wire.

EDM applied to grinding machines is termed EDG. The process uses a graphite wheel as an electrode, and wheels can be up to 12 inches (30.48 cm) in diameter by 6 inches (15.24 cm) wide. The wheel periphery is dressed to the profile required on the workpiece, and the wheel profile can then be transferred to the workpiece as it is traversed past the wheel, which rotates but does not touch the work. EDG machines are highly specialized and are mainly used for producing complex profiles on polycrystalline diamond cutting tools and for shaping carbide tooling such as form tools, thread chasers, dies, and crushing rolls.

**EDM Terms**\*.—*Anode*: The positive terminal of an electrolytic cell or battery. In EDM, incorrectly applied to the tool or electrode.

\* Source: Hansvedt Industries

**Barrel effect:** In wire EDM, a condition where the center of the cut is wider than the entry and exit points of the wire, due to secondary discharges caused by particles being pushed to the center by flushing pressure from above and beneath the workpiece.

**Capacitor:** An electrical component that stores an electric charge. In some EDM power supplies, several capacitors are connected across the machining gap and the current for the spark comes directly from the capacitors when they are discharged.

**Cathode:** The negative terminal in an electrolytic cell or battery. In EDM incorrectly applied to the workpiece.

**Colloidal suspension:** Particles suspended in a liquid that are too fine to settle out. In EDM, the tiny particles produced in the sparking action form a colloidal suspension in the dielectric fluid.

**Craters:** Small cavities left on an EDM surface by the sparking action, also known as pits.

**Dielectric filter:** A filter that removes particles from 5  $\mu\text{m}$  (0.00020 inch) down to as fine as 1  $\mu\text{m}$  (0.00004 inch) in size, from dielectric fluid.

**Dielectric fluid:** The non-conductive fluid that circulates between the electrode and the workpiece to provide the dielectric strength across which an arc can occur, to act as a coolant to solidify particles melted by the arc, and to flush away the solidified particles.

**Dielectric strength:** In EDM, the electrical potential (voltage) needed to break down (ionize) the dielectric fluid in the gap between the electrode and the workpiece.

**Discharge channel:** The conductive pathway formed by ionized dielectric and vapor between the electrode and the workpiece.

**Dither:** A slight up and down movement of the machine ram and attached electrode, used to improve cutting stability.

**Duty cycle:** The percentage of a pulse cycle during which the current is turned on (on time), relative to the total duration of the cycle.

**EDG:** Electrical discharge grinding using a machine that resembles a surface grinder but has a wheel made from electrode material. Metal is removed by an EDM process rather than by grinding.

**Electrode growth:** A plating action that occurs at certain low-power settings, whereby workpiece material builds up on the electrode, causing an increase in size.

**Electrode wear:** Amount of material removed from the electrode during the EDM process. This removal can be end wear or corner wear, and is measured linearly or volumetrically but is most often expressed as end wear percent, measured linearly.

**Electro-forming:** An electro-plating process used to make metal EDM electrodes.

**Energy:** Measured in joules, is the equivalent of volt-coulombs or volt-ampere-seconds.

**Farad:** Unit of electrical capacitance, or the energy-storing capacity of a capacitor.

**Gap:** The closest point between the electrode and the workpiece where an electrical discharge will occur. (See *Overcut*)

**Gap current:** The average amperage flowing across the machining gap.

**Gap voltage:** The voltage across the gap while current is flowing. The voltage across the electrode/workpiece before current flows is called the open gap voltage.

**Heat-affected zone:** The layer below the recast layer, which has been subjected to elevated temperatures that have altered the properties of the workpiece metal.

**Ion:** An atom or group of atoms that has lost or gained one or more electrons and is therefore carrying a positive or negative electrical charge, and is described as being ionized.

**Ionization:** The change in the dielectric fluid that is subjected to a voltage potential whereby it becomes electrically conductive, allowing it to conduct the arc.

**Low-wear:** An EDM process in which the volume of electrode wear is between 2 and 15 percent of the volume of workpiece wear. Normal negative polarity wear ratios are 15 to 40 percent.

**Negative electrode:** The electrode voltage potential is negative relative to the workpiece.

**No-wear:** An EDM process in which electrode wear is virtually eliminated and the wear ratio is usually less than 2 percent by volume.

*Orbit:* A programmable motion between the electrode and the workpiece, produced by a feature built in to the machine, or an accessory, that produces a cavity or hole larger than the electrode. The path can be planetary (circular), vectorial, or polygonal (trace). These motions can often be performed in sequence, and combined with x-axis movement of the electrode.

*Overcut:* The distance between one side of an electrode and the adjacent wall of the workpiece cavity.

*Overcut taper:* The difference between the overcut dimensions at the top (entrance) and at the bottom of the cavity.

*Plasma:* A superheated, highly ionized gas that forms in the discharge channel due to the applied voltage.

*Positive electrode:* The electrode voltage potential is positive with respect to the workpiece. *Negative electrode* is the opposite of this condition.

*Power parameters:* A set of power supply, servo, electrode material, workpiece material, and flushing settings that are selected to produce a desired metal removal rate and surface finish.

*Quench:* The rapid cooling of the EDM surface by the dielectric fluid, which is partially responsible for metallurgical changes in the recast layer and in the heat-affected zone.

*Recast layer:* A layer created by the solidification of molten metal on the workpiece surface after it has been melted by the EDM process.

*Secondary discharge:* A discharge that occurs as conductive particles are carried out along the side of the electrode by the dielectric fluid.

*Spark in:* A method of locating an electrode with respect to the workpiece, using high frequency, low amperage settings so that there is no cutting action. The electrode is advanced toward the workpiece until contact is indicated and this point is used as the basis for setting up the job.

*Sparkout:* A technique used in orbiting, which moves the electrode in the same path until sparking ceases.

*Square wave:* An electrical wave shape generated by a solid state power supply.

*Stroke:* The distance the ram travels under servo control.

*UV axis:* A mechanism that provides for movement of the upper head of a wire EDM machine to allow inclined surfaces to be generated.

*White layer:* The surface layer of an EDM cut that is affected by the heat generated during the process. The characteristics of the layer depend on the material, and may be extremely hard martensite or an annealed layer.

*Wire EDM:* An EDM machine or process in which the electrode is a continuously unspooling, conducting wire that moves in preset patterns in relation to the workpiece.

*Wire guide:* A replaceable precision round diamond insert, sized to match the wire, that guides the wire at the entrance and exit points of a wire cut.

*Wire speed:* The rate at which the wire is fed axially through the workpiece (not the rate at which cutting takes place), adjusted so that clean wire is maintained in the cut slowly enough to minimize waste.

**The EDM Process.**—During the EDM process, energy from the sparks created between the electrode and the workpiece is dissipated by the melting and vaporizing of the workpiece material preferentially, only small amounts of material being lost from the electrode. When current starts to flow between the electrode and the work, the dielectric fluid in the small area in which the gap is smallest, and in which the spark will occur, is transformed into a plasma of hydrogen, carbon, and various oxides. This plasma forms a conducting passageway, consisting of ionized or electrically charged particles, through which the spark can form between the electrode and the workpiece. After current starts to flow, to heat and vaporize a tiny area, the striking voltage is reached, the voltage drops, and the field of ionized particles loses its energy, so that the spark can no longer be sustained. As the voltage then begins to rise again with the increase in resistance, the electrical

supply is cut off by the control, causing the plasma to implode and creating a low-pressure pulse that draws in dielectric fluid to flush away metallic debris and cool the impinged area. Such a cycle typically lasts a few microseconds (millionths of a second, or  $\mu\text{s}$ ), and is repeated continuously in various places on the workpiece as the electrode is moved into the work by the control system.

*Flushing:* An insulating dielectric fluid is made to flow in the space between the workpiece and the electrode to prevent premature spark discharge, cool the workpiece and the electrode, and flush away the debris. For sinker machines, this fluid is paraffin, kerosene, or a silicon-based dielectric fluid, and for wire machines, the dielectric fluid is usually deionized water. The dielectric fluid can be cooled in a heat exchanger to prevent it from rising above about 100°F (38°C), at which cooling efficiency may be reduced. The fluid must also be filtered to remove workpiece particles that would prevent efficient flushing of the spark gaps. Care must be taken to avoid the possibility of entrapment of gases generated by sparking. These gases may explode, endangering life, breaking a valuable electrode or workpiece, or causing a fire.

Flushing away of particles generated during the process is vital to successful EDM operations. A secondary consideration is the heat transferred to the side walls of a cavity, which may cause the workpiece material to expand and close in around the electrode, leading to formation of dc arcs where conductive particles are trapped. Flushing can be done by forcing the fluid to pass through the spark gap under pressure, by sucking it through the gap, or by directing a side nozzle to move the fluid in the tank surrounding the workpiece. In pressure flushing, fluid is usually pumped through strategically placed holes in the electrode or in the workpiece. Vacuum flushing is used when side walls must be accurately formed and straight, and is seldom needed on numerically controlled machines because the table can be programmed to move the workpiece sideways.

Flushing needs careful consideration because of the forces involved, especially where fluid is pumped or sucked through narrow passageways, and large hydraulic forces can easily be generated. Excessively high pressures can lead to displacement of the electrode, the workpiece, or both, causing inaccuracy in the finished product. Many low-pressure flushing holes are preferable to a few high-pressure holes. Pressure-relief valves in the system are recommended.

*Electronic Controls:* The electrical circuit that produces the sparks between the electrode and the workpiece is controlled electronically, the length of the extremely short on and off periods being matched by the operator or the programmer to the materials of the electrode and the workpiece, the dielectric, the rate of flushing, the speed of metal removal, and the quality of surface finish required. The average current flowing between the electrode and the workpiece is shown on an ammeter on the power source, and is the determining factor in machining time for a specific operation. The average spark gap voltage is shown on a voltmeter.

EDM machines can incorporate provision for orbiting the electrode so that flushing is easier, and cutting is faster and increased on one side. Numerical control can also be used to move the workpiece in relation to the electrode with the same results. Numerical control can also be used for checking dimensions and changing electrodes when necessary. The clearance on all sides between the electrode and the workpiece, after the machining operation, is called the overcut or overburn. The overcut becomes greater with increases in the on time, the spark energy, or the amperage applied, but its size is little affected by voltage changes. Allowances must be made for overcut in the dimensioning of electrodes. Sidewall encroachment and secondary discharge can take up parts of these allowances, and electrodes must always be made smaller to avoid making a cavity or hole too large.

*Polarity:* Polarity can affect processing speed, finish, wear, and stability of the EDM operation. On sinker machines, the electrode is generally made positive to protect the electrode from excessive wear and preserve its dimensional accuracy. This arrangement

removes metal at a slower rate than electrode negative, which is mostly used for high-speed metal removal with graphite electrodes. Negative polarity is also used for machining carbides, titanium, and refractory alloys using metallic electrodes. Metal removal with graphite electrodes can be as much as 50 percent faster with electrode negative polarity than with electrode positive, but negative polarity results in much faster electrode wear, so it is generally restricted to electrode shapes that can be redressed easily.

Newer generators can provide less than 1 percent wear with either copper or graphite electrodes during roughing operations. Roughing is typically done with a positive-polarity electrode using elevated on times. Some electrodes, particularly micrograin graphites, have a high resistance to wear. Fine-grain, high-density graphites provide better wear characteristics than coarser, less dense grades, and copper-tungsten resists wear better than pure copper electrodes.

*Machine Settings:* For vertical machines, a rule of thumb for power selection on graphite and copper electrodes is 50 to 65 amps per square inch of electrode engagement. For example, an electrode that is  $\frac{1}{2}$  in<sup>2</sup> (3.2 cm<sup>2</sup>) might use  $0.5 \times 0.5 \times 50 = 12.5$  amps. Although each square inch of electrode surface may be able to withstand higher currents, lower settings should be used with very large jobs or the workpiece may become overheated and it may be difficult to clean up the recast layer. Lower amperage settings are required for electrodes that are thin or have sharp details. The voltage applied across the arc gap between the electrode and the workpiece is ideally about 35 volts, but should be as small as possible to maintain stability of the process.

*Spark Frequency:* Spark frequency is the number of times per second that the current is switched on and off. Higher frequencies are used for finishing operations and for work on cemented carbide, titanium, and copper alloys. The frequency of sparking affects the surface finish produced, low frequencies being used with large spark gaps for rapid metal removal with a rough finish, and higher frequencies with small gaps for finer finishes. High frequency usually increases, and low frequency reduces electrode wear.

*The Duty Cycle:* Electronic units on modern EDM machines provide extremely close control of each stage in the sparking cycle, down to millionths of a second ( $\mu$ s). A typical EDM cycle might last 100  $\mu$ s. Of this time, the current might be on for 40  $\mu$ s and off for 60  $\mu$ s. The relationship between the lengths of the on and off times is called the duty cycle, and it indicates the degree of efficiency of the operation. The duty cycle states the on time as a percentage of the total cycle time, and in the previous example it is 40 percent. Although reducing the off time will increase the duty cycle, factors such as flushing efficiency, electrode and workpiece material, and dielectric condition control the minimum off time. Some EDM units incorporate sensors and fuzzy logic circuits that provide for adaptive control of cutting conditions for unattended operation. Efficiency is also reported as the amount of metal removed, expressed as in<sup>3</sup>/hr.

In the EDM process, work is done only during the on time, and the longer the on time, the more material is removed in each sparking cycle. Roughing operations use extended on time for high metal-removal rates, resulting in fewer cycles per second, or lower frequency. The resulting craters are broader and deeper so that the surface is rougher and the heat-affected zone (HAZ) on the workpiece is deeper. With positively charged electrodes, the spark moves from the electrode toward the workpiece and the maximum material is removed from the workpiece. However, every spark takes a minute particle from the electrode so that the electrode also is worn away. Finishing electrodes tend to wear much faster than roughing electrodes because more sparks are generated in unit time.

The part of the cycle needed for reionizing the dielectric (the off time) greatly affects the operating speed. Although increasing the off time slows the process, longer off times can increase stability by providing more time for the ejected material to be swept away by the flow of the dielectric fluid, and for deionization of the fluid, so that erratic cycling of the servo-mechanisms that advance and retract the electrode is avoided. In any vertical

EDM operation, if the overcut, wear, and finish are satisfactory, machining speed can best be adjusted by slowly decreasing the off time setting in small increments of 1 to 5  $\mu\text{s}$  until machining becomes erratic, then returning to the previous stable setting. As the off time is decreased, the machining gap or gap voltage will slowly fall and the working current will rise. The gap voltage should not be allowed to drop below 35 to 40 volts.

**Metal Removal Rates (MRR):** The amount of metal removed in any EDM process depends largely on the length of the on time, the energy/spark, and the number of sparks/second. The following data were provided by Poco Graphite, Inc., in their *EDM Technical Manual*. For a typical roughing operation using electrode positive polarity on high-carbon steel, a 67 percent duty cycle removed 0.28  $\text{in}^3/\text{hr}$  (4.59  $\text{cm}^3/\text{hr}$ ). For the same material, a 50 percent duty cycle removed 0.15  $\text{in}^3/\text{hr}$  (2.46  $\text{cm}^3/\text{hr}$ ), and a 33 percent duty cycle for finishing removed 0.075  $\text{in}^3/\text{hr}$  (1.23  $\text{cm}^3/\text{hr}$ ).

In another example, shown in the top data row in **Table 1**, a 40 percent duty cycle with a frequency of 10 kHz and peak current of 50 amps was run for 5 minutes of cutting time. Metal was removed at the rate of 0.8  $\text{in}^3/\text{hr}$  (13.11  $\text{cm}^3/\text{hr}$ ) with electrode wear of 2.5 percent and a surface finish of 400  $\mu\text{in}$  Ra. When the on and off times in this cycle were halved, as shown in the second data row in **Table 1**, the duty cycle remained at 40 percent, but the frequency doubled to 20 kHz. The result was that the peak current remained unaltered, but with only half the on time the MRR was reduced to 0.7  $\text{in}^3/\text{hr}$  (11.47  $\text{cm}^3/\text{hr}$ ), the electrode wear increased to 6.3 percent, and the surface finish improved to 300  $\mu\text{in}$  Ra. The third and fourth rows in **Table 1** show other variations in the basic cycle and the results.

**Table 1. Effect of Electrical Control Adjustments on EDM Operations**

On Time ( $\mu\text{s}$ )	Off Time ( $\mu\text{s}$ )	Frequency (kHz)	Peak Current (Amps)	Metal Removal Rate		Electrode Wear (%)	Surface Finish ( $\mu\text{in}$ Ra)
				( $\text{in}^3/\text{hr}$ )	( $\text{cm}^3/\text{hr}$ )		
40	60	10	50	0.8	13.1	2.5	400
20	30	20	50	0.7	11.47	6.3	300
40	10	20	50	1.2	19.66	1.4	430
40	60	10	25	0.28	4.59	2.5	350

**The Recast Layer:** One drawback of the EDM process when used for steel is the recast layer, which is created wherever sparking occurs. The oil used as a dielectric fluid causes the EDM operation to become a random heat-treatment process in which the metal surface is heated to a very high temperature, then quenched in oil. The heat breaks down the oil into hydrocarbons, tars, and resins, and the molten metal draws out the carbon atoms and traps them in the resolidified metal to form the very thin, hard, brittle surface called the recast layer that covers the heat-affected zone (HAZ). This recast layer has a white appearance and consists of particles of material that have been melted by the sparks, enriched with carbon, and drawn back to the surface or retained by surface tension. The recast layer is harder than the parent metal and can be as hard as glass, and must be reduced or removed by vapor blasting with glass beads, polishing, electrochemical or abrasive flow machining, after the shaping process is completed, to avoid cracking or flaking of surface layers that may cause failure of the part in service.

Beneath the thin recast layer, the HAZ, in steel, consists of martensite that usually has been hardened by the heating and cooling sequences coupled with the heat-sink cooling effect of a thick steel workpiece. This martensite is hard and its rates of expansion and contraction are different from those of the parent metal. If the workpiece is subjected to heating and cooling cycles in use, the two layers are constantly stressed and these stresses may cause formation of surface cracks. The HAZ is usually much deeper in a workpiece cut on a sinker than on a wire machine, especially after roughing, because of the increased heating effect caused by the higher amounts of energy applied.

The depth of the HAZ depends on the amperage and the length of the on time, increasing as these values increase, to about 0.012–0.015 inch (0.30–0.38 mm) deep. Residual stress in the HAZ can range up to 650 N/mm<sup>2</sup>. As the HAZ cannot be removed easily, it is best avoided by programming the series of cuts taken on the machine so that most of the HAZ produced by one cut is removed by the following cut. If time is available, cut depth can be reduced gradually until the finishing cuts produce an HAZ having a thickness of less than 0.0001 inch (2.54 mm).

**Workpiece Materials.**—Most homogeneous materials used in metalworking can be shaped by the EDM process. Some data on typical workpiece materials are given in Table 2. Sintered materials present some difficulties caused by the use of a cobalt or other binder used to hold the carbide or other particles in the matrix. The binder usually melts at a lower temperature than the tungsten, molybdenum, titanium, or other carbides, so it is preferentially removed by the sparking sequence, and the carbide particles are thus loosened and freed from the matrix. The structures of sintered materials based on tungsten, cobalt, and molybdenum require higher EDM frequencies with very short on times, so that there is less danger of excessive heat buildup, leading to melting. Copper-tungsten electrodes are recommended for EDM of tungsten carbides. When used with high frequencies for powdered metals, graphite electrodes often suffer from excessive wear.

Workpieces of aluminum, brass, and copper should be processed with metallic electrodes of low melting points such as copper or copper-tungsten. Workpieces of carbon and stainless steel that have high melting points should be processed with graphite electrodes. The melting points and specific gravities of the electrode material and of the workpiece should preferably be similar.

**Table 2. Characteristics of Common Workpiece Materials for EDM**

Material	Specific Gravity	Melting Point		Vaporization Temperature		Conductivity (Silver = 100)
		°F	°C	°F	°C	
Aluminum	2.70	1220	660	4442	2450	63.00
Brass	8.40	1710	930	...	...	...
Cobalt	8.71	2696	1480	5520	2900	16.93
Copper	8.89	1980	1082	4710	2595	97.61
Graphite	2.07	N/A		6330	3500	70.00
Inconel	...	2350	1285	...	...	...
Magnesium	1.83	1202	650	2025	1110	39.40
Manganese	7.30	2300	1260	3870	2150	15.75
Molybdenum	10.20	4748	2620	10,040	5560	17.60
Nickel	8.80	2651	1455	4900	2730	12.89
Carbon Steel	7.80	2500	1371	...	...	12.00
Tool Steel	...	2730	1500	...	...	...
Stainless Steel	...	2750	1510	...	...	...
Titanium	4.50	3200	1700	5900	3260	13.73
Tungsten	18.85	6098	3370	10,670	5930	14.00
Zinc	6.40	790	420	1663	906	26.00

**Electrode Materials.**—Most EDM electrodes are made from graphite, which provides a much superior rate of metal removal than copper because of the ability of graphite to resist thermal damage. Graphite has a density of 1.55 to 1.85 g/cm<sup>3</sup>, lower than most metals. Instead of melting when heated, graphite sublimates, that is, it changes directly from a solid to a gas without passing through the liquid stage. Sublimation of graphite occurs at a temperature of 3350°C (6062°F). EDM graphite is made by sintering a compressed mixture of fine graphite powder (1 to 100 micron particle size) and coal tar pitch in a furnace. The open structure of graphite means that it is eroded more rapidly than metal in the EDM process. The electrode surface is also reproduced on the surface of the workpiece. The sizes of individual surface recesses may be reduced during sparking when the work is moved under numerical control of workpiece table movements.

The fine grain sizes and high densities of graphite materials that are specially made for high-quality EDM finishing provide high wear resistance, better finish, and good reproduction of fine details, but these fine grades cost more than graphite of larger grain sizes and lower densities. Premium grades of graphite cost up to five times as much as the least expensive and about three times as much as copper, but the extra cost often can be justified by savings during machining or shaping of the electrode.

Graphite has a high resistance to heat and wear at lower frequencies, but will wear more rapidly when used with high frequencies or with negative polarity. Infiltrated graphites for EDM electrodes are also available as a mixture of copper particles in a graphite matrix, for applications where good machinability of the electrode is required. This material presents a trade-off between lower arcing and greater wear with a slower metal-removal rate, but costs more than plain graphite.

EDM electrodes are also made from copper, tungsten, silver-tungsten, brass, and zinc, all of which have good electrical and thermal conductivity. However, because these metals have melting points below those encountered in the spark gap, they wear rapidly. Copper with 5 percent tellurium, added for better machining properties, is the most commonly used metal alloy. Tungsten resists wear better than brass or copper and is more rigid when used for thin electrodes but is expensive and difficult to machine. Metal electrodes, with their more even surfaces and slower wear rates, are often preferred for finishing operations on work that requires a smooth finish. In fine-finishing operations, the arc gap between the surfaces of the electrode and the workpiece is very small, and there is a danger of dc arcs being struck, causing pitting of the surface when particles dislodged from a graphite electrode during fine-finishing cuts are not flushed from the gap. If struck by a spark, such a particle may provide a path for a continuous discharge of current that will mar the almost completed work surface.

Some combinations of electrode and workpiece material, electrode polarity, and likely amounts of corner wear are listed in Table 3. Corner wear rates indicate the ability of the electrode to maintain its shape and reproduce fine detail. The column headed Capacitance refers to the use of capacitors in the control circuits to increase the impact of the spark without increasing the amperage. Such circuits can accomplish more work in a given time, at the expense of surface-finish quality and increased electrode wear.

**Table 3. Types of Electrodes Used for Various Workpiece Materials**

Electrode	Electrode Polarity	Workpiece Material	Corner Wear (%)	Capacitance
Copper	+	Steel	2–10	No
Copper	+	Inconel	2–10	No
Copper	+	Aluminum	<3	No
Copper	–	Titanium	20–40	Yes
Copper	–	Carbide	35–60	Yes
Copper	–	Copper	34–45	Yes
Copper	–	Copper-tungsten	40–60	Yes
Copper-tungsten	+	Steel	1–10	No
Copper-tungsten	–	Copper	20–40	Yes
Copper-tungsten	–	Copper-tungsten	30–50	Yes
Copper-tungsten	–	Titanium	15–25	Yes
Copper-tungsten	–	Carbide	35–50	Yes
Graphite	+	Steel	<1	No
Graphite	–	Steel	30–40	No
Graphite	+	Inconel	<1	No
Graphite	–	Inconel	30–40	No
Graphite	+	Aluminum	<1	No
Graphite	–	Aluminum	10–20	No
Graphite	–	Titanium	40–70	No
Graphite	–	Copper	N/A	Yes

*Electrode Wear:* Wear of electrodes can be reduced by leaving the smallest amounts of finishing stock possible on the workpiece and using no-wear or low-wear settings to remove most of the remaining material so that only a thin layer remains for finishing with the redressed electrode. The material left for removal in the finishing step should be only slightly more than the maximum depth of the craters left by the previous cut. Finishing operations should be regarded as only changing the quality of the finish, not removing metal or sizing. Low power with very high frequencies and minimal amounts of offset for each finishing cut are recommended.

On manually adjusted machines, fine finishing is usually carried out by several passes of a full-size finishing electrode. Removal of a few thousandths of an inch from a cavity with such an arrangement requires the leading edge of the electrode to recut the cavity over the entire vertical depth. By the time the electrode has been sunk to full depth, it is so worn that precision is lost. This problem sometimes can be avoided on a manual machine by use of an orbiting attachment that will cause the electrode to traverse the cavity walls, providing improved speed, finish, and flushing, and reducing corner wear on the electrode.

*Selection of Electrode Material:* Factors that affect selection of electrode material include metal-removal rate, wear resistance (including volumetric, corner, end, and side, with corner wear being the greatest concern), desired surface finish, costs of electrode manufacture and material, and characteristics of the material to be machined. A major factor is the ability of the electrode material to resist thermal damage, but the electrode's density, the polarity, and the frequencies used are all important factors in wear rates. Copper melts at about 1085°C (1985°F) and spark-gap temperatures must generally exceed 3800°C (6872°F), so use of copper may be made unacceptable because of its rapid wear rates. Graphites have good resistance to heat and wear at low frequencies, but will wear more with high frequency, negative polarity, or a combination of these.

**Making Electrodes.**—Electrodes made from copper and its alloys can be machined conventionally by lathes, and milling and grinding machines, but copper acquires a burr on run-off edges during turning and milling operations. For grinding copper, the wheel must often be charged with beeswax or similar material to prevent loading of the surface. Flat grinding of copper is done with wheels having open grain structures (46-J, for instance) to contain the wax and to allow room for the soft, gummy, copper chips. For finish grinding, wheels of at least 60 and up to 80 grit should be used for electrodes requiring sharp corners and fine detail. These wheels will cut hot and load up much faster, but are necessary to avoid rapid breakdown of sharp corners.

Factors to be considered in selection of electrode materials are: the electrode material cost/in<sup>3</sup>; the time to manufacture electrodes; difficulty of flushing; the number of electrodes needed to complete the job; speed of the EDM; amount of electrode wear during EDM; and workpiece surface-finish requirements.

Copper electrodes have the advantage over graphite in their ability to be discharge-dressed in the EDM, usually under computer numerical control (CNC). The worn electrode is engaged with a premachined dressing block made from copper-tungsten or carbide. The process renews the original electrode shape, and can provide sharp, burr-free edges. Because of its higher vaporization temperature and wear resistance, discharge dressing of graphite is slow, but graphite has the advantage that it can be machined conventionally with ease.

*Machining Graphite:* Graphites used for EDM are very abrasive, so carbide tools are required for machining them. Graphite does not shear away and flow across the face of the tool as metal does, but fractures or is crushed by the tool pressure and floats away as a fine powder or dust. Graphite particles have sharp edges and, if allowed to mix with the machine lubricant, will form an abrasive slurry that causes rapid wear of machine guiding surfaces. Dust may also cause respiratory problems and allergic reactions, especially if the graphite is infiltrated with copper, so an efficient exhaust system is needed for machining.

Compressed air can be used to flush out the graphite dust from blind holes, for instance, but provision must be made for vacuum removal of the dust to avoid hazards to health and problems with wear caused by the hard, sharp-edged particles. Air velocities of at least 500 ft/min (152 m/min) are recommended for flushing, and of 2000 ft/min (610 m/min) in collector ducts to prevent settling out. Fluids can also be used, but small-pore filters are needed to keep the fluid clean. High-strength graphite can be clamped or chucked tightly but care must be taken to avoid crushing. Collets are preferred for turning because of the uniform pressure they apply to the workpiece. Sharp corners on electrodes made from less dense graphite are liable to chip or break away during machining.

For conventional machining of graphite, tools of high-quality tungsten carbide or polycrystalline diamond are preferred and must be kept sharp. Recommended cutting speeds for high-speed steel tools are 100–300 ft/min (30–91 m/min), tungsten carbide 500–750 ft/min (152–229 m/min), and polycrystalline diamond, 500–2000 surface ft/min (152–610 m/min). Tools for turning should have positive rake angles and nose radii of  $\frac{1}{64}$  to  $\frac{1}{32}$  inch. Depths of cut of 0.015 to 0.020 inch produce a better finish than light cuts such as 0.005 inch because of the tendency of graphite to chip away rather than flow across the tool face. Low feed rates of 0.005 inch/rev for rough- and 0.001 to 0.003 inch/rev for finish-turning are preferred. Cutting off is best done with a tool having an angle of 20°.

For bandsawing graphite, standard carbon steel blades can be run at 2100–3100 surface ft/min (640–945 m/min). Use low power feed rates to avoid overloading the teeth and the feed rate should be adjusted until the saw has a very slight speed up at the breakthrough point. Milling operations require rigid machines, short tool extensions, and firm clamping of parts. Milling cutters will chip the exit side of the cut, but chipping can be reduced by use of sharp tools, positive rake angles, and low feed rates to reduce tool pressure. Feed/tooth for two-flute end mills is 0.003 to 0.005 inch (0.076 to 0.13 mm) for roughing and 0.001 to 0.003 inch (0.025 to 0.076 mm) for finishing.

Standard high-speed steel drills can be used for drilling holes but will wear rapidly, causing holes that are tapered or undersized, or both. High-spiral, tungsten carbide drills should be used for large numbers of holes over  $\frac{1}{16}$  inch (1.59 mm) diameter, but diamond-tipped drills will last longer. Pecking cycles should be used to clear dust from the holes. Compressed air can be passed through drills with through coolant holes to clear dust. Feed rates for drilling are 0.0015 to 0.002 inch/rev for drills up to  $\frac{1}{32}$ , 0.001 to 0.003 inch/rev for  $\frac{1}{32}$ - to  $\frac{1}{8}$ -inch drills, and 0.002 to 0.005 inch/rev for larger drills. Standard taps without fluid are best used for through holes, and for blind holes, tapping should be completed as far as possible with a taper tap before the bottoming tap is used.

For surface grinding of graphite, a medium (60) grade, medium-open structure, vitreous-bond, green-grit, silicon-carbide wheel is most commonly used. The wheel speed should be 5300–6000 surface ft/min (1615–1829 m/min), with traversing feed rates at about 56 ft/min (17.1 m/min). Roughing cuts are taken at 0.005 to 0.010 inch/pass (0.13–0.25 mm/pass), and finishing cuts at 0.001 to 0.003 inch/pass (0.025–0.076 mm/pass). Surface finishes in the range of 18 to 32  $\mu$ inch (0.457–0.813 micron) Ra are normal, and can be improved by longer spark-out times and finer grit wheels, or by lapping. Graphite can be centerless ground using a silicon-carbide, resinoid-bond work wheel and a regulating wheel speed of 195 ft/min (59.4 m/min).

Wire EDM, orbital abrading, and ultrasonic machining are also used to shape graphite electrodes. Orbital abrading uses a die containing hard particles to remove graphite, and can produce a fine surface finish. In ultrasonic machining, a water-based abrasive slurry is pumped between the die attached to the ultrasonic transducer and the graphite workpiece on the machine table. Ultrasonic machining is rapid and can reproduce small details down to 0.002 inch (0.05 mm) in size, with surface finishes down to 8  $\mu$ m (0.203 micron) Ra. If coolants are used, the graphite should be dried for 1 hour at over 400°F (204°C) (but not in a microwave oven) to remove liquids before use.

**Wire EDM.**—In the wire EDM process, with deionized water as the dielectric fluid, carbon is extracted from the recast layer, rather than added to it. When copper-base wire is used, copper atoms migrate into the recast layer, softening the surface slightly so that wire-cut surfaces are sometimes softer than the parent metal. On wire EDM machines, very high amperages are used with very short on times, so that the heat-affected zone (HAZ) is quite shallow. With proper adjustment of the on and off times, the depth of the HAZ can be held below 1 micron (0.00004 inch).

The cutting wire is used only once, so that the portion in the cut is always cylindrical and has no spark-eroded sections that might affect the cut accuracy. The power source controls the electrical supply to the wire and to the drive motors on the table to maintain the preset arc gap within 0.1 micron (0.000004 inch) of the programmed position. On wire EDM machines, the water used as a dielectric fluid is deionized by a deionizer included in the cooling system, to improve its properties as an insulator. Chemical balance of the water is also important for good dielectric properties.

*Drilling Holes for Wire EDM:* Before an aperture can be cut in a die plate, a hole must be provided in the workpiece. Such holes are often “drilled” by EDM, and the wire threaded through the workpiece before starting the cut. The “EDM drill” does not need to be rotated, but rotation will help in flushing and reduce electrode wear. The EDM process can drill a hole 0.04 inch (1 mm) in diameter through 4-inch (101 mm) thick steel in about 3 minutes, using an electrode made from brass or copper tubing. Holes of smaller diameter can be drilled, but the practical limit is 0.012 inch (0.3 mm) because of the overcut, the lack of rigidity of tubing in small sizes, and the excessive wear on such small electrodes. The practical upper size limit on holes is about 0.12 inch (3 mm) because of the comparatively large amounts of material that must be eroded away for larger sizes. However, EDM is commonly used for making large or deep holes in such hard materials as tungsten carbide. For instance, a 0.2-inch (5 mm) hole has been made in carbide 2.9 inch (74 mm) thick in 49 minutes by EDM. Blind holes are difficult to produce with accuracy, and must often be made with cut-and-try methods.

Deionized water is usually used for drilling and is directed through the axial hole in the tubular electrode to flush away the debris created by the sparking sequence. Because of the need to keep the extremely small cutting area clear of metal particles, the dielectric fluid is often not filtered but is replaced continuously by clean fluid that is pumped from a supply tank to a disposal tank on the machine.

*Wire Electrodes:* Wire for EDM generally is made from yellow brass containing copper 63 and zinc 37 percent, with a tensile strength of 50,000–145,000 lb<sub>f</sub>/in<sup>2</sup> (345–1000 MPa), and may be from 0.002–0.012 inch (0.05–0.30 mm) diameter.

In addition to yellow brass, electrode wires are also made from brass alloyed with aluminum or titanium for tensile strengths of 140,000–160,000 lb<sub>f</sub>/in<sup>2</sup> (965–1103 MPa). Wires with homogeneous, uniform electrolytic coatings of alloys such as brass or zinc are also used. Zinc is favored as a coating on brass wires because it gives faster cutting and reduced wire breakage due to its low melting temperature of 419°C, and vaporization temperature of 906°C. The layer of zinc can boil off while the brass core, which melts at 930°C, continues to deliver current.

Some wires for EDM are made from steel for strength, with a coating of brass, copper, or other metal. Most wire machines use wire negative polarity (the wire is negative) because the wire is constantly renewed and is used only once, so wear is not important. Important qualities of wire for EDM include smooth surfaces, free from nicks, scratches and cracks, precise diameters to ±0.00004 inch (±1 micron) for drawn and ±0.00006 inch (±2 μm) for plated, high tensile strength, consistently good ductility, uniform spooling, and good protective packaging.

**METAL CASTING, MOLDING, AND EXTRUSION****Material Properties for Iron and Steel Casting**

Cast irons and cast steels encompass a large family of ferrous alloys, which, as the name implies, are cast to shape rather than being formed by working in the solid state. In general, cast irons contain more than 2 percent carbon and from 1 to 3 percent silicon. Varying the balance between carbon and silicon, alloying with different elements, and changing melting, casting, and heat-treating practices can produce a broad range of properties. In most cases, the carbon exists in two forms: free carbon in the form of graphite and combined carbon in the form of iron carbide (cementite). Mechanical and physical properties depend strongly on the shape and distribution of the free graphite and the type of matrix surrounding the graphite particles.

The four basic types of cast iron are white iron, gray iron, malleable iron, and ductile iron. In addition to these basic types, there are other specific forms of cast iron to which special names have been applied, such as chilled iron, alloy iron, and compacted graphite cast iron.

**Gray Cast Iron.**—Gray cast iron may easily be cast into any desirable form and it may also be machined readily. It usually contains from 1.7 to 4.5 percent carbon, and from 1 to 3 percent silicon. The excess carbon is in the form of graphite flakes, which impart to the material the dark-colored fracture that gives it its name. Gray iron castings are widely used for such applications as machine tools, automotive cylinder blocks, cast-iron pipe and fittings, and agricultural implements.

The American National Standard Specifications for Gray Iron Castings—ANSI/ASTM A48-76 groups the castings into two categories. Gray iron castings in Classes 20A, 20B, 20C, 25A, 25B, 25C, 30A, 30B, 30C, 35A, 35B, and 35C are characterized by excellent machinability, high damping capacity, low modulus of elasticity, and comparative ease of manufacture. Castings in Classes 40B, 40C, 45B, 45C, 50B, 50C, 60B, and 60C are usually more difficult to machine, have lower damping capacity, higher modulus of elasticity, and are more difficult to manufacture. The prefix number indicates minimum tensile strength in pounds per square inch, e.g., 20 is 20,000 psi (138 MPa), 25 is 25,000 psi (172 MPa), 30 is 30,000 psi (207 MPa), etc.

High-strength iron castings produced by the Meehanite-controlled process may have various combinations of physical properties to meet different requirements. In addition to a number of general engineering types, there are heat-resisting, wear-resisting and corrosion-resisting Meehanite castings.

**White Cast Iron.**—When nearly all of the carbon in a casting is in the combined or cementite form, it is known as white cast iron. It is so named because it has a silvery-white fracture. White cast iron is very hard and also brittle; its ductility is practically zero. Castings of this material need particular attention with respect to design since sharp corners and thin sections result in material failures at the foundry. These castings are less resistant to impact loading than gray iron castings, but they have a compressive strength that is usually higher than 200,000 psi (1379 MPa) as compared to 65,000–160,000 psi (448–1103 MPa) for gray iron castings. Some white iron castings are used for applications that require maximum wear resistance but most of them are used in the production of malleable iron castings.

**Chilled Cast Iron.**—Many gray iron castings have wear-resisting surfaces of white cast iron. These surfaces are designated by the term “chilled cast iron” since they are produced in molds having metal chills for cooling the molten metal rapidly. This rapid cooling results in the formation of cementite and white cast iron.

**Alloy Cast Iron.**—This term designates castings containing alloying elements such as nickel, chromium, molybdenum, copper, and manganese in sufficient amounts to appreciably change the physical properties. These elements may be added either to increase the strength or to obtain special properties such as higher wear resistance, corrosion resistance,

or heat resistance. Alloy cast irons are used extensively for such parts as automotive cylinders, pistons, piston rings, crankcases, and brake drums; for certain machine tool castings; for certain types of dies; for parts of crushing and grinding machinery; and for applications where the casting must resist scaling at high temperatures. Machinable alloy cast irons having tensile strengths up to 70,000 psi (483 MPa) or even higher may be produced.

**Malleable-Iron Castings.**—Malleable iron is produced by the annealing or graphitization of white iron castings. The graphitization in this case produces temper carbon which is graphite in the form of compact rounded aggregates. Malleable castings are used for many industrial applications where strength, ductility, machinability, and resistance to shock are important factors. In manufacturing these castings, the usual procedure is to first produce a hard, brittle white iron from a charge of pig iron and scrap. These hard white-iron castings are then placed in stationary batch-type furnaces or car-bottom furnaces and the graphitization (malleablizing) of the castings is accomplished by means of a suitable annealing heat treatment. During this annealing period the temperature is slowly (50 hours) increased to as much as 1650 or 1700°F (899 or 927°C), after which time it is slowly (60 hours) cooled. The American National Standard Specifications for Malleable Iron Castings—ANSI/ASTM A47-77 specifies the following grades and their properties: No. 32520, having a minimum tensile strength of 50,000 psi (345 MPa), a minimum yield strength of 32,500 psi (224 MPa), and a minimum elongation in 2 inches (50.8 mm) of 10 percent; and No. 35018, having a minimum tensile strength of 53,000 psi (365 MPa), a minimum yield strength of 35,000 psi (241 MPa), and a minimum elongation in 2 inches of 18 percent.

**Cupola Malleable Iron:** Another method of producing malleable iron involves initially the use of a cupola or a cupola in conjunction with an air furnace. This type of malleable iron, called cupola malleable iron, exhibits good fluidity and will produce sound castings. It is used in the making of pipe fittings, valves, and similar parts and possesses the useful property of being well suited to galvanizing. The American National Standard Specifications for Cupola Malleable Iron — ANSI/ASTM 197-79 calls for a minimum tensile strength of 40,000 pounds per square inch (276 MPa); a minimum yield strength of 30,000 psi (207 MPa); and a minimum elongation in 2 inches of 5 percent.

**Pearlitic Malleable Iron:** This type of malleable iron contains some combined carbon in various forms. It may be produced either by stopping the heat treatment of regular malleable iron during production before the combined carbon contained therein has all been transformed to graphite or by reheating regular malleable iron above the transformation range. Pearlitic malleable irons exhibit a wide range of properties and are used in place of steel castings or forgings or to replace malleable iron when a greater strength or wear resistance is required. Some forms are made rigid to resist deformation while others will undergo considerable deformation before breaking. This material has been used in axle housings, differential housings, camshafts, and crankshafts for automobiles; machine parts; ordnance equipment; and tools. Tension test requirements of pearlitic malleable iron castings called for in ASTM Standard A220-99 (R2018) are given in the accompanying table.

**Tension Test Requirements of Pearlitic Malleable Iron Castings ASTM A220-99 (R2018)**

Casting Grade Numbers		40010	45008	45006	50005	60004	70003	80002	90001
Min. Tensile Strength	psi	60000	65000	65000	70000	80000	85000	95000	105000
	MPa	414	448	448	483	552	586	655	724
Min. Yield Strength	psi	40000	45000	45000	50000	60000	70000	80000	90000
	MPa	276	310	310	345	414	483	552	621
Min. Elongation in 2 Inch. %		10	8	6	5	4	3	2	1

**Ductile Cast Iron.**—A distinguishing feature of this widely used type of cast iron, also known as spheroidal graphite iron or nodular iron, is that the graphite is present in ball-like form instead of in flakes as in ordinary gray cast iron. The addition of small amounts of magnesium- or cerium-bearing alloys together with special processing produces this spheroidal graphite structure and results in a casting of high strength and appreciable

ductility. Its toughness is intermediate between that of cast iron and steel, and its shock resistance is comparable to ordinary grades of mild carbon steel. Melting point and fluidity are similar to those of the high-carbon cast irons. It exhibits good pressure tightness under high stress and can be welded and brazed. It can be softened by annealing or hardened by normalizing and air cooling or oil quenching and drawing.

Five grades of this iron are specified in ASTM A536-84 (R2014), "Standard Specification for Ductile Iron Castings." The grades and their corresponding matrix microstructures and heat treatments are as follows: Grade 60-40-18, ferritic, may be annealed; Grade 65-45-12, mostly ferritic, as-cast or annealed; Grade 80-55-06, ferritic/pearlitic, as-cast; Grade 100-70-03, mostly pearlitic, may be normalized; Grade 120-90-02, martensitic, oil quenched and tempered. The grade nomenclature identifies the minimum tensile strength, on percent yield strength, and percent elongation in 2 inches. Thus, Grade 60-40-18 has a minimum tensile strength of 60,000 psi, a minimum 0.2 percent yield strength of 40,000 psi, and minimum elongation in 2 inches of 18 percent. Several other types are commercially available to meet specific needs. The common grades of ductile iron can also be specified by just the Brinell Hardness Number, although the appropriate microstructure for the indicated hardness is also a requirement. This method is used in SAE Specification J434C for automotive castings and similar applications. Other specifications not only specify tensile properties but also have limitations in composition. Austenitic types with high nickel content, high corrosion resistance, and good strength at elevated temperatures, are specified in ASTM A439-18.

Ductile cast iron can be cast in molds containing metal chills if wear-resisting surfaces are desired. Hard carbide areas will form in a manner similar to the forming of areas of chilled cast iron in gray iron castings. Surface hardening by flame or induction methods is also feasible. Ductile cast iron can be machined with the same ease as gray cast iron. It finds use as crankshafts, pistons, and cylinder heads in the automotive industry; forging hammer anvils, cylinders, guides, and control levers in the heavy machinery field; and wrenches, clamp frames, faceplates, chuck bodies, and dies for forming metals in the tool and die field. The production of ductile iron castings involves complex metallurgy, the use of special melting stock, and close process control. The majority of applications of ductile iron have been made to utilize its excellent mechanical properties in combination with the castability, machinability, and corrosion resistance of gray iron.

**Steel Castings.**—Steel castings are especially adapted for machine parts that must withstand shocks or heavy loads. They are stronger than wrought iron, cast iron, or malleable iron, and are very tough. The steel used for making steel castings may be produced either by the open-hearth, electric arc, side-blow converter, or electric induction methods. The raw materials used are steel scrap, pig iron, and iron ore, the materials and their proportions varying according to the process and the type of furnace used. The open-hearth method is used when large tonnages are continually required, while a small electric furnace might be used for steels of widely differing analyses, which are required in small lot production. The high frequency induction furnace is used for small quantity production of expensive steels of special composition such as high-alloy steels. Steel castings are used for such parts as hydroelectric turbine wheels, forging presses, gears, railroad car frames, valve bodies, pump casings, mining machinery, marine equipment, engine casings, etc.

Steel castings can generally be made from any of the many types of carbon and alloy steels produced in wrought form and respond similarly to heat treatment; they also do not exhibit directionality effects that are typical of wrought steel. Steel castings are classified into two general groups: carbon steel and alloy steel.

**Carbon Steel Castings.**—Carbon steel castings may be designated as low-carbon medium-carbon, and high-carbon. Low-carbon steel castings have a carbon content of less than 0.20 percent (most are produced in the 0.16 to 0.19 percent range). Other elements present are: manganese, 0.50 to 0.85 percent; silicon, 0.25 to 0.70 percent; phosphorus, 0.05 percent max.; and sulfur, 0.06 percent max. Their tensile strengths (annealed

condition) range from 40,000 to 70,000 pounds per square inch (276–483 MPa). Medium-carbon steel castings have a carbon content of from 0.20 to 0.50 percent. Other elements present are manganese, 0.50 to 1.00 percent; silicon, 0.20 to 0.80 percent; phosphorus, 0.05 percent max.; and sulfur, 0.06 percent max. Their tensile strengths range from 65,000 to 105,000 pounds per square inch (448–724 MPa) depending, in part, upon heat treatment. High-carbon steel castings have a carbon content of more than 0.50 percent and also contain: manganese, 0.50 to 1.00 percent; silicon, 0.20 to 0.70 percent; and phosphorus and sulfur, 0.05 percent max. each. Fully annealed high-carbon steel castings exhibit tensile strengths of from 95,000 to 125,000 pounds per square inch (655–125 MPa). See [Table 1](#) for grades and properties of carbon steel castings.

**Table 1. Mechanical Properties of Steel Castings**

Tensile Strength, ksi (MPa)	Yield Point, ksi (MPa)	Elongation in 2 Inch, Percent	Brinell Hardness Number	Type of Heat Treatment	Application Indicating Properties
Structural Grades of Carbon Steel Castings					
60 (414)	30 (207)	32	120	Annealed	Low electric resistivity. Desirable magnetic properties. Carburizing and case hardening grades. Weldability.
65 (448)	35 (241)	30	130	Normalized	Good weldability. Medium strength with good machinability and high ductility.
70 (483)	38 (262)	28	140	Normalized	
80 (552)	45 (310)	26	160	Normalized and tempered	High strength carbon steels with good machinability, toughness and good fatigue resistance.
85 (586)	50 (345)	24	175		
100 (689)	70 (483)	20	200	Quenched and tempered	Wear resistance. Hardness.
Engineering Grades of Low-Alloy Steel Castings					
70 (483)	45 (310)	26	150	Normalized and tempered	Good weldability. Medium strength with high toughness and good machinability. For high temperature service.
80 (552)	50 (345)	24	170		
90 (621)	60 (414)	22	190	Normalized and tempered <sup>a</sup>	Certain steels of these classes have good high temperature properties and deep hardening properties. Toughness.
100 (689)	68 (469)	20	209		
110 (758)	85 (586)	20	235	Quenched and tempered	Impact resistance. Good low temperature properties for certain steels. Deep hardening. Good combination of strength and toughness.
120 (827)	95 (655)	16	245		
150 (1034)	125 (862)	12	300	Quenched and tempered	Deep hardening. High strength. Wear and fatigue resistance.
175 (1207)	148 (1020)	8	340	Quenched and tempered	High strength and hardness. Wear resistance. High fatigue resistance.
200 (1379)	170 (1172)	5	400		

<sup>a</sup> Quench and temper heat treatments may also be employed for these classes.

ksi = kips per square inch = 1000s of pounds per square inch; MPa = megapascals.

The data in the table above is for general information purposes only and not for use as design or specification limit values. The values listed above have been compiled by the Steel Founders' Society of America as those normally expected in the production of steel castings. The castings are classified according to tensile strength values which are given in the first column. Specifications covering steel castings are prepared by the American Society for Testing and Materials, the Association of American Railroads, the Society of Automotive Engineers, the United States government (federal and military specifications), etc. Refer to publications issued by these organizations for these specifications.

**Alloy Steel Castings.**—Alloy cast steels are those in which special alloying elements such as manganese, chromium, nickel, molybdenum, or vanadium have been added in sufficient quantities to obtain or increase certain desirable properties. Alloy cast steels are comprised of two groups—the low-alloy steels with their alloy content totaling less than 8 percent and the high-alloy steels with their alloy content totaling 8 percent or more. The addition of these various alloying elements in conjunction with suitable heat treatments, makes it possible to secure steel castings having a wide range of properties. The three accompanying tables give information on these steels. The lower portion of [Table 1](#) gives the engineering grades of low-alloy cast steels grouped according to tensile strengths and gives properties normally expected in the production of steel castings. [Table 2](#) and [Table 3](#) give the standard

designations and nominal chemical composition ranges of high-alloy castings which may be classified according to heat or corrosion resistance. The grades given in these tables are recognized in whole or in part by the Alloy Casting Institute (ACI), the American Society for Testing and Materials (ASTM), and the Society of Automotive Engineers (SAE).

The specifications committee of the Steel Founders Society issues a *Steel Castings Handbook* with supplements. Supplement 1 provides design rules and data based on the fluidity and solidification of steel, mechanical principles involved in production of molds and cores, cleaning of castings, machining, and functionality and weight aspects. Data and examples are included to show how these rules are applied. Supplement 2 summarizes the standard steel castings specification issued by the American Society for Testing and Materials (ASTM), Society of Automotive Engineers (SAE), Association of American Railroads (AAR), American Bureau of Shipping (ABS), and Federal authorities, and provides guidance as to their applications. Information is included for carbon and alloy cast steels, high alloy cast steels, and centrifugally cast steel pipe. Details are also given of standard test methods for steel castings, including mechanical, non-destructive (visual, liquid penetrant, magnetic particle, radiographic, and ultrasonic), and testing of qualifications of welding procedures and personnel. Other supplements cover such subjects as tolerances, drafting practices, properties, repair and fabrication welding, of carbon, low alloy and high alloy castings, foundry terms, and hardenability and heat treatment.

**Austenitic Manganese Cast Steel:** Austenitic manganese cast steel is an important high-alloy cast steel which provides a high degree of shock and wear resistance. Its composition normally falls within the following ranges: carbon, 1.00 to 1.40 percent; manganese, 10.00 to 14.00 percent; silicon, 0.30 to 1.00 percent; sulfur, 0.06 percent max.; phosphorus, 0.10 percent, max. In the as-cast condition, austenitic manganese steel is quite brittle. In order to strengthen and toughen the steel, it is heated to between 1830 and 1940°F (999 and 1060°C) and quenched in cold water. Physical properties of quenched austenitic manganese steel that has been cast to size are as follows: tensile strength, 80,000–100,000 psi (552–689 MPa); shear strength (single shear), 84,000 psi (579 MPa); elongation in 2 inches (50.8 mm), 15 to 35 percent; reduction in area, 15 to 35 percent; and 180 to 220 BHN (Brinell Hardness Number). When cold-worked, the surface of such a casting increases to a hardness of 450 to 550 BHN. In many cases the surfaces are cold-worked to

maximum hardness to ensure immediate hardness in use. Heat-treated austenitic manganese steel is machined only with great difficulty since it hardens at and slightly ahead of the point of contact of the cutting tool. Grinding wheels mounted on specially adapted machines are used for boring, planing, keyway cutting, and similar operations on this steel. Where grinding cannot be employed and machining must be resorted to, high-speed tool steel or cemented carbide tools are used with heavy, rigid equipment and slow, steady operation. In any event, this procedure tends to be both tedious and expensive. Austenitic manganese cast steel can be arc-welded with manganese-nickel steel welding rods containing from 3 to 5 percent nickel, 10 to 15 percent manganese, and, usually, 0.60 to 0.80 percent carbon.

**Table 3. Nominal Chemical Composition and Mechanical Properties of Corrosion-Resistant Steel Castings ASTM A743-17**

<sup>a</sup> Remainder is iron.

<sup>b</sup> These mechanical properties apply only when this material is heated to 1875–1925°F (1025–1050°C), quenched in air or oil, and tempered at 1150°F (620°C) minimum, or when annealed at 1400°F (760°C) minimum.

<sup>c</sup> For low ferrite or non-magnetic castings of this grade, the following values shall apply: tensile strength, min, 65 ksi (450 MPa); yield point, min, 28 ksi (195 MPa).

<sup>d</sup> Nominal Chemical Composition for CG6MMN as noted in the ASME standard. Other industry data indicates 20.5–23.5% Chromium, 11.5–13.5% Nickel, with 4–6% Manganese, 1.5–3% Molybdenum.

<sup>e</sup> Nominal Chemical Composition for this grade is not noted in the ASME standard. Other industry data indicates 20–22% Chromium, 23–27% Nickel, with 4.5–5.5% Molybdenum.

### Nonferrous Casting Metals

Nonferrous metals include metal elements and alloys not based on iron. Offering a wide variety of material characteristics and mechanical properties, these casting materials are commonly specified for structural applications that require reduced weight, increased strength, higher melting points, nonmagnetic properties, and/or resistance to chemical and atmospheric corrosion. They also are suitable for electrical and electronic applications. Such metals include aluminum, copper, magnesium, nickel, titanium, zinc, refractory metals (molybdenum and tungsten), and noble metals.

Important considerations in selecting material for a specific mechanical or structural application include how easily the material can be shaped into a finished part and how its properties may be altered in the process—either intentionally or inadvertently. Depending on the end use, metal can be cast into a part and finished. Or it can be cast into an intermediate form (such as ingots), worked, or wrought, by forging, extruding, rolling, or applying other deformation processes, and then finished as needed. Following are the primary nonferrous metals and alloys used in casting. For more information on specific alloys, see *NONFERROUS ALLOYS* starting on page 510.

**Aluminum (Al).**—Aluminum, also spelled aluminium, is a lightweight, silvery-white metal. It has a melting point of 1220°F (660°C) and a density of 163.55 lb/ft<sup>3</sup> (2700 kg/m<sup>3</sup>). The most abundant metallic element in the Earth's crust, aluminum is the most widely used nonferrous metal. While it is thermodynamically the least stable of the main engineering metals, it has the advantage of forming a dense, highly protective alumina film only 20 μin.—60 μin. (0.5 μm—1.5 μm) thick. This film can be reinforced by anodizing and destroyed by salt.

Aluminum is one of the few metals that can be cast by all of the processes. When alloyed with other metals, numerous properties are obtained that make such alloys useful over a broad range of applications. Many organizations publish specific standards for the manufacture of aluminum alloy, including ASTM International and SAE International (specifically, its aerospace standards subgroups). Alloys composed mostly of aluminum have been important in aerospace manufacturing since the introduction of metal-skinned aircraft.

Classification of cast aluminum alloys is developed by the Aluminum Association of the United States. Each cast alloy is designated by a four-digit number with a decimal point separating the third and fourth digits:

1. The first digit indicates the alloy group, according to the major alloying element:

1xx.x aluminum (99.0% minimum)

2xx.x copper (4% to 4.6%)

3xx.x silicon (5% to 17%) with added copper and/or magnesium

4xx.x silicon (5% to 12%)

5xx.x magnesium (4% to 10%)

7xx.x zinc (6.2% to 7.5%)

8xx.x tin

9xx.x others

2. The next two digits indicate the alloy purity or identify the alloy: In the alloys of the 1xx.x series, these digits indicate the level of purity of the alloy—the same as the two digits to the right of the decimal point in the minimum concentration of aluminum (in percent): 150.0 means a minimum 99.50% of aluminum in the alloy, 120.1 means a minimum 99.20% of aluminum. In all other groups of aluminum alloys (2xx.x through 9xx.x), the second and third digits together signify different alloys in the group.
3. The last digit indicates the product form: casting (designated by 0) or ingot (designated by 1 or 2, depending on chemical composition limits). A modification of the original alloy or impurity limits is indicated by a serial letter before the numerical designation. The serial letters are assigned in alphabetical order, starting with A, but omitting I, O, Q, and X. (The letter X is reserved for experimental alloys.)

*Aluminum-Copper (Al-Cu) Cast Alloys* (2xx.x series): These alloys contain 4–4.6% copper, along with small impurities of iron, silicon, and magnesium. Characteristics are heat-treatable, high strength, low fluidity, low ductility, susceptibility to hot cracks, and low corrosion resistance. Aluminum-copper cast alloys are used for cylinder heads for automotive and aircraft engines, pistons for diesel engines, and exhausting system parts.

*Aluminum-Silicon-Copper (Al-Si-Cu) Cast Alloys* (3xx.x series): Aluminum-silicon-copper alloys contain 5–17% silicon and 2–4.5% copper. Characteristics of these alloys are heat-treatable, high strength, good fluidity, low ductility, good machinability, good wear resistance, and decreased corrosion resistance. The copper contributes to strength, and the silicon improves castability and reduces hot shortness; thus, higher silicon alloys are suitable for more complex castings and for permanent mold and die casting processes, which cannot tolerate hot-short alloys. They are used for automotive cylinder blocks and heads, car wheels, aircraft fittings, casings, and other parts of compressors and pumps.

*Aluminum-Silicon (Al-Si) Cast Alloys* (4xx.x series): These alloys contain 5–12% silicon but no copper. Characteristics are non-heat-treatable, moderate strength, moderate ductility, very good cast properties, and good wear and corrosion resistance. Rapid cooling to increase strength and ductility can refine the microstructure. These alloys are used for pump casings, thin wall castings, and cookware.

*Aluminum-Magnesium (Al-Mg) Cast Alloys* (5xx.x series): Containing 4–10% magnesium, characteristics of these alloys are non-heat-treatable, good machinability, and good appearance when anodized. The moderate to relatively poor castability of such alloys and the tendency of magnesium to oxidize increase handling difficulties and, therefore, cost. In general, these alloys are used for sand cast parts.

*Aluminum-Tin (Al-Sn) Cast Alloys* (8xx.x series): Aluminum-tin alloys usually contain about 6% tin and a small amount of copper and nickel to improve strength. Though these compounds are not heat treatable, castability and machinability are good, and wear resistance is very good. They are used for cast bearings, due to tin's excellent lubrication characteristics.

*Aluminum-Zinc (Al-Zn) Cast Alloys* (7xx.x series): With the addition of 6.2–7.5% zinc, these alloys can be heat treated and have good dimensional stability, good machinability (if the alloy contains copper), and good corrosion resistance. They are used for abrasion-resistant parts under various operating conditions, such as axle bushes, shaft sleeves, and worm gears.

**Copper (Cu).**—Copper is a reddish-yellow material with a melting point of 1984.6°F (1084.6°C) and a density of 556.85 lb/ft<sup>3</sup> (8920 kg/m<sup>3</sup>). Usually a good conductor of electricity and heat, copper is one of the most ductile metals, but it is not especially strong or hard. Pure copper is extremely difficult to cast. As copper forms alloys more freely than most metals, casting and other characteristics can be improved by adding small amounts of various elements, including beryllium, chromium, nickel, silicon, silver, tin, and zinc.

*Brass:* This generic term refers to a range of copper-zinc (Cu-Zn) alloys with differing combinations of properties, including strength, hardness, ductility, machinability, resistance to wear and corrosion, and electrical and thermal conductivity.

*Bronze:* Bronze made from copper and tin (Cu-Sn) was the first manmade alloy used thousands of years ago. In modern times, wrought bronzes have been developed with 4–8% tin. These alloys are harder, stronger, and stiffer than wrought brasses and, in strip and wire form, produce a combination of high yield strength and good corrosion resistance.

*Copper-Nickel (Cu-Ni) Alloys:* This combination offers high conductivity, excellent resistance to marine corrosion, and low susceptibility to attachment of marine macroorganisms. The addition of nickel to copper improves strength and corrosion resistance, but good ductility is retained. The two main alloys are 90/10 (90% copper, 10% nickel) and 70/30 (70% copper, 30% nickel).

*Copper-Nickel-Silver (Cu-Ni-Zn) Alloys:* Made from copper, nickel, and zinc but no silver, these alloys can be regarded as special brasses. Containing 10–20% nickel, they

polish to an attractive silvery color, rather than the typical brassy color, which accounts for common use over several centuries.

*Beryllium-Copper (Be-Cu) Alloys:* In the fully heat treated and cold-worked condition, this is the hardest and strongest copper alloy. It is similar in mechanical properties to many high-strength alloy steels but, compared to steels, has better corrosion resistance.

**Magnesium (Mg).**—A shiny gray, solid, lightweight metal, magnesium has a melting point of 1202°F (650°C) and a density of 108.3 lb/ft<sup>3</sup> (1740 kg/m<sup>3</sup>). As the world's lightest metal, with good strength-to-weight ratio, magnesium and its alloys are prevalent in the automotive, airplane, and missile industries. Its compounds also are used as refractory material in furnace linings for producing iron, steel, other nonferrous metals, glass, and cement.

Magnesium is the most electrochemically active metal. Care must be taken in processing to avoid fire hazards, and small particles of the metal, such as metal cutting chips, oxidize rapidly. Magnesium and its alloys are available in both wrought and cast forms.

*Magnesium Alloys:* These light alloys have received renewed interest as substitutes for some conventional structural materials to reduce weight in vehicles. Cast alloys, widely used in interior and power-train components, account for more than 99 percent of magnesium alloys used today, while only a small number of wrought products are used. This is because magnesium alloys lack formability for wrought applications; their high cost also discourages use for some automotive applications.

Rare earth (RE) elements, such as cerium (Ce), gadolinium (Gd), neodymium (Nd), and yttrium (Y), often are used as major alloying elements because of their relatively high solubility in magnesium and effectiveness in precipitation hardening and creep resistance. Commercial wrought magnesium alloys, such as ZK60 and AZ61, are based on magnesium-zinc (Mg-Zn) and magnesium-zinc-aluminum (Mg-Zn-Al) compounds, both of which are age-hardenable. ZK and AZ alloys attain good strength with hot extrusion or rolling; however, age-hardening processes, such as T6 (solution heat treatment and aging) and T8 (cold-work and subsequent aging), do not add strengthening due to softening by recrystallization at the temperature for artificial aging.

## CASTING OF METALS

Casting is an age-old manufacturing process in which a liquid material usually is poured into a mold that contains a hollow cavity of the desired shape. As a result of new technological advances, this traditional form of manufacturing has become more essential than ever.

In metal casting, the mold generally includes runners and risers that facilitate metal filling the cavity. The mold and metal are cooled until the metal solidifies, then the solidified part (*casting*) is recovered from the mold. Subsequent operations are used to remove excess material caused by the casting process (such as the runners and risers), after which the part may solidify further. Metal casting processes are divided into two broad types: expendable-mold casting processes and nonexpendable-mold casting processes.

*Expendable-mold casting* includes sand, plastic, shell, plaster, and investment (lost-wax technique) molding processes, all of which rely on gravity to move the liquid material into casting cavities. The molds in which the molten material solidifies usually are made of non-metallic materials and are temporary—that is, they must be destroyed to remove the casting.

*Nonexpendable-mold casting* refers to casting processes involving a reusable mold. Such molds are designed with two or more sections for easy, precise closing (for molding) and opening (to remove the casting) and can be used for multiple castings. For metal casting, the mold, also called a *die*, is commonly made of metal or ceramic.

*Permanent mold casting* refers to all casting technologies in which the mold cavity is reused many times and is made of a metallic material or graphite. This is the predominant casting method for manufacturing metal shapes. Specifically, about 90 percent of all aluminum castings produced use metal molds, including gravity-fed, low-pressure, and high-pressure die castings.

Permanent metal molds are commonly made of steel or cast iron, with metal or sand cores, though it is desirable and generally more economical to use permanent steel cores to form cavities. When the casting has re-entrant surfaces or cavities from which one-piece permanent metal cores cannot be withdrawn, destructive cores made of sand, shell, plaster, or other materials may be used. This process is called *semipermanent mold casting*. Sectional steel cores also may be used in some instances.

An advantage of permanent metal molds is that they heat up and expand during the pour, so the cavity does not need to be expanded as much as in sand castings. Therefore, the cavity, with the gating system included, can be machined into halves that produce more precise parts with closer dimensional tolerances and smoother surfaces. Permanent mold castings also usually have better mechanical properties than sand castings, as solidification is more rapid and fill is more laminar.

Permanent mold casting is used mostly for aluminum, copper alloys, magnesium, and gray iron, because of their generally lower melting points. Typical parts include automobile pistons, cylinder heads, gears, and kitchenware. Parts that can be made economically generally weigh less than 55 lb (25 kg), though special castings weighing a few hundred kilograms have been made using this process. It may not be economical for small, unique production runs (due to the cost of permanent molds) and generally is not suitable for casting intricate shapes (because of difficulty of removing the part from the mold).

Disadvantages of different types of castings include poor finish; wide tolerance (sand casting); limited workpiece size (shell molds and ceramic molds); patterns with low strength (expendable-pattern casting); expensive, limited shapes (centrifugal casting); porosity (all types); and environmental problems (all types).

### Heating and Pouring the Metal

*Pouring* is the process by which molten metal is transferred to the mold for cooling and solidification to be converted into the intended shape. *Pouring temperature* ( $T_p$ ) is the temperature to which the molten metal must be heated before being poured into molds for cooling and setting.

The heat energy required for heating metal to a pouring temperature is the sum of 1) the heat needed to raise the temperature of a unit mass solid to its melting point; 2) the heat of fusion required to convert it from a solid at its melting point to a liquid without an increase in temperature (see Fig. 1); and 3) the heat needed to raise the molten metal to the desired temperature for pouring. The pouring temperature must take into account heat lost in the transfer of metal through ladles, due both to the heat absorbed by the ladles and to the distance between the furnace and the mold.

Molten metal must be poured carefully to avoid casting defects. For example, too rigorous a stream could cause mold erosion; highly turbulent flows could result in air and inclusion entrapments; and relatively slow filling might generate cold shuts. Thus, design of the gating and venting overflow systems must take into consideration proper control of the liquid metal as it fills the mold.

Fig. 1. Phase Change Diagram of Process of Heating Metal Casting to Pouring Temperature.

Whether the casting process takes place by expendable-mold casting (such as sand casting) or nonexpendable-mold casting (using a permanent metal mold), the basic terminology of the casting process is the same.

### Fluid Flow

Fluid flow is very important in casting. The molten metal is poured through a pouring basin. It then flows through the gating system (comprising sprue, risers, runners, and gates) to fill the mold cavity. (See the gravity casting system shown in Fig. 2.)

The *sprue* is the vertical part of the gating system that connects the *pouring cup* or *pouring basin* and runners; liquid metal enters the mold through the sprue. The *cope* is the top half of the mold. The *runners*, which are cut in the *drag* (the lower part of the mold), form the horizontal portion of the gating system that connects the sprue to the gates. The *gate* is the portion of the runners through which molten metal enters the mold cavity; there may be one or more gates. The *core* is designed to leave an unfilled space in the part. *Risers* are the part of the gating system used to identify when enough liquid material has been poured to fill the mold; it also acts as a reservoir of extra material to compensate for shrinkage during solidification. The *flask* is the molding box or outside of the mold.

Fig. 2. Cross Section of Typical Two-Part Sand Mold

**Gating Design:** Successful casting requires proper design and control of the solidification process to ensure adequate fluid flow in the system. For example, an important function of the gating system in sand casting is to trap contaminants (oxides and other inclusions) in the molten metal by having such contaminants adhere to the walls of the gating system, thereby preventing them from reaching the mold cavity. A properly designed gating system also avoids or minimizes problems such as premature cooling, turbulence, and gas entrapment. Two basic principles of fluid flow are relevant to gating design: Bernoulli's theorem and the law of mass continuity.

**Bernoulli's theorem** states that the sum of the energies in a flowing liquid is constant at any two points. This can be written as:

$$h + \frac{p}{\rho g} + \frac{v^2}{2g} = \text{constant} \quad (1)$$

where  $h$  = elevation above a certain preference plane (datum);  $p$  = pressure at that elevation;  $v$  = velocity of the liquid at that elevation;  $\rho$  = density of the fluid; and  $g$  = gravitation constant.

This concept of conservation of energy requires that (between two different elevations) the following relationship be satisfied as:

$$h_1 + \frac{p_1}{\rho g} + \frac{v_1^2}{2g} = h_2 + \frac{p_2}{\rho g} + \frac{v_2^2}{2g} + f \quad (2)$$

where  $f$  = frictional losses in the liquid as it travels downward through the system.

The **law of mass continuity** states that for incompressible liquids and in a system with impermeable walls, the volume rate of flow remains constant throughout the liquid. So, considering two different locations in the system:

$$Q = A_1 v_1 = A_2 v_2 \quad (3)$$

where  $Q$  = volume rate of flow;  $A$  = cross-sectional area of the liquid stream;  $v$  = the average velocity of the liquid at that cross-sectional location; and subscripts 1 and 2 indicate two different locations in the liquid flow.

**Sprue Design:** The shape of the sprue can be calculated using Equation (2) and Equation (3). Assuming that pressure at the top of the sprue is equal to pressure at the bottom and that there are no frictional losses, the relationship between height and cross-sectional area at any point in the sprue is given by the parabolic relationship:

$$\frac{A_1}{A_2} = \sqrt{\frac{h_1}{h_2}} \quad (4)$$

**Flow Characteristics:** A molten metal's flow characteristics are an important consideration in the gating system because of the possible consequences of turbulence. There are two types of real fluid flow: laminar and turbulent.

In *laminar flow*, fluid moves in layers called *laminae*. Laminar flow need not be in a straight line; the flow may follow curved surfaces. The fluid layers slide smoothly over one another, without fluid being exchanged between the layers.

In *turbulent flow*, secondary random motions are superimposed on the principal flow, and there is an exchange of fluid from one adjacent sector to another. More important, there is an exchange of momentum: slow-moving fluid particles speed up, while fast-moving particles give up their momentum to slower-moving particles and are slowed down.

The factor that determines which type of flow is present is the ratio of the inertial forces to the viscous forces within the fluid. This ratio is expressed by the dimensionless Reynolds number as:

$$R_e = \frac{\rho v L}{\mu} \quad (5)$$

where  $R_e$  = Reynolds number;  $v$  = mean fluid velocity;  $L$  = characteristic length (equal to diameter if cross section is a circle);  $\mu$  = dynamic fluid viscosity;  $\rho$  = density of the fluid.

The higher the  $R_e$ , the greater the tendency for turbulent flow to occur in the gating system: (1) laminar flow:  $0 < R_e < 2000$ ; (2) transition flow:  $20 < R_e < 20,000$ ; (3) turbulent flow:  $R_e > 20,000$ . Turbulent flow leads to inclusions, and therefore a reduction in fluidity.

### Fluidity of Molten Metal

The phrase *fluidity of molten metal* describes the capability of molten metal to fill mold cavities, based on two factors: characteristics of the molten metal and casting parameters. The following characteristics of molten metal influence fluidity:

**Viscosity:** If viscosity (a measure of the metal's deformation in a molten state) and sensitivity to temperature (viscosity index) increase, fluidity decreases.

**Surface Tension:** High surface tension of the liquid metal reduces fluidity. Oxide films that develop on the surface of molten metal increase surface tension and thus can significantly reduce fluidity. Fluxing processes (treating metal with flux to promote melting) in the heating of metals are used to reduce or eliminate oxidation and to improve fluidity of metal surface layers.

**Inclusions:** Metallic and non-metallic inclusions have long been recognized as one of the most important quality issues in metal casting. As insoluble particles, inclusions can have a significant adverse effect on fluidity; the presence of inclusions often is the cause of decreased fluidity.

**Solidification Pattern of the Alloy:** Fluidity is inversely proportional to the freezing temperature range. In general, pure metals and alloys of eutectic composition have the highest values of fluidity. Solid-solution and other alloys have lower fluidity.

**Superheat:** The difference between the melting temperature and the pouring temperature also influences fluidity. For given alloy compositions, if the melt temperature is higher, fluidity increases. The pouring temperature is often specified, rather than the superheat temperature, because it is easier to do so.

**Test for Fluidity.**—Although none is accepted universally, several tests have been developed to quantify fluidity. One such test is the spiral test (Fig. 3a), where the molten metal is made to flow along a channel at room temperature. The distance the metal flows before it solidifies (and stops flowing) is a measure of its fluidity. Obviously, this distance is a function of the thermal properties of both the metal and mold, as well as the design of the channel. Another test for fluidity is the vacuum test (Fig. 3b), which measures the length the metal flows inside a narrow channel when sucked from a crucible by a vacuum pump. Such tests can be useful in simulating casting situations.

Fig. 3. Test Method for Fluidity: a) Spiral Method; b) Vacuum Method

### Heat Transfer

An important consideration in casting is heat transfer during the complete cycle from pouring to solidification and cooling to ambient temperature. Heat flow at different locations in the system is a complex phenomenon that depends on many factors relating to the casting material and mold and process parameters. For instance, when casting thin sections, metal flow rates must be high enough to avoid premature chilling and solidification. However, the flow rate must not be so fast as to cause excessive turbulence, which can have detrimental effects.

### Solidification and Cooling of Metals

At the macro level, *solidification* refers to the phase change of metal from liquid to solid. At the micro level, changes occur in the material as the disordered structure of the liquid transforms into an orderly arrangement of crystals.

Once molten metal has been poured into the mold, it cools rapidly. When the temperature of the liquid drops below the melting point of that metal or alloy, the solidification process begins. This usually takes less than a few minutes. As the temperature drops further, the molten metal loses energy, and crystals begin to form. (This process starts near the mold walls, where cooling occurs first.) These crystals eventually become grains within the final structure.

*Grain size* refers to crystals (*dendrites*) formed during the solidification process. If the metal solidifies slowly, the grains are longer. If it cools quickly, the grains are visibly shorter. Crystals continue to form and harden, until the entire melt is solidified.

Throughout the solidification process, the metal shrinks. It is important to compensate for such shrinking to ensure castings are free of voids and shrink defects. This is accomplished by using risers.

The cooling rate of a casting affects its microstructure, quality, and properties. The cooling curve illustrates how molten metals solidify. There is a fundamental difference between the cooling curve observed during solidification of a pure metal and that of an alloy.

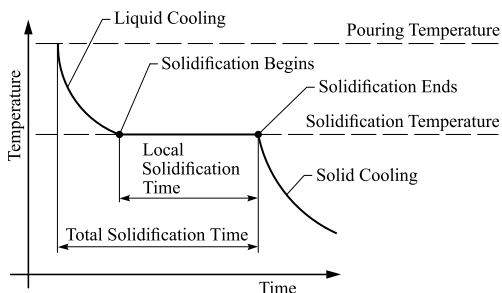

Fig. 4. Cooling Curve for a Poured Pure Metal During Casting

**Solidification of Pure Metal.**—Pure metal solidifies at constant temperature. It has a clearly defined melting (or freezing) point. Fig. 4 shows the cooling curve for a poured pure metal during casting.

After the temperature of the molten pure metal drops to its freezing point, the temperature remains constant while the latent heat of fusion is given off. The *solidification front* (solid–liquid interface) moves through the molten metal, solidifying from the mold walls toward the center.

At the mold walls, the molten metal cools rapidly and first produces a solidified shell of fine, approximately equal-dimension-in-all-direction (equiaxed) grains. Starting with these grains, the grains grow upon themselves, in the opposite direction of the heat transfer out through the mold. Those with favorable orientations—that is, away from the surface of the mold—are columnar in shape; as the driving force of the heat transfer is reduced (farther from the mold walls), the grains again become equiaxed, as well as coarse. Those grains that have substantially different orientations are blocked from further growth.

When the heat is segregated rapidly during solidification, it leads to fine structures due to a decrease in diffusion rates.

**Solidification of Alloys.**—Solidification begins when the temperature of the alloy drops below the point of liquidus, and it is complete when it reaches solidus. A phase diagram and a cooling curve for alloys during casting are shown in Fig. 5.

Fig. 5. Phase Diagram and Cooling Curve for Alloy Composition During Casting

Within the temperature range where solidification begins ( $T_1$ ) and solidification ends ( $T_2$ ), the alloy is in a "mushy" state, with columnar dendrites. The mushy metal is present between the dendrite arms. The width of this mushy zone is an important factor during solidification. It is described by the freezing range as:

$$\text{Freezing range} = T_1 - T_2 \quad (6)$$

Pure metals have no freezing range, and the solidification front moves in a plane without forming a mushy zone.

In alloys with a nearly symmetrical phase diagram, the structure generally is lamellar, with two or more solid phases present, depending on the alloy system. For alloys, a short freezing range generally involves a temperature difference less than 122°F (50°C) and a long freezing range higher than 230°F (110°C). Ferrous castings generally have narrow mushy zones, whereas aluminum and magnesium alloys have wide mushy zones. Slow cooling rates approximately 10<sup>2</sup> K/s result in coarse dendritic structures with large spacing between the dendrite arms. For higher cooling rates, from 10<sup>6</sup> to 10<sup>8</sup> K/s, the structures developed are amorphous.

**Solidification Time.**—Total solidification time is the time required for the casting to solidify from molten metal after pouring. Casting geometry, material, and process determine solidification time.

Chvorinov's rule states that under the same conditions, a casting with a large surface area and small volume will cool more rapidly than a casting with a small surface area and large volume. Therefore, a large sphere solidifies and cools to ambient temperature at a much slower rate than a smaller sphere. The reason is that the volume of a sphere is proportional to the cube of its diameter, and its surface area is proportional to the square of its diameter. Similarly, molten metal in a cube-shaped mold will solidify faster than in a spherical mold of the same volume. According to this rule, solidification time is a function of the volume of a casting and its surface area:

$$\text{Solidification time} = k(V/A)^n \quad (7)$$

where  $V$  is the volume of the casting;  $A$  is the surface area of the casting;  $k$  is the mold constant; and  $n$  is the exponent ( $1.5 < n \leq 2$ , but usually taken as 2). The mold constant  $k$  depends on the properties of the cast metal (heat of fusion, specific heat, and thermal conductivity), mold material, and pouring temperature. The value of  $k$  for a given casting operation can be based on experimental data from previous operations carried out using the same mold material, metal, and pouring temperature, even though the shape of the workpiece might be complex.

During the early stages of solidification, a thin, solidified skin begins to form at the cool mold walls; as time passes, the skin thickens. With flat mold walls, this thickness is proportional to the square root of time.

**Shrinkage.**—Most materials contract or shrink during solidification and cooling. Shrinkage is the result of contraction of the liquid as it cools prior to solidification; contraction during the phase change from liquid to solid; and contraction of the solid as it continues to cool to ambient temperature.

Sometimes, shrinkage can cause cracking in a component as it solidifies. Since the coolest area of a volume of liquid is where it contacts a mold or die, solidification usually begins first at this surface. As the crystals grow inward, the material continues to shrink. If the solid surface is too rigid and will not deform to accommodate the internal shrinkage, the stresses can exceed the tensile strength of the material and cause a crack to form. Shrinkage cavitation also may occur as a material solidifies inward and shrinks to such an extent that not enough atoms are present to fill the available space, and a void is left.

The amount of contraction during the solidification of metals is shown in Table 1. Note that gray cast iron expands, because graphite has a relatively high specific volume, and when it precipitates as graphite flakes during solidification, it causes a net expansion of the metal.

**Table 1. Volumetric Solidification Contraction or Expansion for Various Metals**

Metals	Volumetric Contraction due to:		Solidus Temperature °F (°C)
	Solidification Shrinkage (%)	Cooling Shrinkage (%)	
Aluminum (Al)	7.1	5.1	1220 (660)
Aluminum (Al), 4.5% Copper (Cu)	6.3	5.3	1058 (570)
Aluminum (Al), 12% Silicone (Si)	3.8	4.8	1076 (580)
Gold (Au)	5.1	5.2	1945 (1063)
Bismuth (Bi)	-3.3 (expansion)	1.0	520 (271)
Copper (Cu)	5.1	6.4	1981 (1083)
Iron (Pure) (FE)	3.1	6.0 to 7.5	2795 (1535)
Steel (Various)	2.5 to 3.0	4.2 to 6.0	2732 (1500)
Gray Cast Iron, 2% Carbon (C)	4.0	3.0	2111 (1155)
Gray Cast Iron, 5% Carbon (C)	-2.5 (expansion)	3.0	2098 (1148)
White Cast Iron, 5% Carbon (C)	5.0	3.0	2111 (1155)
Germanium (Ge)	-5.1 (expansion)	1.6	1719 (937)
Magnesium (Mg)	4.2	5.4	1200 (649)
Nickel (Ni)	5.1	7.0	2647 (1453)
Lead (Pb)	2.7	2.8	621 (327)
Tin (Sn)	2.3	1.5	450 (232)
Zinc (Zn)	4.7	4.0	788 (420)

### Defects in Casting

The International Committee of Foundry Technical Associations has developed a standardized nomenclature, consisting of eight basic categories of casting defects:

**Metallic Projections:** Such defects can include fins, flash, or massive projections, such as swells and rough surfaces.

**Cavities:** Various rounded or rough internal or exposed cavities include blowholes, pinholes, and shrinkage cavities.

**Discontinuities:** These can include cracks, cold or hot tearing, and cold shuts. If the solidifying metal is constrained from shrinking freely, cracking and tearing can occur. Coarse grain size and the presence of low-melting-point segregates along the grain boundaries (intergranular) increase the tendency for hot tearing. Cold shut is an interface in a casting that lacks complete fusion because two streams of liquid metal meet from different gates and do not completely fuse.

**Defective Surface:** Surface defects include folds, laps, scars, adhering sand layers, and oxide scale.

**Incomplete Casting:** Misruns can occur due to premature solidification, the molten metal being at too low a temperature, pouring metal too slowly, insufficient volume of metal being poured, or runoff (loss of metal from a mold after pouring).

**Incorrect Dimensions or Shape:** These undesirable results may be caused by factors such as an improper shrinkage allowance, pattern-mounting error, deformed pattern, irregular contraction, or warped casting.

**Inclusions:** Inclusions form during melting, solidification, and molding and generally are non-metallic. They increase stress and reduce strength of the casting. Inclusions may form during melting, when the molten metal reacts with the environment (usually oxygen) or with crucible or mold material. Chemical reactions among components in the molten metal itself may produce inclusions. Spalling of the mold and core surfaces also produces inclusions, indicating the importance of the quality and maintenance of molds.

**Porosity:** Porosity may be caused by shrinkage or gases or both. Thin sections in a casting solidify sooner than thicker regions. As a result, molten metal can flow into thicker

regions that have not yet solidified, and porous regions may develop at their centers due to contraction as the surfaces of the thicker region begin to solidify. Micro-porosity can develop when the liquid metal solidifies and shrinks between dendrites or between dendrite branches.

Porosity caused by shrinkage can be reduced or eliminated by various means. Adequate liquid metal should be provided to avoid cavities caused by shrinkage. Internal or external chills used in sand casting also are an effective means of reducing shrinkage porosity by increasing the rate of solidification in critical regions. Internal chills usually are made of the same material as the casting and are left in the casting; external chills may be made of the same material or of iron, copper, or graphite. With alloys, porosity also may be reduced or eliminated by making the temperature gradient steep. For example, mold materials with higher thermal conductivity may be used. Subjecting the casting to hot isostatic pressing is another method of reducing porosity.

Most obvious porosity defects are caused by entrapment of gases within the molten solution. Because liquid metals have much greater solubility for gases than solid metals, when a metal begins to solidify, dissolved gases are expelled from the solution. Typically, hydrogen precipitates into melt because of contact with the atmosphere or excessive moisture in the flux. Since hydrogen is highly soluble in molten metal, it is best to avoid superheating metals beyond their melting temperature and to avoid holding the material in a molten state any longer than necessary.

To reduce absorption of gases from the atmosphere, which may leave slag or dross, cover molten metal until just prior to pouring it into the mold. Gases also may result from reactions of the molten metal with the mold materials, either accumulating in regions of existing porosity or causing micro-porosity in the casting, particularly in cast iron, aluminum, and copper. Dissolved gases may be removed from the molten metal by flushing or purging with an inert gas or by melting and pouring metal in a vacuum. If the dissolved gas is oxygen, the molten metal can be deoxidized. Steel is usually deoxidized with aluminum, copper-based alloys with phosphorus, silicon, titanium, and zirconium-bearing materials.

If the porosity is spherical and the walls are smooth, porosity usually is the result of gases. If the walls are rough and angular, porosity is likely the result of shrinkage between dendrites. Gross porosity is caused by shrinkage and usually is called a *shrinkage cavity*.

The loss in casting properties measured by a tensile test may reflect the amount of porosity in a casting; because imperfections become areas of higher stress concentration, the percentage of property loss becomes greater when the strength requirement is higher. Porosity also is detrimental to the ductility of a casting and its surface finish, making it permeable and thus affecting the pressure tightness of a cast pressure vessel. A metallographic examination can determine whether porosity exists in a casting. X-ray techniques also are used for nondestructive evaluations of porosity.

## METAL CASTING AND MOLDING PROCESSES

Metal casting processes may be classified in four different ways:

*According to the Mold Type:* (1) expendable mold (destroyed after each casting); or (2) permanent mold (reused many times).

*According to the Type of Pattern Used for Making a Sand Mold:* (1) expendable pattern (melted for each mold), using wax as the pattern material; or (2) permanent pattern (reused for many molds), using wood or metal as the pattern material.

*According to the Type of Core Used for Producing a Hole in Casting:* (1) expendable core (used in both sand and metal molds), using sand as the core material; or (2) permanent core (used with a permanent mold only), using metal as the core material.

*According to the Method by Which the Mold is Filled:* (1) gravity (sand casting, gravity die casting); (2) pressure (low- and high-pressure die casting); or (3) vacuum (vacuum investment casting).

### Sand Casting

Sand casting uses natural or synthetic sand in forming molds. Larger-sized molds use green sand (a mixture of sand, clay, and some water).

*Advantages of Sand Casting:* Ferrous, nonferrous, and even non-metal materials can be cast in this process. Sand can be reused; excess metal poured is cut off and reused as well. Simple, inexpensive tools are required. Intricate shapes can be made by this process, as molten metal flows into small sections. Finally, this process can be used to produce many small components, with no limit on the size or weight of castings.

*Disadvantages of Sand Casting:* Accuracy and surface finish are lacking, requiring additional processing and finishing of parts. Overall, sand casting is a labor-intensive process. However, since sand casting usually is the least expensive way of making a component, its cost advantage over other methods makes it an attractive molding method.

**Sands.**—Most sand casting operations use a refractory material called silica ( $\text{SiO}_2$ ). Sand is inexpensive and has high melting point of  $3110^\circ\text{F}$  ( $1710^\circ\text{C}$ ). Sand can be naturally bonded (bank sand) or synthetic (lake sand). Because its composition can be controlled more accurately, synthetic sand is preferred by most foundries.

Several factors affect the selection of sand for molds. The grains of the sand must be small enough so that it can be packed densely; sand having fine, round grains can be closely packed and form a smooth mold surface. Fine-grained sand enhances mold strength, but fine grains also lower mold permeability. The sand grains must be large enough for good permeability of molds (and cores), which allows the gases and steam that evolve during casting to escape through the pores of the mold.

For proper functioning, mold sand must be clean and preferably new. And the sand mold should have good collapsibility to allow the casting to shrink while cooling, thus avoiding defects such as hot tearing and cracking.

**Types of Sand Molds.**—Sand molds are characterized by the types of sand that compose them and by the methods used to make the molds.

*Green-Sand Molds:* Clay sand is the mixture of natural silica sand, clay, additives, and water. It is the least expensive method of making sand molds, and the sand can be recycled for the next use. Bentonite clay is used to make wet clay sand. Sand in these molds is kept moist or damp while the metal is being poured. As the wet sand has a high moisture content, good air permeability, and low strength, castings can have issues with porosity, coarse, sticky sand, and sand expansion defects.

Green-sand molds are commonly used in hand molding and machine molding. In hand molding, dimensional accuracy is low, so it is generally used only for production of small and medium-sized iron castings and nonferrous alloy castings. But in mechanical molding, the castings have much higher dimensional accuracy, so it is widely used for high-volume production of castings.

*Skin-Dried Method:* In this case, the mold surfaces need to be sprayed with a mixture of 10 percent water to one part molasses or lignin sulfonate after the surfaces are dried, either by storing the mold in air or by using torches.

*Cold-Box Mold:* Various organic and inorganic binders are blended into the sand to bond the grains chemically for greater strength. These molds are dimensionally more accurate than green-sand molds, but they are more expensive.

*No-Bake Mold:* A synthetic liquid resin is mixed with the sand; the mixture hardens at room temperature. Because bonding of the mold in this and in the cold-box process takes place without heat, these processes are called *cold-setting processes*. This type of mold has good dimensional control in high-production applications.

*Dried Molds:* Sand molds that are oven dried (baked) prior to pouring the molten metal are stronger than green-sand molds and impart better dimensional accuracy and surface finish to the casting. However, this method has drawbacks: (a) distortion of the mold is greater; (b) castings are more susceptible to hot tearing because of the lower collapsibility of the mold; and (c) production rates are slower due to the drying time required.

**Features of Sand Molds.**—Major features of sand molds (most shown in Fig. 2) are:

*Cope:* The top half of the flask, mold, or core.

*Drag:* The bottom half of the flask, mold, or core.

*Core:* A core part is inserted into the mold cavity to produce a hole within the mold.

*Core Print:* The region added to the pattern, core, or mold to locate and support the core.

The prints are made of such a size and shape that it would be impossible to set the core in any position except the proper one.

*Mold Cavity:* The combined open area in the molding material and core, where the liquid metal solidifies to produce the casting.

*Gating System:* The network of connected channels that allows molten material to flow into the mold cavity; it includes the sprue, riser, runners, and gates.

*Pouring Cup or Basin:* The part of the gating system that initially receives the molten metal from the pouring vessels and controls its delivery to the rest of the mold.

*Sprue:* The vertical part of the gating system that connects the pouring cup and runners. The liquid metal enters into the mold cavity through the sprue.

*Runners:* The horizontal portion of the gating system, cut into the drag part of the mold, which connects the sprues to the gates.

*Riser:* This part of the gating system normally is used to identify the filling position of the liquid metal in the mold. It also acts as a reservoir for extra molten metal to compensate for shrinkage during solidification.

*Gates:* The controlled entrances from the runners into the mold cavities. Properly designed gates admit liquid metal into the mold cavity without turbulence.

*Vents:* These small holes, in all parts of the mold, provide passage for gases to escape during pouring and solidification of mold metals.

*Parting Line or Parting Surface:* The interface line between the cope and drag halves of the mold or flask.

*Draft:* The taper on the pattern that allows it to be easily withdrawn from the mold.

*Core Box:* This is the mold or die used to produce the cores.

**Patterns.**—Patterns are used to mold the sand mixture into the shape of casting. They may be made of wood, plastic, or metal. Because patterns are used repeatedly to make molds, the strength and durability of the materials selected must reflect the number of castings that the mold will produce. Patterns usually are coated with a parting agent to facilitate their removal from the molds. There are four types of patterns: solid one-piece patterns, split patterns, match-plate patterns, and cope-and-drag patterns.

*One-Piece Patterns:* Also called *loose* or *solid patterns*, one-piece patterns are used for simple shapes and low-quantity production. They usually are made of wood and are inexpensive.

*Split Patterns:* These two-piece patterns are made so that each part forms a portion of the cavity for the casting, enabling casting of complicated shapes.

Fig. 6. Match-Plate Pattern

*Match-Plate Patterns:* These two-piece patterns are constructed by securing each half of one or more split patterns to the opposite sides of a single plate (Fig. 6). The gating system can be mounted on the drag side of the pattern.

Fig. 7. Cope-and-Drag Pattern

**Cope-and-Drag Patterns:** These are similar to match-plate patterns. Except each half of the split pattern is assembled with separate plates, so separate patterns, and possibly separate machines, can be used to make the mold halves. Cope-and-drag patterns (Fig. 7) include a gating and riser system.

**Cores.**—Many cast parts have interior holes (hollow parts) or other cavities in their shape that are not directly accessible from either piece of the mold. Such interior surfaces are formed using inserts called *cores*, which are placed in the mold cavity before casting and removed from the finished part during shakeout and further processing. Like molds, cores must possess strength, permeability, collapsibility, and ability to withstand heat. Hence, cores are made of sand aggregates.

Cores are anchored and supported by *core prints*, recesses added to the pattern that also provide vents for gases to escape. To keep cores from shifting, metal supports (*chaplets*) may be used to anchor the cores.

On pouring and solidification, *chaplets* are integrated into the casting. The portions of the chaplets protruding from the castings are cut off. Fig. 8 illustrates how a core is held in the mold cavity with and without chaplets.

Fig. 8. Core Held in Place in the Mold Cavity: a) Core Held in with Chaplets; b) Core Held without Chaplets

**Sand Molding Techniques.**—These are the steps involved in the traditional technique of making a simple sand mold:

- 1) The drag flask is placed on the board.
- 2) Dry facing sand is sprinkled over the board to provide a nonstick layer.
- 3) The drag half of the pattern is located on the mold board.
- 4) Molding sand is poured in to cover the pattern with the fingers; the drag is filled completely.
- 5) Sand is tightly packed in the drag using *hand rammers*, *peen hammers* (used first close to the drag pattern), and *butt hammers* (used for surface ramming).
- 6) Ramming must be proper (neither too hard nor too soft). Too soft ramming will generate a weak mold and poor imprint of the pattern. Too hard ramming will not allow gases and air to escape, creating bubbles in castings, resulting in defects called *blows*. Also, the making of runners and gates will be difficult.

7) After the ramming is finished, excess sand is leveled and removed with a straight bar (*strike rod*).

8) Vent holes are made in the drag, using a *vent rod*, to the full depth of the flask and the pattern to facilitate removal of gases during pouring and solidification.

9) The finished drag flask is turned upside down, exposing the pattern.

10) The cope half of the pattern is placed on the drag pattern, using locating pins. The cope flask also is located with the help of pins. Dry parting sand is sprinkled all over the drag surface and on the pattern.

11) A sprue pin, used in making the sprue passage, is located some distance from the pattern edge. A riser pin is placed at an appropriate place.

12) Filling, ramming, and venting of the cope are done in the same manner.

13) The sprue and riser are removed. A pouring cup or basin is made at the top to pour the liquid metal.

14) The pattern is removed from the cope and drag.

15) Runners and gates are made by cutting the parting surface with a gate cutter (a piece of sheet metal bent to the desired radius).

16) The core for making a central hole is placed into the mold cavity in the drag, where it is anchored and supported by core prints.

17) The mold is now assembled and ready for pouring.

**Sand Casting Operation.**—After the mold has been shaped and the cores have been placed in position, the two halves (cope and drag) are closed, clamped, and weighed down to prevent separation of the mold sections. The flasks are then subjected to pressure to counteract the force of buoyancy. (Buoyancy results from the weight of liquid metal being displaced by the core, according to Archimedes' law.)

The force tending to lift the cope is equal to the weight of the displaced liquid less the weight of the core. This can be expressed as:

$$F_b = W_m - W_c \quad (8)$$

where  $F_b$  represents the force of buoyancy;  $W_m$  is the weight of molten metal displaced; and  $W_c$  is the weight of the core.

The order of sand casting operation is as follows:

1) A suitable flask or molding box is selected, and space is allowed for ramming in sand.

2) The drag is placed on the molding board upside down. Then the lower part of the pattern is placed on the board inside the flask. Space is left for cutting.

3) Sand is added to fill in the flask and cover the pattern; it is firmly packed using hammers. After properly ramming in sand, the excess is leveled off with straight strike-off bar.

4) Using a vent rod, the vent holes are made in the drag to the full depth of flask to allow gases or air to escape during pouring and solidification.

5) The cope half of pattern is placed over the drag and positioned with locating pins. The cope flask is placed on the drag. The sprue pin is provided for sprue passage, located at a distance from the pattern. And the riser pin is positioned on the pattern.

6) The ramming, filling, and venting processes are repeated.

7) The cope is filled with sand and proper ramming force applied.

8) Excess sand is cut off from mold surface. The riser pin and sprue pin are removed.

9) The molding box is opened, and the pattern is removed from the cope and drag. One or more dry sand cores are mounted in position.

10) The mold is closed by placing the cope on top of the drag and securing the assembly with pins. The flasks are subjected to pressure to counteract buoyant forces in the liquid, which might lift the cope.

11) Molted metal is poured through the riser into the mold cavity.

12) After pouring and solidification, the part is removed with the required pattern shape.

13) The sprue and risers are cut off and recycled.

14) The casting is cleaned, inspected, and heat treated (when necessary).

15) The final casting is inspected using nondestructive testing and destructive methods in accordance with standards.

**Rammed Graphite Molding.**—A rammed graphite mold typically is used for large industrial casting for reactive metals such as titanium and zirconium. It uses graphite instead of sand in a process similar to sand casting. Traditionally, a mixture of properly size-fractionated graphite powder, pitch, corn syrup, and water are rammed against a wooden or fiberglass pattern to form each mold section. The mold sections are air dried, baked at 350°F (177°C), and then fired in a furnace for 24 hours at 1877°F (1025°C), causing the mold to carbonize and harden. Rammed graphite molds must be stored under controlled humidity and temperature.

Mold ramming is a labor-intensive process that cannot be easily mechanized, and the graphite mold is so hard that it must be chiseled off the cast parts. Castings made with this process usually are cleaned in an acid bath, followed, if necessary, by chemical milling, to remove any reaction zone; weld-repaired as needed; and then sandblasted for a good surface appearance.

### Shell Molding

Shell molding is a foundry process in which the molds are made in the form of thin shells. This process can produce many types of castings with close dimensional tolerance and good surface finish at relatively low cost. Shell molding applications include small mechanical parts requiring high precision, including gear housings, cylinder heads, connecting rods, and close-tolerance molding cores.

*Advantages of Shell Molding:* Rigidly bonded sand provides great reproducibility and produces castings near to net shape with intricate detail and high dimensional accuracy of  $\pm 0.010$  in. ( $\pm 0.25$  mm). Castings can range from 1 oz to 25 lb (28 g to 11 kg). The resin-bond strength of the mold allows for smaller draft angles, deep draws, and built-in mold locators that prevent mold shift mismatch.

Because mold shells are thin, permeability for gas escape is increased, allowing use of finer sands. Finer sand and excellent flowability produce dense mold surfaces and contribute to producing complex casting with high-quality finishes with a roughness average of 50  $\mu\text{in}$  (1.25  $\mu\text{m}$ ) Ra. The virtual absence of moisture eliminates moisture-related defects, and the burning resin provides a favorable anti-oxidizing atmosphere for the casting surface. In addition, heat from burning slows the casting-cooling rate, yielding a more machinable structure.

*Disadvantages of Shell Molding:* Since the tooling requires heat to cure the mold, pattern costs and pattern wear can be high. Material costs are higher than for green-sand molding, and energy costs are higher than for other processes.

Shell molds are made in the following operations:

1) A pattern made of a ferrous metal or aluminum is heated to 347–698°F (175–370°C).

2) The pattern is coated with a parting agent, such as silicone.

3) It is clamped to a box or chamber that contains fine sand, mixed with 2.5–4% thermosetting resin binder (such as phenol-formaldehyde) that coats the sand particles.

4) Either the box/chamber is rotated upside down, or the sand mixture is blown over the pattern to coat it.

- 5) The assembly is placed in an oven for a short period of time to complete curing of the resin.
- 6) The shell mold hardens around the pattern.
- 7) The mold is removed from the pattern using built-in ejector pins.
- 8) The second half of the shell mold is made, using the same steps.
- 9) Once complete, the two half shells are bonded or clamped together to form the mold. Support is provided by sand or metal shot in the flask when pouring the molten metal.
- 10) After casting and cooling, the part is cleaned and trimmed.

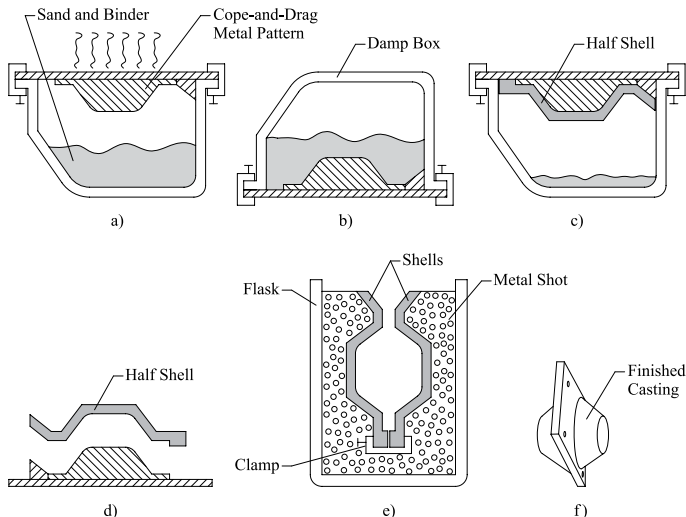

Fig. 9. Shell Molding Process, also called Dump-Box Technique: a) Pattern Heated and Clamped over a Box; b) Box Inverted; c) Box Repositioned; d) Half Shell Stripped from the Pattern; e) Shell Mold, Supported by Metal Shot in Flask, Ready for Poured Metal; f) Finished Casting

### Expendable-Pattern Casting

Sometimes referred to as a *lost foam* process, expendable-pattern casting involves using a unique mold and pattern that must be produced for every casting. The pattern used in this process is made from polystyrene foam, which is 95 percent air bubbles; the material evaporates when liquid metal is poured on it.

The pattern is made by molding. Polystyrene beads and pentane are put inside an aluminum mold and heated. The material expands to fill the mold, taking the shape of the cavity. Then the pattern is removed from the mold and used for the casting processes as follows:

- 1) The pattern is dipped in a slurry of water and clay (or other refractory grains). It is dried to form a hard shell around the pattern.
- 2) The shell-covered pattern is placed in a container with sand for support.
- 3) Liquid metal is poured into a hole at the top.
- 4) The foam evaporates as the metal fills the shell.
- 5) Upon cooling and solidification, the part is removed by breaking the shell.

This process is useful since it is very cheap, can produce complex geometry, and yields good surface finish. There are no runners, risers, gating, or parting lines. Thus, the design process is simplified. This method is used to manufacture crankshafts for engines, aluminum engine blocks, manifolds, and other parts.

### Plaster Mold Casting

Plaster mold casting produces parts with good surface finish and dimensional accuracy, and provide the capability to make parts with thin cross sections. The mold is made by mixing plaster of Paris or simple "plaster" ( $\text{CaSO}_4$ ) with talc and silica flour. This produces a fine white powder that, when mixed with water, forms a clay-like consistency and can be shaped around pattern halves in a flask and allowed to set. The mold halves are extracted carefully from the pattern and then dried in an oven at a temperature range of 248–500°F (120–260°C) to remove moisture.

The mold halves are carefully assembled to form the mold cavity and used for the casting process as follows:

- 1) The mold is preheated to about 248°F (120°C).
- 2) Molten metal is poured in the mold cavity.
- 3) After the metal is solidified and cooled, the plaster mold is broken away from the finished casting.

Plaster casts are relatively soft and not strong enough at temperatures above 2192°F (1200°C). So this method is mainly used to make castings from nonferrous metals, such as aluminum, magnesium, zinc, and copper-based alloys. It cannot be used to cast ferrous materials, because the sulfur in gypsum slowly reacts with iron. Since plaster has lower thermal conductivity, the casting cools slowly, and therefore has more uniform grain structure, with the advantages of less warpage and less residual stresses.

### Ceramic Mold Casting

Ceramic mold casting also is called *cope-and-drag investment casting*. It is similar to the plaster mold process, and the metal is cast the same way, but it uses refractory materials suitable for high-temperature applications. Ceramic mold casting uses a permanent pattern made of plastic, wood, or metal. To make the slurries for molding, fine-grained zircon ( $\text{ZrSiO}_4$ ), aluminum oxide, and fused silica are mixed with bonding agents and poured over the pattern, which has been placed in a flask.

With this process, parts may be cast that weigh as much as 1,540 lb (700 kg). Typically, it is used for impellers, cutters for machining operations, dies for metalworking, and molds for making plastic and rubber components.

The sequence of operations in making a ceramic mold is:

- 1) A pattern is placed in a flask.
- 2) A slurry is poured over the pattern to create the mold.
- 3) It is dried in a low temperature oven, and the pattern is removed.
- 4) The mold is backed by clay for strength and baked in a high-temperature oven to burn off any volatile substances.
- 5) The all-ceramic mold is firmly clamped for use in casting.

The metal is cast the same way as in plaster casting. Although this process is somewhat expensive, it is used because castings can be made that feature good dimensional accuracy and surface finish over a wide range of sizes and intricate shapes. It can be used to make very good quality castings of steel or even stainless steel and parts such as impeller blades for turbines or pumps and rotors for motorboats.

### Precision Investment Casting

Investment casting is a highly developed process that is capable of great casting accuracy and can form extremely intricate contours. The process may be utilized when metals are too hard to machine or otherwise fabricate; when it is the only practical method of producing a part; or when it is more economical than any other method of obtaining work of the quality required. Precision investment casting is especially applicable in producing either exterior or interior contours of intricate form with surfaces so located that they could not be machined readily if at all. The process provides efficient, accurate means of producing such parts as turbine blades, airplane or other parts made from alloys that have high melting points and must withstand exceptionally high temperatures, and many other products. The accuracy and finish of precision investment castings may either eliminate machining entirely or reduce it to a minimum. The quantity that may be produced economically may range from a few to thousands of duplicate parts.

Investment casting uses an expendable pattern, usually of wax or injection-molded plastics. Several wax replicas or patterns are usually joined together or to bars of wax that are shaped to form runner channels in the mold. Wax shapes that will produce pouring funnels also are fastened to the runner bars. The mold is formed by dipping the wax assembly (tree) into a thick slurry containing refractory particles. This process is known as investing. After the coating has dried, the process is repeated until a sufficient thickness of material has been built up to form a one-piece mold shell. Because the mold is in one piece, undercuts, apertures, and hollows can be produced easily. As in shell molding, this invested shell is baked to increase its strength, and the wax or plastics pattern melts and runs out or evaporates (lost-wax casting). Some molds are backed up with solid refractory material that is also dried and baked to increase the strength. Molds for lighter castings are often treated similarly to shell molds described before. Filling of the molds may take place in the atmosphere, in a chamber filled with inert gas or under vacuum, to suit the metal being cast.

**Materials That May Be Cast.**—The precision investment process may be applied to a wide range of both ferrous and nonferrous alloys. In industrial applications, these include alloys of aluminum and bronze, Stellite, Hastelloys, stainless and other alloy steels, and iron castings, especially where thick and thin sections are encountered. In producing investment castings, it is possible to control the process in various ways so as to change the porosity or density of castings, obtain hardness variations in different sections, and vary the corrosion resistance and strength by special alloying.

**General Procedure in Making Investment Castings.**—Precision investment casting is similar in principle to the “lost-wax” process that has long been used in manufacturing jewelry, ornamental pieces, and individual dentures, inlays, and other items required in dentistry, which is not discussed here. When this process is employed, both the pattern and mold used in producing the casting are destroyed after each casting operation, but they may both be replaced readily. The “dispensable patterns” (or cluster of duplicate patterns) is first formed in a permanent mold or die and is then used to form the cavity in the mold or “investment” in which the casting (or castings) is made. The investment or casting mold consists of a refractory material contained within a reinforcing steel flask. The pattern is made of wax, plastics, or a mixture of the two. The material used is evacuated from the investment to form a cavity (without parting lines) for receiving the metal to be cast. Evacuation of the pattern (by the application of sufficient heat to melt and vaporize it) and the use of a master mold or die for reproducing it quickly and accurately in making duplicate castings are distinguishing features of this casting process. Modern applications of the process include many developments such as variations in the preparation of molds, patterns, investments, etc., as well as in the casting procedure. Application of the process requires specialized knowledge and experience.

**Master Mold for Making Dispensable Patterns.**—Duplicate patterns for each casting operation are made by injecting the wax, plastics, or other pattern material into a master

mold or die that usually is made either of carbon steel or of a soft metal alloy. Rubber, alloy steels, and other materials may also be used. The mold cavity commonly is designed to form a cluster of patterns for multiple castings. The mold cavity is not, as a rule, an exact duplicate of the part to be cast because it is necessary to allow for shrinkage and perhaps to compensate for distortion that might affect the accuracy of the cast product. In producing master pattern molds there is considerable variation in practice. One general method is to form the cavity by machining; another is by pouring a molten alloy around a master pattern that usually is made of monel metal or of a high-alloy stainless steel. If the cavity is not machined, a master pattern is required. Sometimes, a sample of the product itself may be used as a master pattern, when, for example, a slight reduction in size due to shrinkage is not objectionable. The dispensable pattern material, which may consist of waxes, plastics, or a combination of these materials, is injected into the mold by pressure, by gravity, or by the centrifugal method. The mold is made in sections to permit removal of the dispensable pattern. The mold while in use may be kept at the correct temperature by electrical means, by steam heating, or by a water jacket.

**Shrinkage Allowances for Patterns.**—The shrinkage allowance varies considerably for different materials. In casting accurate parts, experimental preliminary casting operations may be necessary to determine the required shrinkage allowance and possible effects of distortion. Shrinkage allowances, in inches per inch, usually average about 0.022 for steel, 0.012 for gray iron, 0.016 for brass, 0.012 to 0.022 for bronze, 0.014 for aluminum and magnesium alloys. (See also *Shrinkage* on page 1494.)

**Casting Dimensions and Tolerances.**—Generally, dimensions on investment castings can be held to  $\pm 0.005$  in. and on specified dimensions to as low as  $\pm 0.002$  in. Many factors, such as the grade of refractory used for the initial coating on the pattern, the alloy composition, and the pouring temperature, affect the cast surface finish. Surface discontinuities on the as-cast products therefore can range from 30–300  $\mu\text{in}$  (0.76–7.6  $\mu\text{m}$ ) in height.

**Investment Materials.**—For investment casting of materials having low melting points, a mixture of plaster of Paris and powdered silica in water may be used to make the molds, the silica forming the refractory and the plaster acting as the binder. To cast materials having high melting points, the refractory may be changed to sillimanite, an alumina-silicate material having a low coefficient of expansion that is mixed with powdered silica as the binder. Powdered silica is then used as the binder. The interior surfaces of the mold are reproduced on the casting so, when fine finishes are needed, a first coating of fine sillimanite sand and a silicon ester such as ethyl silicate with a small amount of piperidine, is applied and built up to a thickness of about 0.06 in. (1.5 mm). This investment is covered with a coarser grade of refractory that acts to improve bonding with the main refractory coatings, before the back up coatings are applied.

With light castings, the invested material may be used as a shell, without further reinforcement. With heavy castings the shell is placed in a larger container which may be of thick waxed paper or card, and further slurry is poured around it to form a thicker mold of whatever proportions are needed to withstand the forces generated during pouring and solidification. After drying in air for several hours, the invested mold is passed through an oven where it is heated to a temperature high enough to cause the wax to run out. When pouring is to take place, the mold is pre-heated to between 700 and 1000°C (1292 and 1832°F), to get rid of any remaining wax, to harden the binder and prepare for pouring the molten alloy. Pouring metal into a hot mold helps to ensure complete filling of intricate details in the castings. Pouring may be done under gravity, under a vacuum under pressure, or with a centrifuge. When pressure is used, attention must be paid to mold permeability to ensure gases can escape as the metal enters the cavities.

**Casting Operations.**—The temperature of the flask for casting may range all the way from a chilled condition up to 2000°F (1093°C) or higher, depending upon the metal to be cast, the size and shape of the casting or cluster, and the desired metallurgical conditions. During casting, metals are nearly always subjected to centrifugal force vacuum, or other

pressure. The procedure is governed by the kind of alloy, the size of the investment cavity, and its contours or shape.

**Investment Removal.**—When the casting has solidified, the investment material is removed by destroying it. Some investments are soluble in water, but those used for ferrous castings are broken by using pneumatic tools, hammers, or by shot or abrasive blasting and tumbling to remove all particles. Gates, sprues, and runners may be removed from the castings by an abrasive cutting wheel or a band saw according to the shape of the cluster and machinability of the material.

**Accuracy of Investment Castings.**—The accuracy of precision investment castings may, in general, compare favorably with that of many machined parts. The overall tolerance varies with the size of the work, the kind of metal and the skill and experience of the operators. Under normal conditions, tolerances may vary from  $\pm 0.005$  or  $\pm 0.006$  inch per inch (or mm/mm), down to  $\pm 0.0015$  to  $\pm 0.002$  inch per inch (or mm/mm), and even smaller tolerances are possible on very small dimensions. Where tolerances applying to a lengthwise dimension must be smaller than would be normal for the casting process, the casting gate may be placed at one end to permit controlling the length by a grinding operation when the gate is removed.

**Casting Weights and Sizes.**—Investment castings may vary in weight from a fractional part of an ounce up to 75 lb (34 kg) or more. Although the range of weights representing the practice of different firms specializing in investment casting may vary from about  $\frac{1}{2}$  pound up to 10 or 20 lb (4.5 or 9.1 kg), a practical limit of 10 or 15 lb (4.5 or 6.8 kg) is common. The length of investment castings ordinarily does not exceed 12 or 15 in. (30 or 38 cm), but much longer parts may be cast. It is possible to cast sections having a thickness of only a few thousandths of an inch, but the preferred minimum thickness, as a general rule, is about 0.020 in. (0.50 mm) for alloys of high castability and 0.040 in. (1 mm) for alloys of low castability.

**Design for Investment Casting.**—As with most casting processes, best results from investment casting are achieved when uniform wall thicknesses between 0.040 and 0.375 in. (1 and 10 mm) are used for both cast components and channels forming runners in the mold. Gradual transition from thick to thin sections is also desirable. It is important that molten metal should not have to pass through a thin section to fill a thick part of the casting. Thin edges should be avoided because of the difficulty of producing them in the wax pattern. Fillets should be used in all internal corners to avoid stress concentrations that usually accompany sharp angles. Thermal contraction usually causes distortion of the casting, and should be allowed for if machining is to be minimized. Machining allowances vary from 0.010 in. (0.25 mm) on small, to 0.04 in. (1 mm) on large parts. With proper arrangement of castings in the mold, grain size and orientation can be controlled and directional solidification can often be used to advantage to ensure desired physical properties in the finished components.

**Casting Milling Cutters by Investment Method.**—Possible applications of precision investment casting in tool manufacture and in other industrial applications are indicated by its use in producing high-speed steel milling cutters of various forms and sizes. Removal of the risers, sand blasting to improve the appearance, and grinding the cutting edges are the only machining operations required. The bore is used as cast. Numerous tests have shown that the life of these cutters compares favorably with high-speed steel cutters made in the usual way.

### Hard Mold Casting

Hard mold casting is permanent mold casting. Two halves of a mold are made from materials such as cast iron, steel, bronze, graphite, or refractory metal alloys. The mold cavity and gating system are machined into the mold and become an integral part of it.

To produce castings with internal cavities, cores made of metal or sand aggregate are placed in the mold prior to casting. Typical core materials are oil-bonded or resin-bonded sand, plaster, graphite, gray iron, low-carbon steel, and hot-work die steel.

To increase life of permanent molds, surfaces of the mold cavity usually are coated with refractory slurry (such as sodium silicate and clay) or sprayed with graphite every few castings. These coatings also serve as parting agents, as well as thermal barriers, controlling the rate of cooling of the casting.

The molds are clamped together by mechanical means and heated to about 302–392°F (150–200°C) to facilitate metal flow and reduce thermal damage to the dies due to high temperature gradients. Then molten metal is poured through the gating system. After solidification, the molds are opened, and the casting is removed. Water or fins may be used in cooling the mold, and mechanical ejectors may be needed for removal of complex castings.

Hard mold casting is used mostly for aluminum, magnesium, copper alloys, and gray iron because of their generally lower melting points. Steels also can be cast using graphite or heat-resistant metal molds. This process produces castings with good surface finish, close dimensional tolerances, and uniform and good mechanical properties, and supports high production rates. Typical parts made are automotive pistons, cylinder heads, connecting rods, gear blanks for appliances, and kitchenware.

### Vacuum Casting

Vacuum permanent mold casting (not to be confused with vacuum molding) is similar to low-pressure permanent mold casting, except for the step of filling the mold. In this case, molten metal is sucked upward into the mold by a vacuum pump (Fig. 10).

The permanent mold is enclosed in an airtight bell housing with two openings: the sprue at the bottom, through which molten metal enters the mold, and the vacuum outlet at the top. The sprue opening is submerged below the surface of the molten metal, and the vacuum is drawn within the housing, creating a pressure differential between the mold cavity and the molten metal in the crucible. This pressure differential causes the molten metal to flow up the sprue and into the mold cavity, where it solidifies. The mold is removed from the housing and opened, and the casting is ejected.

By controlling the vacuum, the pressure differential between the mold cavity and the molten metal can be varied, allowing for different fill rates necessitated by certain part designs and gating requirements. This results in tight control of the fill rate, which directly influences soundness of the casting. Because the sprue opening is submerged beneath the surface of the molten metal, only pure alloy, free from oxides and dross, can enter the die cavity. This helps to produce clean, sound castings with minimal foreign materials that detract from strength, appearance, and machinability. With proper part and mold design, this process can greatly reduce or eliminate issues such as voids, shrinks, and gas pockets in critical areas. Typical parts made by vacuum casting include vacuum pump covers, turbine wheels, intake manifolds, and train accessories.

Fig. 10. Vacuum Casting Process a) Before Flow Up of Molten Metal into Cavity; b) After Flow Up of Molten Metal

### Slush Casting

Slush casting is a traditional method of permanent mold casting process in which the molten metal is not allowed to completely solidify in the mold. When the desired thickness is obtained, the remaining molten metal is poured out. This permanent mold casting process can be used to create hollow castings with thin walls, based on the principle that a solidified skin develops first in a casting and becomes thicker with time.

A disadvantage of slush casting is that the casting internal geometry cannot be effectively controlled. But good surface finish and accurate external geometry are possible. Suitable for small production runs, slush casting generally is used for making ornamental and decorative objects, including lamp bases and stems, and toys from metals with low melting temperatures, such as zinc, tin, and lead alloys.

The sequence of operations in slush casting is as follows:

- 1) The molten metal is poured into the metal mold.
- 2) After the desired thickness of the solidified skin is obtained, the mold is inverted, and the remaining molten metal is poured out.
- 3) Upon solidification and cooling, the mold halves are opened, and the casting is removed.

### Pressure Casting

Another variation of permanent mold casting is pressure casting, also known in industry as *low-pressure casting* or *pressure pouring* (Fig. 11). Instead of pouring molten metal into the mold and gravity distributing it throughout the mold, pressure casting uses air (gas) pressure to force the liquid metal through the gating system and the metal casting's cavity.

As in other permanent mold methods, the mold needs to be able to open and close for removal of the workpiece, so complicated casting geometry is limited. However, since the refractory tube is submerged in the molten metal and the metal drawn up into the casting comes from well below the surface, the risk of gas entrapment in the metal and oxidation are greatly reduced. The sequence of operations in pressure casting is as follows:

- 1) The molten metal is forced upward by gas pressure into the graphite or metal mold through the refractory tube, using an overpressure by air of about 12 to 15 psi (0.08 to 0.1 MPa).
- 2) Pressure is maintained until the metal has solidified completely in the mold.

Pressure casting can be used to produce metal castings with superior mechanical properties, good surface finish, and close dimensional accuracy. High setup costs make pressure casting inefficient for mass runs, but excellent productivity rates make it suitable for batch manufacture. This process can be used to cast high-quality manufactured parts. Steel castings, such as railroad car wheels, often are cast in graphite molds using this method.

Fig. 11. Low-Pressure Casting Process

### Die Casting

Die casting is a commonly used type of permanent mold casting process used for producing many components of home appliances, such as stoves, fans, washing machines, dryers, refrigerators; various kinds of motors; toys; and hand tools. Die casting molds, commonly called *dies*, are expensive and require significant lead time to fabricate. However, surface finish and tolerance of die cast parts are so good that there is almost no post-processing required. There are two common types of die casting: hot- and cold-chamber die casting.

**Advantages of Die Casting:** Depending on the casting material, excellent dimensional accuracy can be achieved—typically within 0.005 in. for the first inch (0.127 mm for the first 25 cm) and 0.002 in. for each additional inch (0.051 mm for additional 25 cm). Compared with sand and permanent mold casting, parts can have thinner walls (approximately 0.030 in. or 0.76 mm). Inserts, such as threaded inserts, heating elements, and high-strength bearing surfaces, can be cast in. Casting tensile strength may be as high as 60 ksi (414 MPa). Smooth cast surfaces of 40–100  $\mu\text{in}$  (1–2.5  $\mu\text{m}$ ) Ra reduce or eliminate secondary machining operations. And rapid production rates can be achieved.

**Disadvantages of Die Casting:** Both the casting equipment required and the die components are very costly, so large production volume is needed to make this process economical. The process is limited to high-fluidity metals. Casting weight must be under 24 in. (600 mm) in size and weight between 1 oz (28 g) and 20 lb (9 kg). Parts that need to be hardened and tempered cannot be cast in dies.

Another consideration of the standard die casting process is that the final casting will have a small amount of porosity. This does not accommodate heat treatment or welding, because heat causes gas in the pores to expand, which causes micro-cracks inside the part and exfoliation of the surface. Thus, a related disadvantage of die casting is that it is only suitable for parts in which softness is acceptable.

**Hot-Chamber Process.**—Hot-chamber die casting is one of the two main techniques in the manufacturing process of die casting. A characteristic common to both die casting processes is the use of high pressure to force molten metal through a mold. Advantageous characteristics of manufacturing by die casting, such as a smooth casting surface, can be attributed to the use of pressure to ensure the flow of metal through the die. In hot-chamber die casting (Fig. 12), the die is attached to the casting machine and an integral part of the casting equipment.

Fig. 12. Hot-Chamber Die Casting Process: a) Die Is Closed, Plunger Is in Contact with Molten Metal in Start Position; b) Plunger Forces Metal in Chamber to Flow into Die Cavity, Maintaining Pressure During Solidification; After Plunger Is Withdrawn, Die Is Opened, and Casting Is Ejected

The hydraulic cylinder of the casting machine over the plunger rod provides power to the plunger, which is in contact with the molten metal. At the start of the casting cycle, the plunger is at the top of the hot chamber. As the cycle begins, the hot chamber is filled with liquid metal through the intake port. When the casting machine's hydraulic cylinder forces the plunger downward, it travels past the intake port, cutting off the flow of molten metal to the hot chamber and ensuring the correct amount of molten metal is

in the chamber to fill the cavity of the mold. In preparation for the next cycle of casting, the plunger travels back upward and opens the intake port in the hot chamber, again allowing the chamber to fill with molten metal. Hot-chamber die casting has a high rate of productivity.

Typical materials used in hot-chamber die casting are zinc, lead, and magnesium alloys and other low melting alloys. Common applications of hot-chamber die casting parts include housings with thin walls, often requiring many ribs.

**Cold-Chamber Process.**—Cold-chamber die casting is a permanent mold casting process. Large, robust machines are used to exert the great clamping force necessary to hold the mold closed against very high pressure during the manufacturing process. A metal cold chamber is located at the entrance of the mold. A piston is connected to this chamber, which, in turn, is connected to a power cylinder. At the start of the process, the correct amount of molten metal for a single part is poured into the shot chamber from an external source holding the metal for the cast.

When the power cylinder forces the piston forward in the chamber, it cuts off the intake port. The piston forward forces molten metal into the casting mold cavity with high pressure, which is maintained during solidification. After solidification, the pressure is released, the mold is opened, and the casting is removed using ejector pins.

In comparison with hot-chamber die casting, cold-chamber die casting uses higher pressure to force molten metal into the die cavity. Pressures as high as 3000–50000 psi (21 MPa–345 MPa) may be used. Fig. 13 illustrates the cold-chamber die casting process.

Cold-chamber die casting is ideal for metals with high melting points and corrosive properties, such as aluminum alloys and other alloys with high melting points. This process is used for several automobile components, including pistons, cylinder heads, and engine blocks. Other common die cast parts are propellers, gears, bushings, pumps, and valves.

Fig. 13. Cold-Chamber Die Casting Process: a) Die is Closed, Plunger Withdrawn, and Molten Metal is Poured into Chamber; b) Plunger Forces Metal in Chamber to Flow into Die Cavity, Maintaining Pressure During Solidification; After Plunger is Withdrawn, Die is Opened, and Casting is Ejected

### Centrifugal Casting

As the name suggests, this process involves using a centrifugal force (high-velocity spinning action) to exert pressure on molten metal as it is poured into a die. The die can be set to spinning on a horizontal or vertical axis, depending on the structure required. Usually, a horizontal axis machine is used for long, thin cylinders, and vertical axis machines are used for rings.

This method of casting, also known as liquid forging, is used to manufacture high-integrity cylindrical components, and therefore is a technology of choice for pipes, tube, bearings, rolls, bushes, ball valves, and cylinder liners. Notably, it is used to cast cylinder liners and sleeve valves for piston engines, parts that cannot reliably be manufactured otherwise. Wall thickness of parts can be varied to suit specific needs; this thickness is controlled by the amount of molten metal that is poured, making the centrifugal casting system highly flexible to individual requirements.

Fig. 14. True Centrifugal Casting

There are numerous advantages of centrifugal casting. The force used to distribute the molten metal as it is poured is so strong that it displaces lighter oxides and impurities to the center of the hollow cylinder; it is then easy to remove these impurities during machining. Blowholes, sand residue, hard spots, cavities, and porosity are virtually eliminated, and the resulting uniformity means machining time and material waste are significantly reduced. Due to the finer grain and denser structure of parts cast with centrifugal force, the part's usage life, endurance, and ability to withstand impact without fracturing are increased. The centrifugal process also allows economical production of a wide range of sizes, shapes, and quantities.

Thus, centrifugal casting produces quality parts, reduces manufacturing costs, and provides production flexibility. There are three types of centrifugal casting: true centrifugal casting, semicentrifugal casting, and centrifuge casting.

**True Centrifugal Casting.**—In this technique, molten metal is poured into a rotating mold. The axis of rotation usually is horizontal but can be vertical for short workpieces. (One setup is illustrated in Fig. 14.) Molds are made of steel, iron, or graphite and may be coated with a refractory lining to increase mold life. Mold surfaces can be shaped so that pipes with various external designs can be cast. Cylindrical parts ranging from 0.6 in. to 10 ft. (15 mm to 3 m) in diameter and 52 ft. (16 m) in length can be cast centrifugally, with wall thicknesses ranging from 0.24 to 5 in. (6 to 127 mm).

True centrifugal casting produces parts of good quality, dimensional accuracy, and external surface detail; better mechanical properties can be achieved than in conventional static casting. Non-metallic impurities segregate toward the bore and can be machined off. There is less loss of metal as compared with conventional sand casting. The casting is relatively free from defects, there are no parting lines, and production rates are high. This process is used to produce hollow cylindrical parts, such as pipes, gun barrels, bushings, bearing rings, and streetlamp posts; bimetallic tubes can be made.

Consider how fast the mold must rotate in horizontal centrifugal casting for the process to work successfully. Centrifugal force acting on a rotating body is defined by the following equation:

$$F_c = \frac{mv^2}{R} \quad (9)$$

where  $F_c$  = centrifugal force;  $m$  = mass;  $v$  = velocity; and  $R$  = inside radius of the mold.

Gravitational force is its weight:

$$F_g = mg \quad (10)$$

where  $F_g$  = gravitation force;  $m$  = mass; and  $g$  = acceleration of gravity.

Velocity  $v$  can be expressed as:

$$v = \frac{2\pi RN}{60} = \frac{\pi RN}{30} \quad (11)$$

where  $N$  = rotation speed.

The G-factor is the ratio of centrifugal force divided by gravitation force:

$$GF = \frac{F_c}{F_g} = \frac{mv^2}{R \cdot mg} = \frac{v^2}{Rg} \quad (12)$$

where  $GF$  = gravitation factor.

Solving further, we get:

$$N = \frac{30}{\pi} \sqrt{\frac{2gGF}{D}} = 42.3 \sqrt{\frac{GF}{D}} \quad (13)$$

where  $D$  = inside diameter of the mold.

If the G-factor is too low in centrifugal casting, the liquid metal will not remain forced against the mold wall during the upper half of the circular path but will drop inside the cavity. Too high a speed results in excessive stresses and hot tears in the outside surface of the casting. On an empirical basis,  $GF = 50$  to  $100$  for a metal mold, and  $GF = 25$  to  $50$  for a sand cast mold.

**Semicentrifugal Casting.**—During semicentrifugal casting (Fig. 15), the mold is rotated around its axis of symmetry. The molds used can be permanent or expendable and may contain cores. The detailed shape is given by the shape cavity of the rotating mold. The mold is designed with risers in the center to supply the feed metal.

Centrifugal force is utilized for refilling of melt metal, increase of the filling power in order to cast parts with thin walls, and slag separation. In general, the rotational speed is lower than speeds used in true centrifugal casting—usually it is set so that a G-factor of around 15 is obtained. As this process produces parts in which the central zone (near the axis of rotation) usually has inclusion defects, it is suitable only for parts where these can be machined away, such as cogwheels.

Fig. 15. Semicentrifugal Casting

**Centrifuge Casting.**—The third type of centrifugal casting, centrifuge casting (see Fig. 16) involves molds arranged about the central sprue at the same distance from the center of the axis of rotation. These molds contain all necessary geometry for the cast part, as well as the gating system. During the pouring phase, molten metal is introduced into the central sprue and then travels via runners to the entrance of each mold.

When an object is rotated, force is produced that acts directly away from the center of the axis of rotation. As the centrifuge spins, centrifugal force pushes the metal outward from the center, through the runners into the molds. Once the correct amount of molten metal for the casting is poured and distributed into the molds, the apparatuses continue to rotate while solidification occurs. After the castings have completely solidified, the apparatuses will stop rotating, and the parts can be removed.

Use of centrifugal force helps control specific properties of the cast parts. The method is extensively used for casting smaller parts, including casting gold crowns for teeth in the dental industry.

### Squeeze Casting

Squeeze casting (Fig. 17) combines casting and forging technologies. In contrast to other casting techniques in which a molten metal is poured or injected into the mold cavity after the two parts of the mold are assembled, a squeeze casting mold is closed *after* a portion of molten metal has been poured into the preheated bottom die. The applied pressure and instant contact of the molten metal with the die surface produce a rapid heat transfer condition that yields a pore-free, fine-grain casting with mechanical properties approaching those of a wrought product. Squeeze casting is easily automated to produce near-net to net shape high-quality components.

Because of the high pressure applied during solidification, porosities caused by both gas and shrinkage can be prevented or eliminated. The cooling rate of the casting can be increased by applying high pressure during solidification, since that contact between the casting and the die is improved by pressurization, which results in the formation of fine-grained structures.

With the current emphasis on reducing materials consumption through virtually net shape processing and the demand for higher-strength parts for weight savings, the emergence of squeeze casting as a production process has given materials and process engineers an alternative to traditional approaches to casting and forging. By pressurizing liquid metals while they solidify, near-net shapes can be achieved in sound, dense castings. Squeeze casting is simple and economical, efficient in its use of raw material, has excellent potential for automated operation at high rates of production, and achieves the highest mechanical properties attainable in a cast product. The microstructural refinement and integrity of squeeze cast products are desirable for many critical applications.

Fig. 17. Sequence of Operations in Squeeze Casting Process: a) Pouring Molten Metal in Die; b) Closing Die and Applying Pressure; c) Casting Ejecting

The origins of squeeze casting can be traced back to squeeze forming, which is a process structured in three phases:

- 1) Pouring a known amount of molten metal in a preheated die cavity placed at a lower plate of a press.
- 2) Closing the die, pressurizing the liquid metal, and maintaining the pressure until complete solidification.
- 3) Casting ejecting and handling are done in much the same way as in closed die forging.

As shown in Fig. 17, squeeze casting consists of liquid metal entering a preheated, lubricated die and pressurizing the metal while it solidifies. The load is applied shortly after the metal begins to set and is maintained until the entire casting has solidified. A number of variables can be controlled to influence the soundness of the castings.

### Design Considerations for Casting

When designing cast metal components, several characteristics are inherent in the pouring and solidification of the alloy and its interaction with the mold. These characteristics define the parameters within which the designer can work and affect the casting method chosen, design of casting sections and junctions between sections, surface integrity and appearance, internal integrity of the cast alloy, and dimensional accuracy.

Carefully planned casting geometry allows the foundry to work with the known pouring and solidification characteristics to produce high-quality castings that perform to required specifications, while avoiding costly and time-consuming problems. By understanding the interaction between casting geometry, the material (in both liquid and solid forms), and the casting process, design engineers can anticipate and avoid many iterations to their product design that could otherwise interfere with and delay progress of a project. The following geometry/material/process interactions dictate good casting design.

*Fluid Life:* This refers to the liquid characteristics of the material that give it the ability to flow freely throughout the mold, along narrow sections and into fine surface detail. Fluid life depends on temperature and the unique chemical and metallurgical properties of each metal. At least in part, it determines minimum wall thickness and how long a thin section can be. So, the designer's choice of alloy, with its associated fluid life, will dictate certain structural and aesthetic elements of the design.

*Solidification Shrinkage:* As molten metal cools, shrinkage occurs in three distinct stages: liquid shrinkage, liquid-to-solid shrinkage, and solid shrinkage. Solid shrinkage is the continued shrinkage that occurs as the metal casting cools to ambient temperature in its solid state. Known as "patternmaker's shrinkage," it must be compensated for within the tooling or mold design to ensure that specified final overall dimensions are achieved.

*Slag/Dross Formation:* Some metals are more susceptible to slag and dross formation than others, so are more likely to have small, rounded, non-metallic inclusions within the casting. Design, along with quality and process control, can reduce the quantity and effect of inclusions. Where buoyant slag/dross is likely, a designer may ensure that important surfaces or those to be machined sit low in the mold. With awareness of the likelihood of slag/dross formation for a specific alloy, the foundry engineer can set up the running system (sprues, runners, and gates) to minimize oxidation caused by turbulent flow or entrained air.

*Pouring Temperature:* Pouring temperature can have a significant effect, particularly when the molten metal approaches the mold material's refractory limit. It is important to note that the concentration of heat in one area can cause problems even with some lower temperature alloys. Better geometry design can help heat dissipate into the mold and alleviate such issues.

*Fluid Flow:* Designers should take in account the flow rate of molten metal entering the mold and issues this can cause. A balance needs to be struck between the need to get

the alloy into the mold quickly to avoid oxidization and dross formation, while avoiding turbulence, wall erosion, and core displacement that can occur at higher fluid speeds. Although not altogether preventable in the manufacturing process, turbulence can be reduced by using a gating system that promotes a more laminar flow of the liquid metal. Turbulence caused by sharp corners and abrupt changes in sections within the casting may be mitigated by employing radii (Fig. 18).

Fig. 18. Design Modification to Avoid Abrupt Changes in Sections within Metal Casting: a) Incorrect; b) and c) Correct

The designer also must be aware that fluid flow can introduce unacceptable thermal gradients, particularly if metal flows around a core and rejoins elsewhere in the mold. Designing the casting geometry and running system at the same time can help identify and eradicate these issues.

*Heat Transfer Considerations:* Management of heat within a mold is an important part of the geometry design. At high pouring temperatures, considerable heat must be transferred into the mold in a way that avoids creation of localized hot spots, where the heat cannot efficiently dissipate. This can occur on narrow peninsulas or tight corners, where molten metal surrounds thin areas of the mold. The retained heat slows solidification in that area that can lead to hot tears or pulls—particularly if the geometry design has introduced stress buildup during solid shrinkage, as the softer metal in the hot spot will have lower tensile strength.

As mentioned earlier, directional solidification is important to the manufacture of a part during the metal casting process, in order to ensure that no area of the casting is cut off from the flow of liquid material before it solidifies. To achieve directional solidification within the casting, it is important to control the flow of molten metal and the solidification rate of the different areas of the metal casting. Regulation of thermal gradients is key.

Sometimes there is an area of a metal casting that needs to solidify at a faster rate to ensure proper directional solidification. Planning sections effectively and regulating flow rates within the mold may not be sufficient. To accelerate solidification of a particular section, it may be necessary to employ the use of chills, which act as heat sinks, increasing the cooling rate in the vicinity where they are placed.

Chills are solid geometric shapes of material, manufactured for this purpose. Chills are of two basic types. Internal chills are located inside the mold cavity and usually are made of the same material as the casting. When the metal solidifies, internal chills are fused into the metal casting itself. External chills are located just outside the casting. They are made of a material that can remove heat from the metal casting faster than the surrounding mold material. Possible materials for external chills include iron, copper, and graphite. Fig. 19 demonstrates the use of the two types of chills to solve a hot-spot problem in cross and T junctions.

Designers should remember that thermal inequalities also can occur in the opposite direction if a sharp corner is surrounded by mold material. In this case, rather than a hot spot forming, the area will cool rapidly, which can cause cold cracking and other issues.

Fig. 19. Two Types of Chills: a) Cross Junction with Internal Chill; b) "T" Junction with External Chill

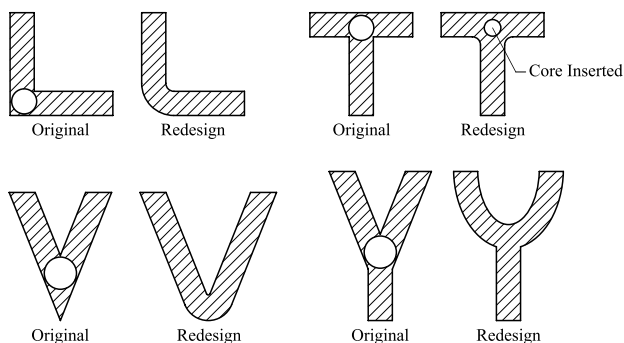

Fig. 20. Redesigned Casting Parts to Avoid Hot Spot and Fillet

**Joint Design Consideration.**—The design of a junction in a casting can cause shrinkage cavities to form. In Fig. 20, L, T, V, and Y junctions are shown. The thickness of the casting here is consistent, though at the center of the junction, there is an area where the casting's solidification is slower than the rest of the junction. These hot spots, circled in the figure, are located such that the material around them, which will undergo solidification first, will cut off the hot spots from the flow of molten metal.

The flow of casting material must be carefully considered when manufacturing such junctions. If there is flexibility in the design of the casting, the designer may want to think about redesigning the junction. Some possible design alternatives are shown in Fig. 20 that should reduce formation of hot spots and shrinkage porosity.

**Location of the Parting Line.**—A parting line in industrial casting of molds is the borderline in which draft angles change direction. That is, it is the dividing line that splits the core and cavity halves of a molded part and is sometimes a starting point for the mold parting surface. In engineering drawings, a parting line is often abbreviated as PL; ASME's Y14.8 standard specifies a symbol.

The parting line of a casting must be determined early in the design processes. In deciding on its location, the part designer and die cast engineer should work together to consider its influence on part functionality, draft angle, wall thickness, metal flow, casting integrity, and tolerances. Often, it is useful to have most geometry in the ejector half; this prevents the casting from sticking in the cover half. Cosmetic surfaces typically are placed on the cover side.

Gates, overflows, and vents will connect to the casting at the parting line. Also, flash will form at the parting line when the pressure from the injected metal tries to force the die halves apart. During the trimming process, the gates, overflows, vents, and flash will have to be removed by the trim die; a well-designed parting line will ease the trimming process.

When flash occurs, it increases the thickness of the parting line, altering dimensions measured across this line. For critical dimensions, it is important to have measurements in only one die half to reduce dimensional tolerance.

The parting line also can affect the life of the die. Metal injected straight onto a surface will erode that surface faster. Designating a parting line that follows the contours of the design and so that metal will flow more smoothly helps to optimize die life, casting quality, and aesthetics of a die cast part.

Since parting lines will be noticeable as a bump on the surface of the part, they should not be located on a sliding surface. Similarly, parting lines should not be located on a sealing surface, where a bump or mismatch would prevent the seal from making complete

contact. The placement of the parting line and orientation of the part determine the number of cores needed, and it is preferable to avoid using cores when possible.

**Location and Design of a Gating System.**—The gating system must be designed to accomplish extremely careful transport of the liquid metal to the mold cavity. Gating system location is defined based on the geometry of the mold, method of casting, and economic aspects. The gating system includes the pouring cup, sprue, risers, runners, and gates. Fig. 21 shows a schematic illustration of a typical gating system in gravity casting.

**Pouring Cup Design:** At the top of the sprue, a *pouring cup* or *pouring basin* is often used to minimize splash and turbulence as metal flows into the sprue. The design of the pouring cup, for an optimal casting process, needs to be such that it can keep the sprue full of molten metal throughout the pour. A constant level of molten metal in the pouring cup is important for a successful casting process; also, if the level of molten metal is maintained in the pouring cup during pouring, then any dross will float and will not enter the mold cavity.

Fig. 21. Typical Riser-Gated Casting

**Sprue Design:** The design of the pouring cup and sprue can affect turbulence. For best results, these should be designed so that the sprue is kept full of molten metal throughout pour. A sprue tapered to a smaller size at its bottom will create a choke, which will help keep the sprue full of molten metal. If a non-tapered sprue is used, a choke can be added when making the runners; it is necessary to have the choke as close as possible to the bottom of the sprue.

A choke also will increase the speed of the molten metal, which is undesirable. To address this problem, an enlarged area at the bottom of the sprue, called a *sprue base*, can be added to decrease the speed of the molten metal. There are two basic types of sprue bases, *enlargement* and *well*. The general rules of thumb for enlargement bases are: the diameter is roughly 2.5 times the width of the runners; the depth is equal to the depth of the runners. The general rules for well bases are: the depth of a well base is twice that of the runners; the cross-sectional area of the base is 5 times the cross-sectional area of the sprue. The bottom of the sprue base should be flat, not rounded like a bowl, or it will cause turbulence in the metal.

**Runner Design:** One of the most important things to keep in mind when designing runners and gates is to avoid sharp edges. Any changes in direction or cross-sectional area should make use of rounded corners. Also make sure the runners and gates are well rammed and smooth; this helps avoid sand erosion and turbulence.

To ensure that metal is not flowing too fast in the runners, the cross-sectional area of the runners should be greater than the area of the choke. And the walls of the runners should be as smooth as possible to avoid causing turbulence. The runners should be filled with metal before the gates; one way to ensure this happens is to put the runners in the drag and the gates in the cope. If a choke is needed in the runner to restrict flow, it should be at least 6 in. (152 mm) from the first gate. The cross-sectional area of runners should decrease as the gates come off them to keep the same gating ratio.

For example, a good gating ratio for aluminum is 1:4:4. The 1 is the cross-sectional area of the choke; the first 4 is the total cross-sectional area of the runners (measured after the choke but before the first gate); and the final 4 is total cross-sectional area of the gates. For example, for a tapered sprue with an exit area of  $0.5 \text{ in}^2$  ( $322 \text{ mm}^2$ ) and two runners with

two gates from each runner, the total runner area should be  $2 \text{ in}^2$  ( $1290 \text{ mm}^2$ ), so that each runner would be  $1 \text{ in}^2$  ( $645 \text{ mm}^2$ ). The total gate area should be  $2 \text{ in}^2$  ( $1290 \text{ mm}^2$ ), and there are four gates, so each gate would have an area of  $0.5 \text{ in}^2$  ( $322 \text{ mm}^2$ ). The gate calculation only works this way if there are an equal number of gates on each runner; if not, divide the area of the runner by the number of gates on that runner to get the area of each gate.

The area of the runners should be reduced just after a gate by an amount equal to the area of that gate. This ensures that each gate in the system will have the same flow of metal, even if it is farther from the sprue. The first bit of metal poured is most likely to be contaminated by air and sand entrapment. A runner extension can be used to prevent this metal from going into the mold cavity; this extension will have the same area as that of the last gate on that runner.

**Riser Design:** Risers are important to ensure a flow of molten metal to the part being cast as it is starting to solidify. Basically, a riser is a vertical portion of the gating system (similar to a straight sprue) that stores the molten metal until it is needed by the casting.

As molten metal solidifies, it shrinks. If it does not have a source of more molten metal to feed it as it shrinks, there will be defects in casting; a riser's purpose is to provide that extra molten metal. This means the metal in the riser must stay liquid longer than metal in the part being cast. Without a riser, heavier parts of the casting will have shrinkage defects, either on the surface or internally.

A riser may be required for every hot spot in a cast part. (In other words, the part of the casting that solidifies last, usually an area with a larger volume of metal.) The risers can be attached to the top or the side of a part. They also may be *blind risers*, which are completely contained in the mold and not open to the air; blind risers cool slower and thus will stay liquid longer. No matter where it is located, any gate that connects a riser to the casting must not be too small; however, it should be as short as possible (preferably half the diameter of the riser), else the material in the gate will solidify too soon and prevent metal in the riser from reaching the casting.

Risers may be upstream from the casting in the runner/gate system. In this case, the metal must flow through the riser prior to reaching the casting. After the pour is completed, the metal in the riser will be hotter than the metal in the casting.

Risers also may be placed downstream, after the casting. Metal flows through the casting to get to the riser, so the metal in the riser will be cooler than the metal in the casting. This could cause a problem if the metal in the casting feeds the riser as it cools.

It is necessary for the metal in the riser to solidify last. Since the more surface area something has, the faster it cools, the surface area of the riser should be minimized for a given volume. The optimum shape for a riser would be a sphere, but that is not an easy shape to mold; next best is a cylinder, which is easier. Ideally, the cylinder's height should be somewhere between one-half and one-and-a-half times the diameter. If possible, the bottom (and top if it is a blind riser) should be spherical or bowl-shaped to help the metal stay molten longer.

### Using Computer Modeling to Optimize Casting Processes

In today's global manufacturing environment, time is money. Casting buyers want foundries to deliver quality cast components with short lead times, regardless of the number of steps in the component's production cycle. To this end, foundries must take a greater role in the initial design of cast components, as well as gating/riser design. The one tool that has become indispensable to foundries when working with their customers to achieve an optimized casting design with minimal lead times is computer modeling. Using solid models, finite element and fatigue analysis, and casting process modeling, foundry workers can make numerous no-cost design revisions on the computer screen.

For most foundries, computer modeling focuses on casting process modeling. This analysis ensures proper mold filling and solidification of the component. However, as foundries have begun to embrace casting process modeling, uses of this analytic tool have expanded.

**Modeling Optimization at Design Conception.**—Some foundries become involved in the design of cast components at conception. In such cases, the foundry is able to optimize a cast component's structure and manufacturability from the beginning of the process, instead of reengineering later in the process. Two computer-aided engineering analysis methods used to optimize the structure of cast components and process of metal casting from conception are topology optimization and multidisciplinary response surface optimization. Both methods utilize casting modeling as the foundation for design iterations.

*Topology Optimization:* This method of layout optimization is most effectively employed in early stages of the design process, ideally at the start. In topology, the only input required is a layout of the package space, a definition of the loads and constraints on the structure, and a mass target. The optimization process starts with a uniform topology (uniform mass distribution) and then modifies the topology to minimize the compliance of the structure. In other words, the mass is moved around in the package structure to achieve the stiffest design for a given mass target. Multiple loading conditions can be input, as well as weighing factors.

Topology optimization can quickly provide information to the design engineer as to the optimal layout of the mass, before concept designs are even developed. This can reduce the number of iterations significantly during design, since optimal part configuration will be known in the beginning. If used on existing designs, the process may be used to reduce structural weight and optimize performance while maintaining mass.

*Multidisciplinary Response Surface Optimization:* This optimization method is used in the conceptual design stage to ensure manufacturability of design. Using solidification modeling, it can increase the quality of casting and productivity of foundries. The steps involved are:

- 1) Set up the optimization problem, including the definition of the baseline problem and a description of the component geometry (finite element, finite difference mesh, material properties, etc.).
- 2) Define process variables and constraints, including fill rates, mold temperatures, etc.
- 3) Define shape variables and constraints.
- 4) Define the objective function (such as minimizing porosity or solidification time)—the key to optimization.
- 5) Set the input parameters, including a solidification modeling input deck.
- 6) Submit the analysis to the solver system (software) and perform an initial run.
- 7) Compare the results of this analysis with the objective function.

In the last step, if the convergence criteria for the objective function are met, the result will be an optimized process. If the criteria are not met, the process will repeat itself. The optimization software then will reconfigure the input and launch a new analysis. The software controls the input of the analysis each time after checking the results of the previous run. The greater the number of variables, the greater number of iterations are required.

The goal of computer modeling is to make the casting right the first time. By first making design changes on a computer, foundries save time and production costs. As the demand for shorter lead times continues, foundries taking the "cast and see" approach without computer modeling analysis will find it difficult to compete.

### Extrusion of Metals

Extrusion is a metalworking process used to produce long, straight semifinished products such as bars, tubes, solid and hollow sections, wire and strips by squeezing a solid slug of metal, either cast or wrought, from a closed container through a die. An analogy to the process is the dispensing of toothpaste from a collapsible tube.

During extrusion, compressive and shear, but no tensile, forces are developed in the stock, thus allowing the material to be heavily deformed without fracturing. The extrusion

process can be performed at either room or high temperature, depending on the alloy and method. Cross sections of varying complexity can also be produced, depending on the materials and dies used.

In the specially constructed presses used for extrusion, the load is transmitted by a ram through an intermediate dummy block to the stock. The press container is usually fitted with a wear-resistant liner and is constructed to withstand high radial loads. The die stack consists of the die, die holder, and die backer, all of which are supported in the press end housing or platen, which resists the axial loads.

The following are characteristics of different extrusion methods and presses:

- 1) The movement of the extrusion relative to the ram. In "direct extrusion," the ram is advanced toward the die stack; in "indirect extrusion," the die moves down the container bore
- 2) The position of the press axis, which is either horizontal or vertical
- 3) The type of drive, which is either hydraulic or mechanical
- 4) The method of load application, which is either conventional or hydrostatic

In forming a hollow extrusion, such as a tube, a mandrel integral with the ram is pushed through the previously pierced raw billet.

*Cold Extrusion:* Cold extrusion has often been considered a separate process from hot extrusion; however, the only real difference is that cold or only slightly warm billets are used as starting stock. Cold extrusion is not limited to certain materials; the only limiting factor is the stresses in the tooling. In addition to the soft metals such as lead and tin, aluminum alloys, copper, zirconium, titanium, molybdenum, beryllium, vanadium, niobium, and steel can be extruded cold or at low deformation temperatures. Cold extrusion has many advantages, such as no oxidation or gas/metal reactions; high mechanical properties due to cold-working if the heat of deformation does not initiate recrystallization; narrow tolerances; good surface finish if optimum lubrication is used; fast extrusion speeds can be used with alloys subject to hot shortness. Examples of cold extruded parts are collapsible tubes, aluminum cans, fire extinguisher cases, shock absorber cylinders, automotive pistons, and gear blanks.

*Hot Extrusion:* Most hot extrusion is performed in horizontal hydraulic presses rated in size from 250 to 12,000 tons. The extrusions are long pieces of uniform cross sections, but complex cross sections are also produced. Most types of alloys can be hot extruded.

Owing to the temperatures and pressures encountered in hot extrusion, the major problems are the construction and the preservation of the equipment. The following are approximate temperature ranges used to extrude various types of alloys:

magnesium, 650–850°F (343–454°C)	aluminum, 650–900°F (343–482°C)	copper, 1200–2000°F (649–1093°C)
steel, 2200–2400°F (1204–1316°C)	titanium, 1300–2100°F (704–1149°C)	
refractory alloys, up to 4000°F (2204°C).	nickel 1900–2200°F (1038–1204°C)	

In addition, pressures range from as low as 5000 psi (34.5 MPa) to over 100,000 psi (690 MPa). Therefore, lubrication and protection of the chamber, ram, and die are generally required. The use of oil and graphite mixtures is often sufficient at the lower temperatures; while at higher temperatures, glass powder, which becomes a molten lubricant, is used.

*Extrusion Applications:* The stress conditions in extrusion make it possible to work materials that are brittle and tend to crack when deformed by other primary metalworking processes. The most outstanding feature of the extrusion process, however, is its ability to produce a wide variety of cross-sectional configurations; shapes can be extruded that have complex,

nonuniform, and nonsymmetrical sections that would be difficult or impossible to roll or forge. Extrusions in many instances can take the place of bulkier, more costly assemblies made by welding, bolting, or riveting. Many machining operations may also be reduced through the use of extruded sections. However, as extrusion temperatures increase, processing costs also increase, and the range of shapes and section sizes that can be obtained becomes narrower.

While many asymmetrical shapes are produced, symmetry is the most important factor in determining extrudability. Adjacent sections should be as nearly equal as possible to permit uniform metal flow through the die. The length of their protruding legs should not exceed 10 times their thickness.

The size and weight of extruded shapes are limited by the section configuration and properties of the material extruded. The maximum size that can be extruded on a press of a given capacity is determined by the "circumscribing circle," which is defined as the smallest diameter circle that will enclose the shape. This diameter controls the die size, which in turn is limited by the press size. For instance, the larger presses are generally capable of extruding aluminum shapes with a 25 in. (63.5 cm) diameter circumscribing circle and steel and titanium shapes with about 22 in. (55.9 cm) diameter circle.

The minimum cross-sectional area and minimum thickness that can be extruded on a given size press are dependent on the properties of the material, the extrusion ratio (ratio of the cross-sectional area of the billet to the extruded section), and the complexity of shape. As a rule, thicker sections are required with increased section size. The table gives approximate minimum cross section and thickness of some commonly extruded metals.

Material	Minimum Cross Section		Minimum Thickness	
	in <sup>2</sup>	mm <sup>2</sup>	in	mm
Carbon and alloy steels	0.40	258	0.120	3
Stainless steels	0.45 - 0.70	290 - 452	0.120 - 0.187	3.0 - 4.8
Titanium	0.50	323	0.150	3.8
Aluminum, Magnesium	< 0.40	< 258	0.040	1.0

Extruded shapes minimize and sometimes eliminate the need for machining; however, they do not have the dimensional accuracy of machined parts. Smooth surfaces with finishes better than 30  $\mu\text{in.}$  (0.762  $\mu\text{m}$ ) rms are attainable in magnesium and aluminum; an extruded finish of 125  $\mu\text{in.}$  (3.175  $\mu\text{m}$ ) rms is generally obtained with most steels and titanium alloys. Minimum corner and fillet radii of  $\frac{1}{64}$  in. (0.39 mm) are preferred for aluminum and magnesium alloys; while for steel, minimum corner radii of 0.030 in. (0.76 mm) and fillet radii of 0.125 in. (3.175 mm) are typical.

*Extrusion of Tubes:* In tube extrusion, the metal passes through a die, which determines its outer diameter, and around a central mandrel, which determines its inner diameter. Either solid or hollow billets may be used, with the solid billet being used most often. When a solid billet is extruded, the mandrel must pierce the billet by pushing axially through it before the metal can pass through the annular gap between the die and the mandrel. Special presses are used in tube extrusion to increase the output and improve the quality compared to what is obtained using ordinary extrusion presses. These special hydraulic presses independently control ram and mandrel positioning and movement.

## POWDER METALLURGY

### Introduction

Powder metallurgy (PM) is a process for forming metal parts by heating compacted metal powders to just below their melting points. The heating treatment is called sintering. Although the modern field of powder metallurgy dates to the early 19th century, over the past quarter century, it has become widely recognized as a superior way of producing high quality parts for a variety of important applications.

Powder metallurgy actually comprises several different technologies for fabricating semidense and fully dense components. The conventional PM process, referred to as press-and-sinter, has been used to produce many complex parts, such as the planetary carrier, helical gears and blades, piston rings, connecting rods, cams, brake pads, bushings, tool steels, tungsten carbides, cermets tool and die materials, magnetic materials, graphite brushes impregnated with copper for electric motors, surgical implants, and many other parts for aerospace, nuclear, and industrial applications.

PM's popularity is due to a number of attributes: a) the advantage that the process offers over other metal-forming technologies such as forging and metal casting, b) its advantages in material utilization, c) shape complexity, d) near-net-shape dimensional control, and others. PM's benefits add up to cost-effectiveness, shape and material flexibility, application versatility, and part-to-part uniformity for improved product quality.

Advantages that make powder metallurgy an important commercial technology include the following:

- eliminates or minimizes machining by producing parts at or close to final dimensions
- eliminates or minimizes scrap losses by typically using more than 97 percent of the starting raw material in the finished part
- permits a wide variety of alloy systems
- produces good surface finishes and tolerances of  $\pm 0.005$  in. ( $\pm 0.13$  mm)
- provides materials that may be heat treated for increased strength or increased wear resistance
- relatively low processing temperatures
- provides controlled porosity for self-lubrication or filtration
- facilitates manufacture of complex or unique shapes that would be impractical or impossible with other metalworking processes
- is suited to moderate- to high-volume component production requirements
- offers long-term performance reliability in critical applications
- is cost-effective and environmentally friendly
- can be automated.

There are some disadvantages associated with PM processing. These include:

- high tooling and equipment cost
- expense of metal powder
- difficulties with storing and handling metal powders (degradation of the metal over time and fire hazards with particular metals)
- variations in material density can cause problems, especially for complex geometries
- limitations on part geometry because metal powders do not readily flow laterally in the die during pressing.

Most parts weigh less than 5.5 lb (2.5 kg), although parts weighing as much as 110 lb (50 kg) can be produced using conventional powder metallurgy equipment. While many of the early powder metallurgy parts, such as bushings and bearings, were very simple shapes, today's sophisticated powder metallurgy process produces components with complex contours and multiple levels and does so quite economically.

### Characteristics of Metal Powders

A powder is defined as a finely divided solid, smaller than 0.039 in. (1 mm) in its maximum dimension. In most cases the powders will be metal, although in many instances they are combined with other materials such as ceramics or polymers. Powders exhibit behavior that is intermediate between that of a solid and a liquid. Powders will flow under gravity to fill containers or die cavities, so in this sense they behave like liquids. They are compressible like a gas. But the compression of a metal powder is essentially irreversible, like the plastic deformation of a metal. Thus, a metal powder is easily shaped, but it has the desirable behavior of a solid after it is processed.

When one deal with powders, the properties of both the individual particles and the collective (bulk) properties of the powder must be considered. The properties of single particles include size, shape, and microstructure, which can be determined by optical or scanning electron microscopic observations. In order to characterize a bulk powder, it is necessary to be able to determine at least the following properties:

*Basic Chemical Composition:* The minimum percentage of the base metal or the percentages of main elements in case of metal alloy powders.

*Impurities:* The percentage of impurities.

*Particle Size Distribution:* (see next section).

*Apparent Density:* The weight per unit volume of a simply poured metal powder, which is always less than the density of the metal itself. It is measured by letting the powder drop freely through a funnel to fill a 1.52 in<sup>3</sup> (25 cm<sup>3</sup>) cylindrical container. The ratio between mass and volume, that is, the apparent density, is provided through leveling and weighing and is expressed in kg/m<sup>3</sup>. The apparent density depends on a series of factors, the more important of which are the metal's true density, powder shape and structure, particle size distribution, corrosion resistance, etc.).

*Flowability:* To assess the speed, standardized funnels with varying calibrated openings are used. A certain amount of powder is poured in the funnel and the flow time is recorded.

**Particle Size Measurement and Distribution.**—The size, distribution, and shape of the powder metal particles influence the physical properties of the parts created. A particle is defined as the smallest unit of a powder. The particles of many metal powders are 0.001 to 0.0078 in. (0.025 to 0.2 mm) in size.

Describing a three-dimensional particle is often a more complex matter than it first appears. For simplicity, it is convenient to describe particle size in terms of one single number. The sphere is the only shape that can be described by one dimension, its diameter (*D*). However, a particle is rarely a perfect sphere. Over the years, particle size analyses of metal powders have been performed using various techniques, including microscope, sieves, aerodynamic time of flight, and laser diffraction. At present, the most popular technique for measuring the size distribution of metal powders is screening and laser diffraction, typically measuring powders in their natural dry state.

*Screening Method:* The most common method used for measured particle size is the use of screens (sieves) of different mesh sizes. The term *mesh count* is used to refer to the number of openings per linear inch of screen.

The basic principle of sieving techniques is as follows. A representative sample of a known weight of particles is passed through a set of sieves of known mesh sizes. The sieves are arranged in downwardly decreasing mesh diameters. The higher the mesh size number, the smaller is the opening in the screen. For example, a mesh size No. 200 has an opening of 0.003 in. (0.074 mm), size No. 100 has an opening of 0.006 in. (0.149 mm), size No. 10 has an opening of 0.078 in. (2 mm). The sieves are mechanically vibrated for a fixed period of time. The weight of particles retained on each sieve is measured and converted into a percentage of the total sample. This method is quick and sufficiently accurate for most purposes.

*Laser Diffraction Method:* Laser diffraction, alternatively referred to as low-angle laser light scattering (LALLS), can be used for the nondestructive analysis of wet or dry

samples, with particles in the size range from microscopic up to 0.080 in. (2 mm). This method has inherent advantages that make it preferable to other options for many different materials.

Laser diffraction-based particle size analysis relies on the fact that particles passing through a laser beam will scatter light at an angle that is directly related to the particles' size. Typically, an He-Ne laser ( $\lambda = 632.8\text{nm}$ ) in the 5 mW to 10 mW range is used as the coherent light source. As particle size decreases, the observed scattering angle increases logarithmically. Scattering intensity is also dependent on particle size, diminishing with particle volume. Large particles, therefore, scatter light at narrow angles with high intensity, whereas small particles scatter light at wider angles but with low intensity.

A typical system consists of: a laser, to provide a source of coherent, intense light of fixed wavelength; a series of detectors to measure the light pattern produced over a wide range of angles; and some kind of sample presentation system to ensure that the material being tested passes through the laser beam as a homogeneous stream of particles in a known, reproducible state of dispersion. The dynamic range of the measurement is directly related to the angular range of the scattering measurement, with modern instruments making measurements from around 0.02 degree to beyond 140 degrees (Fig. 1). The wavelength of light used for the measurements is also important, with smaller wavelengths (e.g., blue light sources) providing improved sensitivity to sub-micron particles.

In laser diffraction, particle size distributions are calculated by comparing a sample's scattering pattern with an appropriate optical model. Traditionally, two different models are used: the Mie theory and Fraunhofer approximation.

The *Mie theory* describes scattering by homogeneous spheres of arbitrary size, and provides a more rigorous solution for the calculation of particle size distributions from light-scattering data. It predicts scattering intensities for all particles, small or large, transparent or opaque. The Mie theory allows for primary scattering from the surface of the particle, with the intensity predicted by the refractive index difference between the particle and the dispersion medium. It also predicts the secondary scattering caused by light refraction within the particle. This is especially important for particles below 0.002 in. (0.05 mm) in diameter, as stated in the international standard for laser diffraction measurements. The Mie approach does not work well for extremely fine particulates in the range below 100 nm, possibly because of increased sensitivity to changes in the refractive index that occur with these materials.

Fig. 1. Typical Laser Diffraction Instrument Layout

**Fraunhofer Diffraction:** For very large particles (relative to the wavelength of light), the diffraction effect can be exploited without reference to the Mie theory or the complex index of refraction. Diffracted light is concentrated in the forward direction, forming the so-called Fraunhofer diffraction rings.

The intensity and distribution of diffracted light around the central beam can be related to particle size, again assuming spherical geometry. The benefit of using Fraunhofer diffraction is that the interpretation is not dependent on the absorptive or refractive properties of the material. On the other hand, the particles being measured are opaque and scatter light at narrow angles. As a result, it is only applicable to large particles and will give an incorrect assessment of fine-particle fractions.

Since laser diffraction is such a popular method of measuring the size of metal powders, an ASTM standard was written to guide proper technique. ASTM B822-02, "Standard Test Method for Particle Size Distribution of Metal Powders and Related Compounds by Light Scattering," provides guidance on the use of laser diffraction for measuring metal powders. The ASTM standard notes the requirement for a representative sample and suggests a micro-sample splitter to minimize sampling errors. When powder in a liquid suspension is measured, the standard points out that it is important to create a stable dispersion.

Laser diffraction is a nondestructive, nonintrusive method that can be used for either dry or wet samples. As it derives particle size data using fundamental scientific principles there is no need for external calibration; well-designed instruments are easy to set up and run, and they require very little maintenance.

**Particle Shape and Internal Structure.**—There are various types of metal powder particle shapes, several of which are illustrated in Fig. 2. The choice depends on the requirements of the final product. The microstructure, bulk and surface properties, and porosity depend on the particle shape. There will be a variety of particle shapes in a collection of metal powders, just as the particle size will vary.

Fig. 2. Schematic Illustration of Several Particle Shapes in Metal Powders:  
a) Acicular; b) Spherical; c) Rounded; d) Spongy; e) Flakey; f) Cubic; g) Angular

The particle shape is widely accepted as important if process operation is to be optimized. One of the simple and most useful measuring techniques is *digital imaging*.

By this technique, particle shape is quantified in two ways. First, the aspect ratio determination is made.

**Aspect Ratio:** In general, the aspect ratio is the ratio of the maximum dimension to the minimum dimension for a given particle and is defined more specifically in this method as the ratio of the maximum and minimum particle dimension that passes through the geometric center of the particle. This is illustrated in Fig. 3.

Fig. 3. Particle Aspect Ratio Definition

The aspect ratio for a spherical particle is 1.0, but for another grain, like a needle-shaped grain (acicular), the ratio might be up to 4. Any amount of loose powder contains pores between the particles. These are cooled open pores but in some cases might be voids in the structure of individual particles (closed pores) and their influence on powder characteristics is minor.

*Shape Factor:* The second determination is defined as a shape factor that attempts to quantify the particle shape as a single number. This is not easy; and there have been many attempts to employ shape factor in the past. However, combining the flatness ratio and elongation ratio allows the shape of the particle to be described by a shape factor.

Flatness ratio  $p$  is the ratio of the short length (thickness  $T$ ) to the intermediate length  $w$ :

$$p = \frac{T}{w} \quad (1)$$

The elongation ratio  $q$  is the ratio of the intermediate length  $w$  to the longest length  $l$ :

$$q = \frac{w}{l} \quad (2)$$

where  $T$  = thickness of particle, in. (mm)

$w$  = intermediate length of particle, in. (mm)

$l$  = longest length of particle, in. (mm)

$$S_f = \frac{p}{q} = \frac{\frac{T}{w}}{\frac{w}{l}} = \frac{lT}{w^2} \quad (3)$$

where  $S_f$  = shape factor

$p$  = flatness ratio

$q$  = elongation ratio

If  $S_f = 1$ , the particle is spherical or cubical  
 $S_f < 1$ , the particle is more elongated and thin  
 $S_f > 1$ , the particle is blade-shaped

*Sphericity:* Sphericity is, naturally, a measure of how spherical an object is. Defined by Wadell in 1932, the sphericity  $\psi$  of a particle is the ratio of the surface area of a sphere with the same volume as the given particle to the surface area of the particle:

$$\Psi = \frac{\pi^{\frac{1}{3}}(6V_p)^{\frac{2}{3}}}{A_p} \quad (5)$$

where  $V_p$  = volume of the particle

$A_p$  = the surface area of the particle

A particle that is a perfect sphere has sphericity value of  $\Psi = 1$ .

**Friction and Flow Characteristics of Particles.**—The friction characteristics of particles play a very important role in the ability of a powder to flow readily and pack tightly. The friction of particle aggregates basically involves two aspects: inter-particle friction and friction between the aggregate and the walls of the container. Both aspects constitute challenging topics, and often both must be considered in dealing with practical problems related to powder materials. Particle mechanics is the branch of knowledge that deals with the mechanics properties and flow of particles and particle aggregates. Friction is a critical aspect of many particle mechanics problems. The most common way to quantify inter-particle friction is by measuring the angle of repose.

*Angle of Repose:* Angle of repose, in general, is an engineering property of granular material. When powders are poured from a narrow funnel onto a horizontal surface, a conical pile will form (Fig. 4).

Fig. 4. Inter-Particle Friction as Indicated by the Angle of Repose

The angle between the horizontal surface and the surface of the pile is known as the angle of repose and is related to the density, surface area, and coefficient of friction of the particles. Materials with a higher angle of repose have greater friction between particles, while smaller angles suggest less friction. Smaller particle size generally indicates greater friction and steeper angles.

**Powder Flow:** A simple definition of powder flowability is the ability of a powder to flow. Flowability is the result of a number of factors and for convenience they may be grouped under the following headings:

- Physical properties of the powder particles, such as their size, shape, hardness, elasticity, porosity, mass, interactions between particles, and so on.
- Environmental factors that affect the powder's bulk properties, such as air or moisture content, external pressure, vibration, etc. These factors modify the physical distribution and arrangement of the particles in the powder mass.
- Individual particle changes caused by factors such as attrition, chemical charge, etc.

Powders will flow under gravity to fill containers or die cavities, so in this sense they behave like liquids. As particles in powders get smaller, they have a greater tendency to adhere to one another rather than to fall away under the influence of gravity. This is due to the fact that the surface area of the particles becomes large in proportion to the mass. Therefore, the surface forces of friction and cohesion begin to dominate gravitational forces as particle size decreases. Increasing interparticle friction and cohesion reduce the flowability of the powder. To reduce interparticle friction and facilitate flow during pressing, lubricants are added to the powders in small amounts.

Particle shape also greatly affects the flow characteristics of powders. Depending on the fabrication method, particles can take on many different shapes, including spherical, rounded, and angular.

The flowability of a powder can be quantified by measuring its gravity-driven flow rate through a calibrated orifice. The conventional method measures the time required for a 50-gram sample to flow through a standardized funnel.

**Packing, Density, and Porosity.**—Packing, density and porosity are based on how much the metal powder will pack down when pressed. A packing of particles is an assemblage of particles and is widely encountered in many industries. Packing characteristics depend on two density measures: true density and bulk density.

**True Density:** True density of the material would be density of the mass if the powder particles were melted and formed into a single piece. During the compression stage the particles are reshuffled, becoming generally closer together as inter-particle pores are eliminated. As the powder is compressed, its density increases. In order to process to its true density, all porosities, open and closed, must be eliminated.

True density of a solid material is defined as the ratio of its mass to its true volume; the true density value is given in many tables as one property of engineering materials. The true density value is calculated as:

$$\rho_t = \frac{M_s}{V_t} \quad (6)$$

where  $\rho_t$  = true density, lb/in<sup>3</sup> (g/cm<sup>3</sup>)

$M_s$  = mass of solid material, lb (g)

$V_t$  = true volume, in<sup>3</sup> (cm<sup>3</sup>)

**Bulk Density:** Bulk density is the density of the powder in its loose uncompressed form. A container of known volume is filled with the powder. The powder is then weighed and the density is determined as:

$$\rho_b = \frac{M_p}{V_p} \quad (7)$$

where  $\rho_b$  = bulk density, lb/in<sup>3</sup> (g/cm<sup>3</sup>)

$M_p$  = powder mass, lb (g)

$V_p$  = volume of powder in uncompressed form, in<sup>3</sup> (cm<sup>3</sup>)

Major factors determining bulk density of a powder are particle size, particle size distribution, particle shape, and cohesiveness. Bulk density is an important property in packaging and powder handling.

**Packing Factor:** The packing factor value is determined as:

$$PF = \frac{\rho_b}{\rho_t} \quad (8)$$

Typical packing factor values are 0.5 to 0.7, meaning that the material will compact 30 to 50 percent.

The packing factor depends on the particle shape, the distribution of the particle sizes, and external pressure applied during compacting of the particle. Vibration of the powders can also increase packing.

**Porosity:** Porosity is the ratio of volume of the pores (empty spaces) in the powder to the bulk volume. This ratio can be expressed as:

$$\phi = \frac{V_p}{V_b} \quad (9)$$

where  $\phi$  = porosity;  $V_p$  = volume of pores, in<sup>3</sup> (cm<sup>3</sup>); and  $V_b$  = bulk volume, in<sup>3</sup> (cm<sup>3</sup>).

Pores, or spaces within the powder, are in large part determined by particle shape and size, since the shape dictates how particles will contact each other. Spaces that exist between particles of a powder and are open to the outside are called open pores. Those spaces expose the external surfaces of powder particles. During compaction of powder, these spaces are eliminated. If any amount of this space remains after pressing, it will result in porosity in the manufactured part. These open pores are permeable to the atmosphere, and they are permeable to fluids such as liquid lubricants and water. The other type of empty spaces that exist in a powder material are called closed pores. These pores are not open to the outside atmosphere. Closed pores can develop during pressing and sintering if the open-pore region becomes closed off. Another type of closed pore exists within the material of powder particles themselves.

In principle:

$$\text{Porosity} + \text{Packing factor} = 1 \quad (10)$$

The issue is complicated by the possible existence of closed pores in some of the particles. If internal pore volumes are included in the above porosity value, then the equation is exact.

### Production of Metallic Powder

A powder can be defined as a finely divided particulate solid. It can be produced in the form of sponges or atomized powders. Generally, any metal can be made into a powder. There are three basic methods for producing metallic powder: atomization, chemical, and electrolytic. Each method can be further subdivided, and powders can also be made by various combinations from each group. As a result, there is a wide range of production routes available, each producing powders with their own particular characteristics.

Which powder production process is used depends on the required production rate, the desired powder properties, and the properties desired in the final part. Chemical and electrolytic methods are used to produce high-purity powders. Mechanical milling is widely used for the production of hard metals and oxides.

**Atomization.**—Atomization involves either spraying or smashing molten metal into smaller particles.

It is the most versatile method for metal powder production. The main operational parameters and physical conditions for a suitable atomization process for different applications in powder production are the following:

- melting (surface tension, viscosity, and temperature range—solidification temperature)
- process type (aimed throughput, energy efficiency)
- product type (particle size distribution).

Atomization is the dominant method for producing metal and pre-alloying powders from aluminum, brass, iron, low-alloy steel, stainless steel, superalloy, titanium alloy, and other alloys. Atomization is the best method because it yields high production rates and favors economies of scale, and because pre-alloying powders can only be produced by atomization.

There are many different processes employed industrially for atomization, several of which are:

- water atomization
- gas/air atomization
- centrifugal atomization.

**Water Atomization:** In water atomization (Fig. 5) the raw material is melted, and then the liquid metal is broken into individual particles. To accomplish this, the melt stock, in the form of elemental, multi-element metallic alloys, is melted in an induction, arc, or other type of furnace. After the metal is molten and homogenous, it is transferred to a tundish, which is a reservoir used to supply a constant, controlled flow of metal into the atomizing chamber. As the metal stream exits the tundish, it is struck by a high-velocity stream of the water.

The water is sprayed at pressures that range from 145 to 1450 psi (1 MPa to 10 MPa). The molten metal stream is disintegrated into fine droplets, which solidify and cool during their fall through the atomizing tank. Particles are collected at the bottom of the tank. Water atomization cools the metal very rapidly, and the process can cause the formation of irregular particles. It can also corrode some metals.

Fig. 5. Water Atomization Method for Producing Metal Powder

**Gas Atomization:** In the area of metal powder production by atomization of molten metal, twin-fluid atomization by means of inert gases is typically used. The main reasons for using this specific atomization technique are:

- the possibility of high throughputs and disintegration of high mass flow rates
- the greater amount of heat transfer between gas and particles for rapid partial cooling of the particles
- the direct delivery of kinetic energy to accelerate the particles towards the substrate/ deposit for compaction
- the minimization of oxidation risks of the atomized materials within the spray process by use of inert gases.

In this process, atomization is accomplished by forcing a molten metal stream through an orifice at moderate pressures (Fig. 6). An inert gas at pressures from 29 to 290 psi (0.2 to 2.0 MPa) is introduced into the metal stream just before it leaves the nozzle, serving to create turbulence as the entrained gas expands (due to heating) and exits into a large collection volume exterior to the orifice. The collection volume is filled with gas to promote further turbulence of the molten metal jet.

Fig. 6. Gas Atomization Method for Producing Metal Powder

This process as compared to water atomization makes a similarly broad distribution and produce very fine powders. However, the process must be operated more slowly than water atomization and the energy needed to compress the gas is far higher than that needed to pump water. Because this cools the metal at a slower rate, it creates a more circular particle. The advantage of the inert gas process is better control of oxygen levels in oxygen-sensitive materials.

**Centrifugal Atomization:** Centrifugal atomization of molten metals is a cost-effective process for powder production and spray deposition. The properties of the powder and deposit produced by this method are determined primarily by the characteristics of the atomized droplets, which in turn are largely dependent on the flow development of the melt on the atomizer.

There are basically two types of centrifugal atomization processes: the rotating disk process and the rotating electrode process.

**Rotating Disk Process:** In this process, the molten metal stream drops onto a rapidly rotating disk or cup on a vertical axis so that centrifugal forces break up the molten metal stream to form, first, a film of molten metal and then to generate particles (Fig. 7a).

Naturally, the material of which the spinning disk or cup is made takes a lot of punishment. Particle sizes are not very fine, unless very high speeds (over 10,000 rpm) are used. An advantage of this process is that it can produce much narrower distributions than gas or water atomization. Thus, excessively fine or oversized particles can be minimized.

Fig. 7. Centrifugal Atomization: (left) Rotating Disk Method; (right) Rotating Electrode Method

**Rotating Electrode Process:** In the rotating electrode process (REP), an arc is struck between a horizontal tungsten cathode and a spinning electrode of the desired metal for pulverization (Fig. 7b). The electric arc (or plasma in later versions) melts the spinning workplace electrode tip, which throws off a shower of the molten metal droplets by centrifugal forces. The droplets solidify as they pass through a cooling gas or vacuum and are collected in a concentric chamber.

A salient characteristic of REP powder particles is their perfectly spherical shape and freedom from satellite particles adhering to them.

**Mechanical Processes.**—There are basically two types of mechanical processes for the production of metal powders: the mechanical comminution process and the mechanical alloying process.

**Mechanical Comminution Process:** Brittle materials such as ferro-alloys (ferro-chromium, ferro-silicon, etc.) are pulverized mechanically in ball mills (Fig. 8). A process known as the coldstream process is finding increasing application for the production of very fine powders such as are required for injection molding.

Milling is the primary method for reducing the size of large particles and particle agglomerates. Ball, hammer, vibratory, attrition, and tumbler mills are some of the commercially available comminuting devices. During milling, forces act on the feed metal to modify the resultant particles. Impact, attrition, shear, and compression all influence powder particle size and shape. Lathe turning is a technique used for materials such as magnesium for creating coarse particles from billets. These particles then are reduced in size by milling or grinding.

Fig. 8. Method of Mechanical Comminution to Obtain Fine Particles

**Mechanical Alloying:** Mechanical alloying is a process for the production of new materials. It takes place in a high-energy mill where two powders of different origin are mixed. By the conversion of mechanical into chemical energy, nanocrystalline structures emerge that cannot be produced by conventional melting methods.

In general, the process can be viewed as a means of assembling metal constituents with a controlled microstructure. If two metals will form a solid solution, mechanical alloying can be used to achieve this state without the need for an excursion into high temperatures. Conversely, if the two metals are insoluble in the liquid or solid state, an extremely fine dispersion of one of the metals in the other can be accomplished. The dispersed phase can result in strengthening of the particles or can impart special electrical or magnetic properties to the powder. The process of mechanical alloying was originally developed as a means of overcoming the disadvantages associated with using powder metallurgy to alloy elements that are difficult to combine.

Some oxides are insoluble in molten metals. Mechanical alloying provides a means of dispersing these oxides into the metals. Examples are nickel-based superalloys strengthened with dispersed thorium oxide ( $\text{ThO}_2$ ) or yttrium oxide ( $\text{Y}_2\text{O}_3$ ). These superalloys have excellent strength and corrosion resistance at elevated temperatures, making them attractive candidate materials for use in applications such as jet engine turbine blades, vanes, and combustors.

**Chemical Processes.**—There are numerous chemical methods for producing powders. Generally, chemical methods result in very fine powder particle sizes.

The most common chemical powder treatments involve oxide reduction, precipitation from solutions, and thermal decomposition. Chemical reduction involves a variety of chemical reactions that reduce the metal into elemental powders. A common process involves liberating metals from their oxides by the use of reducing agents, which attach to the oxygen in the oxide and render metal powders. The powders produced in this way have great variation in properties and yet have closely controlled particle sizes and shapes. Oxide-reduced powders are often characterized as “spongy,” due to pores present within individual particles. Solution-precipitated powders can provide narrow particle size distributions and high purity. Thermal decomposition is most often used to process carbonyls. These powders, once milled and annealed, exceed 99.5 percent purity.

Mill scale and oxidized metallic products are annealed to reduce both the oxygen and carbon contents.  $\text{FeO}$ ,  $\text{Fe}_2\text{O}_3$ , or  $\text{Fe}_3\text{O}_4$ , are reduced in the presence of a reducing atmosphere. In addition, the carbon within the particles is removed via the formation of  $\text{CO}$  and  $\text{CO}_2$ .

Hydrometallurgical manufacturing followed by thermal decomposition constitutes another chemical method. Precipitation of a metal from a solution can be accomplished by using electrolysis, cementation, or chemical reduction. This is done either from a solution containing an ore, or by means of precipitation of a metal hydroxide followed by heating which results in decomposition and reduction.

**Electrolytic Deposition.**—Electrolytic deposition is often categorized as a fourth mode of powder fabrication.

In this process, an electrolytic cell is set up in which the source of the desired metal is the anode. The process involves the precipitation of a metallic element at the cathode of an electrolytic cell (Fig. 9).

Fig. 9. Electrolytic Cell Operation for Deposition of Powder

By the choice of suitable conditions, composition and strength of the electrolyte, temperature, current density, and so on, many metals can be deposited in a spongy or powdery state. Extensive further processing—washing, drying, reducing, annealing, and crushing—may be required. Copper is the main metal produced in this way, but chromium and manganese powders are also produced by electrolysis. In these cases, however, a dense and normally brittle deposit is formed and needs to be crushed to powder. Electrolytic iron was at one time produced on a substantial scale but it has been largely superseded by powders made by less costly processes. Electrolytic powders are of high purity with a dendritic morphology.

**Hybrid Atomization.**—There is increasing demand for fine spherical powder with uniform particle size applicable to advanced powder metallurgy such as metal injection molding, solder for electronics parts, and joining and conductive inks. However, conventional technologies cannot easily produce powders that satisfy such requirements, so a new powder production technology is needed.

The National Institute for Materials Science (NIMS) developed the world's first powder production method, *hybrid atomization* (Fig. 10), which can easily produce powder having 0.0004 in. (0.01 mm) or smaller spherical particles, with uniform size and low oxygen content. Such powders cannot be produced by conventional powder production technology.

Fig. 10. Schematic Illustration of Hybrid Atomization

Hybrid atomization efficiently combines gas atomization with centrifugal atomization. The gas atomization breaks molten metal into pieces of several tens to several hundred micrometers in size using a gas jet. A rotating disk located beneath the spray is driven at high speed up to 66,000 rpm, and the molten disk metal is spread uniformly over the rotating disk using a gas spray flow, thereby forming a thin liquid film of 0.0004 in. (0.01 mm) or less in thickness. Then, the fine droplets are scattered from the edge of the rotating disk to result in a fine spherical powder.

### Powder Manufacturing Processes for Metal Parts

The first modern PM product, the tungsten filament used in electric light bulbs, was developed in the early 1900s. It was followed by tungsten carbide cutting tool materials in the 1930s, automobile parts in the 1960s and 1970s, aircraft turbine engine parts in the 1980s, and, finally, parts made by powder forging, metal injection molding, and warm compacting in the 1990s.

An outline of the manufacturing processes and operations involved in making metal powder parts is shown in Fig. 11.

Fig. 11. Outline of Manufacturing Processes of Metal Parts.

After metallic powder is produced, it can be converted to a solid in different ways. But there are three basic steps in producing PM components that are common to most techniques. Whether the final result is sintered brass, sintered stainless steel, sintered bronze, or any other powder-based element, the three production steps are the same:

- 1) blending and mixing of the powders
- 2) compaction
- 3) sintering.

**Blending and Mixing of the Powders.**—Blending and mixing is carried out for the following purposes: 1) powders made by various processes have different sizes and shapes, so they must be mixed to obtain uniformity; 2) powder of different metals and other materials can be mixed in order to impart special physical and mechanical properties and characteristics to the PM parts; 3) lubricants can be mixed within powders to improve their flow characteristics (reducing friction between metal particles, improving flow of powder materials into the dies, and lengthening die life).

Many of the alloy powders are available premixed—the powder already has the correct material characteristics. Additives, such as admixed lubricants, which coat each powder particle and reduce interparticle friction, usually are added to the mix.

Mixing time depends upon the results desired, and overmixing should be prevented; otherwise the size of particles will be decreased, and they will be hardened. This makes the subsequent compacting operation more difficult. The mixing operation can be carried out in air-inert atmospheres or in liquids, which act as lubricants and make the mixture more uniform.

Blending and mixing is done in a mixer device; some of these are schematically illustrated in Fig. 12; they include the horizontal rotating drum, the rotating double cone, the screw mixer, and the blade mixer.

Fig. 12. Blending and Mixing Devices:

a) Rotating Drum; b) Rotating Double Cone; c) Screw Mixer; d) Blade Mixer

In the drum and double cone methods, the container has bafflers inside to prevent the mixture from the free falling, an action that separates the particles by mass. This is the point at which other materials can be added to the mixture. The other materials consist of lubricants (used to lower the friction between the powder and the die), binders (used to hold some metals together between pressing and sintering), and defloculants (used to allow for better powder flow in the die). Lubricants typically are stearic acid or zinc stearate in a proportion of 0.25 to 5 percent by weight. Because of their high surface area-to-volume ratio, metal powders are explosive; this is particularly true of aluminum (Al), magnesium (Mg), titanium (Ti), zirconium (Zr), and thorium (Th). For that reason, great care must be exercised to protect both workers' health and the general environment during blending and handling.

**Compaction of Metallic Powder.**—After the metallic powders have been blended, compacting is the next step. The purposes of the compacting operation are to obtain the required shape, ensure particle-to-particle interlocking, and make the part sufficiently strong for further processing.

In compaction, the powder is fed into a die cavity, either automatically or by hand by a feed shoe. At the start the powder is at about 2.5 times the final part volume.

The process generally is carried out at room temperature (cold compacting), although it can be done at elevated temperatures (hot compacting). After pressing, the part, which is called a *green compact*, is ejected from the die. Green parts are very frail and can crumble or be damaged very easily. To obtain higher green strengths, the powder must be fed properly into the die cavity, and proper pressure must be developed throughout the part. Fig. 13 shows various stage metallic powder compacting process.

Fig. 13. Compacting Metallic Powder: a) Filled Die Cavity with Powder; b) Initial Position of Upper and Lower Punches; c) Final Position of Upper and Lower Punches; d) Ejection of Part (Green)

The amount of pressure necessary for a compaction operation is to a large degree based on the material. For example, compacting aluminum powder generally requires lower pressure, while compacting iron powder requires relatively higher pressure. The compaction pressure also depends upon the powder characteristics, additives, and the desired density of the green compact. The density of the green compact depends on the applied pressure and the size distribution of the particles. If all particles are of the same size, there will always be some porosity when they are packed together.

Friction force will oppose the movement of particles during processing; therefore, lubrication can reduce the required compaction pressure and also will cause a more uniform distribution of particles during pressing. Lubricant should be applied in the correct quantities.

As the compaction pressure increases, the density of the green compact increases, and the individual particles are pressed together to plastically deform them, increasing their contact and friction but decreasing the pore size. The higher density increases the strength and elastic modulus of a part. Fig. 14 shows density of the powders as a function of pressure.

Fig. 14. Density of the Powders as a Function of Pressure: a) Filled Die Cavity with Powder; b) Initial Position of Upper and Lower Punches; c) Final Position of Upper and Lower Punches

Typical pressed densities for soft iron components would be, e.g., about 85 percent of theoretical density. Compaction pressure rises significantly if higher pressed densities are required, and this practice becomes uneconomical due to higher costs for the larger presses and stronger tools to withstand the higher pressures.

One disadvantage of this technique involves the differences in pressed density that can occur in different parts. Because of friction between metal particles in the powder and friction between the punches and die walls, the density within the part can vary considerably. Density variation can be minimized by proper punch and die design, by control of friction, and by keeping low the length-to-diameter ratio of the part.

**Pressing Force:** The required force for pressing depends on the cross-sectional area of the PM part (area in the horizontal plane for a vertical press) and the pressure needed to compact given metal powders. This force may be calculated by the following formula:

$$F = A_p p_c \quad (11)$$

where  $F$  = required force, lb (N)

$A_p$  = cross-sectional area, in<sup>2</sup> (m<sup>2</sup>)

$p_c$  = compaction pressure, psi (MPa)

Compaction pressures typically range from 1007 to 116030 psi (69 MPa to 800 MPa); however, 20305 to 60191 psi (140 to 415 MPa) is the most common range. **Table 1** shows compaction pressures for various metal powders.

**Table 1. Compaction Pressure for Various Metal Powders**

Material	Compaction Pressures	
	psi	MPa
Porous metals and filters	5802–10153	40–70
Refractory metals and carbides	10298–29008	70–200
Porous bearings	21030–50763	145–350
Machine parts (medium-density iron and steel)	39885–100076	275–690
High-density copper and aluminum parts	36259–39885	250–275
High-density iron and steel parts	100076–239312	690–1650

Most conventional PM compacting is done with mechanical presses, although hydraulic and hybrid (combinations of mechanical, hydraulic, or pneumatic) presses are often used. The mechanical presses may be of the eccentric or crank type. Most presses have capacities of less than 100 tons. Mechanical presses with capacities of the magnitude of a few hundred tons are usually adequate for most PM processing operations. Hydraulic presses with a capacity of several thousand tons are sometimes used for compacting parts that require more force. Double action presses are commonly used; for more complex parts, multiple action presses may be employed. Punch speed must be regulated. Faster compaction of the workpiece can result in higher productivity; however, if the punch speed is too high, air may become trapped in the parts and prevent the parts from compacting correctly.

**Die:** Punch and die surfaces are very important in the powder compacting operation. Some clearance between the punch and die must exist in order for the punch to move within the die. However, in a die with a large clearance, powder particles can become stuck in this clearance, causing problems with the proper movement of the punch. In order to prevent this problem, clearance is designed to be extremely low, typically less than the size of the powder particle.

Most punches and dies are made from hardened tool steels, and the surfaces of the die and punch in the direction of the punch movement are ground and polished or lapped.

**Sintering.**—Sintering is the final step in the PM process. Green powder compacts are heated in a controlled-atmosphere furnace so that adjacent particles fuse together, thus resulting in a solid part with improved mechanical strength compared to the powder compact. The nature and strength of the bond between the particles and the sintered compact depend on the mechanisms of diffusion, the plastic flow, the evaporation of volatile materials in the compact, the recrystallization, the grain growth, and the pore shrinkage. The main variables in sintering are:

- temperature
- time
- furnace atmosphere.

Sintering temperature is below melting point (generally within 70 to 90 percent of the melting point of the metal or alloy), and the metal remains unmelted. The temperature in the furnace is high enough to get metal into the recrystallization zone. In this temperature zone, the metal particles begin to recrystallize into each other. Sintering times average from 1 to 1.5 hours for small parts, such as bushings, to 3 hours for average-size ferrous parts. However, for tungsten parts, average sintering time may go to 8 hours.

Sintering furnaces have three sections: first is a burn-off section for volatilizing the lubricants in the green compact in order to improve bond strength and prevent cracking; second is a high-temperature section for sintering; third is a cooling section.

Hardening sintered parts involves applying a controlled cooling rate in a separate cooling section of the sintering furnace. In the cooling section of the sintering furnace the parts are cooled in a protective atmosphere in order not to be oxidized in contact with air. Dissociated ammonia or nitrogen-based atmospheres are commonly used. Vacuum atmospheres are used for certain metals, such as stainless steel, titanium, and tungsten.

The cooling speed, especially in the temperature range of 1560 to 930°F (850 to 500°C) also affects the mechanical properties, due to phase transformations in the material. During the sintering, a moderate dimensional change takes place. Most materials shrink, but some alloying elements, such as copper, cause material growth. The design of the die must compensate for any anticipated dimensional change. In Fig. 15 is shown a typical heat-treatment cycle in a PM sintering operation.

Fig. 15. Typical Heat-Treatment Cycle in Sintering Operation

**Secondary Operations:** Although PM parts can be used as finished parts, they also may need some additional operations after sintering to improve their properties or to impart special characteristics to the parts.

**Repressing:** A second pressing operation (wherein the part is squeezed in a closed die) serves to decrease porosity (i.e., improve density) for applications where density is very important to achieve the required mechanical or other physical properties. After repressing, the parts are sintered a second time.

**Sizing:** Sizing is forcing the part through a finish die to provide dimensional accuracy.

**Coining:** Coining is a pressworking operation on a sintered part to improve the surface finish by further densification or to press details into its surface.

**Finishing Operations:** Some powder metal parts require additional finishing operations that may include: machining to produce holes or threaded holes, and various other geometric features by milling or other processes; grinding to improve dimensional accordance and surface finish; plating to improve resistance to wear and corrosion and sometimes to improve appearance; and heat treating for hardness and other mechanical properties.

*Joining:* Larger parts and very complex shapes can be obtained by joining. Several techniques exist for joining, such as diffusion bonding, sinter brazing, and laser welding.

*Infiltration:* The interconnected porosity is filled with an alloy having a melting point lower than the sintering temperature of the metal of which the component is made, e.g., copper-based alloys infiltrate ferrous parts, usually during the sintering phase. Infiltration makes the components impermeable, and there is some increase in mechanical properties, but at the expense of dimensional accuracy. Infiltration simplifies some heat treatments. For instance, it is easier to obtain a defined case depth without interconnected porosity.

*Impregnation:* Oil or other fluid is permeated into the parts of a sintered PM part. Sintered parts achieve greater protection against corrosion by being impregnated by oil or another nonmetallic material such as polymer resins that seep into the pore spaces in liquid form and then solidify to create a pressure-tight part. Common products are gears and bearings. Self-lubricating bearings are manufactured by impregnating porous sintered bearings with lubricants; these bearings can only be produced by powder metallurgy.

**Liquid Phase Sintering.**—Liquid phase sintering (LPS) is a subclass of the sintering process and can be defined as sintering involving a coexisting liquid and particulate solid during some part of the thermal cycle. The most common way to obtain the liquid phase is to use a system involving a mixture of two powder metals in which there is a difference in the melting temperatures between the metals. The interaction of the two powders leads to formation of a liquid during sintering. The melted metal thoroughly wets the solid particles, leading to rapid consolidation and giving rapid compact densification without the need for an external force. It is, of course, essential to restrict the amount of liquid phase in order to avoid impairing the shape of the part. Depending on the metals involved, prolonged heating may lead to diffusion of the liquid metal into the solid or the dissolution of solid particles into the liquid melt. In either case, the resulting part is fully dense (having no pores) and strong.

**Isostatic Pressing.**—Isostatic pressing is generally used to produce large PM parts to near-net shapes of varied complexity. Unlike conventional PM, in which the powder is compacted uniaxially through direct contact with tooling, isostatic pressing confines the metal powder within a flexible membrane or hermetic metal or glass container, which acts as a pressure barrier between the powder and the pressurizing medium, whether liquid or gas, that surrounds it. The use of this pressurizing system ensures a uniform compaction pressure from all directions and the absence of die wall friction; it produces a fully homogeneous and uniform grain structure and density irrespective of the shape of the final parts. Other advantages of isostatic pressing are that parts with high length-to-diameter ratios have been produced with very uniform density, strength, toughness, and good surface detail; and that it is possible to compact much larger parts than are possible with other compacting processes. Limitations of isostatic pressing include wider dimensional tolerances than are caused by other compacting processes; greater cost and time than are required by other processes; applicability only to relatively small production quantities (fewer than 10,000). Two of the most commonly used methods are cold isostatic pressing and hot isostatic pressing.

*Cold Isostatic Pressing:* In cold isostatic pressing (CIP), metal powders are contained in a flexible mold that is typically made of rubber or another elastomer material and pressed to the green compact by a fluid. Water or oil is usually used to provide hydrostatic pressure against the mold inside the chamber. The most common pressure is 58,000 psi (400 MPa). As the pressure is isostatic, the resulting pressed component is of uniform density. In CIP processing, the part must be sintered after removal from the mold. Fig. 16 illustrates the processing sequence in cold isostatic pressing.

The advantages of CIP include more uniform density, less expensive tooling, and greater applicability to shorter production runs, typically fewer than 10,000 parts per year.

Fig. 16. Cold Isostatic Pressing

Good dimensional accuracy is difficult to achieve in isostatic pressing, due to the flexible mold. Normally, this technique is only used for roughly shaped components, all of which require considerable secondary operations to produce the final, accurately dimensioned component.

**Hot Isostatic Pressing:** Hot isostatic pressing (HIP) is a manufacturing process that uniquely combines pressure and temperature to produce materials and parts with substantially better properties than other techniques. The pressure medium is an inert gas, usually argon. Powders are usually encapsulated in a sheet metal container (mold), which is assembled of steel sheets and optionally pipes and metallic inserts by TIG welding. The container is tested to make sure it is leak-free and is designed to give the part its full density and desired shape. Once the container is leak-free, the powders are filled into it via a fill tube. In order to achieve maximum and uniform packing of the powders, which is necessary to ensure a predictable and consistent shrinking, a vibration table is used. In special cases such as critical aerospace applications, the filling operation is done under inert gas or vacuum to minimize contamination of the powders. The next step is outgassing to remove adsorbed gases and water vapor. After outgassing, the fill tube is welded to seal the container. The absence of leaking is critical. Otherwise, when the HIP vessel is pressurized, argon will enter the container and become entrapped in the powder mass, creating argon-filled pores, with damaging effects on the mechanical properties.

The container is then placed in a hot isostatic vessel. The HIP vessel is evacuated to eliminate the air. Then, during heating, argon gas pressure is increased in the vessel. After the calculated pressure is reached, further increase in pressure will occur through gas thermal expansion. During the holding time, gas pressure and temperature are kept constant. After this, a rapid cooling takes place, with decreasing pressure and temperature.

The hot isostatic pressing parameters of pressure, temperature and time are predetermined to give the material full density. Chosen temperatures are below solidus (approximately  $0.8 T_{\text{solidus}}$ ) to avoid a liquid phase.

Modern HIP systems can feature uniform rapid cooling (URC) that circulates a lower temperature gas to cool the part at a controlled rate of up to  $212^{\circ}\text{F}/\text{min}$  ( $100^{\circ}\text{C}$ ). The HIP quenching technique cuts cycle time dramatically by shortening the cooling stage by as much as 80 percent. It also provides the benefit of combining heat treatment with HIP in a single step. The uniform rapid cooling restricts grain growth and thermal distortion of the parts and avoids surface contamination by using high purity argon gas.

A HIP unit consists mainly of a pressure vessel, a heating system and an argon gas system. Various HIP constructions are available. Fig. 17 schematically illustrates one type of hot isostatic pressure unit.

Molybdenum furnaces are used for temperatures up to  $2462^{\circ}\text{F}$  ( $1350^{\circ}\text{C}$ ) and 14500 to 43511 psi (100 to 300 MPa).

The sheet metal container remains on the part after the hot isostatic pressing and heat treatment, and it is removed by machining or by chemical milling. After the container has been removed, depending on the type of material and the application, the PM HIP part will be heat treated, machined, and subjected to various types of quality control, such as ultrasonic inspection, dimensional control, and testing of mechanical properties.

Fig. 17. Hot Isostatic Pressing: a) Container is Filled; b) Container is Evacuated and Sealed Hermetically; c) Schematic Illustration of Hot Isostatic Pressing

The main advantages of HIP are that it improves mechanical properties, produces compaction with almost 100 percent density, and increases workability, and that, when incorporated as an integral part of the manufacturing process, it reduces scrap and allows frequent replacement of wrought components.

Further, it maximizes material utilization by improving material properties, so processed parts exhibit higher reliability and longer service life, and parameters can be established to minimize subsequent heat-treatment operations.

Disadvantages of HIP include that it is a relatively expensive process and that good dimensional accuracy of parts is not easy to achieve with this method.

HIP applications include defect healing of castings, consolidation of metal powder (preform on near-net-shaped parts); improving the structural properties of premium investment castings, primarily for aerospace applications, for which the process was initially used; sintering of diamond and carbide tools; and fabrication of metal matrix composites in the aircraft industry.

**Powder Injection Molding.**—Powder injection molding (PIM) refers to the processing of both metal and ceramic powders. When one is dealing with metals or alloying powders, the term *metal injection molding* (MIM) is used. Powder injection molding is an innovative and cost-effective manufacturing process commonly used for complex, high-quality medical and dental components. It is a high-volume, high-quality, cost-effective process that helps eliminate secondary machining operations for metal part production. PIM is very efficient for manufacturing small, intricate, and complex parts with good mechanical properties and geometrical accordance.

The most common used materials for MIM are stainless steel, chrome-nickel steel, iron, and titanium.

The process is generally best suited to parts measuring less than 0.25 in. (6 mm) thick and weighing less than 100 grams. Typical parts are components for watches, precise mechanic instruments, surgical knives, and automobiles. Powder injection molding is a multi-stage process. A general outline of the process is illustrated in Fig. 18.

In MIM, very fine powders ( $\leq 10 \mu\text{m}$ ) are processed as follows:

**Mixing:** Metallic powders are mixed with an organic binder. Regarding the maximum powder content, 60 percent is typically powder and 40 percent is binder. Powder content can be slightly increased by blending different binder particle sizes.

**Pelletizing:** Granular pellets are formed from the mixture into feedstock.

**Molding:** The feedstock then undergoes a process similar to die casting; it is injected into the mold at a temperature of 284–400°F (140–200°C) and under pressure of 445–725 psi (3–5 MPa). High pressure powder injection molding at pressures of 5,000 psi (34 MPa) allows molding of thinner features, albeit with increased mold wear.

**Debinding:** The molded green parts are heated at a low temperature to burn off the binder, or a chemical catalytic is used to remove the binder.

**Sintering:** The parts are sintered in a furnace at sintering temperature (generally within 70 to 90 percent of the melting point of the metal or alloy).

Secondary operations are performed as appropriate. Major advantages of MIM over conventional compaction are that complex shapes can be produced having wall thicknesses as small as 0.1 in. (2.5 mm) and features as small as 0.02 in. (0.5 mm); they can be molded and then easily removed from the dies, and their mechanical properties are nearly equal to those of wrought parts; there is good dimensional tolerance, and high production rates can be achieved using multi-cavity dies.

Fig. 18. Outline of the Powder Injection Molding Process

The major limitations of MIM are the limited availability of fine metal powders and the relatively high cost of production.

**Powder Rolling, Extrusion, and Forging.**—Rolling, extruding, and forging are plastic deformation metal-forming processes. In this section, these processes are described in the context of powder metallurgy.

*Powder Rolling:* This term is applied to the process, now established on an industrial scale, wherein a metal powder is fed continuously into a rolling mill (Fig. 19), which may be heated, and compacted between the rolls into strip at speeds of up to 1.6 ft/s (0.5 m/s). This strip is passed through a sintering furnace and rerolled to the finished size. In general, the product does not have any advantage over strip produced by conventional metal-rolling from bulk, although in some cases superior homogeneity can be demonstrated, as well as freedom from laminations that can arise from bulk defects.

Fig. 19. Powder Rolling Illustration

The main advantages of the process are: low capital cost compared to traditional melting, forging, etc.; fewer operational steps compared with conventional rolling; availability of low-cost raw materials; precision control of composition and ability to use high-purity metals; applicability to composite type mixtures or immiscible components that currently cannot be produced by the conventional methods; and adaptability and versatility, including the ability to roll multilayer structure.

Sheet metal for controlled expansion properties of products such as for alkaline batteries, fuel cell electrodes; and for coins can be made by this process.

**Powder Extrusion:** Extrusion, in general, is a process that forces metal to flow through a shape-forming die. (see *Extrusion of Metals* on page 1519). The powder is placed in a vacuum-tight sheet metal container, then heated and extruded, generally through a cylindrical die. As powder particles pass through the extrusion die, they undergo intense deformation and pressure, which bonds them together and removes porosity between the particles. Because there is a limit to the amount of reduction in cross-sectional area that can be achieved by extrusion, often the billet extruded from one die is then further extruded through a die of smaller diameter to eliminate any trace of porosity. The full-density billets produced in this way can then be cut to length, reheated, and used in a closed forging die to produce complex-shaped parts.

This method is particularly useful in production of aluminum and titanium parts for aircraft. Extrusion of powder also is used to produce billets of specialty alloys of copper and tool steels, which are then machined or formed into finished products.

**Powder Forging:** The purpose of forging, whether performed hot or cold, is to improve part performance. Densification is an essential part of the powder forging process. The powder forging (PF) process is performed in three steps, with the first two similar to normal powder metallurgy processing. A form is pressed as a conventional PM compact, called a *preform*. The mass, density, and shape of the preform are controlled closely to ensure consistency in the characteristics of the final forged part. The preform is sintered with particular attention paid to the reducing of nonmetallic inclusions. The sintered preform can be forged to full density in two ways: direct forging the preforms from the sintering temperature, or forging sintered preforms after reheating to forging temperature. The amount of deformation involved is sufficient to give a final density approaching very closely that of the solid material, and consequently, the mechanical properties are comparable with those of material forged from wrought bar.

Advantages of powder metal forging include the following: improved strength and density; high level static and dynamic properties; material flexibility, from low- to high-alloy steel; minimum weight fluctuations and reduced burr waste; high cost-effectiveness; lower tooling cost; and good dimensional accordance of forged parts.

The powder forging process is used mainly in making parts for the automotive industry. Such parts can have inside and outside spline forms, cam forms, and other forms that require extensive machining. In addition to the well-known connecting rod, other applications include bearing races, torque converter hubs, and differential gear sets.

**Additive Manufacturing with Metal Powder:** Another approach to making parts from metal powders is by additive manufacturing (AM). Additive manufacturing processes use an energy beam, such as a laser, or material jetted from an inkjet print head to bond powder particles into the desired shape, as described in a CAD file, usually layer upon layer. AM processes for metal are derived from rapid prototyping with plastics, described in the section *Additive Manufacturing Plastics* on page 611. With this approach, parts can be made into shapes that cannot be made by conventional processes. For example, AM parts may have internal channels that are not straight or round in cross section. Also, parts can be made with details that are too fine or nested to be reached by conventional machining tools. Another advantage is that multiple parts can be consolidated into one part. Also, most of the powdered material is included in the part, so there is minimal material waste. For a discussion of metal AM processes, see *METAL CASTING, MOLDING, AND EXTRUSION* on page 1480.

### Powder Metallurgy Materials

As precision-engineered materials, metal powders are available in a great variety for fabricating a wide range of products through the PM process. Generally, powder mixes for compacting are prepared from three powder types. The first type is admixed powder, in which elemental alloying powders (such as copper, nickel, graphite, and tin) are added to base element powders (such as iron or copper). The second type is partially alloyed powder, composed of two or more elements with alloying additives that are diffusion-bonded to the base powder during the powder manufacturing process. These powders produce a heterogeneous microstructure with good dimensional control and excellent as-sintered mechanical properties. The third type is prealloyed powder, which is atomized from alloyed furnace melts such that each powder particle has the same nominal composition throughout. Prealloyed powders yield homogeneous phase constituents in the microstructure.

**Conventional Materials.**—For an overview of the scope of conventional materials, refer to Table 2, Table 3, Table 4, and Table 5 that follow. Table 2 lists basic materials for ferrous structural parts. Full specifications for a variety of ferrous PM structural materials are covered in ASTM Standard B783-19 and MPMF Standard 35.

**Table 2. PM Materials for Ferrous Structural Parts**

Material	MPIF Designation Code <sup>a</sup> Composition	Density <sup>b</sup> g/cm <sup>3</sup>	Tensile Strength MPa	Comments
Carbon steel	F-0008 0.8C	6.9	370	Cost-effective
	F-0008-HT 0.8C	6.9	390	
Copper steel	FC-0208 2Cu, 0.8C	6.7	410	Good sintered strength
	FC-0208-HT 2Cu, 0.8C	6.7	590	
Nickel steel	FN-0205 2Ni, 0.5C	7.1	390	Good heat-treated strength, impact energy
	FN-0205-HT 2Ni, 0.5C	7.1	1000	
Low-alloy steel	FL-4405 0.85Mo, 0.5C	7.1	460	Good hardenability, consistency in heat treatment
	FL-4405-HT 0.85Mo, 0.5C	7.1	1100	
Hybrid low-alloy steel	FNL-4405 2Ni, 0.85Mo, 0.5C	7.05	550	Best heat-treated strength, impact energy
	FNL-4405-HT 2Ni, 0.85Mo, 0.5C	7.05	1170	
Diffusion- alloyed steel	FD-0205 1.75Ni, 1.5Cu, 0.5Mo, 0.5C	6.95	540	Best sintered strength
	FD-0205-HT 1.75Ni, 1.5Cu, 0.5Mo, 0.5C	6.95	900	
Sinter hardened steel	FLC-4608-HT 1.35Ni, 1.5Cu, 0.5Mo, 0.8C	7.0	690	Hardenable in sintering
Stainless steel	SS-316N2 17Cr, 12Ni, 2.5Mo SS-430N2 17Cr	6.57.1	410 410	Good corrosion resistance, appearance

<sup>b</sup> Density is given as typical values.

**Table 3** shows basic materials for soft magnetic parts. Complete standard specifications for iron-phosphorous powder metallurgy parts for soft magnetic applications are covered in ASTM Standard A839-15 and MPIF Standard 35.

**Table 3. PM Materials for Soft Magnetic Parts**

Material	MPIF Designation Code <sup>a</sup> Composition	Density <sup>b</sup> g/cm <sup>3</sup>	Magnetic Properties	
			Induction (kG)	Maximum Permeability H/m
Iron	FF-0000 <0.03C	6.6	9.0	1700
Phosphorus iron	FY-4500 0.45P	6.8	10.5	2300
Silicon iron	FS-0300 3Si	7.2	13.0	5000
Nickel iron	FN-5000	7.5	12.0	12000

<sup>a</sup> Reference: MPIF Standard 35, "Materials Standards for PM Structural Parts."

<sup>b</sup> Density is given as typical values.

Some powder materials (PM) for nonferrous structural parts are given in **Table 4**. ASTM Standard B823-15 and MPIF Standard 35 give complete information on nonferrous powder metallurgy (PM) materials for structural parts.

**Table 4. PM Materials for Nonferrous Parts**

Material	MPIF Designation Code <sup>a</sup> Composition	Density <sup>b</sup> g/cm <sup>3</sup>	Usage and Characteristics
Copper	C-0000 0.2 max. other	8.0	Electrical parts, conductivity 85% IACS
Bronze	CTG-1001 10Sn, 1 Graphite	6.2	Self-lubricating bearings, 22% minimum oil content
Red brass	CZ-1000 10Zn	7.9	Hardware items, yield strength 76MPa.
Yellow brass	CZ-3000 30Zn	7.6	Hardware items, yield strength 110MPa
Nickel silver	CNZ-1818 18Ni, 18Zn	7.9	Appearance, corrosion resistance, yield strength 138MPa
Aluminum	4Cu, 0.5Mg, 1Si	2.6	Light weight, corrosion resistance, good electrical, thermal conductivity, T4 condition tensile strength 220MPa.

<sup>a</sup> Reference: MPIF Standard 35, "Materials Standards for PM Structural Parts."

<sup>b</sup> Density is given as typical values.

**Table 5** shows materials used for self-lubricating bearings. More information about these materials, and other PM materials for self-lubricating bearings are given in ASTM Standard B438-17, ASTM B439-18, and MPIF Standard 35.

**Table 5. Materials for Self-Lubricating Bearings**

Material	MPIF Designation Code <sup>a</sup>	Density <sup>b</sup> g/cm <sup>3</sup>	Oil Content Volume%	K Strength MPa
Bronze	CT-1000	6.0-6.4	24	130
	CTG1001-K	6.4-6.8	17	160
Diluted bronze	FCTG-3604-K	6.0-6.4	17	150
Iron graphite	FG-0303-K	5.6-6.0	18	70

<sup>b</sup> Density is given as typical values.

**Advanced Materials.**—Advanced materials outperform conventional materials with superior properties such as toughness, hardness, durability, and elasticity. There is always a real need for better materials; the questions are how much better and at what cost? An applied scientist, with a particular application in mind, will scour lists of known materials looking for one that meets his or her needs. The development of advanced materials can even lead to the design of completely new products, including medical implants and computers.

If existing materials are unsuitable, applied and basic scientists must work together to develop new materials. The area of advanced materials research is very broad in scope and potential applications, and synergism between what is available and what needs to be developed reflects the important and complementary roles of the basic and applied sciences in materials science.

While some advanced materials are already well known, it will take a few more years for others to appear in products. Here, we describe some advanced PM materials that are manufactured using advanced processes such as pressing, metal injection molding, and spray forming. In addition, certain alloys are produced nearly exclusively by PM techniques.

**Superalloys** : A superalloy, or high-performance alloy, is an alloy that exhibits specific desirable properties related to mechanical strength, stability at high temperatures, and surface resistance to oxidization and corrosion. Superalloys typically have a matrix with an austenitic face-centered cubic crystal structure. The use of high alloy PM materials, notably superalloys, is most common in the production of near-net shapes and the forging of preforms for aircraft turbine engines. Economic benefits have been the prime driving force in the use of PM for the manufacture of these high cost alloys.

These superalloys are processed from highly controlled metallurgically alloying elements, usually nickel, cobalt, or nickel-iron. Clean powders are produced by inert gas atomization methods that minimize surface oxidation during processing. After powder screening and cleaning, the powder is compacted using hot isostatic pressing (see *Isostatic Pressing* on page 1539). Thermochemical processing may be performed to enhance mechanical properties or microstructure. Hot extrusion of the atomized powder is an alternate consolidation method (see *Powder Extrusion* on page 1543).

PM processing offers the advantages of a homogeneous microstructure and near-net-shape configuration for a lower cost. As a result, countless pounds of PM superalloy components are now flying in both military and commercial aircraft engines.

Additional applications of superalloys include parts for space vehicles, submarines, nuclear reactors, military electric motors, racing and high-performance vehicles, chemical processing vessels, and heat exchanger tubing.

**Tool Steels**: Tool steel refers to a variety of carbon and alloy steels that are particularly well suited to be made into tools. Their suitability comes from their distinctive hardness, resistance to abrasion, their ability to hold a cutting edge, and their resistance to deformation at elevated temperatures.

It is well known that powder metallurgy provides a means of making new alloys and composites of tool materials, which cannot be made by conventional metallurgy, casting and hot-working methods. Powder metallurgy processing of high-speed steels has gained considerable significance over conventional ingot metallurgy processing.

High-performance tool steels and high-speed steels are produced in mill shapes using PM process techniques. PM tool steels offer these advantages:

- finer grain structures
- improved homogeneity and distribution of secondary and carbide phases
- elimination of secondary stringers
- less distortion in heat treatment
- improved grindability
- greater wear resistance
- improved toughness and fracture strength.

The hot isostatic process has also been used in the production of PM tool steels to near-net tool shapes, such as hobs and shaper cutters. Tool steel parts can also be made by conventional cold compacting combined with high-temperature sintering.

*Refractory Metals:* Refractory metals are a class of metals that are extraordinarily resistant to heat and wear. The expression is mostly used in the contexts of materials science, metallurgy, and engineering. The definition of the elements that belong to this group differs. By one definition, a melting point above 4000°F (2200°C) is necessary to qualify an element as refractory. Five elements, niobium, molybdenum, tantalum, tungsten and rhenium, are included in all definitions. The refractory metals, alloys, and composites are produced using powder metallurgy techniques. Powders of the pure metal are compacted into rectangular bars, sintered by heating using electric current, and further fabricated by cold-working with annealing steps. Refractory metals can be worked into wire, ingots, sheets, or foil.

Some of their applications include tools for working metals at high temperatures, casting molds, chemical-reaction vessels for corrosive environments, nuclear reaction control rods, tantalum capacitors, and tungsten-silver composite circuit breaker contacts. Refractory metals are stable against creep deformation to very high temperatures.

*Beryllium:* As a free element, beryllium is a steel-gray, strong, lightweight and brittle metal. Beryllium increases hardness and resistance to corrosion when alloyed with aluminum, cobalt, copper, iron, and nickel.

Powder metallurgy is the main processing route to produce beryllium components. The vacuum hot processing method results in a fine-grained machinable form of the material. The random orientation and fine grain size of powder metallurgy ingots enable beryllium to be used in structural applications with relatively uniform mechanical properties in all directions.

Vacuum hot pressing has been a standard consolidation technique throughout the development of beryllium technology, and hot isostatic pressing powder is the major form of beryllium in use today. Sometimes, hot isostatic pressing is substituted for the hot pressing step. Due to its light weight, beryllium is used in structural applications; its high flexural rigidity, thermal stability, thermal conductivity, and low density make beryllium a quality aerospace material for high-speed aircraft, missiles, spacecraft, and communication satellites. Because of its low density and atomic mass, beryllium is relatively transparent to X-rays and other forms of ionizing radiation; therefore, it is the most common window material for X-ray equipment and in particle physics experiments. The high thermal conductivities of beryllium and beryllium oxide have led to their use in heat transport and heat sinking applications.

Beryllium is used commercially in the manufacture of telecommunications infrastructure equipment, computers, and cellular phones, thereby helping people around the world to keep in touch. Also, medical lasers made with beryllia ceramics help ophthalmologists to restore or improve eyesight for millions. Beryllium ceramic is the only material that offers the thermal conductivity, strength, and dielectric properties required to contain and control these tiny, high-powered gas laser bores. Copper beryllium connectors transmit precise electrical signals to the delicate surgical instruments and monitoring devices used in the newest, non-invasive surgical techniques. Such techniques reduce patient trauma and infection risk, while speeding the process of healing and recovery.

*Titanium:* Titanium alloys are among the most important of the advanced materials that are key to improved performance in aerospace and conventional systems. This is because of the excellent combination of specific mechanical properties and outstanding corrosion behavior exhibited by titanium alloys. However, discouraging widespread use is the high cost of titanium alloys compared to competing materials. This has led to numerous investigations of various potentially lower cost processes, including powder metallurgy (PM). Titanium powder metallurgy can be divided into categories such as powder injection molding (use of a binder to produce complex small parts); near-net shaping (use of pre-alloyed

and blended elementals in die pressing or isostatic pressing); spraying (high-speed projecting of powder onto a substrate); and laser melting (powder feed or powder layer melted with a laser).

Titanium PM alloys have a combination of low density 2.6 oz/in<sup>3</sup> (4.5 g/cm<sup>3</sup>) and high strength. The strengths vary from 70,000 psi (480 MPa) for some grades of commercial titanium to about 160,000 psi (1100 MPa) for structural titanium alloy products and over 250,000 psi (1725 MPa) for special forms such as wires and springs. Another important characteristic of titanium-based materials is the reversible transformation of the crystal structure from alpha (hexagonal close-packed) structure to beta (body-centered cubic) structure when the temperature exceeds 1634°F (890°C).

The use of PM titanium metal and its alloys continues to increase since PM provides a near-net shape product as compared to more expensive cast, forged, and machined processing. Depending on the application and production quantities, titanium PM near-net products are processed either by conventional press-and-sinter techniques or by hot isostatic pressing. The latter exceeds the minimum wrought alloy specifications.

If the final product is made net-shape by application of hot isostatic pressing (HIP), a lack of texture can result, thus giving equal properties in all directions. Product applications include aerospace/aircraft components, sporting goods, chemical processing equipment, and biomedical systems.

### Design Considerations in Powder Metallurgy

The powder metallurgy manufacturer is often confronted by a drawing for a component designed with a conventional manufacturing process in mind. It is not desirable for the powder metallurgy component manufacturer or designer to attempt to follow these drawings; it is far better to redesign the component so that it can fulfill its design function, while taking full advantage of the powder metallurgy process, in particular the cost-effective manufacture to near-net shape with close dimensional tolerances.

The PM part and the complexity of tooling used to produce it are closely related. Two major factors in the compacting operation influence or control part design: the flow characteristic in the die and the degree of brittleness of the green parts.

Although powder metallurgy industry standards (MPIF Standard 35) provide useful physical and mechanical property design data for engineers familiar with the PM process, those less experienced with this manufacturing process may benefit from additional guidance. In this section, design considerations are divided into three broad areas: size and shapes, design details, and design of typical parts.

**Sizes and Shapes.**—*Part Sizes:* The size limitation of PM parts is based on powder compressibility and press tonnage. Since compaction occurs in the vertical direction, using only top and bottom motions, part lengths in the pressing direction are limited. The compression ratio—the ratio of the height of the loose powder filling the die to the height of the compacted part—also tends to limit vertical part lengths. A length-to-wall thickness ratio greater than 8:1 is difficult to press, and density variations are virtually unavoidable.

*Shapes:* The shape of the part must permit ejection from the die. Part geometry must be compatible with a uniaxial compaction motion in the vertical direction. Significant variations in part length in the cross section require different tooling motions in the compaction press. Cam, gears, and sprockets are readily made. The shape of the part should permit the construction of strong tooling. The part should be designed with as few changes in section thickness as possible: the number of levels in the part should not exceed the number of pressing actions available in the compacting press. With too many levels, density varies considerably and part quality becomes a problem. Face forms on upper or lower punches can provide bosses, pads, lettering, countersinks, and other features. Parts weighing a few grams to about 26 lb (around 12 kg) or more are possible.

**Design Details.**—Successful design for PM rests on an understanding of how the unique aspects of the technology affect the countless details that make up the design of any structural part.

**Holes:** Holes in the pressing direction can be round. Tooling members, which create holes, are called core rods. Lightening holes are frequently added to large parts to reduce projected pressing area, thus making parts lighter and easier to press. Blind holes, blind steps in holes, and tapered holes are readily produced. Side holes have to be produced after a sintering operation, usually by machining.

**Wall Thickness:** Die fill is all-important. As a general rule, walls should not be made any thinner than 0.057 in. (1.45 mm). One should avoid designing long thin walls; they require tooling that is complicated, and the parts themselves have a tendency toward density variation.

**Flatness:** Total measured flatness depends on part thickness and surface area. Thin parts tend to distort more than thick parts during sintering or heat treatment. Repressing improves flatness. Projection bosses are easier to flatten than entire face areas.

**Taper and Draft:** Drafts are generally not required or desired on sides of parts. While drafts on outer sections for ejection are sometimes helpful, producing one demands careful timing of the tools and slower production rates.

**Fillet and Radii:** Generous fillet radii are most desirable. Tooling with such fillets is more economical and longer lasting. Parts made with fillets have greater structural integrity (Fig. 20). Parts with generous radii are more easily and more quickly made.

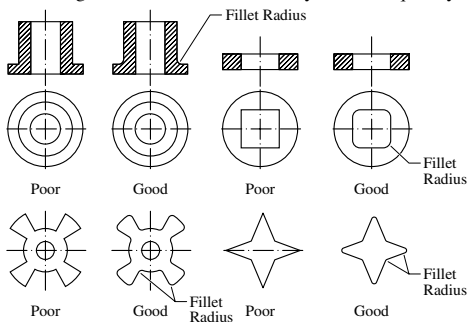

Fig. 20. Examples of PM Parts Showing Poor and Good Designs (Source: Metal Powder Federation)

**Chamfers and Bevels:** Chamfers are necessary on front edges to prevent burring. For example, on bushings (Fig. 21) a 30° to 45° chamfer and 0.005 to 0.015 in. (0.13 to 0.38 mm) flat to eliminate feature edges are the preferred.

$$b = 0.13 \text{ to } 0.38 \text{ mm (0.005 to 0.015 in.)}$$

Fig. 21. Chamfers are Preferred on Parts Edges (Source: Metal Powder Federation)

**Countersinks:** A countersink is a chamfer around a hole for a screw or bolt head (Fig. 22). When the countersink is formed by a punch, a 0.010 in. (0.25 mm) nominal flat is essential in order to avoid sharp, flanged edges on the punch.

Fig. 22. Countersink in Clearance (Source: Metal Powder Federation)

**Flanges:** Flanges or overhands can be produced by step in the die. Too long flanges a causes ejection difficulties. A long flange should incorporate a draft around the flange, a radius at the bottom edge, and radius at the juncture of the flange and component body to reduce stress concentrations and the likelihood of fracture.

**Hubs:** The PM process can readily produce hubs, which are complementary part sections to gears, sprockets, or cams. It is important to include a generous radius between the hub and flange section and to maximize space between the hub and the root diameter of the gear or sprocket.

**Slots and Grooves:** Grooves can be pressed into either end of a part from projections on the punch face, with the following general caveats (Fig. 23). Curved or semicircular grooves are limited to maximum depth of 20 percent of the overall part length. Rectangular grooves are limited to a maximum depth of 15 percent of the thickness of the workpiece in the pressing direction, surfaces parallel to the pressing direction have up to 12° draft, and all corners are radiused. Deep narrow slots and grooves require fragile tool members and should thus be avoided.

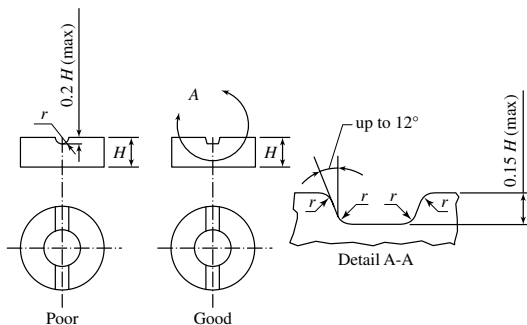

Fig. 23. Semicircular and Rectangular Groove (Source: Metal Powder Federation)

**Undercuts:** Undercuts on the horizontal plane (perpendicular to the pressing direction) cannot be made since they prevent part ejection from the die. Annular grooves must be machined as a second operation (Fig. 24a).

For a part such as that shown in Fig. 24b, where a juncture undercut is needed to allow fit-up to a “dead corner”, an alternative approach is shown in Fig. 24c.

**Tolerances:** For reasons of economics, tolerances no closer than necessary should be specified. Table 6 illustrates tolerances characteristic of PM and competitive near-net-shape forming methods.

Fig. 24. Undercuts: a) Annular Grooves Cannot Be Molded; b) Undercuts Cannot Be Molded; c) Undercut Can Be Molded (Source: Metal Powder Federation)

**Table 6. Tolerances that Can Be Produced in PM Process**

Forming Method	Typical Dimensional Tolerances ( $\pm$ ) (in/in) (mm/100 mm)	Critical Dimensional Tolerances ( $\pm$ ) (in/in) (mm/100 mm)
PM	0.002 (0.203)	0.001 (0.102)
PM (secondary forming)	0.001 (0.102)	0.0005 (0.051)
Cold forming	0.010 (1.016)	0.002 (0.203)
Hot extrusion	0.010 (1.016)	0.003 (0.305)
Fine blanking (single level)	0.0005 (0.013)	0.0002 (0.020)
<b>Die casting<sup>a</sup></b>		
Magnesium and Aluminum	0.002 (0.203)	0.0010 (0.107)
Zinc	0.0025 (0.254)	0.0010 (0.107)
<b>Hot closed-die forging</b>		
Conventional	0.02 (2.032)	0.015 (1.524)
PM perpendicular to press axis	0.0032 (0.325)	0.0025 (0.254) <sup>b</sup>
PM parallel to press axis	0.010 (1.016)	0.005 (0.508)

<sup>a</sup> Die parting line tolerance will be two to three times greater than the data shown.

<sup>b</sup> Fixture-quenched forgings, i.e., forgings clamped for quenching during heat treatment immediately after hot forging, can hold tighter tolerance.

**Design of Typical Parts.**—Although PM is used for a whole host of parts in many different applications, most parts (typical categories include gears, cams, assemblies, and bearings) have their own unique design considerations.

**Gears:** Gears are well-suited to PM production. Carbide dies for production gears provide long life and good accordance. PM gears can be made with blind corners, thus eliminating the need for undercut relief. PM gears can be comminuted with other configuration such as cams, and various other components. PM helical gears are possible; copper infiltration is sometimes used to improve teeth density. Since tooth and shape is not a problem, true involute gear forms are more easily produced through PM than with other fabrication methods. One should keep in mind when designing PM gears that hubs or pinions should be located as far as possible from gear root diameters.

**Cams:** Cams are well-suited to PM production: The process provides excellent surface finishing and part-to-part consistency; the natural finish of a self-lubricating PM cam will often outwear a ground cam surface; for radial cams, the shape is formed in the die; for face cams, the shape is formed in the punch faces.

**Assemblies:** Two or more PM parts can often be joined from a unit that is difficult, if not impossible, to make as a single structure. Capitalizing on PM's flexibility, it is feasible to make assemblies of very difficult materials such as a bronze bearing in a ferrous structural part. PM parts can be joined by conventional methods and also by sintering together

materials of appropriately different characteristics. Copper infiltration during sintering can be used to bond steel parts.

**Bearings:** Bearings are natural products for PM because of its controlled porosity and the resulting self-contained lubricant. Plane bearings, flanged bearings, spherical bearings, and thrust washers are commonly produced with PM technology. The operation environment should be carefully considered: external lubrication, cooling, and hardened or chromium-plated shafts tend to increase permissible loads. Repeated start-stop operation, oscillatory or reciprocating motion, high speed, and temperature extremes tend to decrease permissible loads.

### Economics of Powder Metallurgy

Powder metallurgy is a continually and rapidly evolving technology that embraces most metallic and alloy materials and a wide variety of shapes. PM is a highly developed method of manufacturing reliable ferrous and nonferrous products. The growth of the PM industry during the past few decades is largely attributable to the cost savings associated with net- or near-net-shape processing compared to other metalworking methods such as casting or forging.

The following will explain why powder metallurgy is competitive against alternative production processes. There are two principal reasons for using a powder metallurgy product:

- 1) cost savings
- 2) unique properties attainable only by the PM method

In the automotive sector, which accounts for about 80 percent of structural PM production, the reason for choosing PM is, in the majority of cases, an economic one. Why then is PM more cost-effective?

- A sintered PM part of comparable quality may be cheaper than a cast of wrought component.
- It provides better material utilization with close dimensional tolerances.
- It is suited to high-volume parts production requirements.
- It provides long-term performance reliability in critical applications.

Conventional metal forming or shaping processes, against which PM competes, generally involve significant machining operations from bar stock or from forged or cast blanks. These machining operations can be costly and are wasteful of material and energy. This fact is illustrated in [Table 7](#), which shows that material utilization in excess of 95 percent can be achieved with close dimensional tolerances.

**Table 7. Raw Material Utilization and Energy Requirements of Various Manufacturing Processes**

Manufacturing Process	Raw Material Utilization %	Energy Requirement per kg Finished Part MJ (BTU)
Casting	90	30–38 (23,434–36,017)
Sintering	95	29 (27,486)
Cold or warm extrusion	85	41 (38,860)
Hot-drop forging	75–80	46–49 (43,599–45,495)
Machining process	40–50	66–82 (66,555–77,721)

The example in [Table 7](#) compiles data for a comparison for a production of notch segments for track transmission. The PM process (sintering) has the highest raw material utilization (95 percent) and the lowest energy requirement per kg of finished part compared with other manufacturing processes. The energy savings alone contribute significantly to the economic advantage offered by PM. Compared with forging, machining, and a number of other processes, PM consumes only around 45 to 50 percent of the energy and the number of process steps is greatly reduced.

Equipment costs for conventional PM processing are somewhat similar to those for bulk forging, but the cost increases significantly for HIP methods. Labor costs are not as high in

other processes because operations are primarily performed on highly automated equipment, and the skills required are not as high.

### Powder Metallurgy Standards

Why are PM standards important? Powder metallurgy is a rather young industrial technology. The first local industries were started in the middle of the 20th century. During the next 30–40 years, business expanded primarily within the various continents, but since the last decade, the rate of expansion has accelerated and today the business is truly global.

This global business requires new modern tools to support further growth and sharpening of the weapons to compete with other manufacturing technologies. In this context, ISO standards, ASTM, and MPlF standards support confidence in powder metallurgy and guides end users, often with global presence, to make the right choices in using components and solutions based on metal powder.

**ISO Standards.**—International Powder Metallurgy standards are generated by the ISO technical committee, ISO/TC 119. The five sub-committees of this technical committee have created a range of standards that address sintered metals and hard metals as well as MIM standards. These sub-committees have created the following standards:

- ISO 3252:1999—Terminology
- ISO 3923-1 and -2—Apparent density measurement
- ISO 3953—Tap Density measurement
- ISO 4490—Flow Rate
- ISO 18549-1 and -2—Apparent density and rate at elevated temperatures
- ISO 3927 + Corrigendum 1—Compressibility and uniaxial compression
- ISO 3954—Powder sampling
- ISO 3995—Green strength
- ISO 4491-1, -2, -3 and -4—Oxygen content
- ISO 4496—Acid insoluble content in iron, copper, tin, and bronze powders
- ISO 4497—Particle sizing by dry sieving
- ISO 10076—Particle sizing by sedimentation analysis
- ISO 10070—Specific surface area
- ISO 13944—Lubricant content
- ISO 13947—Non-metallic inclusion content using powder forged specimen
- ISO 14167—Testing of copper infiltration powders
- ISO 4492—Dimensional changes in compaction and sintering
- ISO 2738—Permeable sintered metal materials-density, oil content, open porosity
- ISO 4003—Permeable sintered metal materials-bubble test pore size
- ISO 4022—Permeable sintered metal materials-fluid permeability
- ISO 3369—Density of impermeable sintered materials
- ISO 2739—Radial crushing strength of sintered bushes
- ISO 2740—Tensile test pieces
- ISO 3928—Fatigue test pieces
- ISO 5754—Unnotched impact test pieces
- ISO 3312—Young's modulus measurement
- ISO 3325 + Amendment—Transverse rupture strength
- ISO 4498—Apparent hardness and microhardness
- ISO 14317—Compressive Yield Strength
- ISO/TR 14321—Metallographic preparation and examination
- ISO 4507—Case-hardening depth measurement
- ISO 7625—Sample preparation for chemical analysis of carbon content
- ISO 23519—Sintered metal materials, excluding hard metals
- ISO 28279—Sintered metal materials
- ISO 3326—Magnetization coercivity
- ISO 3327—Transverse rupture strength

- ISO 3738-1 and -2 – Rockwell hardness testing
- ISO 3878 – Vickers hardness testing
- ISO 3907 – Total carbon content
- ISO 3908 – Insoluble carbon content
- ISO 3909 – Cobalt content
- ISO 4489 – Sampling and testing of sintered hardmetals
- ISO 4499-1 and -2 – Metallography
- ISO 4501 – Titanium content
- ISO 4503 and 4883 – X-ray fluorescence analysis
- ISO 4505 – Metallographic assessment of porosity and uncombined carbon
- ISO 4506 – Compression testing
- ISO 4884 – Sampling and testing of powders using sintered test pieces
- ISO 7627-1, -2, -3, -4, -5, and -6 – Chemical analysis by frame atomic spectrometry
- ISO 11877 and 17352 – Silicon in cobalt metal powders
- ISO 28079 – Palmqvist toughness testing
- ISO 28080 – Abrasion tests for hard metals
- ISO 26482 – Lead and cadmium content
- ISO 22394 – Knoop hardness test
- ISO 11876 – Calcium, copper, iron, magnesium, manganese, sodium, nickel, and zinc in cobalt metal powder
- ISO 11873 – Sulfur and carbon contents in cobalt metal powders
- ISO 5755:2012 – Sintered metal materials specifications
- ISO 22068 – Sintered-metal injection-molded material specifications

The participation of the United States in ISO/TC119 is through the member body, the American National Standards Institute (ANSI).

**ASTM Standards.**—The ASTM international committee with the responsibility for development of PM standards is Committee B09 within the general subject Metal Powders and Metal Powders Products. This committee is composed of sub-committees that address specific segments as follows:

- B09.01 – Terminology
- B09.02 – Base Metal Powders
- B09.03 – Refractory Metal Powders
- B09.04 – Bearings
- B09.05 – Structural Parts
- B09.06 – Cemented Carbides
- B09.11 – Near Full Density Powder Metallurgy Materials
- B09.98 – Long Range Planning and Awards

Standards can be found by searching the catalog of each subject area of the sub-committee.

**MPIF Standards.**—The Metal Powder Industry Federation (MPIF) Standard 35 is a family of publications that comprises four separate publications dealing with materials for conventional PM structural parts, PM self-lubricating bearings, powder forged (PF) steel, and metal injection molded parts (MIM). The same materials may appear in more than one publication or section of the standard depending upon their common use, e.g., some structural materials may also be used in bearing applications and vice versa, and stainless steel materials may be manufactured by more than one PM process, such as conventional PM or MIM, dependent upon part design and use.

Powder metallurgy standards available from MPIF include:

- MPIF Standard 35 – Materials Standards for PM Structural Parts
- MPIF Standard 35 – Material Standards for PM Self-Lubricating Bearings
- MPIF Standard 35 – Materials Standards for PM Steel Parts
- MPIF Standard 35 – Materials Standards for PM Metal Injection Molding Parts

### Metal Additive Manufacturing

Additive manufacturing (AM), also known as 3D printing, is a group of processes in which materials are joined selectively to transform information in computer-aided design (CAD) files into three-dimensional (3D) parts. The term “additive” is used to distinguish these processes from “subtractive” (machining, grinding, and chemical or electrical erosion) or forming (casting, rolling, and forging).

ASTM Committee F-42 was organized in 2009 to develop standards for AM. One of the committee's first actions was to define standard terminology, embodied in ASTM Standard F2792 (withdrawn); the current standard is ISO/ASTM 52900:2015. (For more on AM standards, see *Standards for Additive Manufacturing* on page 1565.) This standard groups AM processes into seven categories (listed here alphabetically):

**Binder Jetting:** A liquid bonding agent is selectively deposited to join powdered material, layer by layer, until a 3D shape is formed. The binder is deposited as fine droplets through the jets, or orifices, of an ink-jet printer onto a layer of powder.

**Directed Energy Deposition:** This process fuses material, which may be in the form of metal powder or wire, by melting as it is deposited into the focal point of a directed thermal energy source (laser, electron beam, or plasma arc).

**Material Extrusion:** In this AM process, material is selectively dispensed through a nozzle or orifice. A wide range of extruded materials may be used, from plastics to concrete to food.

**Material Jetting:** Through controlled jetting, droplets of material are selectively deposited to build a form. Materials, which may incorporate photopolymer and wax, are deposited through the orifices of an inkjet printer.

**Powder Bed Fusion:** This AM process uses thermal energy to selectively fuse areas of a powder bed. The energy source—a laser or electron beam—focuses to fuse each layer of powder that builds up the part.

**Sheet Lamination:** In this process, sheets of material are stacked and bonded across their planar interfaces to form an object.

**Vat Photopolymerization:** A specialized liquid photopolymer in a vat is selectively cured by light-activated polymerization. The light source may be a continuously moving laser or a digital array of simultaneous light projections.

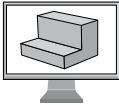

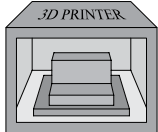

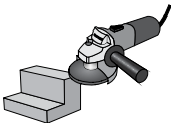

Reviewing this list, it can be seen that the material feed stock may be a liquid, powder, wire or filament, or sheet. In all cases, AM machines selectively convert material in one of these simple forms into a complex, 3D part, generally by adding layer upon layer.

**Additive Manufacturing Workflow.**—Additive manufacturing processes, involving metals or other materials, follow the same basic workflow, as summarized in Table 8. A three-dimensional (3D) model is created using CAD software. (For more on this topic, see *CAD/CAM* on page 1390.) This model is converted into a surface model made up of interfacing triangles, resulting in an STL (Standard Tessellation Language) file. The build file is then sliced into two-dimensional (2D) layers. Each layer profile is used to control the AM machine's motions, which add material in that profile and build the 3D model (Table 8). Typically, the layer thickness is 0.004 in. (0.102 mm), but it can range from 0.0007 to 0.010 in. (0.0178 to 0.254 mm).

AM processes have been adapted for commercial use under various trade names and are used to produce parts in metals, polymers, ceramics, and various composites. For example, the section *Additive Manufacturing Plastics* on page 611 describes processes used for plastics: stereolithography (SLA), which is defined by ASTM as *vat polymerization*; selective laser sintering (SLS), which is an example of *powder bed fusion*; fused deposition modeling (FDM), which is an example of *extrusion*; binder jetting (BJ); and material jetting (MJ).

This section discusses AM processes used to produce metal parts: powder bed fusion (PBF), including selective laser melting (SLM) and electron beam melting (EBM), binder jetting (BJ), and powder- and wire-fed directed energy deposition (DED).

**Table 8. Additive Manufacturing Workflow**

<p><b>Solid Computer Model:</b> A solid model of the part to be produced by an additive manufacturing (AM) process can be imported from an existing file or created using CAD (computer-aided design) software. The model may be reverse engineered, using a laser scanner or other coordinate measuring device to replicate an existing part. In biomedical applications, a CAT (computer-aided tomography) or MRI (magnetic resonance imaging) scan may be used to design a model for a custom-fit implant.</p>	
<p><b>STL File:</b> One of the output formats of CAD software is an STL (Standard Tessellation Language) file. This surface representation of the solid part consists of interconnected triangles generated by algorithms within the CAD software to precisely represent the surface of the solid part without gaps or overlaps. The more complex and curved the surface of the part, the more triangles are needed to represent it.</p>	
<p><b>Virtual Slices:</b> The STL file is positioned and oriented electronically on the 3D printer's build platform. The resulting build file is separated into slices by geometric algorithms in the printer that determine the intersecting points of each horizontal plane with the sides of the triangles in the STL file. These points outline the cross-sections to be printed in each 2D layer that will build up the 3D part.</p>	
<p><b>Additive Manufacturing:</b> CAM (computer-aided manufacturing) software in the AM machine converts the cross-section of each layer into machine instructions that control the motion of a material conversion device. In the <i>powder bed fusion</i> process, this conversion device would be a laser beam that selectively fuses metal powder into a solid layer. In <i>fused deposition modeling</i>, the device would be an extrusion head that deposits a polymer in layers corresponding to cross-sections of the part.</p>	
<p><b>Post-Processing:</b> The completed 3D part is extracted from the build plate, and any supports are removed. If necessary, the part may be heat treated for material strength; in some cases, it may undergo hot isostatic pressing (HIP) to close up porosity. Surfaces requiring a precision fit can be machined or ground. The last step is finishing the part using such standard processes as sanding, shot or grit blasting, and coating.</p>	

**Powder Bed Fusion (PBF).**—Powder bed fusion is ASTM's term for an additive manufacturing process in which a point heat source selectively fuses or melts a region of a powder bed. There are two types of PBF technology; each system has advantages and disadvantages compared to the other.

**Selective Laser Melting (SLM):** In the original ASTM Standard F2792, *laser sintering AM* is defined as a "powder bed fusion process used to produce objects from powdered materials using one or more lasers to selectively fuse or melt particles at the surface, layer by layer, in an enclosed chamber." The definition goes further to note that "sintering" is a historical term and a misnomer, because the process involves full or partial melting, as opposed to traditional powdered metal sintering, in which a compacted powder part is heated below its melting point. For this reason, the term *selective laser melting* is widely used and accurately describes the process. It is similar in principle to *selective laser sintering* (SLS) described in *Additive Manufacturing Plastics* on page 611.

The SLM system is an important technical innovation, with roots dating to the 1990s. Early systems used a gas or disk laser and processed primarily low-melting-point bronze powder, mixed with stainless steel powder that had a higher melting point. Today, SLM systems use a fiber laser as the fusion heat source to completely melt the powder. Typical laser power in metal SLM systems ranges between 100 and 1000 W, and some modern systems have two or four lasers operating simultaneously to increase production rates. Of the metal AM processes, SLM is one of the most widely used.

After the heat source, the most important components of SLM systems are beam deflection optics, which provide scanning capability for selectively melting areas of the powder bed. With scan speeds of up to 23 ft/s (7 m/s), the scanning mirror must be fast, accurate, and reliable.

The final significant optical element is the correction lens, which ensures that the beam is round as it traverses the build platform at different angles. Most systems use an  $f$ -theta lens design with anti-reflection coatings to prevent damage from the beam reflecting back into the laser. A schematic illustration of the laser-beam powder bed fusion process is shown in Fig. 25.

The system consists of a powder bed build area on a build plate that moves in the Z-direction. For each printed slice (see Table 8), the plate moves down by one layer thickness. The powder deposition system then spreads a new layer of powder, and the laser traces the profile of that part slice on the layer of powder. This sequence is repeated until the full 3D part is completed.

Because the laser melts the metal powder, to prevent oxidation, the SLM mechanism is enclosed in a gas-tight chamber containing argon or other nonreactive gases. Typically, powder particle size used in SLM processes is between 0.0008 and 0.0024 in. (0.02 and 0.06 mm). Titanium, stainless steel, and nickel-base superalloys are commonly processed by SLM; aluminum, copper, and gold are more challenging, but some newer machines feature lasers with colors in a green range (~500 nm) that are more readily absorbed by these metals.

Laser spot size is typically 0.0027 in. (0.07 mm) in diameter but may be up to 0.006 in. (0.15 mm) in diameter. At any given instant, metal particles within the laser spot are melted, forming a small pool of molten metal. This pool quickly solidifies, as heat transfers to the solid metal build plate on the first layer or to the previously solidified material in the layers below the current one. Thus, the molten metal pool within the laser spot zone continuously forms and solidifies as the laser spot moves rapidly across the powder layer, much like a mini-welding process.

The high rate of solidification of the molten pool results in very fine microstructure and excellent mechanical properties. Strength of SLM-processed material is often greater than for the same alloy in conventional casting due to this fine microstructure. On the other hand, because the process involves melting and solidification, gas porosity and solidification porosity may form, leading to fine pores throughout the material. Such defects significantly reduce fatigue and impact strengths, though without reducing the final part's yield and tensile strength.

One advantage of AM, and SLM in particular, is that the processes can produce overhangs and internal channels or cavities. In SLM, when material is printed in an overhang, the molten pool sits on loose powder from previously created layers.

Even though molten metal in such an overhang cools and solidifies rapidly, some of the metal seeps down into the spaces between the loose particles, leaving a rough surface on

Fig. 25. Schematic Illustration of Laser Beam Powder Bed Fusion, also known as Selective Laser Melting (SLM)

the bottom of the overhang. This roughness is particularly high if the angle of the overhang, relative to horizontal, is less than 45 degrees. As a result, the as-printed finish of up-facing surfaces will be better than down-facing overhang surfaces. (Surface finish in SLM material may be improved by subsequent shot peening.) Typical surface finishes of up-facing and side-facing surfaces are equivalent to those of investment castings, so only bearing or mounting surfaces may need to be machined.

Since the rate of heat transfer into loose powder is much less than the rate into solid metal, heat transfer from overhangs is reduced and the cooling rate is lower than in layers in the body of a part. Structural supports printed beneath overhangs (Fig. 26) and connected to the base plate provide a path for increased heat transfer from overhangs. Supports also anchor the printed part to the base and reduce distortion due to differences in temperature throughout the part as it is printed. Without such supports, overhanging layers of the printed parts would deflect upward due to thermal stress. A downside of such supports is that they can interfere with printing more than one layer of parts in one build.

Where 3D printed layers overhang loose powder instead of solid layers, more heat is retained, changing the cooling rate.

When these overhanging layers are longer, they can bend upward during cooling, as a result of thermal stress.

This distortion can be prevented with added structures (to be removed later) to reduce thermal stress, support the overhangs, and anchor the part.

Fig. 26. Use of Supports to Anchor Parts in SLM Process

After the part is completed, the unused powder is collected for future use, and the base plate with the parts attached is removed from the SLM machine. Parts usually are cut from the plate using a band saw or wire electrical discharge machining (EDM), supports are removed, and any surfacing is completed.

**Electron Beam Melting (EBM):** Powerful electron beams have been used for welding since the late 1950s. At the beginning of the twenty-first century, this energy source was adapted to powder bed fusion (PBF) as the electron beam melting (EBM) process. EBM is commonly used to process titanium and superalloy powders into net-shaped parts—providing significant material savings over traditional manufacturing processes.

In EBM, a tungsten filament emits electrons at a high voltage of 60,000 V (60 kV). A focusing coil or electromagnetic lens produces a converging Gaussian beam with a spot size of 0.008–0.04 in. (0.203–1.02 mm) and a power of up to 6,000 W; a deflection coil directs the scanning beam over the surface of the powder layer at a speed of 26,000 ft/s (8,000 m/s). These focus and deflection coils are the electronic counterparts of the f-theta and scanning optics of the laser beam systems in SLM. Schematically, the EBM system is similar to that of SLM; however, while the laser beam is moved optically by deflection

mirrors in SLM, the electron beam is moved by electromagnetic coils with no moving parts in EBM, facilitating high-speed scanning.

EBM machines require a vacuum in the build chamber of  $<1 \times 10^{-4}$  mbar in order to prevent obstruction of the focused beam. Similar to SLM machines, EBM machines have a build platform that moves downward one layer thickness for each build cycle, and a powder distribution system, sometimes called a *recoater*, to spread a new layer of powder. But unlike SLM systems, the electron beam repulses powder particles in the build layer. To prevent powder dispersion, each layer of powder in the build box is first partially sintered by rapidly scanning the total surface with the electron beam at low power; this causes the powder particles to adhere to the previous layer and adjoining particles. Then the electron beam power is increased, and the layer profile is scanned, melting powder particles within the beam spot. Because EBM power is much greater than the laser power in SLM, the particle size used is larger, between 0.002 and 0.004 in. (0.055 and 0.105 mm).

Because each layer is partially sintered by quick scan of the electron beam over each powder layer, it is generally not necessary to print support structures for overhangs. Therefore, unlike SLM, the EBM process allows the production of multiple layers of parts in one build. In addition, because each layer is preheated—with the temperature of powder in the build box reaching temperatures around 1300°F (700°C)—temperature variation throughout the build box is very low and distortion due to thermal stress is negligible.

Unlike the SLM process, the unused powder in the EBM process is not loose but is lightly sintered into a cake surrounding the finished part. After the build box cools down, which takes 12–18 hours, the powder cake is removed. An air gun, using the same-sized powder particles as those in the build, is used to impact the cake and break up the unused powder cake into fragments. Particles of the fragmented cake are reused in a future build.

**Binder Jetting (BJ).**—Like SLM and EBM, binder jetting begins with an STL CAD file that is sliced in preparation for layer-by-layer printing (see Table 8), the part is built in a powder bed in which a build plate is lowered one layer thickness for each slice, and a recoater spreads a new layer of metal powder. Unlike the SLM and EBM processes, a printhead with one or more jets passes over the powder surface and deposit binder droplets within the 2D slice profile defined by the CAD file of the 3D part. This sequence is repeated layer by layer, until the 3D part is completed.

In BJ, powder layer thickness ranges between 0.001 and 0.005 in. (0.0254 and 0.127 mm). A useful analogy is to think of the process as an inkjet printhead in a paper printer and each layer of metal powder as the paper sheet. Because binder jetting occurs at room temperature, there are no issues of heat transfer and supports are not needed. Therefore, as with EBM, multiple layers of parts can be made in each build box, increasing productivity.

In BJ, each binder droplet agglomerates powder particles into a building block called a *volume element* or *voxel*—the 3D equivalent of a 2D picture element or pixel. The binder serves as an adhesive, bonding particles in the new powder layer into a voxel and to material in the previous layer (Fig. 27). This bond is not enough to transmit useful loads, but it is sufficient to handle the part during removal of excess powder surrounding the part, removal of the part from the build box, and setup for the next process step. Printed parts are then sent to a sintering furnace, where the binder burns off and the powder particles sinter together at a temperature below the melting point.

Fig. 27. Binder Jetting Process

In one version of this process, the part is lightly sintered, and the remaining volume between particles is filled by infiltration with a lower-melting-point alloy. In such cases, the printed powder is typically stainless steel and the infiltrating material bronze. Average particle size for this method is 0.001–0.002 in. (0.030–0.060 mm). The resulting material is useful for making functional prototypes, because it has properties comparable to high-strength steel.

In another variation, the printed material is sintered to full density. In this case, the materials used may be stainless steel, Inconel, or another high-strength metal. To promote sintering to full density, very small particle size is used, typically 0.0004–0.0006 in. (0.010–0.015 mm).

Metals produced by BJ processes may have residual porosity as high as 2 percent. Because these processes do not use a laser, they can be used to produce parts of copper, gold, and other metals that would reflect laser light. In addition, BJ can be used for ceramic materials. Typical print resolutions are 1200 dots per inch, corresponding to a voxel length of 0.0077 in. (0.196 mm).

**Directed Energy Deposition (DED).**—In this metal AM process, the energy source may be a laser, electron beam, or plasma arc. The material source may be metal powder or metal wire. Unlike the powder bed processes described above, DED processes the powder or feed wire into the focal point of the energy source. Typically, the substrate and part are fitted to a 5-axis motion system, while the energy and powder nozzles remain stationary.

*Powder-Fed DED:* In the most common application of directed energy deposition (Fig. 28), metal powder flows through nozzles at high speed into the focal point of a laser. The powder melts and is deposited layer upon layer onto a substrate or a previously built part. As in powder bed fusion processes, liquid metal in this molten pool solidifies very quickly.

To prevent oxidation of the molten metal, an inert shield gas (argon or nitrogen) engulfs the metal deposition region. Alternately, the entire build system may be enclosed in a chamber containing inert gas. In one typical system, the 5-axis motion and powder application systems are enclosed in a chamber measuring 31 by 31 by 24 in. (800 by 800 by 600 mm) in length, width, and height.

A major advantage of this process is that it does not involve spreading a layer of powder; therefore, it can be used to apply a material surface to an existing part or substrate. DED processes, as a result, are widely used for cladding and repair of existing parts. Another advantage of DED is the high build rate of up to 2.2 lb (1 kg) per hour.

Unlike powder bed processes, powder-fed DED processes have multiple nozzles, each of which can supply a different material. Therefore, material can be deposited with varying composition. For example, if one nozzle applies stainless steel and another supplies

Fig. 28. Directed Energy Deposition with Powder Feed

Fig. 29. Directed Energy Deposition with Wire Feed

Inconel nickel-based superalloy, a part could be built with a relatively low-cost stainless steel base that transitions to the higher cost Inconel surface where greater heat resistance is required.

A major disadvantage of this process is rough surface finish. In addition, because the powder is blown onto the surface, not all of the powder becomes melted, and material losses can range from 20 to 60 percent.

**Wire-Fed DED:** Another approach to DED involves feeding a metal wire from a spool into the focal point of an electron beam (Fig. 29). Energy from an electron beam continuously melts wire fed from a coil into the beam focal point. The motion of the base plate beneath the beam and wire feed builds up the part as directed by the CAD file.

In this case, the process must be carried out in a vacuum chamber, because any gas in the environment would interfere with the electron beam. Wire-fed electron beam DED processes are capable of very high build rates, up to 25 lb (11.3 kg) per hour, and do not result in any direct metal loss. But since such processes essentially involve weld metal build-up, the finish is rough; machining the entire surface is needed to reach desired dimensions and surface finish.

**Hybrid Processes:** Both wire-fed and powder-fed approaches to DED provide the basis for hybrid manufacturing, or combined additive/subtractive manufacturing. The basic form of the part to be produced is made by one of the DED processes, and the finished dimensions and surface finish are achieved by material removal, usually cutting. This sequence of operations can be carried out in one machine with one setup to ensure accuracy. The metal addition device (powder deposition or wire deposition) is attached to the CNC tool disk or carriage and is used to add metal where it is needed, while the usual cutting tools are then used to carry out the subsequent machining and finishing operations.

One way to use such hybrid systems is to fix a conventionally manufactured (by forging or casting) base shape in the hybrid machine, and then add features, such as nozzles or fins, that would be impossible or difficult to form in the conventional process. Then, the overall part can be finish-machined in the same setup.

Hybrid additive/subtractive manufacturing offers a convenient approach for machine shops to enter into additive manufacturing. Some hybrid equipment providers offer retrofit systems—including powder feed, laser, and software in one package—to convert a standard 5-axis CNC system into a hybrid additive/subtractive manufacturing cell.

**Comparing AM with Conventional Processes.**—AM technology is just a few decades old, but great progress has been made in applying these processes to production of tailored, one-of-a-kind or limited-production parts. The majority of current applications involve specialized materials used in aerospace and medical fields. However, serial (mass) production of other manufactured items is economically feasible in some cases—increasingly so as rapid development of AM processes, materials, and applications continues.

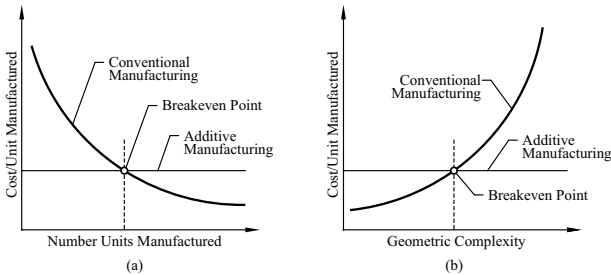

Fig. 30. a) Cost as a Function of Number of Units Manufactured;  
b) Cost as a Function of Geometric Complexity of a Part

Advantages of AM technology include:

- Short lead time and fast prototyping can be achieved using a 3D file.
- Design changes easily can be made, facilitating product development.
- New designs are possible that are not doable with conventional processes.
- Complex assemblies can be combined into a single part.
- Flexibility enables production of customized single- and short-run parts.
- Multiple 3D files for different parts/customers can be handled simultaneously.

Many metal parts currently being made by AM would be cost-prohibitive, difficult, or impossible to produce using conventional manufacturing methods, such as casting or machining. This gives AM an advantage, but only if the right types of parts are selected. Quality requirements play a major role. With most AM processes, good feature detail and surface finish are possible and comparable to metal castings, but surface quality is not comparable to CNC-machined parts, and additional surfacing adds processing time and expense. If a metal part can be produced by conventional processes at a reasonable cost and the number of units to be produced is relatively high, it usually is best to go that route at the present time.

Fig. 30a illustrates cost per unit as a function of number of units manufactured, comparing AM and traditional manufacturing methods. The initial cost of traditional methods is high due to the cost of tooling (molds or dies) or CNC machines and programming, but cost per unit manufactured decreases as these costs are shared over each part produced. Meanwhile, the cost of parts by AM remains the same, regardless of the number of units manufactured. Breakeven between the two production approaches occurs where these curves cross. AM is cost-efficient for small quantities, but traditional production methods yield cost advantages at higher volumes, as suggested by the declining cost curve. The breakeven point may be on the order of 100 to 1,000, with this number being higher for complex shapes.

Geometric complexity of a part has a significant influence on the cost per unit manufactured. Increasing complexity leads to exponentially increasing cost of conventional production technologies for small series production, as shown in Fig. 30b. By contrast with conventional production technologies, manufacturing costs for AM technologies do not increase with higher geometric complexity.

Additive manufacturing also is efficient in terms of energy and materials. In addition to not wasting quantities of expensive metals, the efficiency of AM processes opens the opportunity to produce lightweight components with a buy-to-fly ratio close to 1. (Buy-to-fly ratio is the ratio of the weight of raw material used for a component to the weight of the component itself.)

Fig. 31 illustrates comparative data on energy and material efficiency for production of high-performance parts by conventional CNC machining and AM. (This example is based on using electron beam powder bed fusion to produce a specialized aircraft bracket.) Material waste is extensive in CNC machining, with a buy-to-fly ratio of 8:1, compared to 1.5:1 for AM.

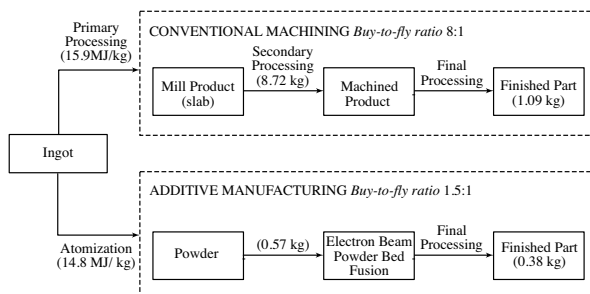

Fig. 31. Comparative Date for Conventional Machining and Additive Manufacturing of a Titanium Aircraft Bracket (Source: MFT and LIGHTEnUp Team)

**Unique Capabilities of Metal AM.**—For a given metal alloy, the cost of material in powder or wire form for additive manufacturing generally is much higher than the cost of bar stock used in conventional manufacturing. In addition, the cost of AM equipment is high and production rate is low, so production costs for AM are high. On the other hand, AM processes do not require tooling and associated production delays, and usually little material is lost. More important, AM can easily make much more complicated designs than can be made by conventional processes.

Conventional manufacturing processes, such as machining, sheet forming, and casting, impose constraints on the design of parts to be made by those processes, as is well known by designers. These constraints control possible configurations when designing a new component. Additive manufacturing processes remove many of those design constraints, though, despite the hype surrounding these technologies, AM also has limitations. Most limitations currently involve feature size and resolution: hole diameter and depth, wall height and thickness, and surface finish. In addition, at a practical level, for most metal AM processes, part features must be such that unused powder can be removed; that is, a completely enclosed hollow chamber must be provided with a hole for removal of internal powder. Nevertheless, AM processes provide great opportunity for expanding the designer's vision. Table 9 compares capabilities of SLM, EBM, BJ, and DED processes for producing metal parts by additive manufacturing.

Within the constraints shown, complex configurations can be conceived that would be difficult or impossible to achieve by conventional manufacturing processes. Four prominent shapes classes are discussed here, though many other complexities can be explored.

**Table 9. Comparison of the Capabilities of AM Processes for Producing Metal Parts**

Feature	Selective Laser Melting (SLM)	Electron Beam Melting (EBM)	Directed Energy Deposition (DED)	Binder Jetting (BJ)
Overhang angle (°)	>45	No limit	>45	No limit
Machining stock (mm)	0.1–0.5	0.5–2.0	1.0–2.0	0.05–0.1
Wall thickness (mm)	0.3–0.5	0.6–1.0	3	0.3
Hole diameter (vertical) (mm)	0.5	1–2	—	0.4
Hole diameter (horizontal) (mm)	8.0	8.0	—	0.4
Clearance (mm)	1	1	—	1
Surface finish upfacing	10–15	20–30	40–50	2
Surface finish downfacing	90–100	130–150	—	2
Porosity (%)	0–0.5	0.1–0.3	—	2–3
Screw threads	Vertical axis	No	No	Yes
Powder recovery	Vacuum	Blast/vacuum	No	Vacuum
Layer thickness (µm)	50–100	150–300	500	25–75
Build rate (kg/hr)	0.05	0.1	1.0	2

*Complex Fins and Blades:* Axisymmetric parts, such as impellers made up of fins or blades on a flat or cone shape, are costly and time-consuming to machine by CNC but are relatively easy using AM. This is one of the rare cases when it is cost-effective to produce an existing design by AM rather than a conventional process. As part complexity is on the extreme right side of the curve, the cost of production by AM will be lower, as shown in Fig. 30b.

*Internal Channels:* Internal fluid flow paths, in parts such as heat exchangers, fuel injectors, and sensors, normally are accomplished by assembling tubes, or by drilling and capping internal passages. These internal pathways usually are round and straight, because tubing is most easily produced with round tubes, and drilling uses cutting surfaces in circular motion. Use of AM processes enables formation of channels in any cross section and along non-straight paths. As a result, heat exchanger configurations can be designed and made by AM that allow for more effective and thus efficient heat transfer between hot and cold fluids.

A notable example of AM for flow control—and one of the first examples of AM used in serial production quantities—is a fuel injector produced by GE for the LEAP gas turbine engine; nineteen fuel injectors are required for each engine. Redesigning the component for AM reduced flow losses and, at the same time, reduced the parts count from twenty to one.

Another example of the benefits of producing internal channels by AM is injection mold tooling. Rapid removal of heat from the injected polymer is key in improving production rate of injection molded parts, as this step takes up about half of the total time for each injection cycle. Internal cooling channels frequently are used to increase heat removal rates; however, such channels are made by drilling straight channels that intersect internally and capping holes that penetrate the outside of the mold. With conformal cooling channels (channels that conform to the outline of the part), heat can be removed more quickly, decreasing the injection cycle time.

In one test of injection molding a non-symmetric part in polyethylene and polycarbonate, the cooling time was reduced by 30 percent, resulting in a 15 percent reduction in cycle time. While this seems a small saving for each cycle, consider the cumulative effect over millions of cycles typically used in injection molding of plastic consumer goods.

*Internal Structures and Topological Optimization:* One of the unique capabilities of AM processes is the ability to produce lattice structures, cellular structures, and organic geometries. Lattice structures involve a network of struts inside a part that remove a large amount of material yet maintain strength of the part. Cellular structures build up a part as an assembly of cells, usually hexagonal in shape. Organic structures are unusual shapes that appear similar to natural materials, such as bone or trees. Such geometries can be developed using *topological optimization* computer programs to analyze stresses in the part under load and remove sections that transmit little or no stress.

*Assemblies and Part Integration:* Part count reduction can be accomplished by designing assemblies as one component. This reduces the need for assembly operations, such as brazing or riveting. In addition, by producing the part in one piece, blend radii can be made at joining surfaces, reducing stress concentrations and potential sources of fatigue failure. While the cost of each part of the assembly may be small, the cumulative cost of tooling for each part, keeping an inventory of each part, plus the cost of assembly, can be greater than the cost of producing the assembly as one component by AM.

*Reasons to Choose AM:* Current AM processes cannot be expected to compete economically with traditional metal manufacturing methods, unless: (1) you absolutely need it as soon as possible without waiting for tooling fabrication or CNC programming, and cost is not an issue; (2) complexity of the part is so great that it actually is less expensive to make by AM than by conventional processes; (3) AM processes provide unique geometric or material characteristics, such as internal conformal cooling channels or part consolidation, that improve performance, so lifecycle cost savings by AM exceed its premium production cost.

To take advantage of opportunities afforded by metal AM processes, it is necessary to consider the entire system, rather than each individual part, for part reduction possibilities and/or potential improvements in system performance. As continuous improvements are made in AM materials, machines, and software, this innovative manufacturing method will become increasingly viable for large-scale production of automobile components and other commodity items.

**Standards for Additive Manufacturing.**—Commercial additive manufacturing is less than four decades old but is expanding at an extremely rapid rate and has attracted business interest worldwide. To support this growth and provide confidence in AM technologies to compete with existing manufacturing technologies, ASTM committee F42 was initiated in 2009 for the purpose of developing standards of practice. The following standards have been developed to date:

*Design Standards:*

- ISO/ASTM 52900-15 Standard Terminology for Additive Manufacturing—General Principles—Terminology
- ISO/ASTM 52910-18 Additive manufacturing—Design—Requirements, guidelines and recommendations
- ISO/ASTM 52915-16 Standard Specification for Additive Manufacturing File Format (AMF) Version 1.2
- ISO/ASTM 52921-13 Standard Terminology for Additive Manufacturing—Coordinate Systems and Test Methodologies

*Materials and Processes:*

- ASTM F2924-14 Standard Specification for Additive Manufacturing Titanium-6 Aluminum-4 Vanadium with Powder Bed Fusion
- ASTM F3001-14 Standard Specification for Additive Manufacturing Titanium-6 Aluminum-4 Vanadium ELI (Extra Low Interstitial) with Powder Bed Fusion
- ASTM F3049-14 Standard Guide for Characterizing Properties of Metal Powders Used for Additive Manufacturing Processes
- ASTM F3055-14a Standard Specification for Additive Manufacturing Nickel Alloy (UNS N07718) with Powder Bed Fusion
- ASTM F3056-14e1 Standard Specification for Additive Manufacturing Nickel Alloy (UNS N06625) with Powder Bed Fusion
- ASTM F3187-16 Standard Guide for Directed Energy Deposition of Metals
- ASTM F3213-17 Standard for Additive Manufacturing—Finished Part Properties—Standard Specification for Cobalt-28 Chromium-6 Molybdenum via Powder Bed Fusion
- ASTM F3301-18a Standard for Additive Manufacturing—Post Processing Methods—Standard Specification for Thermal Post-Processing Metal Parts Made Via Powder Bed Fusion
- ASTM F3091/F3091M-14 Standard Specification for Powder Bed Fusion of Plastic Materials
- ASTM F3184-16 Standard Specification for Additive Manufacturing Stainless Steel Alloy (UNS S31603) with Powder Bed Fusion

*Test Methods:*

- ASTM F2971-13 Standard Practice for Reporting Data for Test Specimens Prepared by Additive Manufacturing
- ASTM F3122-14 Standard Guide for Evaluating Mechanical Properties of Metal Materials Made via Additive Manufacturing Processes

A Partner Standards Developing Organization (PSDO) agreement between ASTM International and the International Organization for Standardization (ISO), signed in 2011, paved the way to create joint AM standards. The agreement's goal was to respond to this burgeoning industry's need for a set of AM standards that would be recognized worldwide. To do this, these organizations began to develop a common roadmap and organizational structure for AM standards, which was announced in 2016. These standards have been approved under the agreement:

- ISO/ASTM 52900 Terminology for AM—General Principles—Terminology
- ISO/ASTM 52901 Guide for AM—General Principles—Requirements for Purchased AM Parts
- ISO/ASTM 52910 Guidelines for Design for AM
- ISO/ASTM 52915 Specification for AM File Format (AMF) Version 1.2 (originally published as F2915-11)
- ISO/ASTM 52921 Terminology for Additive Manufacturing—Coordinate Systems and Test Methodologies (originally published as F2921-11).

## SOLDERING AND BRAZING

Metals may be joined without using fasteners by employing soldering, brazing, and welding. Soldering and brazing utilize capillary action to join two or more adjoined facing (in contact) surfaces of a component; only the filler material melts and solidifies to create a strong bond. Soldering involves the use of a nonferrous metal whose melting point is below that of the base metal and in all cases below 840°F (450°C). Brazing entails the use of a nonferrous filler metal with a melting point below that of the base metal but above 840°F (450°C). In fusion welding, abutting metal surfaces are made molten, are joined in the molten state, and then allowed to cool. The use of a filler metal and the application of pressure are considered optional in the practice of fusion welding.

### Soldering

Soldering is used to provide a convenient joint that does not require any great mechanical strength. It is used in a great many instances in combination with mechanical staking, crimping, or folding, the solder being used only to seal against leakage or to assure electrical contact. Soldering employs lead- or tin-base alloys with melting points below 840°F (450°C) and is commonly referred to as soft soldering. Use of hard solders, silver solders and spelter solders which have silver, copper, or nickel bases and have melting points above 840°F (450°C) is known as brazing. The accompanying table, page 1567, gives some of the properties and uses of various solders that are generally available.

**Forms Available.**—Soft solders can be obtained in bar, cake, wire, pig, slab ingot, ribbon, segment, powder, and foil form, depending on what is needed for the specific use. In bar form they are commonly used for hand soldering. The pigs, ingots, and slabs are used in operations that employ melting kettles. Ribbon, segment, powder, and foil forms are used for special applications, and the cake form is used for wiping. Wire forms are either solid or they contain acid or rosin cores for fluxing. These wire forms, both solid and core-containing, are used in hand and automatic machine applications. Prealloyed powders, suspended in a fluxing medium, are frequently applied by brush and, upon heating, consistently wet the solderable surfaces to produce a satisfactory joint.

**Fluxes for Soldering.**—The surfaces of the metals being joined in the soldering operation must be clean in order to obtain an efficient joint. Fluxes clean the surfaces of the metal in the joint area by removing the oxide coating present, keep the area clean by preventing formation of oxide films, and lower the surface tension of the solder, thereby increasing its wetting properties. Rosin, tallow, and stearin are mild fluxes that prevent oxidation but are not too effective in removing oxides present. Rosin is used for electrical applications, since the residue is non-corrosive and non-conductive. Zinc chloride and ammonium chloride (sal ammoniac), used separately or in combination, are common fluxes that remove oxide films readily.

The residue from these fluxes may in time cause trouble, due to their corrosive effects, if they are not removed or neutralized. Two methods of inactivating and removing this residue are washing with water containing about 5 ounces (142 g) of sodium citrate (for nonferrous soldering) or 1 ounce (28.35 g) of trisodium phosphate (for ferrous and nonferrous soldering) per gallon (1 US gallon = 3.754 liters) followed by a clear water rinse, or washing with commercial water-soluble detergents.

**Methods of Application.**—Solder is applied using a soldering iron, a torch, a solder bath, electric induction or resistance heating, a stream of hot neutral gas, or by wiping. Clean surfaces that are hot enough to melt the solder being applied or accept molten solder are necessary to obtain a good clean bond. Parts being soldered should be free of oxides, dirt, oil, and scale. Scraping and the use of abrasives as well as fluxes are techniques for preparing surfaces for soldering. The procedures followed in soldering aluminum, magnesium, and stainless steel differ somewhat from conventional soldering techniques and are indicated in the material that follows.

## Properties of Soft Solder Alloys Appendix, ASTM B32-08 (R2014)

Nominal Composition <sup>a</sup> Percent				Specific Gravity <sup>b</sup>	Melting Ranges, <sup>c</sup> Degrees Fahrenheit		Uses
Sn	Pb	Sb	Ag		Solidus	Liquidus	
70	30	...	...	8.32	361	377	For soldering zinc and coating metals.
63	37	...	...	8.40	361	361	For soldering printed circuit boards where temperature limitations are critical and in applications where an extremely short melting range is required.
62	36	...	2	8.44	354	372	For soldering silver-coated surfaces.
60	40	...	...	8.65	361	374	"Fine solder" for soldering electrical and electronic connections and for coating metals.
50	50	...	...	8.85	361	421	For general purposes. Most popular of all. Can be used for noncritical electrical soldering and applications such as joining sheet metal, pipe, tubing, and other structural shapes.
45	55	...	...	8.97	361	441	For general purposes. Can be used for noncritical electrical soldering and applications such as joining sheet metal, pipe, tubing, and other structural shapes.
40	60	...	...	9.30	361	460	For dip soldering and as a wiping solder for joining lead pipes and cable sheaths.
35	65	...	...	9.50	361	447	A plumber's solder, but with a lower antimony content.
30	70	...	...	9.70	361	491	For automobile-body solder and for removing heat-strippable insulation during high-temperature (700 to 900°F) [370 to 480°C] tinning of wires.
25	75	...	...	10.00	361	511	For automobile-body solder.
20	80	...	...	10.20	361	531	For automobile-body solder with a lower antimony than alloy Sn20 below.
15	85	...	...	10.50	437 <sup>d</sup>	554	For coating and joining metals.
10	90	...	...	10.80	514 <sup>d</sup>	576	For coating and joining metals.
5	95	...	...	11.30	586	594	For coating and joining metals.
2	98	...	...	11.22	601	611	For soldering automobile radiator cores.
40	58	2	...	9.23	365	448	Similar to Sn40 above, but not recommended for use on galvanized iron.
35	63.2	1.8	...	9.44	365	470	For wiping solders promoting finer grain size and greater strength.
30	68.4	1.6	...	9.65	364	482	For automobile-body solder for filling dents and seams.
25	73.7	1.3	...	9.96	365	504	For automobile-body solder.
20	79	1	...	10.17	363	517	Used for automobile-body solder for filling dents and seams, and for general purposes such as protective coatings on steel sheet where a high tin content alloy is not required.
95	...	5	...	7.25	452	464	For joints on copper in electrical, plumbing, and heating work.
...	94.5	...	5.5	11.3	580	716	This alloy will develop a shearing strength of 1500 psi at 350 °F [177°C]. When soldering hard-drawn brass or copper, the application temperature should not exceed 850 °F [455°C]. Used on thermocouples for aircraft engines, where relatively high operating temperatures will not affect strength of the solder.
...	97.5	...	2.5	11.35	580	580	For use on copper, brass, and similar metals with torch heating. Not recommended in humid environments due to its known susceptibility to corrosion.
1	97.5	...	1.5	11.28	588	588	For use on copper, brass, and similar metals with torch heating. This alloy is used interchangeably with the above alloy Ag2.5, but it has a better shelf life and does not develop a black surface deposit when stored under humid environmental conditions.

<sup>a</sup> Abbreviations of alloying elements are as follows: Sn, tin; Pb, lead; Sb, antimony; and Ag, silver.

<sup>b</sup> The specific gravity multiplied by 0.0361 equals the density in pounds per cubic inch.

<sup>c</sup> The alloys are completely solid below the lower point given, designated "solidus," and completely liquid above the higher point given, designated "liquidus." In the range of temperatures between these two points the alloys are partly solid and partly liquid.

<sup>d</sup> For some engineering design purposes, it is well to consider these alloys as having practically no mechanical strength above 360°F (182°C).

**Soldering Aluminum:** Two properties of aluminum which tend to make it more difficult to solder are its high thermal conductivity and the tenacity of its ever-present oxide film. Aluminum soldering is performed in a temperature range of from 550–770°F (288–410°C), compared to 375–400°F (191–204°C) temperature range for ordinary metals, because of the metal's high thermal conductivity. Two methods can be used, one using flux and one using abrasion. The flux method is most widely used and is known as flow

soldering. In this method flux dissolves the aluminum oxide and keeps it from re-forming. The flux should be fluid at soldering temperatures so the solder can displace it in the joint. In the friction method the oxide film is mechanically abraded with a soldering iron, wire brush, or multi-toothed tool while being covered with molten solder. The molten solder keeps the oxygen in the atmosphere from reacting with the newly exposed aluminum surface; thus, wetting of the surface can take place.

The alloys that are used in soldering aluminum generally contain from 50 to 75 percent tin, with the remainder being zinc. The following aluminum alloys are listed in order of ease of soldering: commercial and high-purity aluminum; wrought alloys containing not more than 1 percent manganese or magnesium; and finally, the heat-treatable alloys, which are the most difficult.

Cast and forged aluminum parts are not generally soldered.

**Soldering Magnesium:** Magnesium is not ordinarily soldered to itself or other metals. Soldering is generally used for filling small surface defects, voids, or dents in castings or sheets where the soldered area is not to be subjected to a load. Two solders can be used: one with a composition of 60 percent cadmium, 30 percent zinc, and 10 percent tin has a melting point of 315° F (157°C); the other has a melting point of 500° F (260°C) and has a nominal composition of 90 percent cadmium and 10 percent zinc.

The surfaces to be soldered are cleaned to a bright metallic luster by abrasive methods before soldering. The parts are preheated with a torch to the approximate melting temperature of the solder being used. The solder is applied and the surface under the molten solder is rubbed vigorously with a sharp pointed tool or wire brush. This action results in the wetting of the magnesium surface. To completely wet the surface, the solder is kept molten and the rubbing action continued. The use of flux is not recommended.

**Soldering Stainless Steel:** Stainless steel is somewhat more difficult to solder than other common metals because of a tightly adhering oxide film on the surface of the metal and because of its low thermal conductivity. The surface of the stainless steel must be thoroughly cleaned. This can be done by abrasion or by clean white pickling with acid. Mixtures that may be used as fluxes for soldering stainless steel include: muriatic (hydrochloric) acid saturated with zinc, or this mixture combined with 25 percent additional muriatic acid, or with 10 percent additional acetic acid, or with 10 to 20 percent additional water solution of orthophosphoric acid. Tin-lead solder can be used successfully. Because of the low thermal conductivity of stainless steel, a large soldering iron is needed to bring the surfaces to the proper temperature, which is reached when the solder flows freely into the area of the joint. Removal of the corrosive flux is important in order to prevent joint failure. Soap and water or a commercial detergent may be used to remove the flux residue.

**Ultrasonic Fluxless Soldering.**—This more recently introduced method of soldering makes use of ultrasonic vibrations, which facilitates the penetration of surface films by the molten solder thus eliminating the need for flux. The equipment offered by one manufacturer consists of an ultrasonic generator and ultrasonic soldering head, which includes a transducer coupling, soldering tip, tip heater, and heating platen. Metals that can be soldered by this method include aluminum, copper, brass, silver, magnesium, germanium, and silicon.

### Brazing

Brazing is a metal joining process that uses a nonferrous filler metal with a melting point below that of the base metals but above 840° F (450°C). The filler metal wets the base metal when molten in a manner similar to that of a solder and its base metal. There is a slight diffusion of the filler metal into the hot, solid base metal or a surface alloying of the base and filler metal. The molten metal flows between the close-fitting metals because of capillary forces.

**Filler Metals for Brazing Applications.**—Brazing filler metals have melting points that are lower than those of the base metals being joined and have the ability when molten to flow readily into closely fitted surfaces by capillary action. The commonly used brazing

**Table 1a. Brazing Filler Metals, Based on Specifications and Appendix of American Welding Society AWS A5.8–1981**

AWS Classification <sup>a</sup>	Nominal Composition, <sup>b</sup> Percent						Temperature, Degrees F			Standard Form <sup>c</sup>	Uses
	Ag	Cu	Zn	Al	Ni	Other	Solids	Liquidus	Brazing Range		
BAISi-2	...	...	...	92.5	...	Si, 7.5	1070	1135	1110–1150	7	For joining the following aluminum alloys: 1060, EC, 1100, 3003, 3004, 5005, 5050, 6053, 6061, 6062, 6063, 6951 and cast alloys A612 and C612. All of these filler metals are suitable for furnace and dip brazing. BAISi-3, -4 and -5 are suitable for torch brazing. Used with lap and tee joints rather than butt joints. Joint clearances run from .006 to .025 inch.
BAISi-3	...	4	...	86	...	Si, 10	970	1085	1160–1120	2, 3, 5	
BAISi-4	...	...	...	88	...	Si, 12	1070	1080	1080–1120	2, 3, 4, 5	
BAISi-5	...	...	...	90	...	Si, 10	1070	1095	1090–1120	7	
BAISi-6	...	...	...	90	...	Si, 7.5; Mg, 2.5	1038	1125	1110–1150	7	BAISi-6 through -11 are vacuum brazing filler metals. Magnesium is present as an O <sub>2</sub> getter. When used in vacuum, solidus & liquidus temperatures are different from those shown.
BAISi-7	...	...	...	88.5	...	Si, 10; Mg, 1.5	1038	1105	1090–1120	7

<sup>a</sup> Al, 9; Zn, 2; Mg, 89.

**Table 2. Guide to Selection of Brazing Filler Metals and Fluxes**

Base Metals Being Brazed	Filler Metals Recommended <sup>a</sup>	AWS Brazing Flux Type No.	Effective Temperature Range, °F (°C)	Flux Ingredients	Flux Supplied As	Flux Method of Use <sup>b</sup>
All brazable aluminum alloys	BA1Si	1	700–1190 (371–643)	Chlorides, Fluorides	Powder	1, 2 3, 4
All brazable magnesium alloys	BMg	2	900–1200 (482–649)	Chlorides, Fluorides	Powder	3, 4
Alloys such as aluminum-bronze; aluminum-brass containing additions of aluminum of 0.5 percent or more	BCuZn, BCuP	4 <sup>c</sup>	1050–1800 (566–982)	Chlorides, Fluorides, Borates, Wetting agent	Paste or Powder	1, 2, 3
Titanium and zirconium in base alloys	BAg	6	700–1600 (371–871)	Chlorides, Fluorides, Wetting agent	Paste or Powder	1, 2, 3
Any other brazable alloys not listed above	All brazing filler metals except BA1Si and BMg	3	700–2000 (371–1093)	Boric acid, Borates, Fluorides, Fluorates, Wetting agent <i>Must contain fluorine compound</i>	Paste, Powder, or Liquid	1, 2, 3
	All brazing filler metals except BA1Si, BMg, and BAg 1 through BAg 7	5	1000–2200 (538–1204)	Borax, Boric acid, Borates, Wetting agent <i>No fluorine in any form</i>	Paste, Powder, or Liquid	1, 2, 3

<sup>a</sup> Abbreviations used in this column are as follows: B, brazing filler metal; Al, aluminum; Si, silicon; Mg, magnesium; Cu, copper; Zn, zinc; P, phosphorus; and Ag, silver.

<sup>b</sup> Explanation of numbering system used is as follows: 1—dry powder is sprinkled in joint region; 2—heated metal filler rod is dipped into powder or paste; 3—flux is mixed with alcohol, water, monochlorobenzene, etc., to form a paste or slurry; 4—flux is used molten in a bath.

<sup>c</sup> Types 1 and 3 fluxes, alone or in combination, may be used with some of these base metals also.

metals may be considered as grouped into the seven standard classifications shown in [Table 1a](#) and [Table 1b](#). These are aluminum-silicon; copper-phosphorus; silver; nickel; copper and copper-zinc; magnesium; and precious metals.

To avoid confusion, [Table 1a](#) and [Table 1b](#) give the filler metal's solidus and liquidus temperatures, rather than the melting and flow points. The solidus is the highest temperature at which the metal is completely solid or, in other words, the temperature above which the melting starts. The liquidus is the lowest temperature at which the metal is completely liquid, that is, the temperature below which the solidification starts.

**Fluxes for Brazing.**—In order to obtain a sound joint the surfaces within and adjacent to the joint must be free from dirt, oil, and oxides or other foreign matter at the time of brazing. Cleaning may be achieved by chemical or mechanical means. Some of the mechanical means employed are filing, grinding, scratch brushing and machining. The chemical means include the use of trisodium phosphate, carbon tetrachloride, and trichloroethylene for removing oils and greases.

Fluxes are used mainly to prevent the formation of oxides and to remove any oxides on the base and filler metals. They also promote free flow of the filler metal during the course of the brazing operation.

They are made available in the following forms: powders; pastes or solutions; gases or vapors; and as coatings on the brazing rods.

In the powder form a flux can be sprinkled along the joint, provided that the joint has been preheated sufficiently to permit the sprinkled flux to adhere and not be blown away by the torch flame during brazing. A thin paste or solution is easily applied and when spread on evenly, with no bare spots, gives a very satisfactory flux coating. Gases or vapors are used in controlled atmosphere furnace brazing where large amounts of assemblies are mass-brazed. Coatings on the brazing rods protect the filler metal from becoming oxidized and eliminate the need for dipping rods into the flux, but it is recommended that flux be applied to the base metal since it may

become oxidized in the heating operation. No matter which flux is used, it performs its task only if it is chemically active at the brazing temperature.

Chemical compounds incorporated into brazing fluxes include borates (sodium, potassium, lithium, etc.), fused borax, fluoborates (potassium, sodium, etc.), fluorides (sodium, potassium, lithium, etc.), chlorides (sodium, potassium, lithium), acids (boric, calcined boric acid), alkalis (potassium hydroxide, sodium hydroxide), wetting agents, and water (either as water of crystallization or as an addition for paste fluxes). [Table 2](#) provides a guide which will aid in the selection of brazing fluxes that are available commercially.

**Methods of Steadying Work for Brazing.**—Pieces to be joined by brazing after being properly joined may be held in a stable position by means of clamping devices, spot welds, or mechanical means such as crimping, staking, or spinning. When using clamping devices care must be taken to avoid the use of devices containing springs for applying pressure because springs tend to lose their properties under the influence of heat. Care must also be taken to be sure that the clamping devices are no larger than is necessary for strength considerations, because a large metal mass in contact with the base metal near the brazing area would tend to conduct heat away from the area too quickly and result in an inefficient braze. Thin sections that are to be brazed are frequently held together by spot welds. It must be remembered that these spot welds may interfere with the flow of the molten brazing alloy and appropriate steps must be taken to be sure that the alloy is placed where it can flow into all portions of the joint.

**Methods of Supplying Heat for Brazing.**—The methods of supplying heat for brazing form the basis of the classification of the different brazing methods and are as follows.

*Torch or Blowpipe Brazing:* Air-gas, oxy-acetylene, air-acetylene, and oxy-other fuel gas blowpipes are used to bring the areas of the joint and the filler material to the proper heat for brazing. The flames should generally be neutral or slightly reducing but in some instances some types of bronze welding require a slightly oxidizing flame.

*Dip Brazing:* Baths of molten alloy, covered with flux, or baths of molten salts are used for dip brazing. The parts to be brazed are first assembled, usually with the aid of jigs, and are dipped into the molten metal, then raised and allowed to drain. The molten alloy enters the joint by capillary action. When the salt bath is used, the filler metal is first inserted between the parts being joined, or, in the form of wire, is wrapped around the area of the joint. The brazing metal melts and flows into the joint, again by capillary action.

*Furnace Brazing:* Furnaces that are heated electrically or by gas or oil with auxiliary equipment that maintains a reducing or protective atmosphere and controlled temperatures therein are used for brazing large numbers of units, usually without flux.

*Resistance Brazing:* Heat is supplied by means of hot or incandescent electrodes. The heat is produced by the resistance of the electrodes to the flow of electricity and the filler metal is frequently used as an insert between the parts being joined.

*Induction Brazing:* Parts to be joined are heated by being placed near a coil carrying an electric current. Eddy current losses of the induced electric current are dissipated in the form of heat raising the temperature of the work to a point higher than the melting point of the brazing alloy. This method is both quick and clean.

*Vacuum Furnace Brazing:* Cold-wall vacuum furnaces, with electrical-resistance radiant heaters, and pumping systems capable of evacuating a conditioned chamber to moderate vacuum (about 0.01 micron) in 5 minutes are recommended for vacuum brazing. Metals commonly brazed in vacuum are the stainless steels, heat-resistant alloys, titanium, refractory metals, and aluminum. Fluxes and filler metals containing alloying elements with low boiling points or high vapor pressure are not used.

**Brazing Symbol Application.**—ANSI/AWS A2.4-2012 symbols for brazing are also used for welding with the exception of the symbol for a scarf joint (see the diagram at the top of page 1574, and the symbol for a scarf joint in the table *Basic Weld Symbols* on page 1619, for applications of brazing symbols). The second, third and fourth figures from the top of the next page show how joint clearances are indicated. If no special joint preparation is required, only the arrow is used with the brazing process indicated in the tail.

Typical Applications of Standard Brazing Symbols

**WELDING**

A number of variables set welding and related processes apart from mechanical fastening methods used to join material. However, practically all welding and related processes currently in use involve heat input and/or upset in the areas where materials are being joined. Modern welding methods may employ manual, machine, semi-automatic, automatic, or robotic controls to deliver welding energy at the point of fusion.

Welding of metals generally requires that materials be heated to a molten state so they can be fused together. The method of applying heat or upset to produce the desired results may involve just a simple flame. The autogenous method—where a torch burns a mixture of (usually) acetylene and oxygen gases to heat the components—is still used for certain work. However, most welding operations today use an electric arc and/or pressure, or they involve the application of complex electric waveforms. In arc welding, a low-voltage, high-current arc is struck between the end of an electrode and the work, generating intense heat that immediately melts the surfaces. Lasers and electrons are also used as the heating medium for some welding operations.

In the welding process, a filler wire or rod is held in the heated zone to add material that replaces the metal consumed by the process. (This usually produces a slightly raised area, which subsequently can be dressed down to a level surface if needed.) Most, if not all, metals are weldable, and the majority can make capable connections. Some welds make joints that are stronger than the base materials being joined, while other welds weaken the workpiece's overall mechanical properties. Though typically the welded joint has properties similar to the base materials.

Metals that can be welded include: carbon and low-alloy steels, stainless steels, tool and die steels, high-alloy steels, cast iron, nickel and cobalt alloys, copper alloys, aluminum alloys, magnesium alloys, titanium, zirconium, hafnium, tantalum, columbium, and others. Dissimilar welds—joining two different metal types (for example, carbon steel to stainless steel)—can be made but may prove difficult or produce undesirable results.

**Electrodes, Fluxes, and Processes**

Electrodes for welding may be made of a tungsten or other alloy that does not melt at welding temperatures (nonconsumable) or of an alloy similar to that of the work so that it melts and acts as the filler wire (consumable). In welding with a nonconsumable electrode, filler metal is added to the pool as welding proceeds. Filler metals that will produce welds having strength properties similar to those of the work are used where high-strength welds are specified.

Briefly, the effects of the main alloying elements in welding filler wires and electrodes are: carbon adds strength but may cause brittle weld metal if cooling is rapid, so low-carbon wire is preferred; silicon adds strength and reduces oxidation, changes fluidity, and gives a flatter weld bead; manganese strengthens and assists deoxidation, plus it reduces effects of sulfur, lowering the risk of hot cracking; sulfur may help form iron sulfide, which increases the risk of hot cracking; and phosphorus, may contribute to hot cracking.

*Fluxes* in (usually) granular form are added to the weld zone, as coatings on the filler wire or as a core in the tube that forms the (consumable) electrode. The flux melts and flows in the weld zone, shielding the arc from the oxygen in the atmosphere, and often contains materials that clean impurities from the molten metal and prevent grain growth during recrystallization.

**Processes.**—There are approximately 100 welding and allied welding processes but the four manual arc welding processes: gas metal arc welding (GMAW) (which is also commonly known as MIG for metal inert gas), flux-cored arc (FCAW), shielded metal arc (SMAW), gas tungsten arc welding (GTAW), account for over 90 percent of the arc welding used in production, fabrication, structural, and repair applications. FCAW and

SMAW use fluxes to shield the arc and FCAW uses fluxes and gases to protect the weld from oxygen and nitrogen. GMAW and GTAW use mixtures of gases to protect the weld.

There are two groups of weld types, groove and fillet, which are self-explanatory. Each type of weld may be made with the work at any angle from horizontal (flat) to inverted (overhead). In a vertical orientation, the electrode tip may move down the groove or fillet (vertical down), or up (vertical up). In any weld other than flat, skill is needed to prevent the molten metal falling from the weld area.

Because of the many variables, such as material to be welded and its thickness, equipment, fluxes, gases, electrodes, degree of skill, and strength requirements for the finished welds, it is not practicable to set up a complete list of welding recommendations that would have general validity. Instead, examples embracing a wide range of typical applications, and assuming common practices, are presented here for the most-used welding processes. The recommendations given are intended as a guide to finding the best approach to any welding job, and are to be varied by the user to fit the conditions encountered in the specific welding situation.

**Heat Input and Weld Distortion.**—When metals are joined in a welding process, a great amount of heat is generated. As this heat melts, coalesces, and joins two or more members at the point of connection, it often changes the position and dimensions of the welded structure to some extent.

When a weld joint is fit-up for welding, the gap between the parts to be welded is filled in with filler metal and/or base metal. As the metal in the gap cools, shrinkage occurs, drawing adjacent surfaces together and strengthening the connection, but also causing movement.

In jobs where part alignment and dimensional tolerances must be maintained, the effect of such weld distortion should be taken into consideration. Tactics to limit or compensate for these factors include heat input control, using welding fixtures, post-weld stress relief, and finish machining and processing operations.

### Gas Metal Arc Welding (GMAW)

The two most cost-effective manual arc welding processes are GMAW and FCAW. These two welding processes are used with more than 50 percent of the arc welding consumable electrodes purchased. Gas metal arc welding modes extend from short-circuit welding, where the consumable electrode wire is melted into the molten pool in a rapid succession of short circuits during which the arc is extinguished, to pulsed and regular spray transfer, where a stream of fine drops and vaporized weld metal is propelled across the continuous arc gap by electromagnetic forces in the arc.

GMAW is the most-used welding process and the two most common GMAW low-carbon steel electrodes used for production welding in North America are the E70S-3 and E70S-6 from the ANSI/AWS Standard A5 series of specifications for arc welding. The E70S-3 contains manganese and silicon as deoxidants and is mainly used for welding low-carbon steels, using argon mixtures as shielding gases. The wire used in E70S-6 electrodes has more silicon than wire used for E70S-3 electrodes, and is preferred where straight CO<sub>2</sub> or argon mixes are used as the shielding gas or if the metal to be welded is contaminated. The deoxidizing properties of the E70S-6 electrode also may be beneficial for high-current, deep-penetration welds, and welds in which higher than normal impact-strength properties are required.

E80S-D2 wire contains more manganese and silicon, plus 0.5 percent molybdenum for welding such steels as AISI 4130, and steels for high-temperature service. The argon + CO<sub>2</sub> mixture is preferred to exert the influence of argon's inertness over the oxidizing action of CO<sub>2</sub>. E70S-2 electrodes contain aluminum, titanium, and zirconium to provide greater deoxidation action and are valuable for welding contaminated steel plate.

When the GMAW welding process is used for galvanized steels, minute welding cracks may be caused by the reaction of the zinc coating on the work with silicon in the electrode. Galvanized steel should be welded with an electrode having the lowest possible silicon

content such as the E70S-3. For welding low-carbon and low-alloy steels with conventional argon mixture shielding gases, there is little difference between the E70S-3 and E70S-6.

**Electrode Diameters.**—One of the most important welding decisions is selecting the optimum GMAW electrode diameter, which should be based on the material thickness, as shown for carbon and stainless steels in Table 1, the compatibility of the electrode current requirements with the material thickness, the mode of weld metal transfer, and the deposition rate potential shown in Table 2. The two most popular GMAW electrode sizes are 0.035 inch (1.0 mm) and 0.045 inch (1.2 mm). Diameters of electrodes used for GMAW exert a strong influence on cost of welding. Table 2 also shows how the weld deposition rate varies in short-circuit and spray transfer modes in welding carbon and stainless steels.

**Table 1. GMAW Electrode Sizes for Welding Carbon and Stainless Steels**

Material Thickness	Electrode Diameter			
	0.030 inch (0.8 mm)	0.035 inch (1.0 mm)	0.045 inch (1.2 mm)	0.062 inch (1.6 mm)
25 to 21 gage (0.020 to 0.032 inch)	yes	...	...	...
20 gage to ¼ inch (0.036 to 0.25 inch)	...	yes	...	...
⅜ to ⅞ inch flat and horizontal	...	...	yes	...
½ inch and up	...	...	...	yes

The table is based on suitability of the electrode size to mode of weld transfer, material thickness, and cost-effectiveness. If a smaller electrode size is selected, the lower deposition rates could increase welding costs by 20 to 60 percent.

**Table 2. Typical Maximum GMAW Deposition Rates for Carbon and Stainless Steels. Constant-Voltage 450-amp Power Source and Standard Wire Feeder**

Weld transfer mode	Electrode Diameter			
	0.030 inch (0.8 mm)	0.035 inch (1.0 mm)	0.045 inch (1.2 mm)	0.062 inch (1.6 mm)
Short circuit	5 lb/h (2.3 kg/h)	7 lb/h (3.2 kg/h)	9 lb/h (4 kg/h)	...
Spray transfer	9 lb/h (4 kg/h)	11 lb/h (5 kg/h)	19 lb/h (8.6 kg/h)	21 lb/h (9.5 kg/h)

For the lowest-cost welds with GMAW electrodes larger than 0.030 inch in diameter, the power source should provide a minimum of 350 amps. The compatibility of the optimum current range of the 0.035-inch (1.0-mm) electrode and its deposition potential make it the first choice for welding of 20 gage to ¼ inch (0.88 to 6.4 mm) thicknesses. For welding thinner sheet metals of 25 to 21 gage, the optimum electrode diameter is 0.030 inch (0.8 mm). The 0.045-inch (1.2-mm) electrode is the most practical choice for spray transfer applications on materials over ¼ inch (6.4 mm) thick and thicker.

As an example, when welding ¼-in. (6.4-mm) thick steel, with 100 percent arc-on time and a labor cost of \$15/h, the deposition rate with a 0.035-in. (0.9-mm) electrode is approximately 11 lb/h (5 kg/h). The labor cost per lb at \$15/h + 11 lb/h = \$1.36/lb (\$3.00/kg). If an electrode of 0.045-in. (1.2-mm) diameter is used for the same application, the deposition rate is 16 lb/h (7.2 kg/h) and at a \$15/h labor rate, the cost of weld metal deposited = \$15/h ÷ 16 lb/h = \$0.93/lb (\$2.00/kg). The 0.045-in. diameter electrode would also cost less per pound than a smaller wire, and the weld time with the 0.045-in. electrode would be reduced, so less shielding gas also would be consumed.

**GMAW Welding of Sheet Steel.**—In GMAW, the short-circuit transfer mode is used to weld carbon steel, low-alloy steel, and stainless steel sheet of 24 gage (0.023 in., or 0.6 mm) to 11 gage (0.12 in., or 3 mm). The most common gage sizes welded with short-circuit transfer are 20 gage to 11 gage (0.88 to 3 mm) and the best GMAW electrode for these thin, sheet

metal gages is the 0.035-in. (1-mm) diameter electrode. The short-circuit current requirements for these operations are typically 50 to 200 amps with voltages in the range of 14 to 22 volts. The optimum short-circuit voltage for the majority of applications is 16 to 18 volts.

**Shielding Gases for Welding Carbon and Low-Alloy Steels.**—With more than 40 GMAW gas mixtures available for welding carbon steels, low-alloy steels, and stainless steels, selection is often confusing. Reactive oxygen and carbon dioxide (CO<sub>2</sub>) are added to argon to stabilize the arc and add energy to the weld. CO<sub>2</sub> can provide more energy to the weld than oxygen. As the CO<sub>2</sub> content in a shielding gas mixture is increased to certain levels, the voltage requirements are increased. Argon + oxygen mixtures will require lower voltages than mixtures containing argon with 10 to 25 percent CO<sub>2</sub>. Helium may also be added to argon if increased weld energy is required.

**Shielding Gases for Short-Circuit Welding of Carbon Steels.**—GMAW short-circuit transfer (SCT) is used mainly for welding thin metals of less than 10 gage, and gaps. With the SCT mode of weld metal transfer, the arc short circuits many times each second. The numerous short circuits switch the arc energy on and off. The short circuits and low current cause the transferred weld to freeze rapidly. Short-circuit transfer on carbon steel gage metals thicker than  $\frac{1}{16}$  in. (1.6 mm) requires a shielding gas that will provide substantial weld energy. For these applications, argon with 15–25 percent CO<sub>2</sub> is recommended.

If short-circuit transfer is used on metals thinner than 18 gage (0.047 in., 1.2 mm), melt-through and distortion often occur. Melt-through and distortion can be reduced on very thin-gage carbon and low-alloy steels by using a shielding gas that provides less weld energy than argon + 15 to 25 percent CO<sub>2</sub> mixes. Argon + oxygen mixtures can utilize lower voltages to sustain the arc. Argon mixed with 2 to 5 percent oxygen is a practical mixture for thin carbon steel of less than 16 gage, where there is sensitivity to heat.

**Shielding Gases for Spray Transfer Welding of Carbon Steels.**—With GMAW spray transfer, all traditional argon gas mixtures will provide spatter-free spray weld transfer, depending on the electrode diameter and welding parameters used. The electrode diameter and the electrode current density influence the formation of the weld metal to be transferred. For example, with a 0.035-inch (0.9 mm) diameter electrode using a mixture containing argon 75 + CO<sub>2</sub> 25 percent, a small globular weld droplet is formed on the end of the electrode tip in the conventional spray transfer parameter range. With the same gas mixture, a 0.045-inch (1.14-mm) diameter electrode, and current above 330 amps, the globular formation disappears and the metal transfers in the spray mode.

Spatter potential stemming from shielding gas, with 0.035 inch (0.90 mm) and smaller diameter electrodes can be controlled by reducing the CO<sub>2</sub> content in the argon mixture to less than 21 percent. Each different shielding gas will primarily influence the open arc spray transfer mode by variations in the weld energy provided through the welding voltage requirements.

Gas selection in spray transfer must be given careful consideration. In welding of clean cold-rolled carbon steel or low-alloy steel less than  $\frac{3}{8}$  inch (9.5 mm) thick, the energy potential of the arc is less important than it is for welding of steels thicker than  $\frac{1}{2}$  inch (13 mm) or steels with mill scale. The energy level of the arc is also a key factor in welding steels for which higher than normal impact properties are specified.

A simple, practical multipurpose gas mixture for carbon and low-alloy steels is argon + 15 to 20 percent CO<sub>2</sub>, and a mixture of argon + 17 percent CO<sub>2</sub> would be ideal. This two-part argon/CO<sub>2</sub> mixture provides higher weld energy than two-component argon + CO<sub>2</sub> mixtures having less than 10 percent CO<sub>2</sub>, argon + oxygen mixtures, or argon + CO<sub>2</sub> + oxygen tri-component mixtures. The argon + 17 percent CO<sub>2</sub> mixture will provide an arc slightly less sensitive to mill scale than the other mixtures mentioned.

The argon + 17 percent CO<sub>2</sub> mixture also has practical benefits in that it provides sufficient weld energy for all GMAW short-circuit and spray transfer applications with cylinder or bulk gases. The argon + 17 percent CO<sub>2</sub> mixture may also be used for all-position FCAW electrodes in welding carbon steels, low-alloy steels, and stainless steels.

**Shielding Gases for GMAW Welding of Stainless Steels.**—The major problems encountered when using GMAW on stainless steels of thinner than 14 gage include controlling potential melt-through, controlling distortion, and black oxidation on the weld surface. These three welding problems have a common denominator, which is heat. The key to welding thin stainless steel is to minimize the potential heat when welding, by appropriate choice of gas mixture.

A popular gas mixture that is often recommended for GMAW welding of thin-gage stainless steel is the three-part helium gas mixture containing helium 90 + argon 7.5 + CO<sub>2</sub> 2.5 percent. In contrast to gas mixtures without helium, the helium tri-mixture requires the use of higher voltages to sustain the arc, which adds unnecessary heat to the heat-sensitive thin-gage welds.

A practical and lower-cost alternative for GMAW short-circuit transfer on stainless steels is an argon mixture with 2 to 4 percent CO<sub>2</sub>. The argon + CO<sub>2</sub> mixture allows use of lower voltages than is practical with argon/helium mixtures, and the lower voltages resulting from the argon + CO<sub>2</sub> mixture will help to reduce distortion and oxidation, and decrease the melt-through potential. The mixture that works with short-circuit transfer is also a logical practical choice for spray transfer welding of stainless steel because it is less oxidizing than argon/oxygen mixtures. Table 3 provides practical gas mixture recommendations for specific applications.

**Table 3. Shielding Gases for Welding Carbon Steels and Stainless Steels**

Application	Gas mixtures					
	Argon + Oxygen	Argon + CO <sub>2</sub> + Oxygen	Argon + 2–4% CO <sub>2</sub>	Argon + 6–10% CO <sub>2</sub>	Argon + 13–20% CO <sub>2</sub>	Argon + 25% CO <sub>2</sub>
Short-circuit melt-through problems; less than 20 gage	1	1	1	1	2	3
Short-circuit 18 to 11 gage	...	...	...	...	1	1
Spray if mill scale or surface problems; carbon steels	...	...	...	...	1	2
Spray if low energy required; carbon steel	1	1	1	1	...	...
Spray, best impact strengths, lowest porosity; carbon steels	...	...	...	...	1	...
Best single gas mixture for carbon steels	...	...	...	...	1	...
Short-circuit; stainless steels	...	...	1	...	...	...
Spray; stainless steels	2	...	1	...	...	...
Best single gas mixture for stainless and duplex steels	...	...	1	...	...	...

Preferred choice of shielding gas is 1, followed by 2 and 3.

For GMAW spray transfer welding of stainless steels thicker than 11 gage, the traditional GMAW shielding gas has been argon 98 + oxygen 2 percent. The argon + oxygen mixture provides excellent, stable, spray transfer, but the oxygen promotes oxidation, leaving the weld with a black surface. To reduce the oxidation, the 2 percent oxygen can be replaced with the less oxidizing 2–4 percent CO<sub>2</sub>.

**Shielding Gases for GMAW Welding of Aluminum.**—For GMAW welding of aluminum, helium is added to argon to provide additional weld energy, increasing penetration

using a 0.030-in. (0.8-mm) or 0.035-in. (1-mm) diameter GMAW electrode, for instance, to weld 16-gage carbon or stainless steel with a conventional 200- to 450-amp constant-voltage power source and wire feeder, the wire feed control is set to the ten o'clock position for a feed rate of 210 in/min (5.3 m/min). With digital wire feed units, the short-circuit current range is typically between 100 and 400 in/min (2.54 and 10.16 m/min), so a good starting point is to set the wire feeder at 210 in/min (5.3 m/min). The welding voltage is set to 17.

Many welders set their parameters by an established mark on the equipment or by the sound of the arc as the weld is being made. The sound of the arc, influenced by the optimum current and voltage set, should be a consistent, smooth, crackling noise. If the SCT sound is harsh, the voltage should be increased slightly. If the sound is soft, the voltage should be decreased in volt increments until the sound becomes a smooth crackle. For welding metals thicker than 16 gage but less than 10 gage, the wire feed control should be moved to the eleven o'clock position (280 in/min, or 7.1 m/min), and the voltage reset to 18.

Welding of thicknesses less than 16 gage should be started with the wire feed control at the nine o'clock position (140 in/min, or 3.6 m/min) and the voltage control set to 16. The parameters discussed above apply when using argon mixtures containing 15 to 25 percent CO<sub>2</sub>.

**GMAW Spray Transfer.**—In the spray transfer mode, spatter is often caused by the voltage being set so low that the electrode runs into the weld, resulting in expulsion of molten metal from the weld pool. GMAW spray transfer is normally used for welding carbon, low-alloy, and stainless steels of a minimum thickness of  $\frac{1}{8}$  in. (3.2 mm).

In Table 4, typical deposition rates with a 0.045-in. (1.2-mm) carbon steel electrode are compared with rates for larger carbon steel GMAW and flux-cored electrodes. These welds are typically carried out in the flat and horizontal positions. The practical GMAW electrode diameters commonly used for spray transfer are 0.035-in. (1-mm), 0.045-in. (1.2-mm), and 0.062-in. (1.6-mm) diameter. The most cost-effective GMAW electrode that also has the greatest range of applications on metals over  $\frac{3}{16}$  in. thick is the 0.045-in. (1.2-mm) diameter size.

**Table 4. Typical Deposition Rates for Carbon Steel Welding Electrodes**

Electrode Diameter		Electrode Type	Amperage	Deposit Rates	
inch	mm			lb/h	kg/h
0.035	1.0	GMAW	350	11	5
0.045	1.2	GMAW	380	13	6
0.062	1.6	GMAW	400	14	6.4
$\frac{1}{16}$	1.6	FCAW	350	15	7
$\frac{3}{32}$	2.4	FCAW	450	16	7.3

**GMAW Spray Transfer Welding of Metal Thicknesses Less than  $\frac{1}{4}$  in. (6.4 mm).**—

The most versatile GMAW electrode for a welding shop that welds carbon, low-alloy, and stainless steels from 20 gage to  $\frac{1}{4}$  in. (6.4 mm) thick is the 0.035 in. (1.0 mm) diameter electrode. The traditional practical spray transfer current range of between 200 and 350 amps for the 0.035 in. electrode is well suited for welding thicknesses from 10 gage to  $\frac{1}{4}$  in. (6.4 mm).

The correct parameters for a 0.035 in. (1 mm) electrode and spray transfer welding are found on the wire feed unit between the one and five o'clock positions, or, on a digital wire feeder, between 420 and 700 in/min (10.7 and 17.8 m/min). In the drawing at the left in Fig. 2, the spray transfer wire feed range is shaded. When the wire feed rate has been set, the voltage should be fine-tuned so that the electrode wire tip is just touching the weld and a smooth crackling sound without spatter is produced.

An optimum single spray transfer mode current setting for a 0.035-in. (1-mm) diameter electrode for most welding applications is approximately 280 amps with the wire feed set at the three o'clock position for 560 in/min. Manual or high-speed mechanized welds on material of 10 gage to  $\frac{1}{4}$  in. thick can be made at the three o'clock wire feed position with

only an adjustment for voltage, which should be set initially at 31 volts, when using an argon + CO<sub>2</sub> mixture.

**GMAW Spray Transfer for Metal Thicknesses  $\frac{1}{4}$  in. (6.4 mm) and Up.**—The 0.045-in. (1.2-mm) diameter is the most cost-effective GMAW electrode for spray transfer welding of carbon, low-alloy, and stainless steels  $\frac{1}{4}$  in. and thicker. A  $\frac{7}{16}$ -in. (11.2-mm) single-pass, no-weave, fillet weld can be produced with this electrode. If larger single-pass welds are required, use of flux-cored electrodes should be considered.

Fig. 2. GMAW Spray Transfer Parameters with 0.035-inch (0.9-mm) Diameter Electrodes

A 400-amp power source is a practical cost-effective unit to use with the 0.045-in. diameter electrode. Globular spray transfer, obtained at the ten o'clock position on the wire feed adjustment knob, starts at current levels of approximately 230 amps and requires a wire feed rate of approximately 210 in/min (90 mm/s). Most spray applications are carried out in the higher-energy, deeper-penetrating 270- to 380-amp range, or between twelve and two o'clock wire feed positions giving 350 to 490 in/min (150 to 210 mm/s). In this range, in which there is minimum weld spatter, the weld deposits are in the form of minute droplets and vaporized weld metal.

The quadrants at the top in Fig. 3 show some typical settings for feed rate, voltage, and current, with different shielding gases. An ideal starting point with a 0.045-in. (1.2-mm) diameter electrode is to set the wire feed rate knob at the one o'clock position, or 420 in/min, at which rate the current drawn, depending on the power source used, should be about 320 to 350 amps. The best starting voltage for the 0.045-in. (1.2-mm) electrode is 30 volts. The arc length should then be set as indicated in Fig. 4. With current over 400 amps at 560 in/min, the 0.045-in. diameter electrode may produce a turbulent weld puddle and a digging arc, which can lead to lack of fusion, porosity, and cracks.

**GMAW Spray Transfer with 0.062-in. (1.6-mm) Diameter Electrodes.**—Electrode wire of 0.062-in. (1.6-mm) diameter is the largest size in normal use and is often chosen for its high-deposition rates. Due to the high-current requirements for the spray transfer mode, use of these thicker electrodes is generally restricted to metal thicknesses of  $\frac{1}{2}$  in. (13 mm) and thicker. The high-current requirement reduces ease of welding. This electrode size is suitable for mechanized welding in which fillet welds greater than  $\frac{3}{8}$  in. (9.6 mm) are required.

As indicated at the lower left in Fig. 3, the current range for 0.062-in. (1.6-mm) electrodes is narrow and most welds are made in the range of 360 to 420 amps, or between the ten and eleven o'clock positions on the wire feed control unit for 210 to 280 in/min (90 to 120 mm/s). The quadrants at the lower center and lower right in Fig. 3 show deposition rates in lb/h and kg/h for 0.045-in. (1.2-mm) and 0.062-in. (1.6-mm) diameter electrodes.

Some optimum settings for GMAW welding with a mixture of argon + 15 to 20 percent CO<sub>2</sub> gases are given in Table 5.

Fig. 3. GMAW Spray Transfer Parameters for Various Electrodes and Gases

Table 5. Optimum Settings for GMAW with Argon + 15–20 percent CO<sub>2</sub>

Diameters		Mode	Wire Feed Rates		Amps	Volts
inch	mm		in/min	m/min		
0.035	1.0	short circuit	210	5.3	140	17
		spray transfer	560	14.2	280	29–30
0.045	1.2	short circuit	210	5.3	190	18
		spray transfer	420	10.7	380	30–31
0.052	1.4	spray transfer	280	7.1	370	31–32
0.062	1.6	spray transfer	280	7.1	410	31–32

Note: If argon + oxygen gas mixtures are used, voltage should be lowered by 1 to 4 volts for the spray transfer mode. The faster the weld travel speed, the lower the voltage required.

**Spray Transfer Voltage.**—The usual setting for spray transfer welding with commonly used electrode diameters is between 25 and 35 volts (see Fig. 4A). To set the optimum voltage for GMAW spray transfer, set the voltage initially so that it is too high, usually between

30 and 35 volts. With excess voltage, there should be a visible gap between the tip of the electrode and the weld, and the arc sound should be free from crackle. With the sequence shown in Fig. 4, the voltage should now be reduced until a consistent smooth crackle sound is produced. If the voltage is lowered too much, the electrode will run into the weld, making a harsh crackling sound, and the resulting weld expulsion will cause spatter.

Fig. 4. Setting Optimum Voltage for GMAW Spray Transfer Welding

### Flux-Cored Arc Welding

FCAW welding offers unique benefits for specific applications, but flux-cored consumable electrodes cost more than the solid electrodes used in gas metal arc welding, so users need to be aware of FCAW benefits and disadvantages compared with those of GMAW welding. Generally, flux-cored electrodes designed for use without a shielding gas are intended for welding outdoors. Most indoor FCAW welding is done with gas-shielded FCAW welding electrode wire. Some Standards for gas-shielded FCAW electrodes for various countries are listed in Table 6.

Table 6. Standards for Gas-Shielded, Flux-Cored Welding Electrodes

Steel Type	Country	Standard
Low-Carbon Steels	United States	AWS A5.20
	Canada	CSA W48.5
	Japan	JIS Z3313
	Germany	DIN 8559
Low-Alloy Steels	United States	AWS A5.29
	Canada	CSA W48.3-M
	United Kingdom	BS 639-2492
Stainless Steels	United States	AWS A5.22

**All-Position, Gas-Shielded Electrodes.**—The term “all-position” does not necessarily mean that these electrodes are the best choice for all positions. Also, flux-cored electrodes may meet all standard specifications, but there will inevitably be subtle differences

in weld transfer characteristics and recommended current, voltage, and other settings between electrodes made by different manufacturers. The chemistry and slag of the electrodes developed for welding in the flat and horizontal positions (E70T-X) typically provide superior results when they are used for flat and horizontal applications where the surface conditions of the plate are suspect or large, deep-penetrating welds are required. All-position electrodes are intended for, and best used in, vertical and overhead welds. For extensive welding in flat or horizontal positions, the welder is better served with the electrodes designed for these specific positions.

All-position, gas-shielded FCAW electrodes provide unique benefits and potential for cost savings. In contrast with short-circuit GMAW, or pulsed GMAW, the all-position FCAW electrodes used for vertical up welding of carbon, low-alloy, or stainless steels are simpler to operate, are capable of greater weld quality, and will provide two to three times the rate of weld deposition. The electrode most commonly used in the United States for vertical up welding on carbon steels is the type E71T-1. The equivalent to the E71T-1 standardized electrode specification now in use in other countries include: Canada, E4801T9; Germany, SGR1; and Japan, YFW 24.

If the end user selects the correct all-position electrode diameter, the routine weaving of the electrode during vertical up and overhead applications may be minimized. Keeping the weld weave to a minimum reduces the skill level needed by the welder and increases the potential for consistent side-wall fusion and minimum porosity. If weaving is necessary, a straight-line oscillation technique is often preferred. Typical settings for welding with various sizes of gas-shielded FCAW electrodes are shown in Table 7.

**Table 7. Typical Settings for Welding with Gas-Shielded FCAW Electrodes**

Electrode Diameter inch (mm)	Vertical Up Welds		Flat and Horizontal Welds	
	Feed rate	Current	Feed rate	Current
0.035 (1)	450 ipm (11.4 m/min)	165 amps	630 ipm (16.0 m/min)	250 amps
		28 volts		30 volts
0.045 (1.2)	350 ipm (8.9 m/min)	200 amps	560 ipm (14.2 m/min)	280 amps
		25 volts		26 Volts
0.052 (1.4)	240 ipm (6.1 m/min)	200 amps	520 ipm (13.2 m/min)	300 amps
		25 volts		30 volts
0.062 (1.6)	210 ipm (5.3 m/min)	240 amps	350 ipm (8.9 m/min)	340 amps
		25 volts		29 volts
$\frac{3}{32}$ (2.4)	...		210 ipm (5.3 m/min)	460 amps
				32 volts

**Material Condition and Weld Requirements.**—Practical considerations for selecting a gas-shielded, flux-cored electrode depend on the material condition and weld requirements. FCAW electrodes are beneficial if the surface of the material to be welded is contaminated with mill scale, rust, oil, or paint; the fillet weld size is to be over  $\frac{3}{8}$  in. (9.6 mm) wide (a GMAW single-pass fillet weld with an electrode size of 0.045 in. is typically  $\frac{3}{8}$  in. wide); the weld is vertical up, or overhead; the required impact strengths and other mechanical properties are above normal levels; crack resistance needs to be high; and increased penetration is required.

**Selecting an FCAW Electrode.**—Selection of FCAW electrodes is simplified by matching the characteristics of flux-cored types with the material and weld requirements listed above. Once the correct electrode type is selected, the next step is to choose the optimum size. In selecting an all-position, flux-cored electrode for vertical up or overhead welding, the steel thickness is the prime consideration. Selecting the optimum electrode diameter allows the high current capability of the electrode to be fully used to attain maximum

deposition rates and allows use of the highest penetrating current without concern for excessive heat-related problems during welding. When used in the optimum current range, the deposited filler metal matches the required amount of filler metal for the specific size of the weld, determined by the plate thickness.

The following suggestions and recommendations are made for FCAW welding of carbon, low-alloy, and stainless steels having flat surfaces. For vertical up welds on steels of thicknesses from  $\frac{1}{8}$  to  $\frac{3}{16}$  in. (3.2 to 4.8 mm) and for vertical up welds on pipe in the thickness range of  $\frac{1}{4}$  to  $\frac{1}{2}$  in. (6.4 to 13 mm), consider the 0.035-in. (1.0-mm) diameter E71T-1 electrode. For vertical up welds on steels in the range of  $\frac{1}{4}$  to  $\frac{3}{8}$  in. (6.4 to 9.6 mm) thickness, consider the 0.045-in. (1.2-mm) diameter E71T-1 electrode or, in nonheat-sensitive applications, the 0.062-in. (1.6-mm) diameter E71T-1 electrode. For vertical up welds on steels of over  $\frac{3}{8}$  in. (9.6 mm) thickness, consider the 0.062-in. (1.6-mm) diameter E71T-1 electrodes for optimum deposition rates. For flat and horizontal welds on steels of  $\frac{3}{8}$  to  $\frac{3}{4}$  in. (9.6 to 19 mm) thickness, consider the  $\frac{1}{16}$ -in. (1.6-mm) diameter E70T-X electrodes. For flat and horizontal welds on steels over  $\frac{3}{4}$  in. (19 mm) in thickness, consider the  $\frac{3}{32}$ -in. (2.4-mm) E70T-X electrodes.

**FCAW Welding of Low-Carbon Steels.**—Low-carbon steel is usually called carbon steel or mild steel. The most-used FCAW electrode for welding carbon steels in the flat or horizontal welding positions is the type E70T-1, which is suited to welding of reasonably clean steel using single-pass or multi-pass welds. Type E70T-2 has added deoxidizers and is suited to surfaces with mill scale or other contamination. This type is used when no more than two layers of weld are to be applied. Type E70T-5 is used for single-pass or multi-pass welds where superior impact properties or improved crack resistance are required. The E70T-X electrodes typically range in size from 0.045 to  $\frac{3}{32}$  in. (1.2 to 2.4 mm) in diameter. Type E71T-1 all-position electrodes are available in diameters of 0.035 in. (1 mm) to 0.062 in. (1.6 mm). With the FCAW process, multi-pass welds are defined as a condition where three or more weld passes are placed on top of each other.

**Settings for Gas-Shielded, All-Position, FCAW Electrodes.**—The optimum setting range (volts and amps) for vertical up welding with all-position FCAW electrodes is rather narrow. The welder usually obtains the greatest degree of weld puddle control at the recommended low to medium current settings. The electrode manufacturers' recommended current range for an E71T-1 electrode of 0.045-in. (1.2-mm) diameter for vertical up welding may be approximately 130 to 250 amps. Using the 0.045-in. (1.2-mm) diameter electrode at 250 amps for a vertical up weld in  $\frac{1}{4}$ -in. (6.4-mm) thick steel, the welder may find that after 3 to 4 inches (75–100 mm) of weld, the weld heat built up in the steel being welded is sufficient to make the weld puddle fluidity increasingly difficult to control. Reducing the current to 160–220 amps will make it possible to maintain control over the weld puddle.

A typical optimum setting for a vertical up weld with an E71T-1, 0.035-in. (1.2-mm) diameter, all-position electrode is as follows. First, set the wire feed rate. If the wire feeder maximum rate is 650 to 750 in/min (16.5–19.0 m/min), the setting mark on the adjustment knob should be set between the one and two o'clock positions on the dial to obtain a feed rate of 450 in/min (11 m/min). If the wire feeder has a digital readout, the rate setting should be the same. At the 450-in/min setting, the welding current with the 0.035-in. all-position electrode should be optimized at between 160 and 170 amps. The welding voltage should be set at 27 to 28 volts with the electrode tip just touching the weld. If there is a gap causing the weld puddle to become too fluid, the voltage should be lowered. If the electrode runs into the weld, causing spatter, the voltage needs to be increased.

With the above conditions, welding steel of  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thickness will deposit 5 to 7 lb/h (2.2 to 3 kg/h). The 0.035-in. electrode is also ideal for welding steel pipe with wall thicknesses of less than  $\frac{1}{2}$  in. (13 mm). The thickness of the pipe after beveling controls the size of electrode to be used. The 0.035-in. (6.4-mm) electrode can produce a  $\frac{1}{4}$ -in. (6.4-mm) vertical up fillet weld on such a pipe without weaving.

**Contact Tip Recess.**—The dimension labeled contact tip recess in Fig. 2, and indicated as  $\frac{1}{8}$  in. (3 mm), should be about  $\frac{1}{2}$  in. (13 mm) for a minimum electrode extension of  $\frac{3}{4}$  in. (19 mm), for FCAW welding. This dimension is critical for obtaining high-quality welds with all-position electrodes because they have a fast-freezing slag and operate with low to medium current and voltage. If the recess dimension is less than the optimum, the voltage may be lower than the minimum recommended, and if the settings are less than the minimum, the fast-freezing slag may solidify too rapidly, causing excess porosity or “worm tracks” on the weld surface.

The recommended length of electrode extension for all-position FCAW, E71T-1 electrodes is  $\frac{3}{4}$  to 1 in. (19 to 25 mm). The size of this extension not only affects the minimum required parameters, but a long electrode extension also ensures preheating of the electrode and allows lower current to be used. Preheating the electrode is further beneficial as it reduces moisture on the electrode surface, and in the electrode flux. When a change is made from the GMAW to the FCAW process, welders must be aware of the influence on weld quality of the electrode extension in the FCAW process.

**Porosity and Worm Tracks.**—As mentioned above, porosity and worm tracks typically result from a combination of incorrect electrode extension, incorrect welding settings, humidity, electrode moisture, refill scale, rust, paint, oils, or poor welding technique. Where humidity levels are high, potential for porosity and worm tracks increases. The FCAW process is less sensitive to mill scale than the GMAW spray transfer mode but mill scale will often cause excess weld porosity. The best way to avoid the effects of mill scale, rust, oil, and surface contaminants is to grind the area to be welded.

Another way to reduce porosity is to keep weaving to a minimum. If the correct size flux-cored electrode is used, weaving can be kept to a minimum for most flux-cored applications. The forehand technique produces the best weld bead surface on fillet weld beads up to  $\frac{3}{4}$  in. (19 mm) steel thickness in the flat and horizontal weld positions. On larger single-pass fillet welds, the backhand technique is beneficial because the voltage directed at the weld provides additional weld puddle control to the fluid welds. The backhand technique used for flat and horizontal welds produces a more convex weld bead, reduces potential for porosity, and increases penetration.

If porosity or worm tracks occur, the prime solution is in weld practices that increase heat at the weld, but the following remedies can also be tried. Grind clean the surface to be welded; use recommended electrode extensions; increase current (wire feed rate) decrease voltage; use the backhand welding technique; slow down travel speed, consider use of a different electrode formulation containing increased deoxidizers, avoid weaving; change from argon + CO<sub>2</sub> mixture to straight CO<sub>2</sub>; and provide a protective cover to keep the electrode spool clean and dry.

**Welding with 0.045-in. (1.2-mm) Diameter All-Position Electrodes.**—Fig. 5 shows wire feed settings for welding of steel with 0.045-in. (1.2-mm) diameter, E71T-1 all-position electrodes using a mixture of argon + 15 to 25 percent CO<sub>2</sub> as the shielding gas, and an electrode extension of  $\frac{3}{4}$  in. (18 mm). Parameters for vertical up welding, shown at the left in Fig. 5, include setting the wire feed rate at the twelve o'clock position, or about 350 in/min, using 200 to 190 amps, and setting the voltage between 24 and 25 volts. Optimum parameters for flat welding, shown at the right in Fig. 5 include setting the wire feed rate at three o'clock position, or 560 in/min (240 mm/s), and 270 amps at 25 to 27 volts.

**Welding with 0.052-in. (1.3-mm) Diameter All-Position Electrodes.**—Settings for vertical up and flat welding with all-position E71T-1 electrodes of 0.052-in. (1.3-mm) diameter are seen at the left in Fig. 6. These electrodes are suited to welding steel having thicknesses of  $\frac{1}{4}$  in. (6 mm) and thicker. For vertical up welding, the wire feed rate is set between the ten and eleven o'clock positions, or 250 in/min (106 mm/s), with about 200 amps at 25 volts. Flat welding with these electrodes is best done with the wire feed rate set between the two and three o'clock positions, or 490 to 560 in/min (207 to 237 mm/s), giving approximately 300 amps at 28 volts.

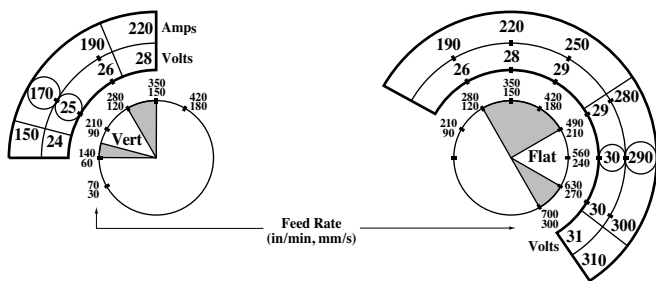

Fig. 5. Wire Feed and Voltage Settings for FCAW Welding with 0.045-in. (1.2-mm) Diameter E71T-1 Electrodes, with Optimum Settings Circled.

Settings for all-position E71T-1 electrodes of 0.062-in. (1.6-mm) diameter, shown at the right in Fig. 6, for vertical up welding are just before the ten o'clock position, or 190 in/min, giving 230 to 240 amps with voltage adjusted to 24–25 volts. For flat welding, the wire feed is set to the twelve o'clock position, giving 340–350 amps with a voltage of 29–30 volts.

**High-Deposition, All-Position Electrodes.**—Vertical up weld deposition rates of 10 to 14 lb/h can be achieved with the E71T-1, 0.062-in. (1.6-mm) and 0.045-in. (1.2-mm) flux-cored electrodes. Settings are shown in Fig. 6 for E71T-1, FCAW electrodes of 0.052- and 0.062-in. (1.4- and 1.6-mm) diameter. These electrodes are suited to applications in which the steel thickness is  $\frac{1}{4}$  in. and thicker, and are the most cost-effective diameter for all-position welds on carbon and stainless steels of  $\frac{1}{4}$  in. (6.35 mm) thickness and thicker. In contrast, vertical up welds, using GMAW or SMAW, may deposit an average of 2 to 4 lb/h (1 to 2 kg/h). Deposition rates are based on welding 60 minutes of each hour. Pulsed GMAW provides deposition rates of 3 to 6 lb/h (1.3–2.7 kg/h). Average rates for vertical up welding with all-position, flux-cored electrodes are shown in Table 8.

Fig. 6. Wire Feed and Voltage Settings for Vertical Up Welding with 0.052- and 0.062-in. Diameter Electrodes

The average deposition rates in Table 9 are to be expected with FCAW electrodes available today. Special electrodes are also available that are specifically designed to provide higher deposition rates. A typical manual welder, welding on steel of  $\frac{1}{4}$  to  $\frac{3}{8}$  in. thickness for 30 minutes of each hour with an all-position flux-cored 0.062-in. (1.6-mm) or 0.045-in. (1.2-mm) diameter electrode would deposit about 4–5 lb/h.

**Table 8. Deposition Rates for Vertical Up Welding with All-Position, Flux-Cored Electrodes (ET71T-1)**

Electrode Diameter		Typical Deposition Rate Range		Average Deposition Rate	
inch	(mm)	lb/h	(kg/h)	lb/h	(kg/h)
0.035	(1)	2.7–6.5	(1.2–3)	5	(2.3)
0.045	(1.2)	5–11	(2.3–5)	8	(3.6)
0.052	(1.4)	4–8	(1.8–3.6)	6.5	(3)
0.062	(1.6)	4–11	(1.8–5)	8.5	(4)

**Table 9. Average Deposition Rates for Flat and Horizontal Welds**

Process	Electrode Size		Cost-Effective Current Range (amps)	Optimum Current (amps)	Deposition Rate	
	inch	(mm)			lb/h	(kg/h)
GMAW spray transfer	0.035	(1)	250–350	285	9	(4)
	0.045	(1.2)	300–400	385	13	(5.9)
	0.052	(1.4)	350–470	410	11	(5)
	0.062	(1.6)	375–500	450	17	(7.7)
FCAW	0.045	(1.2)	225–310	300	14	(6.4)
	0.052	(1.4)	260–350	310	15	(6.8)
	0.062	(1.6)	300–400	340	15	(6.8)
	$\frac{3}{32}$	(2.4)	380–560	460	17	(7.7)

The average deposition rates of pulsed GMAW and FCAW for vertical up welds are similar for applications where the steel thickness is  $\frac{1}{8}$  in. (3.2 mm) or less. On steels thicker than  $\frac{1}{8}$  in., where the current may be increased, and larger-diameter all-position FCAW electrodes may be used, deposition rates will be much greater than with pulsed GMAW. Compared with GMAW electrodes for pulsed welding, FCAW all-position electrodes require less costly equipment, less welding skill, and have potential for increased weld fusion with less porosity than with GMAW pulsed techniques.

**Electrode Diameters and Deposition Rates.**—A cost-effective welding shop can achieve deposition rates on flat and horizontal welds of 12 to 15 lb/h (5 to 7 kg/h) with both the GMAW 0.045-in. wire and the 0.062-in. flux-cored wire electrodes, without welder discomfort, and with welds of consistent quality.

The first consideration in selecting the optimum size of gas-shielded FCAW E70T-X electrode for manual flat and horizontal welds on steels thicker than  $\frac{1}{4}$  in. (6.4 mm) is the current requirements needed to achieve deposition rates of 12 to 15 lb/h (5 to 7 kg/h). Large-size electrodes of  $\frac{3}{32}$ -in. (2.4-mm) diameter require 500 amps or more to attain optimum deposition rates. These  $\frac{3}{32}$ -in. diameter electrodes are often used with power sources in the 300–400 amp range, but even when the power source provides 500 to 600 amps, welding is often performed at the low end of the electrode's current requirements. With the large,  $\frac{3}{32}$ -in. diameter electrodes, welder appeal is low, smoke is often excessive, and deposition rates are often only comparable with smaller, easier-to-operate FCAW electrodes.

Typical deposition rates for flat and horizontal welds with various electrode sizes and weld settings are shown in Table 9. In connection with this table, it may be noted that high deposition rates in welding steel plate thicker than  $\frac{1}{4}$  in. require use of currents above the minimum shown for the various sizes of electrodes. The optimum current requirements for the most popular electrode sizes indicate that a 450-amp power source is the most suitable for welding steel of more than  $\frac{1}{4}$  in. thickness. The two most cost-effective and

versatile consumables for thin and thick steel sections are the 0.045 in. for GMAW and the 0.062 in. for FCAW electrodes.

The approach to a welding application is critical to achievement of optimum weld quality at minimum cost. In many applications, minimal consideration is given to weld costs. Half of every man-hour of welding in many shops could be saved with selection of the correct electrode diameter used with optimum parameter settings. A practical point that is often overlooked in selection of FCAW electrodes is that the larger the electrode diameter, the more restricted is the application thickness range. Large FCAW electrodes such as the  $\frac{3}{32}$  in. (2.4 mm) are neither suitable nor cost-effective for the common steel thickness range of  $\frac{1}{4}$  to  $\frac{1}{2}$  in. (6.4 to 13 mm). Smaller FCAW electrodes such as the  $\frac{1}{16}$ -in. (1.6-mm) diameter, are suitable for both thin and thick applications. A  $\frac{1}{16}$ -in. diameter FCAW electrode used in the 300- to 350-amp range provides excellent deposition rates with superior welder appeal and negligible smoke.

Large-diameter  $\frac{3}{32}$ -in. (2.4-mm) electrodes are popular for manual applications. However, from a practical point of view, this electrode size is often better suited to mechanized high-current welding in which the high currents required for optimum deposition rates may be safely used without health risks. Use of an electrode at 60 to 80 percent of its welding current capability indicates that the correct diameter electrode has been selected for the application. When an electrode is used at its maximum-current capability, it shows that the next size larger electrode should be preferred, and when the low end of the current capability is in use, the electrode selected is typically too large.

**The 0.062-in. (1.6-mm) Diameter, E70T-X Electrode.**—The 0.062-in. (1.6-mm) diameter FCAW electrode is the most practical size of its type and will provide excellent deposition rate potential with a practical current range and the broadest application range. Settings for the common  $\frac{1}{16}$ -in. diameter E70T-1 electrode are shown in Fig. 7. With the GMAW process, a  $\frac{3}{8}$ - to  $\frac{7}{16}$ -in. (9.6- to 11-mm) minimum-weave fillet weld is typically the maximum size that can be made in a single pass. The 0.062-in. ( $\frac{1}{16}$ -in., 1.6-mm) FCAW electrode can easily produce a  $\frac{3}{4}$ -in. (19-mm), nonweave, single-pass fillet weld. This size of electrode is also a practical choice for welding steel of  $\frac{1}{4}$  in. (6.4 mm) or greater thickness. From a cost perspective, FCAW consumable electrodes should be used whenever the GMAW process is not suitable.

Fig. 7. Settings for  $\frac{1}{16}$ -in. (1.6-mm) FCAW, E70T-X Electrodes

The average deposition efficiency of a flux-cored electrode is 85 percent, which means that for every 100 lb or kg of electrode material used, 85 lb or kg ends up as weld material. In contrast, the average deposition efficiency of a GMAW electrode used with argon mixtures and correct equipment settings should be a minimum of 99 percent.

**Shielding Gases and FCAW Electrodes.**—The E70T-X flux-cored electrodes that are recommended for flat and horizontal welds use CO<sub>2</sub> gas shielding. Because of new OSHA welding smoke restrictions, manufacturers of FCAW electrodes now provide E70T-X consumable electrodes that can be used with less reactive argon + CO<sub>2</sub> mixtures to reduce smoke levels. The fast-freezing slag, all-position, E71T-1 flux-cored electrodes can use either CO<sub>2</sub> or argon + 15 to 25 percent CO<sub>2</sub> mixtures for welding carbon, low-alloy, or stainless steels. The argon + CO<sub>2</sub> mixture is often selected because it provides the highest energy from a reactive gas mixture with a compatible voltage range.

Instead of CO<sub>2</sub>, welders often prefer the arc characteristics, lower smoke levels, and lower voltage requirements of the argon + CO<sub>2</sub> mixtures for all-position welding. However, if lower reactive argon mixtures such as argon + oxygen, or argon with less than 13 percent CO<sub>2</sub>, are used, the weld voltage requirements and the arc plasma energy are reduced, adding to the possibility of changing the mechanical properties significantly, increasing the porosity, and raising the potential for forming worm tracks.

### Shielded Metal Arc Welding

With the shielded metal arc welding (SMAW) process, commonly known as stick welding, it is most important to select an electrode that is suited to the application. For welding austenitic stainless or high-alloy steels, the electrode is first selected to match the mechanical and chemical requirements of the metal to be welded. Secondary requirements such as the welding position, penetration potential, deposition capabilities, and ease of slag removal are then considered. Many electrodes for SMAW welding of low- to medium-carbon steels have unique characteristics making them the most suitable and cost-effective for a specific welding application.

In interpreting the ANSI/AWS Standard specification code for SMAW electrodes shown in Table 10, for example, E60XX, the E stands for a low-carbon steel, metal arc welding electrode. The next two digits, such as 60 or 70, indicate the approximate tensile strength of the weld deposit in thousands of psi.

Of the last two digits, the next (second to last) number indicates the positions in which the electrode can be used: 1 = indicates the electrode is suitable for use in flat, horizontal, vertical, and overhead positions; 2 = the electrode can be used in the flat position for all welding types, and in the horizontal position for fillet welds only; 4 = the electrode is suitable for use in the flat, horizontal, vertical-down, and overhead positions. Note that number "3" is no longer used as a position designation.

The final digit, combined with the above, indicates the type of flux coating, as shown in Table 10.

**Table 10. Significance of Digits, ANSI/AWS A5.18-1979**

Third and Fourth Digits	Flux Type and Characteristics, SMAW Electrodes
10	High-cellulose coating bonded with sodium silicate. Deep penetration, energetic spray-type arc. All-positional, DCEP <sup>a</sup> only
11	Similar to 10 but bonded with potassium silicate to permit use with AC or DCEP
12	High-rutile coating, bonded with sodium silicate. Quiet arc, medium penetration, all-positional, AC or DCEN
13	Similar to 12 but bonded with sodium silicate and with easily ionized materials added. Gives steady arc on low voltage. All-positional, AC or DCEN
14	Similar to 12 with addition of medium amount of iron powder. All-positional, AC or DC
15	Lime-fluoride coating (basic low-hydrogen) bonded with sodium silicate. All-positional. For welding high-tensile steels. DCEP only

**Table 10.** (Continued) **Significance of Digits, ANSI/AWS A5.18-1979**

Third and Fourth Digits	Flux Type and Characteristics, SMAW Electrodes
16	Similar to 15 but bonded with potassium silicate. AC or DCEP
18	Similar to 15 but with addition of iron powder. All-positional, AC or DC
20	High iron-oxide coating bonded with sodium silicate. Flat or HV positions. Good X-ray quality. AC or DC
24	Heavy coating containing high percentage of iron powder for fast deposition rates. Flat and horizontal positions only. AC or DC
27	Very heavy coating with ingredients similar to 20 and high percentage of iron powder. Flat or horizontal positions. High X-ray quality. AC or DC
28	Similar to 18 but heavier coating and suited for use in flat and HV positions only. AC or DC
30	High-iron-oxide-type coating but produces less fluid slag than 20. For use in flat position only (primarily narrow-groove butt welds). Good X-ray quality. AC or DC

<sup>a</sup> DC = direct current, AC = alternating current, EP = electrode positive, EN = electrode negative.

British Standard BS 639:1986 defines requirements for covered carbon- and carbon-manganese-steel electrodes for manual metal arc welding, depositing weld metal having a tensile strength of not more than 650 N/mm<sup>2</sup>. Appendix A of this standard lists minimum mandatory and optional characteristics of these electrodes. The extensive classifications provide for electrodes to be rated for strength, toughness, and covering (STC), with codes such as E 51 5 4 BB [160 30 H]. In this series, E indicates that the electrode is covered and is for manual metal arc welding. The next two digits (51) indicate the strength (tensile, yield, and elongation) properties. The next digits (5 and 4) give the temperatures at which minimum average impact strengths of 28J (at -40°C) and 47J (at -30°C), using Charpy V-notch test specimens, are required. The next group is for the covering and the BB stands for basic, high efficiency. Other letters are B for basic; C for cellulosic; R for rutile, RR for rutile, heavy coated; and S for other.

The letters in brackets are optional, and the first group indicates the efficiency, which is the ratio of the mass of weld metal to the mass of nominal diameter core wire consumed with the largest diameter electrode, rounded up to the nearest multiple of 10. The next digit (3) is the maker's advice for the position(s) to be used. Codes for this category include 1, all positions; 2, all positions except vertical down; 3, flat, and for fillet welds, horizontal/vertical; 4, flat; 5, flat, vertical/down; and for fillet welds, horizontal/vertical; and 9, other. The digit at (0), which may have numbers from 0 to 9, shows the polarity, and the minimum open-circuit voltage to be used for that electrode. A 0 here indicates that the electrode is not suited for use with AC. The (H) is included only for hydrogen-controlled electrodes that will deposit not more than 15 ml of diffusible hydrogen for each 100 g of deposited weld metal. The corresponding ISO Standard for BS 639 is ISO 2560. Low-alloy steel electrodes and chromium and chromium nickel steel electrodes are covered in BS 2493 and BS 2926.

The most common electrodes used for the SMAW process are the AWS types E60XX and E70XX. SMAW welding electrode Standards are issued by the American Welding Society (AWS), the British Standards Institute (BS), Canada (CSA), Germany (DIN), and Japan (JIS) and are shown in Table 11.

**AWS E60XX Electrodes.**—Characteristics of the E60XX electrodes influence the weld position capability, ease of slag removal, penetration potential, weld travel speed capability, and weld deposition rates. These electrodes are designed for welding low-carbon steels and they provide welds with typical tensile strength in the range of 58,000–65,000 lb<sub>f</sub>/in<sup>2</sup> (400–448 MPa), depending on the specific electrode utilized, the base metal condition and chemistry, and the amount of weld dilution. In selecting an electrode for SMAW welding, knowing that the mechanical and chemical requirements have been matched, it is necessary to choose electrodes with characteristics that influence the features required, as shown in Table 11.

**Table 11. Characteristics of SMAW Welding Electrodes Made to Standards of Various Countries**

Standard	Description
AWS E6010 CSA E41010 BS E4343C10 DIN E4343C4 JIS D3410	Designed for welding pipe and general structures. Excellent for all-position and vertical down welding. Slag is light and easy to remove. Deep, penetrating arc. Low deposition rates. Polarity DC + (electrode positive).
AWS E6011 CSA E41011 BS E4343C13 DIN E4343C4 JIS D4311	Similar to E6010 but modified to allow use of AC. Excellent for welding sheet metal corner joints vertical down. Polarity AC or DC + (electrode positive).
AWS 6012 CSA E41012 BS E4332R12 DIN E4332R(C) JIS D4313	Designed for welding sheet metal and light structural steels. Medium penetration suitable for gaps or where minimum weld dilution is needed. Ideal for flat, horizontal, or vertical down welding. Will weld faster than the E6010-11 electrode. Polarity AC or DC—(electrode negative).
AWS E6013 CSA E41013 BS E4332R21 DIN E4332R3 JIS D4313	Excellent AC or DC—performance. All-position. Shallow penetration. Good choice for low open-circuit welding machines. AC or DC both excellent on thin structural applications. Polarity AC or DC (DC both polarities).
AWS 6027 CSA 41027 BSE4343A13035 DIN 4343AR11 JIS D4327	Iron powder is added to the flux to provide higher deposition rates. Ideal for multipass groove and fillet welding in flat and horizontal positions. Polarity AC or DC (both polarities).

Table 12 shows approximate current requirements for AWS E60XX electrodes for welding sheet metal carbon steels. The current ranges specified vary slightly with different electrode manufacturers. For welding sheet metal start at the low end of the given current requirements with electrodes of  $\frac{3}{16}$ -in (5-mm) diameter or smaller. For metals thicker than 10 gage (0.134 in.), start in the center of the current range, then adjust to suit. A high DC current may result in arc blow, and improved results may then be obtained with AC.

**Table 12. Diameters of AWS E6010/E6011 SMAW Electrodes for Welding Low-Carbon Steel Sheet Metal**

SWG of Sheet Metal to be Welded	Electrode Diameter		Current Starting Level (amps)
	in.	(mm)	
18	$\frac{3}{32}$	(2.5)	45–60
16–14	$\frac{1}{8}$	(3.2)	80–110
12	$\frac{5}{32}$	(4)	125–135
10	$\frac{3}{16}$	(5)	135–150

For welding thicker materials, a good starting setting is in the middle of the current range shown in Table 12. In welding material less than  $\frac{1}{4}$ -in. (6.4-mm) thick, vertically, with an E6010 electrode, try a  $\frac{1}{8}$ -in. (3.2-mm) electrode at 90 to 100 amps. For welding thicknesses between  $\frac{3}{16}$  and  $\frac{5}{16}$  in. (5 and 8 mm) with the E6010 electrode, vertically, try the  $\frac{5}{16}$ -in. (8-mm) diameter electrode at 100 to 125 amps. For thicknesses of  $\frac{3}{8}$  to 1 in. (9.5 to 25 mm), try a  $\frac{3}{16}$ -in. (5-mm) diameter electrode at 155 to 165 amps.

Recommended current ranges, shown in Table 13 for the various sizes of AWS E60XX electrodes most commonly used for welding carbon steel, will give optimum results with SMAW electrodes. An ideal starting point for the current setting for any SMAW electrode diameter is in the middle of the range. The current ranges shown are average values taken from literature of electrode manufacturers in three different countries.

**Table 13. Current Ranges for AWS E60XX SMAW Electrodes**

Electrode Diameter		E6010/E6011	E6012	E6013	E6027
in.	(mm)	(amps)	(amps)	(amps)	(amps)
$\frac{1}{16}$	(1.6)	...	25–50	20–40	...
$\frac{3}{32}$	(2.5)	40–75	40–100	50–100	...
$\frac{1}{8}$	(3.2)	75–130	85–140	75–135	120–180
$\frac{5}{32}$	(4)	90–170	115–185	110–185	155–245
$\frac{3}{16}$	(5)	135–220	145–240	150–235	200–300
$\frac{1}{4}$	(6.4)	205–325	250–390	240–340	300–410
$\frac{5}{16}$	(8)	260–420	290–480	310–425	370–480

**AWS E70XX Electrodes.**—Information on the most commonly used AWS E70XX electrodes is given in Table 15. For critical welding applications, low-hydrogen electrodes are typically used. It is most important that manufacturers' instructions regarding storage requirements for keeping low-hydrogen electrodes free from moisture are followed. Current ranges for welding low-carbon steel sheet metal with E70XX electrodes of diameters from  $\frac{3}{32}$  to  $\frac{3}{16}$  in. (2.5 to 5 mm) are shown in Table 14. The optimum starting point is in the middle of the current range indicated.

**Table 14. Current Ranges for SMAW E70XX Welding Electrodes**

Electrode Diameter		E7014	E7018	E7024
in.	(mm)	(amps)	(amps)	(amps)
$\frac{3}{32}$	(2.5)	75–120	70–105	85–135
$\frac{1}{8}$	(3.2)	110–155	110–160	130–180
$\frac{5}{32}$	(4)	145–210	150–215	175–240
$\frac{3}{16}$	(5)	190–280	180–275	230–315
$\frac{7}{32}$	(5.5)	255–335	255–350	280–370
$\frac{1}{4}$	(6.4)	330–415	295–360	325–450
$\frac{5}{16}$	(8)	380–490	370–480	390–530

In using AWS E7018 electrodes for vertical up welding of plate thicknesses of  $\frac{3}{16}$  to  $\frac{5}{16}$  in. (5 to 8 mm), try a  $\frac{1}{8}$ -in. (3.2-mm) diameter electrode. For vertical up welding of thicknesses greater than  $\frac{5}{16}$  in. (8 mm), try a  $\frac{5}{32}$ -in. (4-mm) electrode. With AWS E7018 electrodes, to make horizontal fillet welds in plate thicknesses of 10 swg (0.135 in., 3.4 mm), try a  $\frac{3}{16}$ -in. (5-mm) electrode, for  $\frac{1}{4}$ -in. (6.4-mm) plate, try the  $\frac{7}{32}$ -in. (5.5-mm) electrode, and for steel plate thicker than  $\frac{1}{4}$  in., try the  $\frac{1}{4}$ -in. (6.4-mm) diameter electrode.

**Table 15. Characteristics of AWS Electrodes for SMAW Welding**

Standard	Description
AWS E7014 CSA E48014 BS E5121RR11011 DIN E5121RR8 JIS D4313	An iron-powder, all-position electrode for shallow penetration. Excellent for vertical down and applications with poor fit. Similar to AWS E6012-E6013 with added iron powder. For welding mild and low-alloy steels. Polarity AC or DC, + or –.

**Table 15.** (Continued) **Characteristics of AWS Electrodes for SMAW Welding**

Standard	Description
AWS E7018 CSA E48018 BS E5154B11026(H) DIN E5154B(R)10 JIS D5016	An iron-powder, low-hydrogen, all-position electrode. Excellent for rigid, highly stressed structures of low- to medium-carbon steel. Can also be used for welding mild and high-strength steels, high-carbon steels, and alloy steels. Polarity AC or DC + reverse polarity.
AWS 7024 CSA E48024 BS E5122RR13034 DIN E5122RR11 JIS D4324	An iron-powder electrode with low hydrogen, usable in all positions. Excellent for high-amperage, large, fillet welds in flat and horizontal positions. Polarity AC or DC, + or -.
AWS E7028 CSA E48028 BS E514B12036(H) DIN E5143B(R)12 JIS D5026	An iron-powder, low-hydrogen electrode suitable for horizontal fillets and grooved flat position welding. Higher deposition rates. More cost-effective than the AWS E7018 electrode. Polarity AC or DC + reverse polarity.

The E7024 electrode is suggested for horizontal fillet welds. For 10-gage (0.135-in, 3.4-mm) material, try the  $\frac{1}{8}$ -in. (3.2-mm) diameter electrode; for above 10-gage to  $\frac{3}{16}$ -in. (5-mm) material, try the  $\frac{5}{32}$ -in. (4-mm) diameter electrode. For plate of  $\frac{3}{16}$ - to  $\frac{1}{4}$ -in. thickness, try the  $\frac{3}{16}$ -in. size, and for plate thicker than  $\frac{1}{4}$  in., try the  $\frac{1}{4}$ -in. (6.4-mm) electrode.

### Gas Tungsten Arc Welding

Often called TIG (for tungsten inert gas) welding, gas tungsten arc welding (GTAW) uses a nonconsumable tungsten electrode with a gas shield, and was, until the development of plasma arc welding (PAW), the most versatile of all common manual welding processes. Plasma arc welding is a modified GTAW process. In contrast to GTAW, plasma arc welding has less sensitivity to arc length variations, superior low-current arc stability, greater potential tungsten life, and the capability for single-pass, full-penetration welds on thick sections.

In examining a potential welding application, the three primary considerations are: achieving a quality weld, ease of welding, and cost. Selecting the optimum weld process becomes more complex as sophisticated electronic technology is applied to conventional welding equipment and consumable electrodes. Rapid advances in gas metal arc and PAW welding power source technology, and the development of many new flux-cored electrodes, have made selection of the optimum welding process or weld consumable more difficult. When several manual welding processes are available, the logical approach in considering GTAW for production welding is to first examine whether the job can be welded by gas metal arc or flux-cored methods.

**GTAW Welding Current.**—A major benefit offered by GTAW, compared with GMAW, FCAW, or SMAW, is the highly concentrated, spatter-free, inert heat from the tungsten arc, which is beneficial for many applications. The GTAW process can use any of three types of welding current, including direct-current straight polarity, electrode negative (DC-), direct-current reverse polarity, electrode positive (DC+), and alternating current with high frequency for arc stabilization (ACHF). Each of the different current types provides benefits that can be used for a specific application.

**GTAW Direct-Current Straight Polarity (DC-):** The most common GTAW current is straight polarity, where the electrode is connected to the negative terminal on the power source and the ground is connected to the positive terminal. Gas tungsten arc welding is used with inert gases such as argon, and argon + helium to weld most metals. During a DC- straight-polarity weld, electrons flow from the negative tungsten electrode tip and pass through the electric field in the arc plasma to the positive workpiece, as shown in Fig. 8.

Plasma is a high-temperature, ionized, gaseous column that is formed when electrons in the arc collide with the shielding gas molecules. The gas atoms lose one or more electrons, leaving them positively charged. The electrons and the resulting plasma are concentrated at the electrode tip, where they cause the plasma pressure to be at its greatest. The electron density thins out as the electrons travel from the straight-polarity, negatively charged, tungsten electrode across the open arc. As the electrons traverse the arc to the work, the resulting arc column width increases slightly, controlled in part by the electromagnetic forces generated by the current. With the increase in the arc column width, the density and pressure of the plasma decrease. The electrons collide with the work, liberating much heat. The downward pressure of the plasma is exerted against the surface of the weld pool. The gas ions in the plasma are positively charged and greater in mass than the electrons.

In DC-, straight-polarity welding, the positive gas ions are drawn to the negative electrode. The electron flow to the weld ensures that most of the arc heat is generated at the positive work side of the arc. This current setup provides maximum penetration potential, as indicated in Fig. 8. With DC-, straight polarity, the tungsten electrode can carry a higher current and operate at lower temperatures than with the other current arrangements.

*Direct-Current Reverse Polarity (DC+):* With direct-current positive polarity (DC+), the tungsten electrode is connected to the power-source positive terminal so that the electrons flow from the negative work to the positive electrode. As illustrated in Fig. 9, the electrons impinging on the electrode tip reverse the direction of the heat concentration that occurs with straight polarity, as described above. Approximately two-thirds of the heat generated with DC+ reverse polarity is at the electrode tip, and the electrode becomes very hot, even with low current levels. DC+ reverse polarity requires large-diameter electrodes.

Fig. 8. Straight Polarity (DC-) Provides Highest Electrode Current Capacity and Deepest Penetration Potential

In the current range of 100 to 150 amps, DC+ reverse polarity requires a  $\frac{1}{4}$ -in. (6.4-mm) diameter electrode. This larger electrode produces a weld puddle almost twice as wide as that produced by a 120-amp,  $\frac{1}{16}$ -in. (1.6-mm) diameter, DC- straight polarity electrode. Most of the heat is generated at the electrode tip with DC+ reverse polarity, so penetration is much less than with DC- straight polarity. With DC+ reverse polarity, the positive gas ions in the arc plasma are drawn to the negative workpiece where they bombard and break up the surface oxides that form on metals such as aluminum and magnesium. However, the best welding method for aluminum and magnesium is to use alternating current (AC), which combines the benefits of DC- straight and DC+ reverse polarity.

*Alternating Current (AC):* The surface oxides formed on metals such as aluminum and magnesium disturb the arc and reduce the weld quality. Welding of these metals requires DC+ reverse or AC polarity to break up the surface oxides. An alternating current (AC) cycle consists of one-half cycle of straight polarity and one-half cycle of reverse polarity. With alternating current, the cleaning action benefits of the reverse-polarity arc can be combined with the electrode current-carrying capacity of the straight-polarity

arc. In welding aluminum and magnesium, the half cycles of AC polarity may become unbalanced. During the AC cycle, the reverse electrode-positive portion of the cycle is restricted by the oxides on the surfaces of these materials. The surface oxides are poor conductors and make it difficult for the electrons generated by the reverse-polarity part of the cycle to flow from the work to the electrode tip, but they do not upset the straight polarity in which the electrons flow from the electrode to the work.

Fig. 9. Direct-Current (DC+) Reverse Polarity Provides a Shallow, Wide, Weld Pool

**DC Component:** The part of the reverse-polarity cycle of alternating current (AC) that is upset by the poor conductivity of the oxides is changed into direct-current, straight polarity (DC-) and is directed back to the power source where it may cause overheating. The feedback is referred to as the DC component and its characteristics are important in deciding which process to use because, if an AC power source designed for shielded metal arc welding is to be used to weld aluminum by the GTAW process, the power source must be derated to protect the equipment. The power-source manufacturer will provide information on the level of derating required.

Power sources are available for GTAW that provide a balanced AC wave, and manufacturers will provide information about the benefits of balanced wave versus unbalanced wave, GTAW power sources, and equipment to protect against the DC component.

**High Frequency and AC:** To maintain the stability of the alternating-current (AC) arc when the positive cycle of the arc is upset by the aluminum oxide, and to avoid contamination of the tungsten electrode, high-frequency current is used to assist in arc ignition during each AC cycle. In direct-current, straight-polarity (DC-) welding of carbon and stainless steels, the high-frequency current is typically selected by the HF arc start-only switch. During AC welding of steels without oxide problems, the HF switch may be left on the arc start-only setting. When AC is used on aluminum, magnesium, or other metals with poor electron-conductive oxides, the HF switch should be moved to the continuous setting.

High-frequency current is also beneficial in that it promotes gas ionization. The more positively charged molecules produced, the more cleaning action takes place in the direct-current, reverse-polarity (DCRP) cycle.

**Selecting the Tungsten Electrode-Type.**—Use of the correct tungsten electrode composition is vital to producing good-quality GTAW welds. Tungsten has the highest melting temperature of all metals. Pure tungsten provides a low-current capacity and requires addition of such alloying elements as thorium or zirconium to increase the current-carrying capability. The electrode diameter and the electrode tip configuration also require consideration as both have a great influence on the performance and application potential of GTAW welding.

Table 17 shows typical compositions of commonly used GTAW tungsten electrode materials from the American Welding Society AWS A5.12 Standard. New electrode

compositions have been designed that utilize other alloys and rare-earth metals. These electrodes are designed for longer lives in both GTAW and plasma welding.

**Pure Tungsten:** Pure tungsten electrode material provides good arc stability with alternating current (AC). Tungsten has low current capacity and low resistance to electrode contamination. Pure tungsten is good for low-amperage welding of aluminum and magnesium alloys. On medium- to high-current ferrous applications, there is a potential for tungsten inclusions in the weld.

With DC, the current capacity of pure tungsten is lower than with the alloyed tungsten electrodes. During AC welding, a molten ball shape forms at the pure tungsten electrode tip, and this formation is desirable for welding aluminum.

**Table 16. Selection of Gas Tungsten Arc Welding (GTAW) Electrodes**

Base Metal	Electrode	Current	Recommendations
Carbon, low-alloy, stainless, and nickel steels	Thoriated	DCEN	Use EWZr electrodes with AC on thin materials
Aluminum	Zirconium or pure tungsten	AC	Use EWZr on critical applications
Aluminum	Thoriated zirconium	DCEP	Use EWZr or EWP electrodes with DCEP on thin sections
Copper and copper alloys	Thoriated	DCEN	Use EWZr or EWP with AC on thin sections
Magnesium	Zirconium	AC	Use DCEP with same electrode on thin sections
Titanium	Thoriated	DCEN	...

**Table 17. Common Tungsten Electrode Compositions**

Classification	Color	Tungsten (%)	Thorium Oxide (%)	Zirconium Oxide (%)
EWP	Green	99.50	...	...
EWTh-1	Yellow	98.50	0.8–1.2	...
EWTh-2	Red	97.50	1.7–2.2	...
EWTh-3	Blue	98.95	0.35–0.55	...
EWZr	Brown	99.20	...	0.15–0.4

In the classification column, E = electrode; W = tungsten; P = pure; Th = thoriated (thorium oxide); Zr = zirconiated (zirconium oxide). The colors are codes used by manufacturers to identify the material. Tungsten percentages are minimum requirements. The EWTh-3 is also called striped tungsten because it is made with a strip of thoriated material along the length. This electrode needs to be preheated by striking an arc to melt the tip, providing for the thorium and the tungsten to combine before welding is started.

The electrode recommendations in [Table 16](#) are a guide to attaining good-quality GTAW welds from the venous types of polarities available.

**Electrode and Current Selection.**—[Table 18](#) and [Table 19](#) show approximate current recommendations for common electrode types and diameters. The GTAW electrode size should be selected so that its midrange current provides the energy required for the intended application. If the electrode is too thin, excess current may be required, causing the electrode to wear too quickly or melt and contaminate the weld. If the electrodes used are found to be constantly at the top end of the current range, a change should be made to the next larger size. [Table 20](#) and [Table 21](#) show recommended sizes of electrodes and filler metal rods or wires for welding various thicknesses of carbon, low-alloy, and stainless steels and aluminum.

**Table 18. Recommended Current Ranges for Thoriated GTAW Electrodes**

Electrode	Current Range (amps)
1/16 in. (1.6 mm)	60–150
3/32 in. (2.4 mm)	150–250
1/8 in. (3.2 mm)	250–400
5/32 in. (4 mm)	400–500

The electrode selected must suit the application and the current capacity of the power source.

**Table 19. Current Ranges for EWP and EWZr GTAW Electrodes**

Electrode		Ampere Range AC Balanced		Ampere Range AC Unbalanced	
in.	(mm)	EWP	EWZr	EWP	EWZr
$\frac{1}{16}$	(1.6)	30–80	60–120	50–100	70–150
$\frac{3}{32}$	(2.4)	60–130	100–180	100–160	140–235
$\frac{1}{8}$	(3.2)	100–180	160–250	150–210	225–325
$\frac{5}{32}$	(4)	160–240	200–320	200–275	300–400

**Table 20. Electrode and Current Recommendations for Carbon, Low-Alloy, and Stainless Steels**

Material Thickness		Electrode Diameter		Filler Rod Diameter		Current Range (amps)	
in.	(mm)	in.	(mm)	in.	(mm)	DCEN	EWTh
$\frac{1}{16}$	(1.6)	$\frac{1}{16}$	(1.6)	$\frac{1}{16}$	(1.6)	60–100	
$\frac{1}{8}$	(3.2)	$\frac{3}{32}$	(2.4)	$\frac{3}{32}$	(2.4)	150–170	
$\frac{3}{16}$	(4.8)	$\frac{3}{32}$	(2.4)	$\frac{1}{8}$	(3.2)	180–220	
$\frac{1}{4}$	(6.4)	$\frac{1}{8}$	(3.2)	$\frac{5}{32}$	(7.2)	260–300	

Note: The shielding gas is argon at 15 to 20 cu ft/h (CFH). For stainless steel, reduce the current by approximately 10 percent.

**Table 21. Recommendations for GTAW Welding of Aluminum with EWPElectrodes Using AC and High-Frequency Current**

Material Thickness		Electrode Diameter		Filler Rod Diameter		AC Current Range
in.	(mm)	in.	(mm)	in.	(mm)	(amps)
$\frac{1}{16}$	(1.6)	$\frac{1}{16}$	(1.6)	$\frac{1}{16}$	(1.6)	40–70
$\frac{1}{8}$	(3.2)	$\frac{3}{32}$	(2.4)	$\frac{3}{32}$	(2.4)	70–125
$\frac{3}{16}$	(4.8)	$\frac{1}{8}$	(3.2)	$\frac{1}{8}$	(3.2)	110–170
$\frac{1}{4}$	(6.4)	$\frac{5}{32}$	(4)	$\frac{3}{16}$	(4.8)	170–220

**Thoriated Electrodes:** In contrast with the pure EWP electrodes, thoriated electrodes have a higher melting temperature and up to about 50 percent more current-carrying capacity, with superior arc starting and arc stability. These electrodes are typically the first choice for critical DC welding applications, but do not have the potential to maintain a rounded ball shape at the tip. The best welding mode for these electrodes is with the tip ground to a tapered or fine point.

**Zirconiated Electrodes:** Tungsten electrodes with zirconium are practical for critical applications and have less sensitivity to contamination and superior current capacity than pure tungsten electrodes.

**Protecting and Prolonging Electrode Life:** To improve tungsten electrode life, the tip should be tapered in accordance with the manufacturer's recommendations. There must also be preflow, postflow shielding gas coverage to protect the electrode before and after the weld. When possible, high frequency should be used to avoid scratch starts, which contaminate the electrode. The shortest possible electrode extension should be employed, to avoid the possibility of the electrode touching the filler or weld metal. The grinding wheel used to sharpen the tungsten must not be contaminated from grinding other metals or with dirt.

**Filler Metals.**—Specifications covering composition and mechanical properties for GTAW filler metal are published by the American Welding Society under the following classifications: A5.7, copper and copper alloys; A5.9, chromium and chromium nickel; A5.10, aluminum; A5.14, nickel; A5.16, titanium; A5.18, carbon steels; A5.19, magnesium; and A5.28, low-alloy steels.

Filler metals must be kept dry and clean if they are to be used satisfactorily.

**Shielding Gases.**—Inert gases such as argon, and argon + helium mixtures are most commonly used for GTAW. Helium provides greater thermal conductivity and additional arc voltage potential than argon, and is normally added to argon when more weld energy is required for improved penetration and increased mechanized welding travel speeds. Argon gas mixtures containing 30 to 75 percent helium provide benefits for manual welding of aluminum over  $\frac{3}{8}$  in. (9.6 mm) thick; mechanized welding of aluminum where high speeds are required; mechanized welding of carbon and stainless steels where good penetration is needed; mechanized welding of stainless steel where good penetration and faster speeds are required; and for copper of  $\frac{1}{4}$  in. (6.4 mm) thickness and thicker.

Shielding gas purity for GTAW welding is important. Welding-grade argon is supplied at a purity of at least 99.996 percent and helium is produced to a minimum purity of 99.995 percent. However, shielding gases may be contaminated due to poor cylinder filling practices. If impure gas is suspected, the following test is suggested. With the HF and power on, create an arc without welding and hold the arc for about 30 seconds. Examine the electrode tip for signs of unusual coloration, oxidation, or contamination, which result from impurities in the shielding gas.

### PLASMA ARC WELDING (PAW)

When an electric current passes between two electrodes through certain gases, the energy of the gas molecules is increased so that they accelerate and collide with each other more often. With increases in energy, the binding forces between the nuclei and the electrons are exceeded, and electrons are released from the nuclei. The gas now consists of neutral molecules, positively charged atoms, and negatively charged electrons. The plasma gas is said to be ionized, so that it is capable of conducting electric current. Plasma forms in all welding arcs but in plasma arc welding it is generated by a series of events that begins with inert gas passing through the welding torch nozzle. High-frequency current is then generated between the tungsten electrode (cathode) and the torch nozzle (anode), forming a low-current pilot arc. The ionized path of this nontransferred arc is then transferred from the tungsten electrode to the work, and a preset plasma current is generated.

The above sequence of events provides the ionized path for the plasma current between the electrode and the work so that arcing between the electrode and the nozzle ceases. (Nontransferred arcs may be used for metal spraying or nonmetallic welds.) Forcing the ionized gas through the small orifice in the nozzle increases both the level of ionization and the arc velocity, and arc temperatures between 30,000 and 50,000°F (16,650 and 27,760°C) are generated.

**Gases for Welding.**—Argon is the preferred gas for plasma arc welding (PAW) as it is easily ionized and the plasma column formed by argon can be sustained by a low voltage. The low thermal conductivity of argon produces a plasma column with a narrow, concentrated hot core surrounded by a cooler outer zone. Argon plasmas are suited to welding steel up to  $\frac{1}{8}$  in. (3.2 mm). For thicker materials, requiring a hotter arc and using higher current melt-in technique, a mixture of argon 25 + helium 75 percent may be used. Additions of helium and hydrogen to the gas mixture improve heat transfer, reduce porosity, and increase weld travel speed. For welding materials thinner than  $\frac{1}{8}$  in. thick by the plasma gas keyhole method (full penetration welds), gases may contain up to 15 percent hydrogen with the

remainder argon. Good results are obtained with argon + 5 percent hydrogen in welding stainless and nickel steels over  $\frac{1}{8}$  in. thick.

**Shielding Gases.**—A shielding gas is needed to protect the narrow plasma arc column and the weld pool, and generally is provided by mixtures of argon, argon + hydrogen, argon + helium, or argon + O<sub>2</sub> + CO<sub>2</sub>, depending on compatibility with the material being welded. Shielding gas flow rates vary from 5 to 35 cu ft/h (2.4 to 17 l/min). However, if argon is used for both plasma and shielding, the plasma gas will become less concentrated. The normally tight plasma arc column will expand in contact with the colder shielding gas, reducing ionization and thus concentration and intensity of the plasma column. With no shielding gas, the tight column is unaffected by the surrounding oxygen and nitrogen of the atmosphere, which are not easily ionized.

*Hydrogen* is added to the shielding gas when welding low-alloy steels of less than  $\frac{1}{16}$  in. (1.6 mm) thickness, or stainless and nickel steels, with many benefits. The hydrogen molecules dissociate in contact with the arc at temperatures of about 7,000°F (3,870°C) and the energy thus created is released when the hydrogen molecules recombine on contact with the work surface. The diatomic molecular action creates a barrier around the plasma, maintaining column stiffness. Hydrogen in the shielding gas combines with oxygen in the weld zone, releasing it into the atmosphere and keeping the weld clean. Hydrogen reduces the surface tension of the weld pool, increasing fluidity, and the added energy increases penetration.

*Helium* mixed with the argon shielding gas is beneficial for all metals as it increases the ionization potential, allowing use of higher voltages that give increased welding temperatures. Flow rates are in the range of 15 to 50 cu ft/h (7 to 24 l/min). Arc-starting efficiency is reduced with pure helium, but adding 25 percent of argon helps both arc starting and stability. Helium additions of 25 to 75 percent are made to obtain increased thermal benefits.

Argon + CO<sub>2</sub> shielding gas mixtures are beneficial in fusion welding of carbon steels. A mixture of argon with 20 to 30 percent CO<sub>2</sub> improves weld fluidity. Shielding gas mixtures of argon + CO<sub>2</sub> with an argon + 5 percent hydrogen plasma should be considered for welding carbon steel of  $\frac{1}{16}$  to  $\frac{1}{4}$  in. thickness. Steels with higher amounts of carbon have higher heat conductivity and need application of more heat than is needed with stainless steels. Manufacturers usually make recommendations on types of gas mixtures to use with their equipment.

**PAW Welding Equipment.**—The PAW process uses electrode negative (DCEN) polarity in a current range from 25 to 400 amps, and equipment is offered by many manufacturers. Solid-state inverter units are available with nonmechanical contactors. Most PAW units contain a high-frequency generator, a small DC power supply, controls for welding and shielding gas mixtures, and a torch coolant control. A weld sequencer is recommended, especially for keyhole mode welding, but it is also useful in automated fusion welding. The sequencer provides control of up-slope and down-slope conditions for gas mixtures and current, so that it is possible to make welds without run-on and run-off tabs, as is necessary with circumferential welds.

Generally, plasma arc torches are liquid-cooled using deionized water in the coolant lines to the torch to avoid effects of electrolysis. Electrodes are usually tungsten with 2 percent thorium. If the welding shop already has a constant-current power supply and a coolant recirculator, plasma arc welding may be used by addition of a pilot arc welding console and a torch.

**Applications.**—Fusion welding is the main use for plasma arc welding. The process is used for high-volume, repetitive, high-duty cycle, manual and automated operations on lap, flange, butt, and corner fusion welds, in all positions. Joint design for materials less than 0.01 in. (0.254 mm) thick may require a flange type joint for rigidity and to allow use of extra, weld metal reinforcement. Filler metal may be added during fusion welding,

and automated hot or cold wire feeders can be used. Fusion welding uses a soft, less-restricted arc with low gas flows, and the current level may vary from approximately 25 to 200 amps. The soft arc is obtained by setting the end of the tungsten electrode level with the face of the torch nozzle, in which position lower currents and gas flows are required. With these conditions, the weld bead is slightly wider than a bead produced with a recessed electrode.

*Low-Current Plasma Fusion Welding:* With the reduced consumption of gas and electric current, the low-current plasma fusion welding method is ideal for welding metals down to 0.001 in. (0.025 mm) in thickness, as the low-current plasma pilot arc allows arcs to be started consistently with currents of less than 1 amp. With currents below 1 amp, the pilot arc is usually left in the continuous mode to maintain the arc. In the conditions described, arc stability is improved and the process is much less sensitive to variations in the distance of the torch from the workpiece. Given this height tolerance, setting up is simplified, and with the smaller torches required, it is often easier to see the weld pool than with the GTAW process. Some plasma welding units incorporate gas flow meters that are designed for low flow rates, and currents in the range of 0.1 to 15 amps can be selected.

Low-current plasma arc welding is more economical than other gas tungsten arc welding methods, especially with solid-state inverter systems and smaller torches. The process is useful for sealing type welds where joint access is good, and for welding components of office furniture, household items, electronic and aerospace parts, metallic screening, and thin-wall tubing.

*Keyhole mode welding* describes a method whereby abutting edges of two plates are melted simultaneously, forming a vapor capillary (or keyhole) and the resulting molten-walled hole moves along the joint line. This method requires the end of the tungsten electrode to be positioned well back inside the torch nozzle to produce a high-velocity, restricted arc column with sufficient energy to pierce the workpiece. This mode is also used for the plasma cutting process, but the major difference is that welding uses very low plasma flow rates of the order of 1 to 3 cu ft/h (0.5 to 1.4 l/min) for work thicknesses of  $\frac{1}{16}$  to  $\frac{5}{32}$  in. (1.6 to 4 mm). These low rates avoid unwanted displacement of the weld metal. After the arc pierces the workpiece, the torch moves along the weld line and the thin layer of molten metal is supported by surface tension as it flows to the rear of the line of movement, where it solidifies and forms the weld.

As it passes through the keyhole, the high-velocity plasma gas column flushes the molten weld pool and carries away trapped gases and contaminants that otherwise would be trapped in the weld. Plasma arc keyhole welding is affected less by surface and internal defects in the work material than is the GTAW process. Most metals that can be welded by the gas tungsten arc method can be plasma arc welded with the conventional DC electrode, negative keyhole method, except aluminum, which requires a variable polarity keyhole method.

Plasma keyhole welding is usually automated because it requires consistent travel speed and torch height above the work. A typical operation is welding steel with square abutting edges (no bevels) in thicknesses of 0.09 to 0.375 in. (2.3 to 9 mm), where 100 percent penetration in a single pass is required. Producing square-groove butt welds in materials thicker than  $\frac{1}{2}$  in. by the plasma arc keyhole process requires some edge preparation and several filler passes. The finished weld is uniformly narrow and the even distribution of heat means that distortion is minimized.

**Welding Aluminum.**—The variable polarity plasma arc (VPPA) process was developed for welding metals that form an oxide skin, such as aluminum. Electrode negative (straight) polarity is necessary for the plasma arc to provide sufficient heat to the workpiece and minimize heat buildup in the tungsten electrode. With electrode negative polarity, electrons move rapidly from the negative cathode tungsten electrode to the positive anode workpiece, generating most of the heat in the workpiece. Because of the oxide skin

on aluminum, however, straight polarity produces an erratic arc, poor weld fluidity, and an irregularly shaped weld bead. The oxide skin must be broken up if the metal flow is to be controlled, and this breakup is effected by a power supply that constantly switches from negative to positive polarity.

A typical cycle uses a 20-ms pulse of electrode negative polarity and a 3-ms pulse of electrode positive polarity. The pulses are generated as square waves and the positive (cleaning) pulse is set at 30 to 80 amps higher than the negative pulse for greater oxide-breaking action. The tenacious oxide skin is thus broken constantly and the rapid cycle changes result in optimum cathode cleaning with minimum deterioration of the tungsten electrode and consistent arc stability. Varying polarity has advantages in both gas metal arc and plasma arc welding, but with the keyhole process it allows single-pass, square-groove, full-penetration welds in materials up to  $\frac{1}{2}$  in. (12.7 mm) thick.

The VPPA process ensures extremely low levels of porosity in weld areas in aluminum. VPPA welding is often used in the vertical up position for aluminum because it provides superior control of root reinforcement, which tends to be excessive when welding is done in the flat position. Pulsing in the VPPA process when welding aluminum of  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thickness in the flat position gives satisfactory root profiles. Pulsing gives improved arc control in keyhole welds in both ferrous and nonferrous metals and is beneficial with melt-in fusion welding of thin materials as it provides better control of heat input to the workpiece.

### Plasma Arc Surface Coating

*Plasma Arc Surfacing* uses an arc struck between the electrode and the workpiece, or transferred arc, to apply coatings of other metals or alloys to the workpiece surface. This high-temperature process produces homogeneous welds in which the ionized plasma gas stream melts both the work surface and a stream of powdered alloy or filler wire fed into the arc. Dilution of the base metal can be held below 5 percent if required. With arc temperatures between 25,000 and 50,000°F (14,000 and 28,000°C), deposition occurs rapidly, and a rate of 15 lb/h (6.8 kg/h) of powdered alloy is not unusual. Deposition from wire can be performed at rates up to 28 lb/h (12.7 kg/h), much higher than with oxygen/fuel or gas metal/arc methods.

In the nontransferred arc process used for coating of surfaces, the arc is struck between the electrode and the torch nozzle so that it does not attach to the work surface. This process is sometimes called metal spraying, and is used for building up surfaces for hard facing and for application of anticorrosion and barrier layers. Argon is frequently used as the plasma gas. As the coating material in the form of powder or wire enters the plasma, it is melted thoroughly by the plasma column and is propelled toward the work at high velocity to form a mechanical bond with the work surface. Some 500 different powder combinations are available for this process so that a variety of requirements can be fulfilled and deposition rates up to 100 lb/h (45 kg/h) can be achieved.

The plasma arc process allows parts to be modified or recovered if worn, and surfaces with unique properties can be provided on new or existing components. Low levels of porosity in the deposited metal can be achieved. Metal spraying can be performed manually or automatically, and its use depends primarily on whether a mechanical bond is acceptable. Other factors include the volume of parts to be treated, the time needed for the process and for subsequent finishing, the quality requirements for the finished parts, rejection rates, and costs of consumable materials and energy.

Some systems are available that can use either metal powder or wire as the spray material, and can be operated at higher voltage settings that result in longer plasma arc lengths at temperatures over 10,000°F (5,537°C). With these systems, the plasma velocity is increased to about 12,000 ft/s (3,658 m/s), giving an extremely dense coating with less than 1 percent porosity. Current ranges of 30 to 500 amps are available, and nitrogen is frequently used as the plasma gas, coupled with CO<sub>2</sub>, nitrogen, or compressed air

as the shielding gas. Gas flow rates are between 50 and 350 cubic feet per hour (24 and 165 l/min). Large or small surface areas can be coated at low cost, with minimum heat input, if other aspects of the process are compatible with the product being made.

### Plasma Arc Cutting of Metals

Higher current and gas flow rates than for plasma arc welding are used for the plasma arc cutting (PAC) process, which operates on DC straight polarity, and uses a transferred arc to melt through the material to be cut. The nozzle is positioned close to the work surface and the velocity of the plasma jet is greatly increased by a restricting nozzle orifice so that it blows away the metal as it is melted to make the cut.

The higher energy level makes the process much faster than cutting with an oxygen/fuel torch on cutting steel of less than  $\frac{1}{2}$  in. (12.7 mm) thick, but the process produces kerfs with some variation in the width and in the bevel angle, affecting the precision of the part. Some of the molten metal may recast itself on the edges of the cut and may be difficult to remove.

For more information on plasma arc cutting, refer to *NONTRADITIONAL MACHINING AND CUTTING* starting on page 1342.

### Cutting Metals with an Oxidizing Flame

The oxyhydrogen and oxyacetylene flames are especially adapted to cutting metals. When iron or steel is heated to a high temperature, it has a great affinity for oxygen and readily combines with it to form various oxides, and causing the metal to be disintegrated and burned with great rapidity. The metal-cutting or burning torch operates on this principle. A torch tip is designed to preheat the metal, which is then burned or oxidized by a jet of pure oxygen. The kerf or path left by the flame is suggestive of a saw cut when the cutting torch has been properly adjusted and used. The traversing motion of the torch along the work may be controlled either by hand or mechanically.

**Arc Cutting.**—According to the *Procedure Handbook of Arc-Welding Design & Practice*, published by The Lincoln Electric Co., a steel may be cut easily, and with great accuracy by means of the oxyacetylene torch. All metals, however, do not cut as easily as steel. Cast iron, stainless steels, manganese steels, and nonferrous materials are not as readily cut and shaped with the oxyacetylene cutting process because of their reluctance to oxidize. For these materials, arc cutting is often used to good advantage.

The cutting of steel is a chemical action. The oxygen combines readily with the iron to form iron oxide. In cast iron, this action is hindered by the presence of carbon in graphite form. Thus, cast iron cannot be cut as readily as steel; higher temperatures are necessary and cutting is slower. In steel, the action starts at bright red heat, whereas in cast iron, the temperature must be nearer to the melting point to obtain a sufficient reaction.

**The Cutting Torch.**—The ordinary cutting torch consists of a heating jet using oxygen and acetylene, oxygen and hydrogen, or, in fact, any other gas that, when combined with oxygen, will produce sufficient heat. By the use of this heating jet, the metal is first brought to a sufficiently high temperature, and an auxiliary jet of pure oxygen is then turned onto the red-hot metal, and the action just referred to takes place. Some cutting torches have a number of preheating flame ports surrounding the central oxygen port, so that a preheating flame will precede the oxygen regardless of the direction in which the torch is moved. This arrangement has been used to advantage in mechanically guided torches. The rate of cutting varies with the thickness of the steel, the size of the tip, and the oxygen pressure.

**Adjustment and Use of Cutting Torch.**—When using the cutting torch for the cutting of steel plate, the preheating flame first comes into contact with the edge of the plate and quickly raises it to a white-hot temperature. The oxygen valve is then opened, and as the pure oxygen comes into contact with the heated metal, the latter is burned or oxidized.

**Metals That Can Be Cut.**—Metals such as wrought iron and steels of comparatively low-carbon content can be cut readily with the cutting torch. High-carbon steels may be cut successfully if preheated to a temperature that depends somewhat on the carbon content. The higher the carbon content, the greater the degree of preheating required. A black heat is sufficient for ordinary tool steel, but a low red heat may be required for some alloy tool steels. Brass and bronze plates have been cut by interposing them between steel plates.

**Cutting Stainless Steel.**—Stainless steel can be cut readily by the flux-injection method. The elements that give stainless steels their desirable properties produce oxides that reduce the flame cutting operation to a slow melting-away process when the conventional oxyacetylene cutting equipment is used. By injecting a suitable flux directly into the stream of cutting oxygen before it enters the torch, the obstructing oxides can be removed. Portable flux feeding units are designed to inject a predetermined amount of the flux powder. The rate of flux flow is accurately regulated by a vibrator type of dispenser with rheostat control. The flux-injection method is applicable either to machine cutting or to a hand-controlled torch. The operating procedure and speed of cutting are practically the same as in cutting mild steel.

**Cutting Cast Iron.**—The cutting of cast iron with the oxyacetylene torch is practicable, although it cannot be cut as readily as steel. The ease of cutting seems to depend largely on the physical character of the cast iron, very soft cast iron being more difficult to cut than harder varieties. The cost is much higher than that for cutting the same thickness of steel, because of the larger preheating flame necessary and the larger oxygen consumption. In spite of this extra cost, however, this method is often economical. The slag from a cast-iron cut contains considerable melted cast iron, whereas in steel, the slag is practically free from particles of the metal, indicating that cast-iron cutting is partly a melting operation. Increased speed and decreased cost often can be obtained by feeding a steel rod, about  $\frac{1}{4}$  inch (6.35 mm) in diameter, into the top of the cut, beneath the torch tip. This rod furnishes a large amount of slag that flows over the cut and increases the temperature of the cast iron. Special tips are used because of the larger amounts of heat and oxygen required.

**Mechanically Guided Torches.**—Cutting torches used for cutting openings in plates or blocks or for cutting parts to some definite outline are often guided mechanically or by numerical control. Torches guided by pantograph mechanisms are especially adapted for tracing the outline to be cut from a pattern or drawing. Other designs are preferable for straight-line cutting and one type is designed for circular cutting.

**Cutting Steel Castings.**—When cutting steel castings, care should be taken to prevent burning pockets in the metal when the flame strikes a blowhole. If a blowhole is penetrated, the molten oxide will splash into the cavity and the flame will be diverted. The presence of the blowhole is generally indicated by excessive sparks. The operator should immediately move the torch back along the cut and direct it at an angle so as to strike the metal beneath the blowhole and burn it away if possible beyond the cavity. Cutting in the normal position then may be resumed.

**Thickness of Metal That Can Be Cut.**—The maximum thickness of metal that can be cut by these high-temperature flames depends largely upon the gases used and the pressure of the oxygen, which may be as high as 150 lb/in<sup>2</sup> (1034 kPa). The thicker the metal, the higher the pressure required. When using an oxyacetylene flame, it might be practicable to cut iron or steel up to 12 or 14 inches (30.5 or 35.6 cm) in thickness, whereas an oxyhydrogen flame has been used to cut steel plates 24 inches (61 cm) thick. The oxyhydrogen flame will cut thicker material principally because it is longer than the oxyacetylene flame and can penetrate to the full depth of the cut, thus keeping all the oxide in a molten condition so that it can be easily blown out by the oxygen cutting jet. A mechanically guided torch will cut thick material more satisfactorily than a hand-guided torch, because the flame is directed straight into the cut and does not wobble, as it tends to do when the torch is held by hand. With any flame, the cut is less accurate and the kerf wider, as the thickness of the

metal increases. When cutting light material, the kerf might be  $\frac{1}{16}$  inch (1.59 mm) wide, whereas for heavy stock, it might be  $\frac{1}{4}$  or  $\frac{3}{8}$  inch (6.35 or 9.5 mm) wide.

### Hard Facing

Hard facing is a method of adding a coating, edge, or point, of a metal or alloy capable of resisting abrasion, corrosion, heat, or impact, to a metal component. The process can be applied equally well to new parts or old worn parts. The most common welding methods used to apply hard-facing materials include the oxyacetylene gas, shielded-metal arc, submerged arc, plasma arc, and inert-gas-shielded arc (consuming and nonconsuming electrode). Such coatings can also be applied by a spraying process, using equipment designed to handle the coating material in the form of a wire or a powder.

**Hard-Facing Materials.**—The first thing to be considered in the selection of a hard-facing material is the type of service the part in question is to undergo. Other considerations include machinability, cost of hard-facing material, porosity of the deposit, appearance in use, and ease of application. Only generalized information can be given here to guide the selection of a material as the choice is dependent upon experience with a particular type of service. Generally, the greater the hardness of the facing material, the greater is its resistance to abrasion and shock or impact wear. Many hardenable materials may be used for hard facing such as carbon steels, low-alloy steels, medium-alloy steels, and medium-high alloys but none of these is outstanding. Some of the materials that might be considered to be preferable are high-speed steel, austenitic manganese steel, austenitic high-chromium iron, cobalt-chromium alloy, copper-base alloy, and nickel-chromium-boron alloy.

**High-Speed Steels.**—These steels are available in the form of welding rods (RFe5) and electrodes (EFe5) for hard facing where hardness is required at service temperatures up to 1100°F (593°C) and where wear resistance and toughness are also required. Typical surfacing operations are done on cutting tools, shear blades, reamers, forming dies, shearing dies, guides, ingot tongs, and broaches using these metals.

*Hardness:* These steels have a hardness of 55 to 60 on the Rockwell C scale in the as-welded condition and a hardness of 30 Rockwell C in the annealed condition. At a temperature of 1100°F (593°C), the as-deposited hardness of 60 Rockwell C falls off very slowly to 47 Rockwell C. At about 1200°F (649°C), the maximum Rockwell C hardness is 30.

*Resistance Properties:* As deposited, the alloys can withstand only medium impact, but when tempered, the impact resistance is increased appreciably. Deposits of these alloys will oxidize readily because of their high molybdenum content but can withstand atmospheric corrosion. They do not withstand liquid corrosives.

*Other Properties or Characteristics:* The metals are well suited for metal-to-metal wear especially at elevated temperatures. They retain their hardness at elevated temperatures and can take a high polish. For machining, these alloys must first be annealed. Full hardness may be regained by a subsequent heat treatment of the metal.

**Austenitic Manganese Steels.**—These metals are available in the form of electrodes (EFeMn) for hard facing when dealing with metal-to-metal wear and impact. Uses include facing rock-crushing equipment and railway frogs and crossings.

*Hardness:* Hardness of the as-deposited metals are 170 to 230 BHN, but they can be work-hardened to 450 to 550 BHN very readily. For all practical purposes, these metals have no hot hardness as they become brittle when reheated above 500–600°F (260–316°C).

*Resistance Properties:* These metals have high impact resistance. Their corrosion and oxidation resistance are similar to those of ordinary carbon steels. Their resistance to abrasion is only mediocre compared with hard abrasives like quartz.

*Other Properties or Characteristics:* The yield strength of the deposited metal in compression is low, but any compressive deformation rapidly raises it until plastic flow ceases.

This property is an asset in impact wear situations. Machining is difficult with ordinary tools and equipment; finished surfaces are usually ground.

**Austenitic High-Chromium Irons.**—These metals are available in rod (RFeCr-A) and electrode (EFeCr-A) form and are used for facing agricultural machinery parts, coke chutes, steel mill guides, sand-blasting equipment, and brick-making machinery.

*Hardness:* The as-welded deposit ranges in hardness from 51 to 62 Rockwell C. Under impact, the deposit work hardens somewhat, but the resulting deformation also leads to cracking and impact service is therefore avoided. Hot hardness decreases slowly at temperatures up to 800 and 900°F (427 and 482°C). At 900°F (482°C), the instantaneous hardness is 43 Rockwell C. In 3 minutes under load, the hardness drops to 37 Rockwell C. At 1200°F (649°C), the instantaneous hardness is 5 Rockwell C. The decrease in hardness during hot testing is practically recovered on cooling to ambient temperatures.

*Resistance Properties:* Deposits will withstand only light impact without cracking. Dynamic compression stresses above 60,000 psi (414 MPa) should be avoided. These metals exhibit good oxidation resistance up to 1800°F (982°C) and can be considered for hot wear applications where hot plasticity is not objectionable. They are not very resistant to corrosion from liquids and will rust in moist air, but are more stable than ordinary iron and steel. Resistance to low-stress scratching is outstanding and is related to the amount of hard carbides present. However, under high-stress grinding abrasion, performance is only mediocre and they are not deemed suitable for such service.

*Other Properties or Characteristics:* The deposited metals have a yield strength (0.1 percent offset) of between 80,000 and 140,000 pounds per square inch (552 and 965 MPa) in compression and an ultimate strength of from 150,000 to 280,000 psi (1034–1930 MPa). Their tensile strength is low and therefore tension uses are avoided in design. These deposits are considered to be commercially unmachinable and are also very difficult to grind. When ground, a grinding wheel of aluminum oxide abrasive with a 24-grit size and a hard (Q) and medium-spaced resinoid bond is recommended for off-hand high-speed work and a slightly softer (P) vitrified bond for off-hand low-speed work.

**Cobalt-Base Alloys.**—These metals are available in both rod (RCoCr) and electrode (ECoCr) form and are frequently used to surface the contact surfaces of exhaust valves in aircraft, truck, and bus engines. Other uses include parts such as valve trim in steam engines, and on pump shafts, where conditions of corrosion and erosion are encountered. Several metals with a greater carbon content are available (CoCr-B, CoCr-C) and are used in applications requiring greater hardness and abrasion resistance but where impact resistance is not mandatory or expected to be a factor.

*Hardness:* Hardness ranges on the Rockwell C scale for gas-welded deposits are as follows: CoCr-A, 38 to 47; CoCr-B, 45 to 49; and CoCr-C, 48 to 58. For arc-welded deposits, hardness ranges (Rockwell C) as follows: CoCr-A, 23 to 47; CoCr-B, 34 to 47; and CoCr-C, 43 to 58. The values for arc-weld deposits depend for the most part on the base metal dilution. The greater the dilution, the lower the hardness. Many surfacing alloys are softened permanently by heating to elevated temperatures, however, these metals are exceptional. They do exhibit lower hardness values when hot but return to their approximate original hardness values upon cooling. Elevated-temperature strength and hardness are outstanding properties of this group. Their use at 1200°F (649°C) and above is considered advantageous but between 1000 and 1200°F (538–649°C), their advantages are not definitely established, and at temperatures below 1000°F (538°C), other surfacing metals may prove better.

*Resistance Properties:* In the temperature range from 1000 to 1200 degrees F (538–649°C), weld deposits of these metals have a great resistance to creep. Tough martensitic steel deposits are considered superior to cobalt-base deposits in both flow resistance and toughness. The chromium in the deposited metal promotes the formation of a thin, tightly adherent scale that provides a scaling resistance to combustion products of internal

combustion engines, including deposits from leaded fuels. These metals are corrosion-resistant in such media as air, food, and certain acids. It is advisable to conduct field tests to determine specific corrosion resistance for the application being considered.

*Other Properties or Characteristics:* Deposits are able to take a high polish and have a low coefficient of friction and therefore are well suited for metal-to-metal wear resistance. Machining of these deposits is difficult; the difficulty increases in proportion to the increase in carbon content. CoCr-A alloys are preferably machined with sintered carbide tools. CoCr-C deposits are finished by grinding.

**Copper-Base Alloys.**—These metals are available in rod (RCuAl-A2, RCuAl-B, RCuAl-C, RCuAl-D, RCuAl-E, RCuSi-A, RCuSn, RCuSn-D, RCuSn-E, and RCuZn-E) and electrode (ECuAl-A2, ECuAl-B, ECuAl-C, ECuAl-D, ECuAl-E, ECuSi, ECuSn-A, ECuSn-C, ECuSn-E, and ECuZn-E) forms and are used in depositing overlays and inlays for bearing, corrosion-resistant, and wear-resistant surfaces. The CuAl-A2 rods and electrodes are used for surfacing bearing surfaces between the hardness ranges of 130 to 190 BHN as well as for corrosion-resistant surfaces. The CuAl-B and CuAl-C rods and electrodes are used for surfacing bearing surfaces of hardness ranges 140 to 290 BHN. The CuAl-D and CuAl-E rods and electrodes are used on bearing and wear-resistant surfaces requiring the higher hardnesses of 230 to 390 BHN such as are found on gears, cams, wear plates, and dies. The copper-tin (CuSn) metals are used where a lower hardness is required for surfacing, for corrosion-resistant surfaces, and sometimes for wear-resistant applications.

*Hardness:* Hardness of a deposit depends upon the welding process employed and the manner of depositing the metal. Deposits made by the inert-gas metal-arc process (both consumable and nonconsumable electrode) will be higher in hardness than deposits made with the gas, metal-arc, and carbon-arc processes because lower losses of aluminum, tin, silicon, and zinc are achieved due to the better shielding from oxidation. Copper-base alloys are not recommended for use at elevated temperatures because their hardness and mechanical properties decrease consistently as the temperature goes above 400°F (204°C).

*Resistance Properties:* The highest impact resistance of the copper-base alloy metals is exhibited by CuAl-A2 deposits. As the aluminum content increases, the impact resistance decreases markedly. CuSi weld deposits have good impact properties. CuSn metals as deposited have low impact resistance and CuZn-E deposits have a very low impact resistance. Deposits of the CuAl filler metals form a protective oxide coating upon exposure to the atmosphere. Oxidation resistance of CuSi deposits is fair and that of CuSn deposits are comparable to pure copper. With the exception of the CuSn-E and CuZn-E alloys, these metals are widely used to resist many acids, mild alkalis, and salt water. Copper-base alloy deposits are not recommended for use where severe abrasion is encountered in service. CuAl filler metals are used to overlay surfaces subjected to excessive wear from metal-to-metal contact such as gears, cams, sheaves, wear plates, and dies.

*Other Properties or Characteristics:* All copper-base alloy metals are used for overlays and inlays for bearing surfaces with the exception of the CuSi metals. Metals selected for bearing surfaces should have a Brinell hardness of 50 to 75 units below that of the mating metal surface. Slight porosity is generally acceptable in bearing service as a porous deposit is able to retain oil for lubricating purposes. CuAl deposits in compression have elastic limits ranging from 25,000 to 65,000 (172 to 448 MPa) and ultimate strengths of 120,000 to 171,000 (827 to 1179 MPa). The elastic limit and ultimate strength of CuSi deposits in compression are 22,000 and 60,000 (152 to 414 MPa), respectively. CuZn-E deposits in compression have an elastic limit of only about 5000 (34 MPa) and an ultimate strength of 20,000 (138 MPa). All copper-base alloy deposits can be machined.

**Nickel-Chromium-Boron Alloys.**—These metals are available in both rod (RNiCr) and electrode (ENiCr) form and their deposits have good metal-to-metal wear resistance, good low-stress, scratch-abrasion resistance, corrosion resistance, and retention of

hardness at elevated temperatures. These properties make the alloys suitable for use on seal rings, cement pump screws, valves, screw conveyors, and cams. Three different formulations of these metals are recognized (NiCr-A, NiCr-B, and NiCr-C).

**Hardness:** Hardness of the deposited NiCr-A from rods range from 35 to 40 Rockwell C; of NiCr-B rods, 45 to 50 Rockwell C; of NiCr-C rods, 56 to 62 Rockwell C. Hardness of the deposited NiCr-A from electrodes ranges from 24 to 35 Rockwell C; of NiCr-B from electrodes, 30 to 45 Rockwell C; and of NiCr-C electrodes, 35 to 56. The lower hardness values and greater ranges of hardness values of the electrode deposits are attributed to the dilution of deposit and base metals. Hot Rockwell C hardness values of NiCr-A electrode deposits range from 30 to 19 in the temperature range from 600–1000°F (316–538°C) from instantaneous loading to a 3-minute loading interval. NiCr-A rod deposits range from 34 to 24 in the same temperature range and under the same load conditions. Hot Rockwell C hardness values of NiCr-B electrode deposits range from 41 to 26 in the temperature range from 600 to 1000°F (315–538°C) from instantaneous loading to a 3-minute loading interval. NiCr-B rod deposits range from 46 to 37 in the same temperature range and under the same load conditions. Hot Rockwell C hardness values of NiCr-C electrode deposits range from 49 to 31 in the temperature range from 600 to 1000 degrees F from instantaneous loading to a 3-minute loading interval. NiCr-C rod deposits range from 55 to 40 in the same temperature range and under the same load conditions.

**Resistance Properties:** Deposits of these metal alloys will withstand light impact fairly well. When plastic deformation occurs, cracks are more likely to appear in the NiCr-C deposit than in the NiCr-A and NiCr-B deposits. NiCr deposits are oxidation-resistant up to 1800°F (982°C). Their use above 1750°F (954°C) is not recommended because fusion may begin near this temperature. NiCr deposits are completely resistant to atmospheric, steam, salt water, and salt spray corrosion and to the milder acids and many common corrosive chemicals. It is advisable to conduct field tests when a corrosion application is contemplated. These metals are not recommended for high-stress grinding abrasion. NiCr deposits have good metal-to-metal wear resistance, take a high polish under wearing conditions, and are particularly resistant to galling. These properties are especially evident in the NiCr-C alloy.

**Other Properties or Characteristics:** In compression, these alloys have an elastic limit of 42,000 psi (290 MPa). Their yield strength in compression is 92,000 psi (634 MPa) (0.01 percent offset), 150,000 psi (1034 MPa) (0.10 percent offset), and 210,000 psi (1448 MPa) (0.20 percent offset). Deposits of NiCr filler metals may be machined with tungsten carbide tools using slow speeds, light feeds, and heavy tool shanks. They are also finished by grinding using a soft-to-medium vitrified silicon carbide wheel.

**Chromium Plating.**—Chromium plating is an electrolytic process of depositing chromium on metals either as a protection against corrosion or to increase the surface-wearing qualities. The value of chromium-plating plug and ring gages has probably been more thoroughly demonstrated than any other single application of this treatment. Chromium-plated gages not only wear longer, but when worn, the chromium may be removed and the gage replated and reground to size.

In general, chromium-plated tools have operated well, giving greatly improved performance on nearly all classes of materials such as brass, bronze, copper, nickel, aluminum, cast iron, steel, plastics, asbestos compositions, and similar materials. Increased cutting life has been obtained with chromium-plated drills, taps, reamers, files, broaches, tool tips, saws, thread chasers, and the like. Dies for stamping, drawing, hot forging, die casting, and for molding plastics materials have shown greatly increased life after being plated with hard chromium.

Special care is essential in grinding and lapping tools preparatory to plating the cutting edges, because the chromium deposit is influenced materially by the grain structure and hardness of the base metal. The thickness of the plating may vary from 0.0001 to 0.001 or 0.002 inch, the thicker platings being used to build up undersize tools such as taps and

reamers. A common procedure in the hard chromium plating of tools, as well as for parts to be salvaged by depositing chromium to increase diameters, is as follows:

- 1) Degrease with solvent; 2) Mount the tools on racks; 3) Clean in an anodic alkali bath held at a temperature of 82°C (180°F) for 3 to 5 minutes; 4) Rinse in boiling water; 5) Immerse in a 20 percent hydrochloric acid solution for 2 to 3 seconds; 6) Rinse in cold water; 7) Rinse in hot water; 8) Etch in a reverse-current chromic acid bath for 2 to 5 minutes; 9) Place work immediately in the chromium plating bath; and 10) Remove hydrogen embrittlement, if necessary, by immersing the plated tools for 2 hours in an oil bath maintained at 177°C (350°F).

Chromium has a very low coefficient of friction. The static coefficient of friction for steel on chromium-plated steel is 0.17, and the sliding coefficient of friction is 0.16. This value may be compared with the static coefficient of friction for steel on steel of 0.30 and a sliding coefficient of friction of 0.20. The static coefficient of friction for steel on babbitt is 0.25, and the sliding coefficient of friction 0.20, whereas for chromium-plated steel on babbitt, the static coefficient of friction is 0.15, and the sliding coefficient of friction is 0.13. These figures apply to highly polished bearing surfaces. Articles that are to be chromium plated in order to resist frictional wear should be highly polished before plating so that full advantage can be taken of the low coefficient of friction that is characteristic of chromium. Chromium resists attack by almost all organic and inorganic compounds, except muriatic and sulfuric acids. The melting point of chromium is 2930°F (1610°C), and it remains bright up to 1200°F (649°C). Above 1200 degrees F, a light adherent oxide forms and does not readily become detached. For this reason, chromium has been used successfully for protecting articles that must resist high temperatures, even above 2000°F (1093°C).

### Electron-Beam (EB) Welding

Heat for melting of metals in electron-beam welding is obtained by generating electrons, concentrating them into a beam, and accelerating them to between 30 and 70 percent of the speed of light, using voltages between 25 and 200 kV. The apparatus used is called an electron-beam gun, and it is provided with electrical coils to focus and deflect the beam as needed for the welding operation. Energy input depends on the number of electrons impinging on the work in unit time, their velocity, the degree of concentration of the beam, and the traveling speed of the workpiece being welded. Some  $6.3 \times 10^{15}$  electrons/s are generated in a 1-mA current stream. With beam diameters of 0.01 to 0.03 in. (0.25 to 0.76 mm), beam power can reach 100 kW and power density can be as high as  $10^7$  W/in<sup>2</sup> ( $1.55 \times 10^4$  W/mm<sup>2</sup>), higher than most arc welding levels.

At these power densities, an electron beam can penetrate steel up to 4 in thick and form a vapor capillary or keyhole, as described earlier. Although patterns can be traced by deflecting the beam, the method used in welding is to move the electron gun or the workpiece. A numerical control, or computer numerical control, program is used because of the accuracy required to position the narrow beam in relation to the weld line.

Equipment is available for electron-beam welding under atmospheric pressure or at various degrees of vacuum. The process is most efficient (produces the narrowest width and deepest penetration welds) at high levels of vacuum, of the order of  $10^{-6}$  to  $10^{-3}$  torr or lower (standard atmospheric pressure is about 760 torr, or 760 mm of mercury), so that a vacuum chamber large enough to enclose the work is needed. Operation in a vacuum minimizes contamination of the molten weld material by oxygen and nitrogen. Gases produced during welding are also extracted rapidly by the vacuum pump so that welding of reactive metals is eased. However, the pumping time and the size of many workpieces restrict the use of high-vacuum enclosures.

At atmospheric pressures, scattering of the beam electrons by gas molecules is increased in relation to the number of stray molecules and the distance traveled, so that penetration depth is less and the beam spread is greater. In the atmosphere, the gun-to-work distance

must be less than about 1.5 in. (38 mm). Electron-beam welding at atmospheric pressure requires beam-accelerating voltages above 150 kV, but lower values can be used with a protective gas. Helium is preferred because it is lighter than air and permits greater penetration. Argon, which is heavier than air and allows less penetration, can also be used to prevent contamination.

Required safety precautions, such as radiation shields to guard workers against the effects of X-rays when the electron beam strikes the work, are essential when electron-beam welding is done at atmospheric pressure. Such barriers are usually built into enclosures that are designed specifically for electron-beam welding in a partial vacuum. Adequate ventilation is also required to remove ozone and other gases generated when the process is used in the atmosphere.

Carbon, low-alloy, and stainless steels; high-temperature and refractory alloys; copper and aluminum alloys can be electron-beam welded, and single-pass, reasonably square, butt welds can be made in materials up to 1 in. (25.4 mm) thick at good speeds with nonvacuum equipment rated at 60 kW. Edges of thick material to be electron-beam welded require precision machining to provide good joint alignment and minimize the joint gap. Dissimilar metals usually may be welded without problems.

Because of the heat-sink effect, electron-beam welds solidify and cool very rapidly, causing cracking in certain materials such as low-ferrite stainless steel. Although capital costs for electron-beam welding are generally higher than for other methods, welding of large numbers of parts and the high welding travel rates make the process competitive.

### Pipe Welding

**Pipe Welding.**—Welding of (usually steel) pipe is commonly performed manually, with the pipe joint stationary, or held in a fixture whereby rotation can be used to keep the weld location in a fixed, downhand, position. Alternatively, pipe may need to be welded on site, without rotation, and the welder then has to exert considerable skill to produce a satisfactory, pressure-tight joint. Before welding stationary pipe, a welder must be proficient in welding in the four basic positions: 1G flat, 2G horizontal, 3G vertical, and 4G overhead, depicted in Fig. 1 at the top in Fig. 1a, Fig. 1b, Fig. 1c, and Fig. 1d.

#### Positioning of Joint Components in Pipe Welding

Fig. 1a. Flat  
Position 1G

Fig. 1b. Horizontal  
Position 2G

Fig. 1c. Vertical  
Position 3G

Fig. 1d. Overhead  
Position 4G

Fig. 1e. Horizontal Position 2G  
Pipe Axis Vertical

Fig. 1f. Position 5G  
Pipe Fixed, Axis Horizontal

Fig. 1g. Position 6G  
Pipe Fixed, Axis Inclined

At the bottom of Fig. 1 are pipe joints in three positions, the first of which, Fig. 1e, corresponds to the 2G horizontal (non-rotational) position in the upper row. The remaining two are respectively 5G, Fig. 1f, representing pipe with the weld in a fixed vertical (non-rotational) position; and 6G, Fig. 1g, that typifies pipe to be welded at an angle and not rotated during welding.

For satisfactory pipe welding, consideration must be given to the chemical composition and thickness of the metal to be welded; selection of a suitable electrode material composition and size; determination of the current, voltage and wire feed rate to be used; preparation of the joint or edges of the pipes; and ways of holding the pipes in the positions needed while welding is carried out. High-quality tack welds, each about 1.5 inches (38 mm) long, and projecting about  $\frac{1}{16}$  inch (1.6 mm) beyond the inner wall of the pipe, are usually made to hold the parts of the assembly in position during welding.

SMAW (stick) welding was used almost exclusively for pipe welding until the advent of MIG welding with its potential for much greater rates of deposition. It cannot be emphasized too strongly that practices suitable for SMAW cannot be transferred to MIG welding, for which greater expertise is required if satisfactory welds are to be produced. MIG short-circuit, globular, and spray transfer, and pulsed MIG, with flux or metal-cored consumables (electrodes) can now all be used for pipe welding. Use of all-position, flux-cored, MIG consumables in particular, can reduce skill requirements, improve weld quality, and hold down costs in pipe welding.

Among the important items involved in the change to the MIG process is the automatic wire feeder. With today's wire feeding equipment, an increase of one increment on the dial, say from the 9 to the 10 o'clock position, can increase the wire feed rate by 70 in/min (1.8 m/min). As an example, such an increase could raise the weld current from 110 to 145 amps and the weld voltage from 16 to 17, resulting in an increase of 40 percent in the energy supplied to the weld. Another vital parameter is the amount that the wire sticks out from the contact tip. In low-parameter, short-circuit welding, a small change in the wire stick-out can alter the energy supplied to the weld by 20 to 30 percent.

*Root passes:* Whatever welding process is selected, the most important step in pipe welding, as in other types of welding, is the root pass, which helps to determine the degree of penetration of the weld metal, and affects the amount of lack of fusion in the finished weld. During the root pass, the action of the arc in the weld area should reshape the gap between the adjacent sides of the joint into a pear-shaped opening, often called a "keyhole." As the work proceeds, this keyhole opening is continuously being filled, on the trailing side of the weld, by the metal being deposited from the electrode. The keyhole travels along with the weld so that the root pass produces a weld that penetrates slightly through the inner wall of the pipe.

MIG short-circuit root welding of carbon steel pipe requires a gap of  $\frac{5}{32} \pm \frac{1}{32}$  inch ( $4 \pm 0.8$  mm), between the ends of the pipe, and the width of the root faces (at the base of the bevels) should be  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm). The recommended bevel angle for MIG pipe welding is  $40^\circ$  ( $80^\circ$  included angle) and the maximum root gap is  $\frac{3}{16}$  inch (4.8 mm). The root pass in 1G welds should be made in the vertical-down direction with the electrode held between the 2 and 3 o'clock positions. When an 0.035-inch (0.9-mm) diameter E70S-3 MIG wire is used with the above root dimensions, weaving is not needed for the root pass except when welding over tack welds.

*Fill Passes:* In welding carbon steel pipe in the 1G position with an 0.035-inch diameter electrode wire, MIG short circuit fill passes should use a minimum of 135 amps and be done in the vertical-up position. Fill passes should deposit a maximum thickness of no more than  $\frac{1}{8}$  inch (3.2 mm). Inclusion of  $\text{CO}_2$  gas in the mixture will improve weld

fusion. With flux-cored electrodes, the minimum amount of wire stick out is  $\frac{3}{4}$  inch (19 mm). Weld fusion can be improved in welding pipe of 0.4 inch (10 mm) wall thickness and thicker by preheating the work to a temperature between 400 and 500°F (204 and 260°C).

**Horizontal Pipe Welding:** In 1G welds (see Fig. 1a), the pipe should be rotated in the direction that moves the solidifying area away from the wire tip, to minimize penetration and resulting breakthrough. Welding of pipe in the 2G, horizontal position is made more difficult by the tendency for the molten metal to drip from the weld pool. Such dripping may cause an excessively large keyhole to form during the root-welding pass, and in subsequent passes electrode metal may be lost. Metal may also be lost from the edge of the upper pipe, causing an undercut at that side of the weld.

**Vertical-down Welding:** With the pipe axis horizontal (as in the 5G position in Fig. 1f), vertical-down welding is usually started at the top or 12 o'clock location, and proceeds until the 6 o'clock location is reached. Welding then starts again at the 12 o'clock location and continues in the opposite direction until the 6 o'clock location is reached. Vertical-down welding is mainly used for thin-walled, low-carbon steel pipe of  $\frac{1}{8}$  to  $\frac{5}{16}$  inch (3.2 to 7.9 mm) wall thickness, which has low heat-retaining capacity so that the weld metal cools slowly, producing a soft and ductile structure. The slow rate of cooling also permits faster weld deposition, and, when several beads are deposited, causes an annealing effect that may refine the entire weld structure.

**Vertical-up Welding:** In the 5G position, vertical-up welding normally begins at the 6 o'clock location and continues up to the 12 o'clock location, the weld then being completed by starting at the 6 o'clock location on the other side of the pipe and traversing up to the 12 o'clock location again. Vertical-up welding is more suited to pipe with thick walls and to alloy steels. However, the greater heat sink effect of the heavy-walled pipe may result in a faster cooling rate and embrittlement of the material, especially in alloy steels. The cooling rate can be reduced by slowing the rate of traverse and depositing a heavier bead of metal, both facilitated by welding in the vertical-up direction.

Using a thicker electrode and higher current for thicker-walled pipe to reduce the number of beads required may result in dripping from the molten puddle of metal. Defects such as pin holes, lack of fusion, and cold lap, may then appear in the weld. Vertical-up welding of pipe in the 5G, fixed, horizontal position, Fig. 1f, used for thick-walled pipe, is probably the most difficult for a welder, but once mastered will form the basis for other methods of pipe welding. Starting at the 6 o'clock location, the arc for the root pass is struck overhead, with the electrode at an angle of 5 to 10° from the vertical, on the joint, not on the tack weld. A long arc should be maintained for a short-period while weaving the electrode to pre-heat the area ahead of the weld. Only small amounts of filler metal will be transferred while this long arc is maintained in the overhead position. The electrode tip is then advanced to establish the correct arc length and held in position long enough for the keyhole to form before starting to lay down the root bead, moving up toward the 12 o'clock location.

**Thin-wall Pipe:** The optimum globular/spray parameters for welding rotated, (1G position) thin-wall pipe of less than 12 inch (305 mm) diameter are 0.035-inch (1 mm) electrode wire fed at 380–420 in/min (9.7–10.7 m/min) with a protective gas mixture of argon 80 to 85, CO<sub>2</sub> 15 to 20 percent, and current of 190 to 210 amps. These conditions will provide deposition rates of about 6 lb/hr (3 kg/hr).

**Use of Flux-Cored Electrodes.**—Small diameter, flux cored electrodes developed in the eighties are still a rarity in many pipe welding shops, but flux cored welding can produce

consistent, high-quality, low-cost welds on carbon steel or stainless pipe. Flux cored E71T-1, 0.035-inch (1 mm) diameter wire provides a continuous, medium energy, open arc, with a practical current range of 135 to 165 amps for welding pipe. This current range is similar to the optimum MIG short-circuit current range, and is 25 to 30 percent less current than the minimum open arc spray transfer current for an 0.035-inch (1 mm) diameter MIG wire.

In contrast to MIG short circuit welding, FCAW works with an open arc and no short circuits. The FCAW arc energy is continuous, and, in contrast to short-circuit transfer, provides increased weld fusion potential. The weld metal from the flux-cored tubular wire is transferred from the periphery and the center of the wire, resulting in broad coverage of the weld. The plasma in the flux cored arc is wider than MIG plasma, and the flux-cored arc is less focused and easier to control than the MIG spray arc.

Open arc, gas shielded, flux-cored welding can produce spray type transfer at lower currents than open arc MIG spray transfer. With FCAW, the current density is high because the electrode wire cross-sectional area is less than that of the same size MIG solid wire due to the central core of flux. This higher density provides for improved weld penetration potential. The FCAW process produces slag, which serves as a mold to hold the fluid molten metal in place, an ideal arrangement for vertical-up and overhead welds.

All position, flux-cored wires require less operator skill for vertical-up and overhead welds than MIG, SMAW, and TIG processes. Fill passes can also be completed in 30 to 50 percent less time with all-position, flux-cored wires than with MIG short circuit and SMAW wires.

For good quality FCAW, welders need to know the best root and bevel dimensions, and the importance of maintaining those dimensions for continuous weld fusion; the preferred direction of pipe rotation; the diameter of flux cored electrode best suited for welding thin wall pipe; the optimum parameter range for that electrode on 1G and 5G welds; the preferred amount of wire stick out (typically 0.7 inch or 18 mm); and how to fine tune the voltage. When flux-cored welding is to be used for the fill passes, MIG short circuit welding is recommended for the root welds to reduce the possibility of slag from the flux being trapped in the weld. Higher weld deposit rates are provided with flux-cored, vertical-up welding, and there is the temptation to weld faster with a process that's easy to use. Conservative wire feed settings are recommended unless the high deposition rates are shown to provide consistent weld fusion. Wire feed settings should allow the welder time to control and direct the weave into the critical groove locations.

**Complete Weld Fusion.**—It is essential that new weld metal deposits be completely fused with the pipe components, and with metal laid down in successive passes. Factors that can prevent complete fusing are too numerous to list here. Some basic rules that, if followed, will improve weld fusion and quality in MIG welding in the 1G and 5G positions are:

- 1) The maximum gap at the root should be  $\frac{3}{16}$  inch (5 mm).
- 2) The root land should be  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm) wide.
- 3) A bevel angle of 80° inclusive should be used for MIG and flux-cored welding of pipe to provide width for weaving and improve fusion.
- 4) An 0.035-in MIG electrode should have a minimum short circuit current of 135 amps for fill passes.
- 5) Tack and root welds should be made in the vertical-down position.
- 6) Tack welds should be about 1.5 in (38 mm) long by  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm) thick.
- 7) Short circuit fill passes should be made in the vertical-up position.
- 8) With flux-cored electrodes, a minimum of 0.7 inch (18 mm) wire stick out from the contact tip must be maintained.

- 9) Current and voltage must be related to the pipe wall thickness.
- 10) Argon + 25 percent CO<sub>2</sub> is recommended for short circuit welding of pipe roots.
- 11) Use of undiluted CO<sub>2</sub> gas will improve MIG weld fusion in fill passes because of the "digging" action of the arc, and the increased weld energy.
- 12) With pipe wall thicknesses of 0.4 inch (10 mm) or greater, preheating to between 400 and 500°F (205 and 260°C) will help make fusion complete.

**Other Methods.**—Pulsed MIG is a viable alternative to flux-cored for all-position welds on 5G pipe, but requires more costly equipment. The pulsed MIG process however, has few advantages over conventional MIG and flux-cored when the latter are used correctly. Pulsed MIG may have some advantage on mechanized 5G welds and on welding of stainless steel pipe in the 5G position.

Metal-cored electrode wire also has few advantages for pipe welds because they work best with low-energy gas welds, which cancels out the increased current density claimed for them.

On most manual pipe welds, the welder needs time to control and direct the weave to ensure even heating and avoid lack of fusion. Satisfactory welds are often performed at travel speeds of 4 to 12 in/min (0.10–0.31 m/min) giving deposit rates of 3–5 lb/hr (1.36–2.27 kg/hr).

### Pipe Welding Procedure

Because of the variety of parameter combinations that can be used in pipe welding, it is suggested that charts be prepared and displayed in welding booths to remind welders of the basic settings to be used. Examples of such charts for tack, root, fill and cover passes, are included in what follows:

**FCAW 5G (Non-Rotated) MIG Welding of Thick-Walled, Carbon Steel Pipes, Procedure for Root Welding.**—This procedure can be applied to most pipe sizes, and should be given special consideration for 5G (non-rotated) welds on carbon steel pipe with  $\frac{3}{8}$  inch (10 mm) wall thickness and thicker.

#### *Pipe and Weld Data*

*Pipe bevel included angle* = 80

*Root face land* =  $\frac{3}{32} \pm \frac{1}{32}$  inch (2.4 ± 0.8 mm)

*Root gap between faces* =  $\frac{5}{32} \pm \frac{1}{32}$  inch (4 ± 0.8 mm)

*Electrode for root weld* = 0.035-inch (0.9 mm) diameter, E70S-3 flux-cored

*Gas* = argon with 15–25% CO<sub>2</sub>

*Gas flow rates* = 30 to 40 cubic ft/hr (0.85–1.13 m<sup>3</sup>/hr)

Set wire feeder to 210–280 in/min (10 to 11 o'clock position on many feeders) for current of 140–170 amps, 17–18 volts.

*Wire extension:* For MIG root weld, set contact tip to stick outside the nozzle,  $\frac{1}{16}$  to  $\frac{1}{8}$  inch (1.6 to 3 mm). Maintain  $\frac{3}{8}$  to  $\frac{5}{8}$  inch (10 to 16 mm) maximum wire stick out from contact tip.

*Tack Welding Procedures for FCAW 5G Pipe Welds:* Make tack welds 1.5 to 2 inches (38 to 50 mm) long. After welding, grind full length of tack to thickness of approximately  $\frac{1}{16}$  inch (1.6 mm). Feather tack ends back  $\frac{3}{8}$  to  $\frac{1}{2}$  inches (9.5 to 13 mm).

On pipes of less than 6 inches (15 cm) outside diameter, use three tack welds, equally spaced, starting at 12 o'clock.

On pipes over 6 inches outside diameter use 4 tack welds. Locate tack welds at 12, 3, 6, and 9 o'clock.

*Root Welding Procedures for FCAW 5G Pipe Welds:* Root weld MIG vertical-down. Weld sequence: 12 to 3, 9 to 6, 3 to 6, and 12 to 9 o'clock positions.

Start and finish MIG root welds at tack centers. Use slight weave oscillation over tacks. No weave necessary if  $\frac{1}{8}$ - to  $\frac{5}{32}$ -inch root gap is maintained. Weaving may be required if root gap is less than  $\frac{1}{8}$  inch (3 mm). Weaving is also beneficial for root welds between 7 and 6 o'clock, and between 5 and 6 o'clock. After each root pass, blend the starts and stops back to the original tack thickness.

To complete the root, ensure that the weld stops and starts on the last tack, and that the root weld center is ground flat or slightly concave. Remove any slag islands.

**FCAW 5G (Non-rotated) MIG Welding of Thick-Walled, Carbon-steel Pipes, Procedure for Fill and Cover Welds.**—This procedure can be applied to most common pipe sizes, and should be given special consideration for 5G (non-rotated) welds on carbon steel pipe with  $\frac{3}{8}$  inch (10 mm) wall thickness and thicker.

*Pipe and Weld Data*

*Electrode for fill and cover passes* = 0.035 inch (0.9 mm) diameter,  
71T-1 flux-cored

*Gas* = argon with 15–25% CO<sub>2</sub>

*Gas flow rates* = 30 to 40 cubic ft/hr

Set an initial wire feed rate of 350 to 450 in/min (12 to 1 o'clock position on typical wire feed unit), 135–165 amps, 25–28 volts. Alternatively, use a wire feed setting of 350 in/min (12 o'clock on wire feed unit), which should result in about 135–145 amps, 25–26 volts. If the weld pool and weld heat build up permit, increase the wire feed rate to 380 in/min (between the 12 and 1 o'clock positions), 150 amps, 27 volts. Try also a wire feed setting of 420 in/min (1 o'clock on the wire feeder), 165 amps, 28 volts. Determine the low and maximum wire feed rates to be used by examination of the weld fusion obtained in sectioned test samples.

*Wire extension:* Adjust contact tip so it is recessed  $\frac{1}{2}$  inch within the nozzle to provide a total wire stick out from the contact tip of 0.7 to 1 inch (18 to 25 mm).

*Fill and Cover Pass Procedures for FCAW 5G Pipe Welds:* Weld vertical-up. If the pipe diameter allows the fill pass to be made in two passes, start at the 7 o'clock position and weld to the 1 o'clock position. This approach is preferable to starting and finishing on the root tacks. Starting at the 7 o'clock position will ensure that optimum weld energy is achieved as the first pass welds over the initial 6 o'clock root tack location. Use the grinder to feather the first 1 inch (25 mm) of the weld start and stop of the first pass, before applying the second vertical-up weld pass. Use a slight weave action for the fill pass.

Remove all flux-cored slag between weld passes. Make sure no fill pass is greater in depth than  $\frac{1}{8}$  inch (3 mm). Use a straight weave across the root face. At the bevel edge use a slight upward motion with the gun. The motion should be no greater than the wire diameter. Then use a slight back step for added bevel fusion and to avoid undercuts.

Leave  $\frac{1}{32}$  to  $\frac{1}{16}$  inch (0.8 to 1.6 mm) of the groove depth to provide for the optimum cover pass profile. The bevel edge will act as a guide for the cover pass weld. If more weld fusion is required for pipe thicker than  $\frac{3}{8}$  inch (10 mm), after the root weld is complete, preheat the pipe to between 400 and 600°F (200–300°C) before welding. Preheating is typically not necessary for a cover pass.

For pipe diameters on which the welder needs more than two passes for the vertical-up welds, the recommended sequence for vertical-up welding is:

- 1) First pass, weld from the 7 to the 4 o'clock position. Start with a slight forehand nozzle angle. At the 4 o'clock position, the gun should be at the same angle as the pipe.
- 2) Second pass, weld from the 10 to the 1 o'clock position, then grind all stops and start again at the 1-inch (25 mm) position.
- 3) Third pass, weld from the 4 to the 1 o'clock position.
- 4) Fourth pass, weld from the 7 to the 10 o'clock position.

**FCAW 5G (Non-rotated) Welding of Thin-Walled Carbon Steel Pipes, Procedure for Root, Fill and Cover Pass Welding.**—This procedure can be applied to most common pipe sizes, and should be given special consideration for 5G (non-rotated) welding of carbon steel pipe with wall thicknesses up to  $\frac{3}{8}$  inch (10 mm).

*Pipe and Weld Data*

*Electrode for root weld* = 0.035 inch diameter, E70S-6 flux cored

*Gas* = argon with 15–25% CO<sub>2</sub>

*Gas flow rates* = 30 to 40 cubic ft/hr

*Root Welding Procedure for 5G Welds:* Use root welding data from *Root Welding Procedures for FCAW 5G Pipe Welds*, above.

*Fill and Cover Pass Procedures for 5G Welds:* Use MIG short-circuit, vertical-up for fill and cover passes. Electrode wire and gas, same as for root weld.

Weld vertical-up. If the vertical-up fill pass can be made in two passes, weld from the 7 to the 1 o'clock position, to avoid starting and finishing on the root tacks. Starting just past 6 o'clock ensures that optimum weld energy is achieved as the first pass welds over the initial 6 o'clock root tack location. Feather 1 inch (25 mm) of the weld start and stop on the first pass with the grinder before applying the second vertical-up weld pass. Use a slight weave action.

Use MIG short-circuit wire feed, 200–230 in/min 125–135 amps, 19–22 volts. Start at optimum 210 in/min (10 o'clock on the wire feeder) for 130 amps, 21–22 volts. Fine tune voltage by listening to arc sound to obtain a consistent rapid crackle sound.

Electrode sticks out  $\frac{1}{2}$  to  $\frac{5}{8}$  inch, contact tip flush with nozzle end.

Remove MIG surface slag islands between weld passes. No fill pass should be thicker than  $\frac{1}{8}$  inch (3 mm). Use straight weave across the root face. At the bevel, use a slight upward motion with the gun. The motion should be no greater than the wire diameter. Then use a slight back step for added bevel fusion and to avoid possibility of undercut.

For the cover pass, leave  $\frac{1}{32}$  to  $\frac{1}{16}$  inch of the groove depth for the optimum cover pass profile. The bevel edge will act as a guide for the cover pass weld.

If more weld fusion is required after the root is complete and between fill passes, pre-heat pipe to 200–400°F (93–204°C).

For pipe diameters on which more than two passes are required for the circumference the weld sequence is:

- 1) First pass, weld from the 7 to the 4 o'clock position. Start with a slight forehand nozzle angle. At the 4 o'clock position the gun should point straight at the joint;
- 2) Second pass, weld from the 10 to the 1 o'clock position, then grind all stops and starts for at least 1 inch (25 mm);
- 3) Third pass, weld from the 4 to the 1 o'clock position; and
- 4) Fourth pass, weld from the 7 to the 10 o'clock position.

## Weld and Welding Symbols

**American National Standard Weld and Welding Symbols.**—Graphical symbols for welding provide a means of conveying complete welding information from the designer to the welder by means of drawings. The symbols and their method of use (examples of which are given in the table following this section) are part of the American National Standard ANSI/AWS A2.4-2012 sponsored by the American Welding Society.

In the Standard a distinction is made between the terms *weld symbol* and *welding symbol*. Weld symbols, shown in the table *Basic Weld Symbols*, are ideographs used to indicate the type of weld desired, whereas welding symbol denotes a symbol made up of as many as eight elements conveying explicit welding instructions.

The eight elements which may appear in a welding symbol are: reference line; arrow; basic weld symbols; dimensions and other data; supplementary symbols; finish symbols; tail and specification; and process or other reference.

The standard location of elements of a welding symbol are shown in Fig. 1.

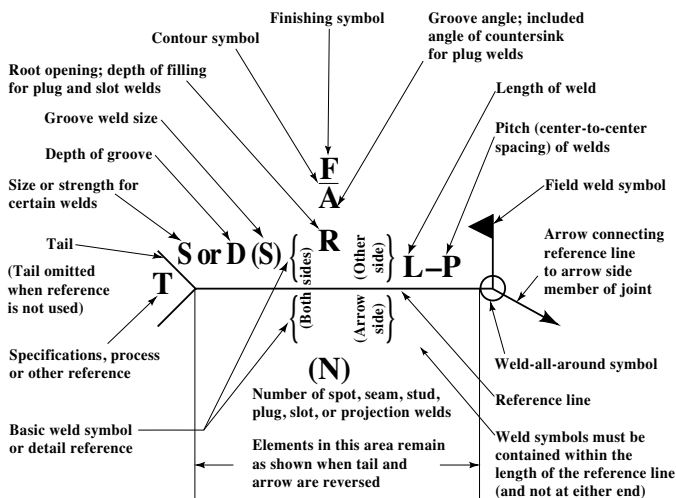

Fig. 1. Standard Location of Elements of a Welding Symbol

**Reference Line:** This is the basis of the welding symbol. All other elements are oriented with respect to this line. The arrow is affixed to one end and a tail, when necessary, is affixed to the other. Weld symbols should be contained within the length of this line.

**Arrow:** This connects the reference line to one side of the joint in the case of groove, fillet, flange, and flash or upset welding symbols. This side of the joint is known as the *arrow side* of the joint. The opposite side is known as the *other side* of the joint. In the case of plug, slot, projection, and seam welding symbols, the arrow connects the reference line to the outer surface of one of the members of the joint at the center line of the weld. In this case the member to which the arrow points is the *arrow side* member; the other member is the *other side* member. In the case of bevel and J-groove weld symbols, a two-directional arrow pointing toward a member indicates that the member is to be chamfered.

**Basic Weld Symbols:** These designate the type of welding to be performed. The basic symbols which are shown in the table *Basic Weld Symbols* are placed approximately in the center of the reference line, either above or below it or on both sides of it as shown in Fig. 1. Welds on the arrow side of the joint are shown by placing the weld symbols on the side of the reference line towards the reader (lower side). Welds on the other side of the joint are shown by placing the weld symbols on the side of the reference line away from the reader (upper side).

**Supplementary Symbols:** These convey additional information relative to the extent of the welding, where the welding is to be performed, and the contour of the weld bead. The “weld-all-around” and “field” symbols are placed at the end of the reference line at the base of the arrow as shown in Fig. 1 and the table *Supplementary Weld Symbols*.

**Dimensions:** These include the size, length, spacing, etc., of the weld or welds. The size of the weld is given to the left of the basic weld symbol and the length to the right. If the length is followed by a dash and another number, this number indicates the center-to-center spacing of intermittent welds. Other pertinent information such as groove angles, included angle of countersink for plug welds and the designation of the number of spot or projection welds are also located above or below the weld symbol. The number designating the number of spot or projection welds is always enclosed in parentheses.

**Contour and Finish Symbols:** The contour symbol is placed above or below the weld symbol. The finish symbol always appears above or below the contour symbol (see Fig. 1).

The following finish symbols indicate the method, not the degrees of finish: C—chipping; G—grinding; M—machining; R—rolling; and H—hammering.

For indication of surface finish refer to the section *SURFACE TEXTURE* starting on page 808.

**Tail:** The tail which appears on the end of the reference line opposite to the arrow end is used when a specification, process, or other reference is made in the welding symbol. When no specification, process, or other reference is used with a welding symbol, the tail may be omitted.

**Melt-Thru Symbol:** The melt-thru symbol is used only where 100 percent joint or member penetration plus reinforcement are required.

**Table 1. Basic Weld Symbols**

Groove Symbols								
Square	Scarf	V	Bevel	U	J	Flare-V	Flare-bevel	
Other Weld Symbols								
Fillet	Plug <sup>a</sup>	Slot	Stud	Spot or projection	Seam	Back or backing	Surfacing	Edge

<sup>a</sup> Ø designates a round hole for a plug.

For examples of basic weld symbol applications see *Application of American National Standard Welding Symbols* starting on page 1622.

Table 2. Supplementary Weld Symbols

Weld all around	Field weld	Melt-thru	Backing or spacer material	Contour		
				Flush	Convex	Concave
						

*Specification, Process, or Other Designation:* These are placed in the tail of the welding symbol and are in accordance with the American National Standard. They do not have to be used if a note is placed on the drawing indicating that the welding is to be done to some specification or that instructions are given elsewhere as to the welding procedure to be used.

*Letter Designations:* American National Standard letter designations for welding and allied processes are shown in the table on page 1621.

*Further Information:* For complete information concerning welding specification by the use of standard symbols, reference should be made to American National Standard ANSI/AWS A2.4-2012, which may be obtained from either the American National Standards Institute or the American Welding Society listed below.

**Welding Codes, Rules, Regulations, and Specifications.**—Codes recommending procedures for obtaining specified results in the welding of various structures have been established by societies, institutes, bureaus, and associations, as well as state and federal departments.

The latest codes, rules, etc., may be obtained from these agencies, whose names and addresses are listed as follows: PV = Pressure Vessels; P = Piping; T = Tanks; SB = Structural and Bridges; S = Ships; AC = Aircraft Construction; and EWM = Electrical Welding Machinery.

WELDING SYMBOLS

Application of American National Standard Welding Symbols

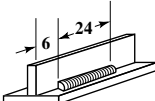

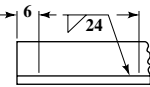

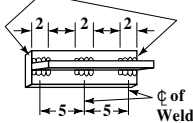

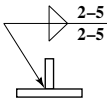

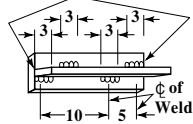

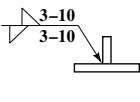

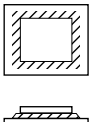

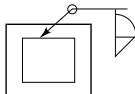

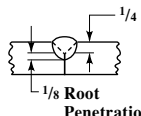

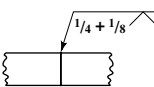

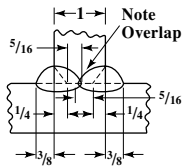

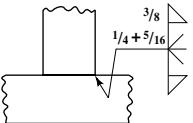

Desired Weld	Symbol	Symbol Meaning
		Symbol indicates fillet weld on <i>arrow side</i> of the joint.
		Symbol indicates square-groove weld on <i>other side</i> of the joint.
		Symbol indicates bevel-groove weld on both sides of joint. Breaks in arrow indicate bevels on upper member of joint. Breaks in arrows are used on symbols designating bevel and J-groove welds.
		Symbol indicates plug weld on <i>arrow side</i> of joint.
		Symbol indicates resistance-seam weld. Weld symbol appears on both sides of reference line, indicating that <i>arrow</i> and <i>other side</i> of joint references have no significance.
		Symbol indicates electron beam seam weld on <i>other side</i> of joint.

## Application of American National Standard Welding Symbols (Continued)

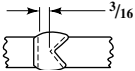

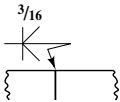

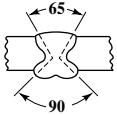

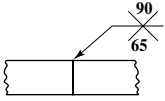

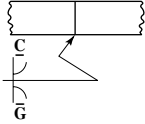

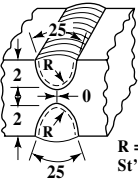

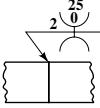

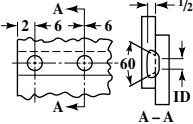

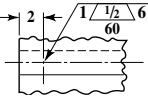

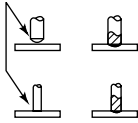

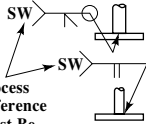

Desired Weld	Symbol	Symbol Meaning
<p>Groove Weld Made Before Welding Other Side</p>  <p>Back Weld</p>		Symbol indicates single-pass back weld.
		Symbol indicates a built-up surface $\frac{1}{8}$ inch thick.
		Symbol indicates a bead-type back weld on the <i>other side</i> of joint, and a J-groove grooved horizontal member (shown by break in arrow) and fillet weld on <i>arrow side</i> of the joint.
		Symbol indicates two fillet welds, both with $\frac{1}{2}$ -inch leg dimensions.
		Symbol indicates a $\frac{1}{2}$ -inch fillet weld on <i>arrow side</i> of the joint and a $\frac{1}{4}$ -inch fillet weld on <i>far side</i> of the joint.
	 <p>Orientation Shown on Drawing</p>	Symbol indicates a fillet weld on <i>arrow side</i> of joint with $\frac{1}{4}$ - and $\frac{1}{2}$ -inch legs. Orientation of legs must be shown on drawing.

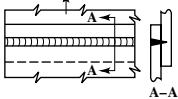

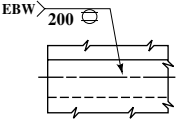

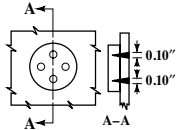

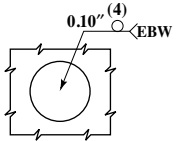

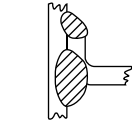

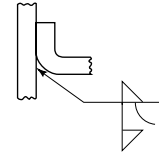

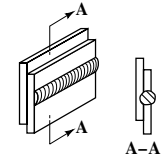

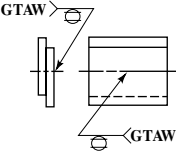

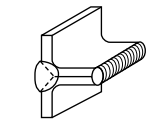

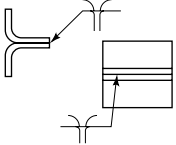

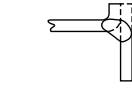

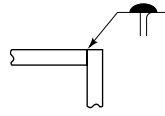

**Application of American National Standard Welding Symbols (Continued)**

Desired Weld	Symbol	Symbol Meaning
		Symbol indicates a 24-inch long fillet weld on the <i>arrow side</i> of the joint.
<p><b>Locate Welds at Ends of Joint</b></p> 		Symbol indicates a series of intermittent fillet welds each 2 inches long and spaced 5 inches apart on centers directly opposite each other on both sides of the joint.
<p><b>Locate Welds at Ends of Joint</b></p> 		Symbol indicates a series of intermittent fillet welds each 3 inches long and spaced 10 inches apart on centers. The centers of the welds on one side of the joint are displaced from those on the other.
		Symbol indicates a fillet weld around the perimeter of the member.
		Symbol indicates a 1/4-inch V-groove weld with a 1/8-inch root penetration.
		Symbol indicates a 1/4-inch bevel weld with a 5/16-inch root penetration plus a subsequent 3/8-inch fillet weld.

**Application of American National Standard Welding Symbols (Continued)**

Desired Weld	Symbol	Symbol Meaning
		<p>Symbol indicates a bevel weld with a root opening of <math>\frac{3}{16}</math> inch.</p>
		<p>Symbol indicates a V-groove weld with a groove angle of 65 degrees on the <i>arrow side</i> and 90 degrees on the <i>other side</i>.</p>
		<p>Symbol indicates a flush surface with the reinforcement removed by chipping on the <i>other side</i> of the joint and a smooth grind on the <i>arrow side</i>. The symbols <i>C</i> and <i>G</i> should be the user's standard finish symbols.</p>
 <p>R = User's St'd.</p>		<p>Symbol indicates a 2-inch U-groove weld with a 25-degree groove angle and no root opening for both sides of the joint.</p>
		<p>Symbol indicates plug welds of 1-inch diameter, a depth of filling of <math>\frac{1}{2}</math> inch and a 60-degree angle of countersink spaced 6 inches apart on centers.</p>
<p><b>Preparation</b></p> 	 <p><b>Process Reference Must Be Placed on Symbol</b></p>	<p>Symbol indicates all-around bevel and square-groove weld of these studs.</p>

**Application of American National Standard Welding Symbols (Continued)**

Desired Weld	Symbol	Symbol Meaning
<p><b>Min. Acceptable Shear Strength 200 lb/lin. in.</b></p> 		<p>Symbol indicates an electron beam seam weld with a minimum acceptable joint strength of 200 pounds per linear inch.</p>
		<p>Symbol indicates four 0.10-inch diameter electron beam spot welds located at random.</p>
		<p>Symbol indicates a fillet weld on the <i>other side</i> of joint and a flare-bevel-groove weld and a fillet weld on the <i>arrow side</i> of the joint.</p>
		<p>Symbol indicates gas tungsten-arc seam weld on <i>arrow side</i> of joint.</p>
		<p>Symbol indicates edge-flange weld on <i>arrow side</i> of joint and flare-V-groove weld on <i>other side</i> of joint.</p>
		<p>Symbol indicates melt-thru weld. By convention, this symbol is placed on the opposite side of the reference line from the corner-flange symbol.</p>

### Nondestructive Testing

Nondestructive testing (NDT) methods are used to examine a material, component, or assembly to measure thickness, determine structure, and/or search for surface or internal cracks, material flaws, or other nonhomogeneities. "Nondestructive" refers to a method of examination that does not affect or impair the use of the subject for its intended purpose. NDT is particularly useful in the welding process.

**Nondestructive Testing Methods.**—The primary NDT methods, introduced below, include ultrasonic, radiography, magnetic particle, penetrant, and eddy current. Excellent references, including books and standards, as well as certification and qualification programs, provide in-depth information on the principles and applications of each approach.

**Ultrasonic Testing (UT):** The workhorse of NDT, ultrasonic testing utilizes high-frequency sound waves. An electronic pulser/receiver drives a transducer, which sends ultrasonic sound waves through a test subject. These waves travel at the same distinct speed for any given material or medium that has matter (see Table 1). The time and distance that sound waves travel through a substance and echo off a reflecting surface can be analyzed to determine medium characteristics, measure thickness, and detect and evaluate flaws.

**Table 1. Material Velocities**

Medium	Velocity		Time/Distance Traveled		Distance/Time Traveled	
	in/second	cm/second	second/mile	second/km	mile/second	km/second
Air (68°F/20°C)	14,016	35,601	4.5	2.80		
Water (68°F/20°C)	57,992	147,300	1.09	0.68		
Steel 1020	232,008	589,300			3.7	5.95
Aluminum 6061-T6	247,992	629,900			3.9	6.27
Beryllium	507,000	1,287,780			8.0	12.87

The calibration of the instrumentation is critical and must be carried out with reference blocks of the same material and velocity. This allows accurate measurement of the time and distance that a sound wave has traveled to and from a reflecting surface. Whether measuring a backwall for thickness or locating the depth and size of discontinuities, the accuracy of test results is only as reliable as the calibration. For the plate shown in Fig. 1, calculation of the angle, thickness, and sound path distance are required; these are obtained with formulas frequently used for ultrasonic testing.

Fig. 1. Shear Wave Welding Inspection

Standard formulas use the refracted angle, thickness, and sound path distance to calculate the flaw depth and location. Other formulas are used to calculate acoustic impedance, nearfield, wavelength, and angular relationships. For instance, a formula developed from Snell's law is used to calculate incident and refracted angles.

**Radiographic Testing (RT):** Favored by many industries, due to the insight provided, radiographic testing is another method of detecting subsurface discontinuities and other material variations. It involves transmission of radiation through the material being tested, with the results recorded on photographic film or the digital equivalent. In general, areas of reduced thickness or lower-density material absorb less radiation, and more is

transmitted to the film or digital sensors. As shown in Fig. 2, this produces relatively darker regions in the resulting imagery, as compared to thicker and/or denser areas.

Fig. 2. Radiographic Absorption Effect on a Steel Step Wedge

RT can detect voids, such as porosity, slag, and tungsten inclusions, that indicate weld discontinuities. Critical flaws, including cracks and incomplete fusion, are more difficult to see unless the radiation source is oriented at a suitable direction with respect to the flaw. A key advantage of using radiographic film or digital media is that a permanent record of the testing can be stored.

A disadvantage of RT (unlike UT) is that it requires access to both sides of the material: one for the transmission source and the other for the film. Another issue is the danger posed to humans by exposure to radiation, particularly when using portable X-ray equipment involving isotopes such as iridium-192 and cobalt-60. Training in radiation safety is mandatory, along with safeguards to protect personnel in the test vicinity.

**Magnetic Particle Testing (MT):** Used to detect surface and near-surface discontinuities that are primarily linear in nature, magnetic particle testing is relatively easy to use, is low in cost, and provides immediate results. However, it is only effective on ferromagnetic materials.

Magnetization is achieved by passing an electric current through the material, or by using an external magnetizing coil; permanent magnets also may be used. Finely divided magnetic particles—either as a dry powder or suspended in liquid carrier—are applied to and removed from the part during magnetization. An example of longitudinal magnetization is shown below in Fig. 3a. If there are no discontinuities interrupting the flow of the current, the magnetic particles are easily removed. However, if there is an interruption in the flow of current, as shown in Fig. 3b, flux leakage occurs, creating new north and south poles, and the particles remain fixed at the discontinuity.

Fig. 3a. Magnetic Flux Lines

Fig. 3b. Interruption of Flow

Evaluation of test results is arguably the most critical stage of MT and requires distinguishing among false, nonrelevant, and relevant indications. Experience and familiarity with codes and specifications, application of proper techniques, stringent equipment performance checks, and adherence to the detailed and qualified procedure are essential.

**Penetrant Testing (PT):** Widely used to reveal surface discontinuities on numerous materials—all metals (including aluminum, titanium, magnesium, and other nonferrous compounds), glass, ceramics, and various composites—penetrant testing works on the principle of capillary attraction. This surface tension phenomenon permits liquids to be drawn into tight crevices, regardless of orientation or gravitational forces.

After the test area is cleaned, a dye concentrate is applied to and left on the material for a specific (dwell) time. When the penetrant is removed, the part usually is dried, and a developer is applied. The developer acts as an absorbent, drawing the remaining penetrant out of discontinuities open to the surface. Observing the test surface under appropriate lighting *immediately* after application of the developer assists proper interpretation of indications, though the final evaluation cannot be performed before the minimum developer dwell time has elapsed.

Utilizing the appropriate method as shown in Table 2, very large parts can be tested, or numerous small parts, such as turbine and compressor blades, can be processed simultaneously.

**Table 2. Classification of Penetrant Materials and Processes**

Type I	Fluorescent penetrants	May be used with all developers
Type II	Visible (color contrast) penetrants	Nonaqueous and aqueous developers
Method A	Water-washable visible dye penetrants	Water-washable fluorescent penetrants
Method B	Post-emulsified visible or fluorescent	Lipophilic emulsifier (oil-based)
Method C	Solvent removable	Visible or fluorescent penetrants
Method D	Post-emulsified fluorescent penetrants	Hydrophilic emulsifier (water-based)
Developers	Dry powder, nonaqueous	Water suspended, water soluble

*Note:* Sensitivity levels available are 1, 2, 3, and 4 (4 is the highest).

PT is versatile enough to be used in the field with or without electricity, is relatively low cost, and is easy to use. However, it is time-consuming and usually requires additional cleaning of the part after testing is complete.

**Eddy Current Testing (ET):** This sophisticated NDT method can be used to detect conductivity variations; discontinuities; material thickness, including plating or cladding on a base material; and spacing between conductive layers. Based on the principle of electromagnetism, ET uses the inductive properties of alternating current flowing through a primary coil to develop an alternating magnetic field. Interruption of this magnetic field causes an impedance change in the coil, recorded as a phase change by the instrumentation.

In theory, ET is much more complex; it was not until the early 1980s that explanatory material was produced that made this process understandable to laypersons. While ET is a high-speed process, it has a limited depth of penetration, depending on such factors as the test frequency, type of coil, and conductivity of materials being tested.

**Other NDT Methods.**—In addition to the five primary NDT methods discussed above, there are six other methods recognized by the American Society of Nondestructive Testing (ASNT), including visual testing. Each has unique advantages and limitations.

**Visual Testing (VT):** Being the first inspection, visual acuity examination generally is required for NDT certification. Many factors can affect VT, including cleanliness, brightness, glare, surface condition, shape, size, and temperature of an object. While the most important instrument in visual testing is the human eye, direct visual aids, such as light sources, magnifiers, cameras, and measuring devices are commonly used to verify conformance to industry codes, standards, and specification requirements.

**Thermal/Infrared Testing (IR):** The laws of thermodynamics can be applied to the detection of many anomalies in metals, cements, and composites, as well as in the chemical industries. When there is a difference of temperature between two objects, or when an object changes temperature, the net flow energy is transferred from warmer areas to cooler areas or vice versa, until thermal equilibrium is reached. For example, IR can detect moisture that has intruded into the insulation of buildings and liquid CO<sub>2</sub> storage tanks.

**Acoustic Emission Testing (AE):** This NDT method is commonly used to detect and locate faults in mechanically loaded components or structures. When a material is subjected to mechanical loading or stress, such discontinuities release energy in the form of stress waves that can be detected by strategically placing sensors, which pick up these signals and convert the energy into voltage. The voltage is then electronically amplified and timing circuits are used to process the AE signal data and identify the fault.

**Leak Testing (LT):** Leak testing detects a flow of gas or liquid through the wall of a vessel, via a discontinuity (such as a hole, crack, or bad seal). Leaks require a pressure difference and travel from higher to lower pressure, whether from inside an object with greater pressure than the surrounding atmospheric pressure, or from the atmosphere to inside a vessel under a vacuum. Techniques for LT include mass spectrometer, halogen diode, pressure change, and bubble testing.

**Neutron Radiography (NRT):** This technique is often used with conventional radiographic testing. But neutrons interact with the nucleus of the atom, rather than with the electrons, and are absorbed by matter very differently than X-rays and gamma rays. NRT is ideal for imaging light elements with low atomic numbers (such as hydrogen, water, carbon, and plastics) and penetrating heavy elements with high atomic numbers (such as aluminum, lead, steel, and titanium). Thus, neutron radiographs can show organic materials or water, with many structural materials being nearly transparent.

**Magnetic Flux Leakage (MFL):** This method uses a direct current (DC) magnetizing field to create flux density to bring a material to near saturation. Surface or internal discontinuities, such as cracks, pits, and other defects, interrupt the flux field, causing it to leak beyond the test surface. The longitudinal and transverse magnetizing fields enable identification of defects in both directions. Sensors and configured inspection devices gather and transmit data for processing and analysis.

**Nondestructive Testing Symbol Application.**—The application of NDT symbols is covered in American National Standard ANSI/AWS A2.4-2012. This standard also includes the letters used to indicate each basic testing method: Acoustic Emission (AET), Eddy Current (ET), Leak (LT), Magnetic Particle (MT), Neutron Radiographic (NRT), Penetrant (PT), Proof (PRT), Radiographic (RT), Ultrasonic (UT), and Visual (VT).

**Testing Symbol Elements:** The testing symbol consists of the following elements: number of tests (N), length of section to be tested (L), reference line, test in field, test-all-around symbol, tail, arrow, and specification or other reference. The standard locations of the testing symbol elements are shown in Fig. 4.

Fig. 4. Locations of Testing Symbol Elements

The arrow connects the reference line to the part to be tested. The side of the part that the arrow points to is considered the *arrow side*. The side opposite the arrow side is considered the *other side*.

**Location of Testing Symbol:** Tests to be made on the arrow side of the part are indicated by positioning the testing symbol on the side of the reference line toward the reader (Fig. 5a).

Tests to be made on the other side of the part are indicated by the testing symbol being on the side of the reference line away from the reader (Fig. 5b).

Fig. 5a. Position of Testing Symbols Indicates Tests to Be Made on the Arrow Side

Fig. 5b. Position of Testing Symbols Indicates Tests to Be Made on the Other Side

To specify where only a certain length of a section is to be considered, the actual length or percentage of length to be tested is shown to the right of the test symbol. To specify the number of tests to be taken on a joint or part, the number of tests is shown in parentheses.

Tests to be made on both sides of the part are indicated by test symbols on both sides of the reference line. Where nondestructive symbols have no arrow or other significance, the testing symbols are centered in the reference line.

**Direction of Radiation:** When specified, the direction of radiation may be shown, in conjunction with the radiographic or neutron radiographic basic testing symbols, by means of a radiation symbol located on the drawing at the desired angle.

Fig. 6. Indicating Direction of Radiation

**Tests Made All Around the Joint:** To specify tests to be made all around a joint a circular test-all-around symbol is used.

Fig. 7. Specifying Circular Testing

**Areas of Revolution:** For NDT of areas of revolution, the area is indicated by the test-all-around symbol and appropriate dimensions.

**Plane Areas:** The area to be examined is enclosed by straight broken lines having a small circle around the angle apex at each change in direction.

**Combination of Symbols:** Various nondestructive basic testing symbols may be combined. Also, NDT and welding symbols may be combined.

## FINISHING OPERATIONS

## Power Brush Finishing

Power brush finishing is a production method of metal finishing that employs wire, elastomer bonded wire, or non-metallic (cord, natural fiber or synthetic) brushing wheels in automatic machines, semi-automatic machines and portable air tools to smooth or roughen surfaces, remove surface oxidation and weld scale or remove burrs.

**Description of Brushes.**—Brushes work in the following ways: the wire points of a brush can be considered to act as individual culling tools so that the brush, in effect, is a multiple-tipped cutting tool. The fill material, as it is rotated, contacts the surface of the work and imparts an impact action which produces a coldworking effect. The type of finish produced depends upon the wheel material, wheel speed, and how the wheel is applied.

Brushes differ in the following ways: 1) fill material (wire—carbon steel, stainless steel; synthetic; Tampico; and cord); 2) length of fill material (or trim); and 3) the density of the fill material.

To aid in wheel selection and use, the accompanying table made up from information supplied by *The Osborn Manufacturing Company* lists the characteristics and major uses of brushing wheels.

**Use of Brushes.**—The brushes should be located so as to bring the full face of the brush in contact with the work. Full face contact is necessary to avoid grooving the brush. Operations that are set up with the brush face not in full contact with the work require some provision for dressing the brush face. When the tips of a brush, used with full face contact, become dull during use with subsequent loss of working clearance, reconditioning and resharpener is necessary. This is accomplished simply and efficiently by alternately reversing the direction of rotation during use.

**Deburring and Producing a Radius on the Tooth Profile of Gears.**—The brush employed for deburring and producing a radius on the tooth profile of gears is a short trim, dense, wire-fill radial brush. The brush should be set up so as to brush across the edge as shown in Fig. 1A. Line contact brushing, as shown in Fig. 1B should be avoided because the Crisp face will wear non-uniformly; and the wire points, being flexible, tend to flare to the side, thus minimizing the effectiveness of the brushing operation. When brushing gears, the brushes are spaced and contact the tooth profile on the center line of the gear as shown in Fig. 2. This facilitates using brush reversal to maintain the wire brushing points at their maximum cutting efficiency.

The setup for brushing spline bores differs from brushing gears in that the brushes are located off-center, as illustrated in Fig. 3. When helical gears are brushed, it is sometimes necessary to favor the acute side of the gear tooth to develop a generous radius prior to shaving. This can be accomplished by locating the brushes as shown in Fig. 4. Elastomer bonded wire-filled brushes are used for deburring fine pitch gears. These brushes remove the burrs without leaving any secondary roll. The use of bonded brushes is necessary when the gears are not shaved after hobbing or gear shaping.

### Adjustments for Eliminating Undesirable Conditions in Power Brush Finishing

Undesirable Condition	Possible Adjustments for Eliminating Condition
Brush works too slowly	<ol style="list-style-type: none"> <li>(1) Decrease trim length and increase fill density.</li> <li>(2) Increase filament diameter.</li> <li>(3) Increase surface speed by increasing R.P.M. or outside diameter.</li> </ol>
Brush works too fast	<ol style="list-style-type: none"> <li>(1) Reduce filament diameter.</li> <li>(2) Reduce surface speed by reducing R.P.M. or outside diameter.</li> <li>(3) Reduce fill density.</li> <li>(4) Increase trim length.</li> </ol>
Action of brush peens burr to adjacent surface	<ol style="list-style-type: none"> <li>(1) Decrease trim length and increase fill density.</li> <li>(2) If wire brush tests indicate metal too ductile (burr is peened rather than removed), change to nonmetallic brush such as a treated Tampico brush used with a burring compound.</li> </ol>
Finer or smoother finish required	<ol style="list-style-type: none"> <li>(1) Decrease trim length and increase fill density.</li> <li>(2) Decrease filament diameter.</li> <li>(3) Try treated Tampico or cord brushes with suitable compounds at recommended speeds.</li> <li>(4) Use auxiliary buffing compound with brush.</li> </ol>
Finish too smooth and lustrous	<ol style="list-style-type: none"> <li>(1) Increase trim length.</li> <li>(2) Reduce brush fill density.</li> <li>(3) Reduce surface speed.</li> <li>(4) Increase filament diameter.</li> </ol>
Brushing action not sufficiently uniform	<ol style="list-style-type: none"> <li>(1) Devise hand-held or mechanical fixture or machine which will avoid irregular off-hand manipulation.</li> <li>(2) Increase trim length and decrease fill density.</li> </ol>

### Polishing and Buffing

The terms "polishing" and "buffing" are sometimes applied to similar classes of work in different plants, but according to approved usage of the terms, there is the following distinction: Polishing is any operation performed with wheels having abrasive glued to the working surfaces, whereas buffing is done with wheels having the abrasive applied loosely instead of imbedding it into glue; moreover, buffing is not so harsh an operation as ordinary polishing, and it is commonly utilized to obtain very fine surfaces having a "grainless finish."

**Polishing Wheels.**—The principal materials from which polishing wheels are made are wood, leather, canvas, cotton cloth, plastics, felt, paper, sheepskin, impregnated rubber, canvas composition, and wool. Leather and canvas are the materials most commonly used in polishing wheel construction. Wooden wheels covered with material to which emery or some other abrasive is glued are employed extensively for polishing flat surfaces,

**Characteristics and Applications of Brushes Used in Power Finishing**

Brush Type	Description	Operating Speed Range, sfpm	Uses	Remarks
Radial, short trim dense wire fill	Develops very little impact action but maximum cutting action.	6500	Removal of burrs from gear teeth and sprockets. Produces blends and radii at juncture of intersecting surfaces.	Brush should be set up so as to brush across any edge. Reversal of rotation needed to maintain maximum cutting efficiency of brush points.
Radial, medium to long trim twisted knot wire fill	Normally used singly and on portable tools. Brush is versatile and provides high impact action.	7500-9500 for high speeds. 1200 for slow speeds.	For cleaning welds in the automotive and pipeline industries. Also for cleaning surfaces prior to painting, stripping rubber flash from molded products and cleaning mesh-wire conveyor belts.	Surface speed plays an important role since at low speeds the brush is very flexible and at high speeds it is extremely hard and fast cutting.
Radial, medium to long trim crimped wire fill	With the 4- to 8-inch diameter brush, part is hand held. With the 10- to 15-inch diameter brush, part is held by machine.	4500-6000	Serves as utility tool on bench grinder for removing feather grinding burrs, machining burrs, and for cleaning and producing a satin or matte finish.	Good for hand held parts as brush is soft enough to conform to irregular surfaces and hard-to-reach areas. Smaller diameter brushes are not recommended for high-production operations.
Radial, sectional, non-metallic fill (treated and untreated Tampico or cord)	Provides means for improving finish or improving surface for plating. Works best with grease base deburring or buffing compound.	5500-6500 7500 for polishing	For producing radii and improving surface finish. Removes the sharp peaks that fixed abrasives leave on a surface so that surface will accept a uniform plating. Polishing marks and draw marks can be successfully blended.	Brush is selective to an edge which means that it removes metal from an edge but not from adjoining surfaces. It will produce a very uniform radius without peening or rolling any secondary metal.
Radial, wide-face, nonmetallic fill (natural fibers or synthetics)	Can be used with flow-through mounting which facilitates feeding of cold water and hot alkaline solutions through brush face to prevent buildup.	750-1200 for cleaning steel. 600 when used with slurries	For cleaning steel. Used in electrolytic tinplate lines, continuous galvanizing and annealing lines, and cold reduction lines. Used to produce dull or matte-type finishes on stainless steel and synthetics.	Speeds above 3600 sfpm will not appreciably improve operation as brush wear will be excessive. Avoid excessive pressures. Ammeters should be installed in drive-motor circuit to indicate brushing pressure.

**Characteristics and Applications of Brushes Used in Power Finishing (Continued)**

Brush Type	Description	Operating Speed Range, sfpm	Uses	Remarks
Radial, wide face, metallic fill	This brush is made to customer's specifications. It is dynamically balanced at the speed at which it will operate.	2000-4000	Removes buildup of aluminum oxide from work rolls in aluminum mill. Removes lime or magnesium coatings from certain types of steel. Burnishes hot-dipped galvanized steel to produce a minimum spangled surface.	Each brush should have its own drive. An ammeter should be present in drive-motor circuit to measure brushing pressure. If strip is being brushed, a steel backup roll should be opposite the brush roll.
Radial, wide face, strip (interrupted brush face)	Performs cleaning operations that would cause a solid face brush to become loaded and unusable.	When cleaning conveyor belts, brush speed is 2 to 3 times that of conveyer belt.	Need for cleaning rubber and fabric conveyor belts of carry-back material which would normally foul snubber pulley and return idlers.	Designed for medium- to light-duty work. Brush face does not load.
Radial, Cup, Flared End, and Straight End, wire fill elastomer bonded	Extremely fast cutting with maximum operator safety. No loss of wire through fatigue. Always has uniform face.	3600-9000	For removing oxide weld scale, burrs, and insulation from wire.	Periodic reversing of brush direction will result in a brush life ten times greater than non-bonded wheels. Fast cutting action necessitates precise holding of part with respect to brush.
Cup, twisted knot wire fill	Fast cutting wheel used on portable tools to clean welds, scale, rust, and other oxides.	8000-10,000  4500-6500 for deburring and producing a radius around periphery of holes.	Used in shipyards and in structural steel industry. For cleaning outside diameter of pipe and removing burrs and producing radii on heat exchanger tube sheets and laminations for stator cores.	Fast acting brush cleans large areas economically. Setup time is short.
Radial, wire or treated Tampico or cord	For use with standard centerless grinders. Brush will not remove metal from a cylindrical surface. Parts must be ground to size before brushing.	...	For removing feather grinding burrs and improving surface finish. Parts of 24 microinches can be finished down to 15 to 10 microinches. Parts of 10 to 12 microinches can be finished down to 7 to 4 microinches.	Follows centerless grinding principles, except that accuracy in pressure and adjustment is not critical. A machine no longer acceptable for grinding can be used for brushing.

especially when good edges must be maintained. Cloth wheels are made in various ways; wheels having disks that are cemented together are very hard and used for rough, coarse work, whereas those having sewn disks are made of varying densities by sewing together a larger or smaller number of disks into sections and gluing them.

Wheels in which the disks are held together by thread or metal stitches and which are not stiffened by the use of glue usually require metal side plates to support the canvas disks. Muslin wheels are made from sewed or stapled buffs glued together, but the outer edges of a wheel frequently are left open or free from glue to provide an open face of any desired depth. Wool felt wheels are flexible and resilient, and the density may be varied by sewing two or more disks together and then cementing to form a wheel. Solid felt wheels are quite popular for fine finishing but have little value as general utility wheels. Paper wheels are made from strawboard paper disks and are cemented together under pressure to form a very hard wheel for rough work. Softer wheels are similarly made from felt paper. The "compress" canvas wheel has a cushion of polishing material formed by pieces of leather, canvas, or felt, that are held in a crosswise radial position by two side plates attached to the wheel hub. This cushion of polishing material may be varied in density to suit the requirements; it may be readily shaped to conform to the curvature of the work and this shape can be maintained. Sheepskin polishing wheels and paper wheels are little used.

**Polishing Operations and Abrasives.**—Polishing operations on such parts as chisels, hammers, screwdrivers, wrenches, and similar parts that are given a fine finish but are not plated, usually require four operations, which are "roughing," "dry fining," "greasing," and "coloring." Roughing is frequently regarded as a solid grinding wheel job. Sometimes there are two steps to the greasing operation—rough and fine greasing. For some hardware, such as the cheaper screwdrivers, wrenches, etc., the operations of roughing and dry fining are considered sufficient. For knife blades and cutlery, the roughing operation is performed with solid grinding wheels and the polishing is known as fine or blue glazing, but these terms are never used when referring to the polishing of hardware parts, plumbers' supplies, etc. A term used in finishing German silver, white metal, and similar materials is "sand-buffing," which, in distinction from the ordinary buffing operation that is used only to produce a very high finish, actually removes considerable metal, as in rough polishing or flexible grinding. For sand-buffing, pumice and other abrasive powders are loosely applied.

Aluminum oxide abrasives are widely used for polishing high-tensile-strength metals such as carbon and alloy steels, tough iron, and nonferrous alloys. Silicon carbide abrasives are recommended for hard, brittle substances such as gray iron, cemented carbide tools, and materials of low tensile strength such as brass, aluminum, and copper.

**Buffing Wheels.**—Buffing wheels are manufactured from disks (either whole or pieced) of bleached or unbleached cotton or woolen cloth, and they are used as the agent for carrying abrasive powders, such as tripoli, crocus, rouge, lime, etc., which are mixed with waxes or greases as a bond. There are two main classes of buffs, one of which is known as the "pieced-sewed" buffs, and is made from various weaves and weights of cloth. The other is the "full-disk" buffs, which are made from specially woven material. Bleached cloth is harder and stiffer than unbleached cloth, and is used for the faster cutting buffs. Coarsely woven unbleached cloth is recommended for highly colored work on soft metals, and the finer woven unbleached cloths are better adapted for harder metals. When working at the usual speed, a stiff buff is not suitable for "cutting down" soft metal or for light plated ware, but is used on harder metals and for heavy nickel-plated articles.

**Speed of Polishing Wheels.**—The proper speed for polishing is governed to some extent by the nature of the work, but for ordinary operations, the polishing wheel should have a peripheral speed of about 7500 ft/min (2286 m/min). If run at a lower speed, the work tends to tear the polishing material from the wheel too readily, and the work is not as good in quality. Muslin, felt, or leather polishing wheels having wood or iron centers should be run at peripheral speeds varying from 300 to 7000 ft/min (91–2133 m/min). It is

rarely necessary to exceed 6000 ft/min (1829 m/min), and for most purposes, 4000 ft/min (1219 m/min) is sufficient. If the wheels are kept in good condition, in perfect balance, and are suitably mounted on substantial buffing lathes, they can be used safely at speeds within the limits given. However, manufacturers' recommendations concerning wheel speeds should be followed, where they apply.

**Grain Numbers of Emery.**—The numbers commonly used in designating the different grains of emery, corundum, and other abrasives are 10, 12, 14, 16, 18, 20, 24, 30, 36, 40, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 200, ranging from coarse to fine, respectively. These numbers represent the number of meshes per linear inch in the grading sieve. An abrasive finer than No. 200 is known as "flour" and the degree of fineness is designated by the letters CF, F, FF, FFF, FFFF, and PCF or SF, ranging from coarse to fine. The methods of grading flour-emery adopted by different manufacturers do not exactly agree, the letters differing somewhat for the finer grades. Again, manufacturers' recommendations should be followed.

**Grades of Emery Cloth.**—The coarseness of emery cloth is indicated by letters and numbers corresponding to the grain number of the loose emery used in the manufacture of the cloth. The letters and numbers for grits ranging from fine to coarse are as follows: FF, F, 120, 100, 90, 80, 70, 60, 54, 46, and 40. For large work roughly filed, use coarse cloth such as numbers 46 or 54, and then finer grades to obtain the required polish. If the work has been carefully filed, a good polish can be obtained with numbers 60 and 90 cloth, and a brilliant polish can be achieved by finishing with number 120 and flour-emery.

**Mixture for Cementing Emery Cloth to a Lapping Wheel.**—Many proprietary adhesives are available for application of emery cloth to the periphery of a buffing or lapping wheel, and generally are supplied with application instructions. In the absence of such instructions, clean the wheel thoroughly before applying the adhesive, and then rub the emery cloth down so as to exclude all air from between the surface of the wheel and the cloth.

### Etching and Etching Fluids

**Etching Fluids for Different Metals.**—A common method of etching names or simple designs upon steel is to apply a thin, even coating of beeswax or some similar substance which will resist acid; then mark the required lines or letters in the wax with a sharp-pointed scribe, thus exposing the steel (where the wax has been removed by the scribe point) to the action of an acid, which is finally applied. To apply a very thin coating of beeswax, place the latter in a silk cloth, warm the piece to be etched, and tub the pad over it. Regular coach varnish is also used instead of wax, as a "resist."

An etching fluid ordinarily used for carbon steel consists of nitric acid, 1 part; water, 4 parts. It may be necessary to vary the amount of water, as the exact proportion depends upon the carbon content and whether the steel is hard or soft. For hard steel, use nitric acid, 2 parts; acetic acid, 1 part. For high-speed steel, nickel or brass, use nitro-hydrochloric acid (nitric, 1 part; hydrochloric, 4 parts). For high-speed steel it is sometimes better to add a little more nitric acid. For etching bronze, use nitric acid, 100 parts; muriatic acid, 5 parts. For brass, nitric acid, 16 parts; water, 160 parts. Dissolve 6 parts potassium chlorate in 100 parts of water; then mix the two solutions and apply.

A fluid which may be used either for producing a frosted effect or for deep etching (depending upon the time it is allowed to act) is composed of 1 ounce sulphate of copper (blue vitriol);  $\frac{1}{4}$  ounce alum;  $\frac{1}{2}$  teaspoonful of salt; 1 gill of vinegar, and 20 drops of nitric acid. For aluminum, use a solution composed of alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces; water, 40 ounces (1 ounce = 0.02957 liter).

Various acid-resisting materials are used for covering the surfaces of steel rules etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine and very closely spaced, as on machinists' scales which are divided into hundredths or

sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent any under-cutting of the acid: the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 percent of asphaltum, 25 percent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; then the work is held at a slight angle and the paraffin is poured on its upper surface. The melted paraffin forms a thin protective coating.

### Conversion Coatings and the Coloring of Metals

**Conversion Coatings.**—Conversion coatings are thin, adherent chemical compounds that are produced on metallic surfaces by chemical or electrochemical treatment. These coatings are insoluble, passive, and protective, and are divided into two basic systems: oxides or mixtures of oxides with other compounds, usually chromates or phosphates. Conversion coatings are used for corrosion protection, as an adherent paint base; and for decorative purposes because of their inherent color and because they can absorb dyes and colored sealants.

Conversion coatings are produced in three or four steps. Pretreatment often involves mechanical surface preparation followed by decreasing and/or chemical or electrochemical cleaning or etching. Then thermal, chemical, or electrochemical surface conversion processes take place in acid or alkaline solutions applied by immersion spraying, or brushing. A post treatment follows, which includes rinsing and drying, and may also include sealing or dyeing. If coloring is the main purpose of the coating, then oiling, waxing, or lacquering may be required.

**Passivation of Copper.**—The blue-green patina that forms on copper alloys during atmospheric exposure is a passivated film; i.e., it prevents corrosion. This patina may be produced artificially or its growth may be accelerated by a solution of ammonium sulfate, 6 pounds (2.7 kg); copper sulfate, 3 ounces (85 g); ammonia (technical grade, 0.90 specific gravity), 1.34 fluid ounces (39.6 cc); and water, 6.5 gallons (24.6 liters). This solution is applied as a fine spray to a chemically cleaned surface and is allowed to dry between each of five or six applications. In about 6 hours a patina somewhat bluer than natural begins to develop and continues after exposure to weathering.

Small copper parts can be coated with a passivated film by immersion in or brushing with a solution consisting of the following weight proportions: copper, 30; nitric acid, concentrated, 60; acetic acid (6%), 600; ammonium chloride, 11; and ammonium hydroxide (technical grade, 0.90 specific gravity), 20. To prepare the solution, the copper is dissolved in the nitric acid before the remaining chemicals are added, and the solution is allowed to stand for several days before use. A coating of linseed oil is applied to the treated parts.

**Coloring of Copper Alloys.**—Metals are colored to enhance their appearance, to produce an undercoat for an organic finish, or to reduce light reflection. Copper alloys can be treated to produce a variety of colors, with the final color depending on the base metal composition, the coloring solution's composition, the immersion time, and the operator's skill. Cleaning is an important part of the pretreatment; nitric and sulfuric acid solutions are used to remove oxides and to activate the surface.

The following solutions are used to color alloys that contain 85 percent or more of copper. A dark red color is produced by immersing the parts in molten potassium nitrate, at 1200–1300°F (649–704°C), for up to 20 seconds, followed by a hot water quench. The parts must then be lacquered. A steel black color can be obtained by immersing the parts in a 180°F (82°C) solution of arsenious oxide (white arsenic), 4 ounces (113 g); hydrochloric acid

(1.16 specific gravity), 8 fluid ounces (23.6 cc); and water, 1 gallon (3.9 liters). The parts are immersed until a uniform color is obtained; they are scratch brushed while wet, and then dried and lacquered. A light brown color is obtained using a room-temperature solution of barium sulfate, 0.5 ounce (14g); ammonium carbonate, 0.25 ounce (7g); and water, 1 gallon (3.8 liters).

The following solutions are used to color alloys that contain less than 85 percent copper. To color brass black, parts are placed in an oblique tumbling barrel made of stainless steel and covered with 3 to 5 gallons (11.2 to 19.8 liters) of water. Three ounces (85 g) of copper sulfate and 6 ounces (170 g) of sodium thiosulfate are dissolved in warm water and added to the barrel's contents. After tumbling for 15 to 30 minutes to obtain the finish, the solution is drained from the barrel, and the parts are washed thoroughly in clean water, dried in sawdust or air-blasted and, if necessary, lacquered. To produce a blue-black color, the parts are immersed in a 130–175°F (54–79°C) solution of copper carbonate 1 pound (450 g); ammonium hydroxide (0.89 specific gravity), 1 quart (940 cc); and water, 3 quarts. Excess copper carbonate should be present. The proper color is obtained in 1 minute. To color brass a hardware green, immerse the parts in a 160°F (71°C) solution of ferric nitrate, 1 ounce (28 g); sodium thiosulfate, 6 ounces; and water, 1 gallon. To color brass a light brown, immerse the parts in a 195–212°F (91–100°C) solution of potassium chlorate, 5.5 ounces; nickel sulfate, 2.75 ounces (170 g); copper sulfate, 24 ounces (680 g); and water, 1 gallon (3.8 liters).

*Post treatment:* The treated parts should be scratch brushed to remove any excess or loose deposits. A contrast of colors may be obtained by brushing with a slurry of fine pumice, hand nabbing with an abrasive paste, mass finishing, or buffing to remove the color from the highlights. In order to prolong the life of parts used for outdoor decorative purposes, a clear lacquer should be applied. Parts intended for indoor purposes are often used without additional protection.

**Coloring of Iron and Steel.**—Thin black oxide coatings are applied to steel by immersing the parts to be coated in a boiling solution of sodium hydroxide and mixtures of nitrates and nitrites. These coatings serve as paint bases and, in some cases, as final finishes. When the coatings are impregnated with oil or wax, they furnish fairly good corrosion resistance. These finishes are relatively inexpensive compared to other coatings.

*Phosphate Coatings* are applied to iron and steel parts by reacting them with a dilute solution of phosphoric acid and other chemicals. The surface of the metal is converted into an integral, mildly protective layer of insoluble crystalline phosphate. Small items are coated in tumbling barrels; large items are spray coated on conveyors.

The three types of phosphate coatings in general use are zinc, iron, and manganese. Zinc phosphate coatings vary from light to dark gray. The color depends on the carbon content and pretreatment of the steel's surface, as well as the composition of the solution. Zinc phosphate coatings are generally used as a base for paint or oil, as an aid in cold-working, for increased wear resistance, or for rustproofing. Iron phosphate coatings were the first type to be used; they produce dark gray coatings and their chief application is as a paint base. Manganese phosphate coatings are usually dark gray; however, since they are used almost exclusively as an oil base, for break in and to prevent galling, they become black in appearance. In general, stainless steels and certain alloy steels cannot be phosphated. Most cast irons and alloy steels accept coating with various degrees of difficulty depending on alloy content.

**Anodizing Aluminum Alloys.**—In the anodizing process, the aluminum object to be treated is immersed as the anode in an acid electrolyte, and a direct current is applied. Oxidation of the surface occurs, producing a greatly thickened, hard, porous film of aluminum oxide. The object is then immersed in boiling water to seal the porosity and render the film impermeable. Before sealing, the film can be colored by impregnation with dyes or pigments. Special electrolytes may also be used to produce colored anodic films directly

in the anodizing bath. The anodic coatings are used primarily for corrosion protection and abrasion resistance, and as a paint base.

The three principal types of anodizing processes are: chromic, in which the active agent is chromic acid; sulfuric, in which the active agent is sulfuric acid, and hard anodizing, in which sulfuric acid is used by itself or with additives in a low-temperature electrolyte bath. Most of the anodic coatings range in thickness from 0.2 to 0.7 mil. The hard anodizing process can produce coatings up to 2 mils. The chromic acid coating is less brittle than the sulfuric, and, since the chromic electrolyte does not attack aluminum, it does not present a corrosion problem when it is trapped in crevices. The chromic coating is less resistant to abrasion than the sulfuric, but it cannot be used with alloys containing more than 5 percent copper due to corrosion of the base metal.

*Chemical Conversion Coatings for Aluminum:* Chemical conversion coatings for aluminum alloys are adherent surface layers of low volatility oxide, phosphate, or chromate compounds produced by the reaction of the metal surface with suitable reagents. The conversion coatings are much thinner and softer than anodic coatings but they are less expensive and serve as an excellent paint base.

**Magnesium Alloys.**—Chemical treatment of magnesium alloys is used to provide a paint base and to improve corrosion resistance. The popular conversion “dip” coatings are chrome pickle and dichromate treatments, and they are very thin. Anodic coatings are thicker and harder, and, after sealing, give the same protection against corrosion, although painting is still desirable.

**Titanium Alloys.**—Chemical conversion coatings are used on titanium alloys to improve lubricity by acting as a base for the retention of lubricants. The coatings are applied by immersion, spraying, or brushing. A popular coating bath is an aqueous solution of phosphates, fluorides, and hydrofluoric acid. The coating is composed primarily of titanium and potassium fluorides and phosphates.

### Plating

**Surface Coatings.**—The following is a list of military plating and coating specifications.

*Anodize (Chromic and Sulfuric), MIL-A-8625F:* Conventional Types I, IB, and II anodic coatings are intended to improve surface corrosion protection under severe conditions or as a base for paint systems. Coatings can be colored with a large variety of dyes and pigments. Class 1 is non-dyed; Class 2 dyed. Color is to be specified on the contract. Prior to dyeing or sealing, coatings shall meet the weight requirements.

Type I and IB coatings should be used on fatigue critical components (due to thinness of coating). Type I unless otherwise specified shall not be applied to aluminum alloys with over 5% copper or 7% silicon or total alloying constituents over 7.5%. Type IC is a mineral or mixed mineral/organic acid that anodizes. It provides a non-chromate alternative for Type I and IB coatings where corrosion resistance, paint adhesion, and fatigue resistance are required. Type IIB is a thin sulfuric anodizing coating for use as non-chromate alternatives for Type I and IB coatings where corrosion resistance, paint adhesion, and fatigue resistance are required. Be sure to specify the class of anodic coating and any special sealing requirements.

Types I, IB, IC, and IIB shall have a thickness between 0.00002 and 0.0007 inch (0.5 and 17.78  $\mu\text{m}$ ). Type II shall be between 0.0007 and 0.0010 inch (17.8 and 25.4  $\mu\text{m}$ ).

*Black Chrome, MIL-C-14538C:* A hard, non-reflective, abrasion, heat and corrosion resistant coating approximately 0.0002 in. (5.08  $\mu\text{m}$ ) thick. Provides limited corrosion protection, but added protection can be obtained by specifying underplate such as nickel. Color is a dull dark gray, approaching black and may be waxed or oiled to darken.

Black chromium has poor throwing power, and conforming anodes are necessary for intricate shapes. Apply coating after heat treating and all mechanical operations are performed. Steel parts with hardness in excess of 40 RC (Rockwell C scale) shall be stress

relieved prior to plating by baking one hour or more, 300–500°F (149–260°C) and baked after plating, 375 ± 25°F (190 ± 14°C) for 3 hours.

**Black Oxide Coating, MIL-C-13924C:** A uniform, mostly decorative black coating for ferrous metals used to decrease light reflection. Only very limited corrosion protection under mild corrosion conditions. Black oxide coatings should normally be given a supplementary treatment.

Used for moving parts that cannot tolerate the dimensional change of a more corrosion resistant finish. Use alkaline oxidizing for wrought iron, cast and malleable irons, plain carbon, low alloy steel and corrosion resistant steel alloys. Alkaline-chromite oxidizing may be used on certain corrosion resistant steel alloys tempered at less than 900°F (482°C). Salt oxidizing is suitable for corrosion resistant steel alloys that are tempered at 900°F or higher.

**Cadmium, QQ-P-416F:** Cadmium plating is required to be smooth, adherent, uniform in appearance, free from blisters, pits, nodules, burning, and other defects when examined visually without magnification. Unless otherwise specified in the engineering or procurement documentation, the use of brightening agents in the plating solution to modify luster is prohibited on components with a specified heat treatment of 180 ksi (1241 MPa) minimum tensile strength (or 40 RC) and higher. Either a bright (not caused by brightening agents) or dull luster shall be acceptable. Baking on Types II and III shall be done prior to application of supplementary coatings. For Classes 1, 2, and 3 the minimum thicknesses shall be 0.0005, 0.0003, and 0.0002 inch (12.7, 7.62, and 5.08 μm) respectively.

Type I is to be used as plated. Types II and III require supplementary chromate and phosphate treatment respectively. Chromate treatment required for type II may be colored iridescent bronze to brown including olive drab, yellow and forest green. Type II is recommended for corrosion resistance. Type III is used as a paint base and is excellent for plating stainless steels that are to be used in conjunction with aluminum to prevent galvanic corrosion. For Types II and III the minimum cadmium thickness requirement shall be met after the supplementary treatment.

**Chemical Films, MIL-C-5541E:** The materials that qualify produce coatings that range in color from clear to iridescent yellow or brown. Inspection difficulties may arise with clear coatings because of their invisibility.

Class 1A chemical conversion coatings are intended to provide corrosion prevention when left unpainted as well as to improve adhesion of paint finish systems on aluminum and aluminum alloys. May be used on tanks, tubings, and component structures where paint finishes are not required for the exterior surfaces but are required for the interior surfaces.

Class 3 chemical conversion coatings are intended for use as a corrosive film for electrical and electronic applications where lower resistant contacts are required. The primary difference between Class 1A and Class 3 coating is thickness.

**Chemical Finish: Black, MIL-F-495E:** A uniform black corrosion retardant for copper. Coating has no abrasion resistance. Used to blacken color and reduce gloss on copper-alloy surfaces other than food service and water supply items. Also used as a base for subsequent coatings such as lacquer, varnish, oil, and wax.

**Chrome, QQ-C-320B:** Has excellent hardness, wear resistance, and erosion resistance. In addition chrome has a low coefficient of friction, is resistant to heat, and can be rendered porous for lubrication purposes.

Types I and II have bright and satin appearances respectively.

Class 1 is used as plating for corrosion protection and Class 2, for engineering plating. Class 1 and 2 both shall have a minimum thickness of 0.00001 in. (0.25 μm) on all visible surfaces. If thickness is not specified use 0.002 in (50.8 μm).

Class 2a will be plated to specified dimensions or processed to specified dimensions after plating. Class 2b will be used on parts below 40 RC and subject to static loads or

designed for limited life under dynamic loads. Class 2c will be used on parts below 40 RC and designed for unlimited life under dynamic loads. Class 2d parts have hardness of 40 RC or above, which are subject to static loads or designed for unlimited life under dynamic loads. Class 2e parts have hardness of 40 RC or above, which are designed for unlimited life under dynamic loads.

All coated steel parts having a hardness of 36 RC and higher shall be baked at a minimum of  $375 \pm 25^\circ\text{F}$  ( $190 \pm 14^\circ\text{C}$ ) per the following conditions. With a tensile strength of 160–180 ksi (1103–1241 MPa), the time at temperature will be 3 hr.; at 181–220 ksi (1248–1517 MPa), the time will be 8 hr.; and at 221 ksi (1524 MPa) and above, the time will be 12 hr.

**Copper, MIL-C-14550B:** Has good corrosion resistance when used as an undercoat. A number of copper processes are available, each designed for a specific purpose such as, to improve brightness (to eliminate the need for buffing), high speed (for electro-forming), and fine grain (to prevent case-hardening).

All steel parts having a hardness of 35 RC and higher shall be baked at  $375 \pm 25^\circ\text{F}$  ( $190 \pm 14^\circ\text{C}$ ) for 24 hours, within 4 hours after plating to provide hydrogen embrittlement relief. Plated springs and other parts subject to flexure shall not be flexed prior to baking operations.

Class 0 will have a thickness 0.001 - 0.005 in. (25.4–127  $\mu\text{m}$ ) and is used for heat-treatment stop-off; Class 1 is 0.001 in. (25.4  $\mu\text{m}$ ) and is used to provide carburizing shield, also for plated through printed circuit boards. Class 2 is 0.0005 in. (12.7  $\mu\text{m}$ ) thick and is used as an undercoat for nickel and other platings. Class 3 is 0.0002 in. (5.08  $\mu\text{m}$ ) thick and is used to prevent basis metal migration into tin (prevents poisoning solderability). Class 4 is 0.0001 in. (2.54  $\mu\text{m}$ ) thick.

**Tin Lead, MIL-P-81728A:** It has excellent solderability. Either a matte or bright luster is acceptable. For electronics components, use only parts with a matte or flow brightened finish.

For brightened electronic components, the maximum thickness will be 0.0003 in. (7.62  $\mu\text{m}$ ) Tin 50 to 70% by weight and with a lead remainder, 0.0003-0.0005 in. (7.62–12.7  $\mu\text{m}$ ).

**Magnesium Process, MIL-M-3171C:** Process #1-A chrome pickle treatment for magnesium. Color varies from matte gray to yellow-red. Has only fair corrosion resistance (< 24 hours, 20 percent salt spray resistance).

#7-A dichromate treatment for magnesium. Color varies from light brown to gray depending on alloy. Only fair corrosion resistance (< 24 hours, 20 percent salt spray resistance).

#9-A galvanic anodize treatment for magnesium. Produces a dark brown to black coating. Designed to give a protective film on alloys which do not react to Dow No. 7 treatment. Only fair corrosion resistance (< 24 hours, 20 percent salt spray resistance).

Type/Class	Thickness (inch)	Comments
Type I	Removes metal. (approx. 0.0006 for wrought, less for die castings.) No dimensional change	Used for protecting magnesium during shipment, storage and machining. Can be used as a paint base. NOTE: Must remove Type I coating before applying Type III and Type IV treatments.
Type III	...	Note: precleaning and pickling may result in dimensional changes due to metal loss.
Type IV	No dimensional change	Can be used as a paint base, and is applicable to all magnesium alloys. Used where optical properties (black) are required on close tolerance parts. NOTE: Precleaning and pickling may result in dimensional changes due to metal loss.

**Magnesium Anodic Treatment, MIL-M-45202C:** The HAE anodic finish is probably the hardest coating currently available for magnesium. It exhibits stability at high temperatures and has good dielectric strength. It serves as an excellent paint base. It requires resin seal or paint for maximum corrosion protection.

Coatings range from thin clear to light gray-green, to thick dark-green coatings. The clear coatings are used as a base for subsequent clear lacquers or paints to produce a final appearance similar to clear anodizing on aluminum. The light gray-green coatings are used in most applications which are to be painted. The thick, dark-green coating offers the best combination of abrasion resistance, protective value and paint base characteristics.

Type/Class	Typical Thickness	Comments
Type I, Light coating.		
Class A	0.2 mil	Tan coating (HAE)
Grade 1	...	Without post treatment (dyed)
Grade 2	...	With bifluoride-dichromate post treatment
Class C	0.3 mil	Light green coating (Dow #17)
Type II, Heavy coating		
Class A	1.5 mil	Hard brown coating (HAE)
Grade 1	...	Without post treatment
Grade 3	...	With bifluoride-dichromate post treatment
Grade 4	...	With bifluoride-dichromate post treatment including moist heat aging
Grade 5	...	With double application of bifluoride-dichromate post treatment including moist heat aging.
Class D	1.2 mil	Dark green coating (Dow #17)

*Electroless Nickel, AMS 2404C, AMS 2405B, AMS 2433B:* Is typically used as a coating to provide a hard-ductile, wear-resistant, and corrosion-resistant surface for operation in service up to 1000F, to provide uniform build-up on complex shapes.

AMS 2404C, is deposited directly on the basis metal without a flash coating of other metal, unless otherwise specified. AMS 2405B, is deposited directly on the basis metal except where parts fabricated from corrosion resistant steels or alloys where a "strike" coating of nickel or other suitable metal is required, unless otherwise specified. AMS 2433B, is a type of electroless nickel typically used to enhance the solderability of surfaces, but usage is not limited to such applications. Generally, the plate shall be placed directly on the basis metal. However, aluminum alloys shall be zinc immersion coated per ASTM B253 followed by copper flash; corrosion resistant steels and nickel and cobalt alloys or other basis metals may use a nickel or copper flash undercoat when the purchaser permits.

*Electroless Nickel Preparation:* Parts having a hardness higher than 40 RC and have been machined or ground after heat treatment shall be suitably stress-relieved before cleaning and plating.

After treatment, parts having a hardness of 33 RC and over shall be heated to  $375 \pm 15^\circ\text{F}$  ( $190.5 \pm 8.5^\circ\text{C}$ ) for 3 hours. If such treatment is injurious to the parts, bake at  $275 \pm 15^\circ\text{F}$  ( $135 \pm 8.5^\circ\text{C}$ ) for 4 hours.

*Electroless Nickel, Low-Phosphorous, Note:* If permitted by drawing, the maximum hardness and wear resistance are obtained by heating parts for 30–60 minutes, preferably in an inert atmosphere, at  $750^\circ\text{F} \pm 15^\circ\text{F}$  ( $399 \pm 8^\circ\text{C}$ ) except aluminum parts shall be baked at  $450 \pm 15^\circ\text{F}$  ( $231.5 \pm 8.5^\circ\text{C}$ ) for 4 hours. If such heating is not specified, bake at  $375 \pm 15^\circ\text{F}$  ( $190.5 \pm 8.5^\circ\text{C}$ ) for 3 hours. If this treatment is injurious to parts or assemblies, bake at  $275^\circ\text{F}$  ( $135^\circ\text{C}$ ) for 5 hours.

Plating: nickel-thallium-boron (Electroless Deposition) and nickel-boron (Electroless Deposition)

Preparation: All fabrication-type operations shall be completed.

Post-treatment: Cold-worked or heat-treated parts and aluminum alloys and other parts requiring special thermal treatment shall be post treated as agreed upon by purchaser and vendor. Other plated parts within 4 hours after plating shall be heat treated for 90 ± 10 minutes at  $675^\circ\text{F} \pm 15^\circ\text{F}$  ( $357.5 \pm 8.5^\circ\text{C}$ ).

*Electropolishing, ASTM B912-02 (2018)*: This process electrolytically removes or diminishes scratches, burrs, and unwanted sharp edges from most metals. Electropolishing can be expected to reduce roughness average (Ra) by approximately 10 to 35 percent, with 50 percent improvement possible in some cases. By eliminating microscopic defects and impurities, electropolishing can improve both corrosion resistance and fatigue life of parts.

In addition, this process passivates exposed surfaces, with results superior to chemical passivation methods. Finishes from satin to mirror-bright are produced by controlling time, temperature, or both. Stainless steels are the most commonly electropolished materials, but many metals are good candidates for the process.

Material thickness loss during electropolishing typically is 0.0002–0.0007 in. (5–18  $\mu\text{m}$ ) but may be as much as 0.003 inch (76  $\mu\text{m}$ ). The amount removed depends on desired surface improvement and usually can be controlled to within 0.0001 in. (2.5  $\mu\text{m}$ ). Parts with tight tolerances can be electropolished if process parameters are well planned and controlled.

Parts to be electropolished must be placed on racks. Features such as deep bores may require additional cathodes, and complex parts may need custom process tooling.

*Gold, MIL-G-45204C*: Has a yellow to orange color depending on the proprietary process used. Will range from matte to bright finish depending on basis metal. It has good corrosive resistance and a high tarnish resistance. It provides a low contact resistance, is a good conductor of electricity, and has excellent solderability. If the hardness grade for the gold coating is not specified, Type I shall be furnished at a hardness of Grade A, and Type II furnished at a hardness of Grade C.

For soldering, a thin pure soft gold coating is preferred. A minimum and maximum thickness 0.00005 and 0.00010 inch (1.27 and 2.54  $\mu\text{m}$ ), respectively, shall be plated.

Unless otherwise specified, gold over silver underplate combinations shall be excluded from electronics hardware. Silver or copper plus silver may not be used as an underplate unless required by the item specification. When gold is applied to brass bronze or beryllium copper, or a copper plate or strike, an antidiffusion underplate such as nickel shall be applied.

Type I is 99.7% gold minimum (Grades A, B, or C); Type II is 99.0% (Grades B, C, or D); and Type III is 99.9% (Grade A only).

Grade A is 90 Knoop maximum; Grade B is 91–129 Knoop; Grade C is 130–200 Knoop; and Grade D is 201 Knoop and over.

Class 00 has a thickness of 0.00002 inch (0.5  $\mu\text{m}$ ) minimum; Class 0, 0.00003 inch (0.76  $\mu\text{m}$ ); Class 1, 0.00005 inch (1.3  $\mu\text{m}$ ); Class 2, 0.0001 inch (2.5  $\mu\text{m}$ ); Class 3, 0.0002 inch (5  $\mu\text{m}$ ); Class 4, 0.0003 inch (7.6  $\mu\text{m}$ ); Class 5, 0.0005 inch (12.7  $\mu\text{m}$ ); and Class 6, 0.0015 inch (38.1  $\mu\text{m}$ ).

*Hard Anodize, MIL-A-8625F*: The color will vary from light tan to black depending on alloy and thickness. Can be dyed in darker colors depending on the thickness. Coating penetrates base metal as much as builds up on the surface. The term thickness includes both the buildup and penetration. It provides a very hard ceramic type coating. Abrasion resistance will vary with alloy and thickness of coating. Has good dielectric properties.

Do not seal coatings where the main function is to obtain maximum abrasion or wear resistance. When used for exterior applications requiring corrosion resistance but permitting reduced abrasion, the coating shall be sealed (boiling deionized water or hot 5% sodium dichromate solution, or other suitable chemical solutions).

Type III will have a thickness specified on the contract or applicable drawing. If not specified use a nominal thickness of 0.002 inch (50.8  $\mu\text{m}$ ). Hard coatings may vary in thickness by 0.0005–0.0045 inch (12.7–114.3  $\mu\text{m}$ ).

Class 1 shall not be dyed or pigmented. Class 2 shall be dyed and the color specified on the contract. The process can be controlled to very close thickness tolerances. Where maximum serviceability or special properties are required, consult metal finisher for best alloy choice. Thick coatings, those over 0.004 inch (101  $\mu\text{m}$ ), will tend to break down sharp edges. Can be used as an electrical insulation coating. "Flash" hard anodize may be used instead of conventional anodize for corrosion resistance and may be more economical in conjunction with other hard anodized areas.

*Lubrication, Solid Film MIL-L-46010D*: The Military Plating Specification establishes the requirements for three types of heat cured solid film lubricants that are intended to

reduce wear and prevent galling, corrosion, and seizure of metals. For use on aluminum, copper, steel, stainless steel, titanium, and chromium, and nickel bearing surfaces.

Types I, II, and III have a thicknesses of 0.008 - 0.013 mm. No single reading less than 0.005 mm or greater than 0.018 mm.

Type I has a curing temperature of  $150 \pm 15^\circ\text{C}$  and an endurance life of 250 minutes; Type II,  $204 \pm 15^\circ\text{C}$  and 450 minutes; and Type III is a low volatile organic compound (VOC) content lubricant with cure cycles of  $150 \pm 15^\circ\text{C}$  for 2 hours, or  $204 \pm 15^\circ\text{C}$  for 1 hour with an endurance life of 450 minutes. Color 1 has a natural product color and Color 2 has a black color.

**Nickel, QQ-N-290A:** There is a nickel finish for almost any need. Nickel can be deposited soft, hard-dull, or bright, depending on process used and conditions employed in plating. Thus, hardness can range from 150–500 HV (Vickers). Nickel can be similar to stainless steel in color, or can be a dull gray (almost white) color. Corrosion resistance is a function of thickness. Nickel has a low coefficient of thermal expansion. All steel parts having a tensile strength of 220,000 or greater shall not be a nickel plate without specific approval of procuring agency.

Class 1 is used for corrosion protection. Plating shall be applied over an underplating of copper or yellow brass on zinc and zinc based alloys. In no case, shall the copper underplate be substituted for any part of the specified nickel thickness. Class 2 is used in engineering applications.

Grade A has a thickness of 0.0016 inch (41  $\mu\text{m}$ ); Grade B, 0.0012 in. (30.48  $\mu\text{m}$ ); Grade C, 0.001 in. (25.4  $\mu\text{m}$ ); Grade D, 0.0008 in. (20.32  $\mu\text{m}$ ); Grade E, 0.0006 in. (15.24  $\mu\text{m}$ ); Grade F, 0.0004 in. (10.16  $\mu\text{m}$ ); and Grade G, 0.002 in (50.8  $\mu\text{m}$ ).

**Palladium, MIL-P-45209B:** A gray, dense deposit good for undercoats. Has good wear characteristics, corrosion resistance, catalytic properties, and good conductivity. The thickness shall be 0.00005 in. (1.27  $\mu\text{m}$ ) unless otherwise specified.

Steel springs and other steel parts subject to flexure or repeated impact and of hardness greater than 40 RC are heated to  $375 \pm 25^\circ\text{F}$  ( $190 \pm 14^\circ\text{C}$ ) for 3 hours after plating.

**Chemical Passivation, ASTM A967:** This process aims to improve the corrosion resistance of parts by removing contaminants from surfaces and facilitating formation of a passive oxide layer. Commercial passivation is performed on austenitic, ferritic, and martensitic stainless steels of the 200, 300, and 400 series, and related variants such as precipitation-hardening stainless steels.

Passivation methods included in the standard are nitric acid immersion, citric acid immersion, and electrochemical treatment (See *Electropolishing, ASTM B912-02 (2018)* on page 1644). Nitric acid has long been used for chemical passivation, but safety and environmental concerns have led to the increasing use of citric acid, when possible. Various grades of stainless steel respond to passivation and related chemistry differently, so care must be taken when specifying a process.

The efficacy of chemical passivation depends on the amount of dynamic contact between the fluid and critical part surfaces. For parts with complex geometry, deep bores, or blind holes, the process may require agitation, repositioning, and use of fixtures.

**Phosphate Coating, Light, TT-C-490D:** This specification covers cleaning methods and pretreatment processes.

Methods / Types	Typical Thickness (in.)	Comments
Cleaning Methods		
	...	Light coating for use as a paint base.
Method I	...	Mechanical or abrasive cleaning (for ferrous surfaces only).
Method II	...	Used for solvent cleaning.
Method III	...	Used for hot alkalines (for ferrous surfaces only).
Method IV	...	Emulsion.
Method V	...	Used for alkaline derusting (for ferrous surfaces only).
Method VI	...	Phosphoric acid.

Methods / Types	Typical Thickness (in.)	Comments
Pretreatment Coatings		
Type I	...	Zinc phosphate. Class 1-spray application; Class 2A and 2B-Immersion or Dip application
Type II	...	Aqueous Iron Phosphate
Type III	0.0003 – 0.0005	Organic pretreatment coating
Type IV	...	Non-aqueous iron phosphate
Type V	...	Zinc phosphate

Type I is intended as a general all-purpose pretreatment prior to painting. Type II and IV are intended primarily for use where metal parts are to be formed after painting. Type III is intended for use where size and shape preclude using Type I, II, or IV and where items containing mixed metal components are assembled prior to treatment.

**Phosphate Coating: Heavy, DOD-P-16232-F:** The primary differences are that Type M is used as a heavy manganese phosphate coating for corrosion and wear resistance and Type Z is used as a zinc phosphate coating.

Type M has a thickness from 0.0002-0.0004 in. (5–10  $\mu\text{m}$ ) and Type Z, 0.0002-0.0006 in. (5–15  $\mu\text{m}$ ) Class 1, for both types has a supplementary preservative treatment or coating as specified; Class 2, has a supplementary treatment with lubricating oil; and Class 3, no supplementary treatment is required. For Type M, Class 4 is chemically converted (may be dyed to color as specified) with no supplementary coating or supplementary coating as specified. For Type Z, Class 4 is the same as Class 3.

This coating is for medium and low alloy steels. The coatings range from gray to black in color. The "heavy" phosphate coatings covered by this specification are intended as a base for holding/retaining supplemental coatings which provide the major portion of the corrosion resistance. "Light" phosphate coatings used for a paint base are covered by other specifications. Heavy zinc phosphate coatings may be used when paint and supplemental oil coatings are required on various parts or assemblies.

**Rhodium, MIL-R-46085B:** Rhodium is metallic and similar to stainless steel in color, has excellent corrosion and abrasion resistance, is almost as hard as chromium, and has a high reflectivity. Thicker coatings of Rhodium are very brittle.

Class/Types	Thickness (in.)	Comments
Type I	...	Over nickel, silver, gold, or platinum.
Type II	...	Over other metals, requires nickel undercoat.
Class 1	0.000002	Used on silver for tarnish resistance.
Class 2	0.00001	
Class 3	0.00002	Applications range from electronic to nose cones —
Class 4	0.00010	wherever wear, corrosion resist solderability and reflectivity
Class 5	0.00025	are important.

Parts having a hardness of 33 RC or above shall be baked at 375°F (191°C) for 3 hours prior to cleaning. Parts having hardness of 40 RC and above shall be baked within 4 hours after plating at 375°F (191°C) for 3 hours.

**Silver, QQ-S-365D:** Silver has an increasing use in both decorative and engineering fields, including electrical and electronic fields.

Silver is white matte to very bright in appearance. Has good corrosion resistance, depending on base metal and will tarnish easily. Its hardness varies from about 90–135 BHN (Brinell Hardness Number) depending on process and plating conditions. Solderability is excellent, but decreases with age. Silver is the best conductor of electricity. Has excellent lubricity and smear characteristics for antigalling uses on static seals, bushing, etc. Stress

relief steel parts at a minimum  $375 \pm 25^\circ\text{F}$  ( $190 \pm 14^\circ\text{C}$ ) or more prior to cleaning and plating if they contain or are suspected of having damaging residual tensile stresses.

All types and grades will have a minimum thickness of 0.0005 in. (12.7  $\mu\text{m}$ ) unless otherwise specified. Type I is matte, Type II is semi-bright, and Type III is bright. Grade A has a chromate post-treatment to improve tarnish resistance. In contrast Grade B has no supplementary treatment.

*Tin, MIL-T-10727C:* There are two different types of coating methods used, electrodeposited (based on Use ASTM B545 standard specification for electrodeposited coatings of tin) and hot dipped.

Thickness as specified on drawing (thickness is not part of the specification) is 0.0001–0.0025 inch (2.5–63.5  $\mu\text{m}$ ), flash for soldering; 0.0002–0.0004 inch (5.08–10.16  $\mu\text{m}$ ), to prevent galling and seizing; 0.0003 inch (7.62  $\mu\text{m}$ ) minimum, where corrosion resistance is important; and 0.0002–0.0006 inch (5.08–15.24  $\mu\text{m}$ ) to prevent formation of case during nitriding.

Color is a gray-white color in plated condition. Tin is soft, but very ductile. It has good corrosion resistance, and has excellent solderability. Tin is not good for low temperature applications.

If a bright finish is desired to be used in lieu of fused tin, specify Bright Tin plate. Thickness can exceed that of fused tin and deposit shows excellent corrosion resistance and solderability.

*Vacuum Cadmium, MIL-C-8837B:* Is used primarily to provide corrosion resistance to ferrous parts free from hydrogen contamination and possible embrittlement. Recommended on steels with a strength of  $2.2 \times 10^3$  psi (1517 MPa) or above.

Coating is applied after all machining, brazing, welding, and forming has been completed. Prior to coating, all steel parts shall be stress relieved by baking at  $375 \pm 25^\circ\text{F}$  ( $190 \pm 14^\circ\text{C}$ ) for 3 hours if suspected of having residual tensile stresses. Immediately prior to coating, lightly dry abrasive blast areas are to be coated.

Type I shall be as plated; and Types II and III require supplementary chromate and phosphate treatments respectively.

Classes 1, 2, and 3 have thicknesses of 0.0005, 0.0003, and 0.0002 inch (12.7, 7.62, and 5.08  $\mu\text{m}$ ) respectively.

Cadmium coating shall not be used, if in service, temperature reaches  $450^\circ\text{F}$  ( $232^\circ\text{C}$ ).

A salt spray test is required for type II and is 96 hours.

*Zinc, ASTM B633:* This specification covers requirements for electrodeposited zinc coatings applied to iron or steel articles to protect them from corrosion. It does not cover zinc-coated wire or sheets.

Type I will be as plated; Type II will have colored chromate conversion coatings; Type III will have colorless chromate conversion coatings; and Type IV will have phosphate conversion coatings.

High strength steels (tensile strength over 1700 MPa or 246,500 psi) shall not be electroplated.

Stress relief: All parts with ultimate tensile strength 1000 MPa (145,000 psi) and above at minimum  $190^\circ\text{C}$  ( $374^\circ\text{F}$ ) for 3 hours or more before cleaning and plating.

Hydrogen embrittlement relief: All electroplated parts 1200 MPa (174,000 psi) or higher shall be baked at  $190^\circ\text{C}$  ( $374^\circ\text{F}$ ) for 3 hours or more within 4 hours after electroplating.

Corrosion Resistance Requirements	
Types	Test Period Hr.
II	96
III	12

**Flame Spraying Process**

In this process, the forerunner of which was called the metal spraying process, metals, alloys, ceramics, and cermets are deposited on metallic or other surfaces. The object may be to build up worn or undersize parts, provide wear-resisting or corrosion-resisting surfaces, correct defective castings, etc.

Different types of equipment are available that provide the means of depositing the coatings on the surfaces. In one, wire is fed automatically through the nozzle of the spray gun; then a combustible gas, oxygen and compressed air serve to melt and blow the atomized metal against the surface to be coated. The gas usually used is acetylene but other gases may be used. Any desired thickness of metal may be deposited and the metals include steels, ranging from low to high carbon content, various brass and bronze compositions, babbitt metal, tin, zinc, lead, nickel, copper, and aluminum. The movement of the spray gun, in covering a given surface, is controlled either mechanically or by hand. In enlarging worn or undersize shafts, spindles, etc., it is common practice to clamp the gun in a lathe toolholder and use the feed mechanism to traverse the gun at a uniform rate while the metal is being deposited upon the rotating workpiece. The spraying operation may be followed by machining or grinding to obtain a more precise dimension.

Some typical production applications using the wire process are the coating of automotive exhaust valves, refinishing of transfer ink rollers for the printing industry and the rebuilding of worn truck clutch plates. Other production applications include the metallizing of glass meter box windows, the spraying of aluminum onto cloth gauze to produce electrolytic condenser plates, and the spraying of zinc or copper for coating ceramic insulators.

With another type of equipment, metal, refractory, and ceramic powder are used instead of wire. Ordinarily this equipment employs the use of two gases, oxygen and a fuel gas. The fuel gas is usually acetylene but in some instances hydrogen may be used. When hand-held, a small reservoir supplies the powder to the equipment but a larger reservoir is used for lathe-mounted equipment or for large-scale production work. The four basic types of coating powders used with this equipment are ceramics, oxidation-resistant metals and alloys, self-bonding alloys, and alloys for fused coatings. These powders are used to produce wear-resistant, corrosion-resistant, heat-resistant, and electrically conductive coatings.

Still other equipment employs the use of plasma flame with which vapors of materials are raised to a higher energy level than the ordinary gaseous state. Its use raises the temperature ceiling and provides a controlled atmosphere by permitting employment of an inert or chemically inactive gas so that chemical action, such as oxidation, during the heating and application of the spray material can be controlled. The temperatures that can be obtained with commercially available plasma equipment often exceed 30,000°F (16,650°C) but for most plasma flame spray processes the temperature range of from 12,000 to 20,000°F (6650–11,093°C) is optimum. Plasma flame spray materials include alumina, zirconia, tungsten, molybdenum, tantalum, copper, aluminum, carbides, and nickel-base alloys.

Regardless of the equipment used, what is important is the proper preparation of the surface that will receive the sprayed coating. Preparation activities include the degreasing or solvent cleaning of the surface, undercutting of the surface to provide room for the proper coating thickness, abrasive or grit blasting the substrate to provide a roughened surface, grooving (in the case of flat surfaces) or rough threading (in the case of cylindrical work) the surface to be coated, preheating the base metal. Methods of obtaining a bond between the sprayed material and the substrate are: heating the base, roughening the base, or spraying a "self-bonding" material onto a smooth surface; however, heating alone is seldom used in machine element work as the elevated temperatures required to obtain the proper bond causes problems of warpage and surface corrosion.

## TORQUE AND TENSION IN FASTENERS

**Tightening Bolts.**—Bolts are often tightened by applying torque to the head or nut, which causes the bolt to stretch. The stretching results in bolt tension or preload, which is the force that holds a joint together. Torque is relatively easy to measure with a torque wrench, so it is the most frequently used indicator of bolt tension. Unfortunately, a torque wrench does not measure bolt tension accurately, mainly because it does not take friction into account. The friction depends on bolt, nut, and washer material, surface smoothness, machining accuracy, degree of lubrication, and the number of times a bolt has been installed. Fastener manufacturers often provide information for determining torque requirements for tightening various bolts, accounting for friction and other effects. If this information is not available, the methods described in what follows give general guidelines for determining how much tension should be present in a bolt, and how much torque may need to be applied to arrive at that tension.

High preload tension helps keep bolts tight, increases joint strength, creates friction between parts to resist shear, and improves the fatigue resistance of bolted connections. The recommended preload  $F_i$ , which can be used for either static (stationary) or fatigue (alternating) applications, can be determined from:  $F_i = 0.75 \times A_t \times S_p$  for reusable connections, and  $F_i = 0.9 \times A_t \times S_p$  for permanent connections. In these formulas,  $F_i$  is the bolt preload,  $A_t$  is the tensile stress area of the bolt, and  $S_p$  is the proof strength of the bolt. Determine  $A_t$  from screw-thread tables or by means of formulas in this section. Proof strength  $S_p$  of commonly used ASTM and SAE steel fasteners is given in this section and in the section on metric screws and bolts for those fasteners. For other materials, an approximate value of proof strength can be obtained from:  $S_p = 0.85 \times S_y$ , where  $S_y$  is the yield strength of the material. Soft materials should not be used for threaded fasteners.

Once the required preload has been determined, one of the best ways to be sure that a bolt is properly tensioned is to measure its tension directly with a strain gage. Next best is to measure the change in length (elongation) of the bolt during tightening, using a micrometer or dial indicator. Each of the following two formulas calculates the required change in length of a bolt needed to make the bolt tension equal to the recommended preload. The change in length  $\delta$  of the bolt is given by:

$$\delta = F_i \times \frac{A_d \times l_t + A_t \times l_d}{A_d \times A_t \times E} \quad (1) \quad \text{or} \quad \delta = \frac{F_i \times l}{A \times E} \quad (2)$$

In Equation (1),  $F_i$  is the bolt preload;  $A_d$  is the major-diameter area of the bolt;  $A_t$  is the tensile-stress area of the bolt;  $E$  is the bolt modulus of elasticity;  $l_t$  is the length of the threaded portion of the fastener within the grip; and  $l_d$  is the length of the unthreaded portion of the grip. Here, the grip is defined as the total thickness of the clamped material. Equation (2) is a simplified formula for use when the area of the fastener is constant, and gives approximately the same results as Equation (1). In Equation (2),  $l$  is the bolt length;  $A$  is the bolt area; and  $\delta$ ,  $F_i$ , and  $E$  are as described before.

If measuring bolt elongation is not possible, the torque necessary to tighten the bolt must be estimated. If the recommended preload is known, use the following general relation for the torque:  $T = K \times F_i \times d$ , where  $T$  is the wrench torque,  $K$  is a constant that depends on the bolt material and size,  $F_i$  is the preload, and  $d$  is the nominal bolt diameter. A value of  $K = 0.2$  may be used in this equation for mild-steel bolts in the size range of  $\frac{1}{4}$  to 1 inch (6.35–25.4 mm). For other steel bolts, use the following values of  $K$ : nonplated black finish, 0.3; zinc-plated, 0.2; lubricated, 0.18; cadmium-plated, 0.16. Check with bolt manufacturers and suppliers for values of  $K$  to use with bolts of other sizes and materials.

The proper torque to use for tightening bolts in sizes up to about  $\frac{1}{2}$  inch (12.7 mm) may also be determined by trial. Test a bolt by measuring the amount of torque required to fracture it (use bolt, nut, and washers equivalent to those chosen for the real application). Then, use a tightening torque of about 50 to 60 percent of the fracture torque determined by the test. The tension in a bolt tightened using this procedure will be about 60 to 70 percent of the elastic limit (yield strength) of the bolt material.

The table that follows can be used to get a rough idea of the torque necessary to properly tension a bolt by using the bolt diameter  $d$  and the coefficients  $b$  and  $m$  from the table; the approximate tightening torque  $T$  in ft-lb for the listed fasteners is obtained by solving the equation  $T = 10^{b+m \log d}$ . This equation is approximate, for use with unlubricated fasteners as supplied by the mill. See the notes at the end of the table for more details on using the equation.

**Wrench Torque  $T = 10^{b+m \log d}$  for Steel Bolts, Studs, and Cap Screws (see notes)**

Fastener Grade(s)	Bolt Diameter $d$ (in.)	$m$	$b$
SAE 2, ASTM A307	$\frac{1}{4}$ to 3	2.940	2.533
SAE 3	$\frac{1}{4}$ to 3	3.060	2.775
ASTM A449, A354-BB, SAE 5	$\frac{1}{4}$ to 3	2.965	2.759
ASTM A325 <sup>a</sup>	$\frac{1}{2}$ to $1\frac{1}{2}$	2.922	2.893
ASTM A354-BC	$\frac{1}{4}$ to $\frac{3}{8}$	3.046	2.837
SAE 6, SAE 7	$\frac{1}{4}$ to 3	3.095	2.948
SAE 8	$\frac{1}{4}$ to 3	3.095	2.983
ASTM A354-BD, ASTM A490 <sup>a</sup>	$\frac{3}{8}$ to $1\frac{3}{4}$	3.092	3.057
Socket Head Cap Screws	$\frac{1}{4}$ to 3	3.096	3.014

<sup>a</sup> Values for permanent fastenings on steel structures.

Usage: Values calculated using the preceding equation are for standard, unplated industrial fasteners as received from the manufacturer; for cadmium-plated cap screws, multiply the torque by 0.9; for cadmium-plated nuts and bolts, multiply the torque by 0.8; for fasteners used with special lubricants, multiply the torque by 0.9; for studs, use cap screw values for equivalent grade.

**Preload for Bolts in Loaded Joints.**—The following recommendations are based on MIL-HDBK-60, a subsection of FED-STD-H28, Screw Thread Standards for Federal Service. Generally, bolt preload in joints should be high enough to maintain joint members in contact and in compression. Loss of compression in a joint may result in leakage of pressurized fluids past compression gaskets, loosening of fasteners under conditions of cyclic loading, and reduction of fastener fatigue life.

The relationship between fastener fatigue life and fastener preload is illustrated by Fig. 1. An axially loaded bolted joint in which there is no bolt preload is represented by line OAB, that is, the bolt load is equal to the joint load. When joint load varies between  $P_a$  and  $P_b$ , the bolt load varies accordingly between  $P_{Ba}$  and  $P_{Bb}$ . However, if preload  $P_{B1}$  is applied to the bolt, the joint is compressed and bolt load changes more slowly than the joint load (indicated by line  $P_{B1}A$ , whose slope is less than line OAB) because some of the load is absorbed as a reduction of compression in the joint. Thus, the axial load applied to the joint varies between  $P_{Ba'}$  and  $P_{Bb'}$  as joint load varies between  $P_a$  and  $P_b$ . This condition results in a considerable reduction in cyclic bolt-load variation and thereby increases the fatigue life of the fastener.

**Preload for Bolts in Shear.**—In shear-loaded joints, with members that slide, the joint members transmit shear loads to the fasteners in the joint and the preload must be sufficient to hold the joint members in contact. In joints that do not slide (i.e., there is no relative motion between joint members), shear loads are transmitted within the joint by frictional forces that mainly result from the preload. Therefore, preload must be great enough for the resulting friction forces to be greater than the applied shear force. With high applied shear loads, the shear stress induced in the fastener during application of the preload must also

be considered in the bolted-joint design. Joints with combined axial and shear loads must be analyzed to ensure that the bolts will not fail in either tension or shear.

Fig. 1. Bolt Load in a Joint with Applied Axial Load

**General Application of Preload.**—Preload values should be based on joint requirements, as outlined before. Fastener applications are generally designed for maximum utilization of the fastener material; that is to say, the fastener size is the minimum required to perform its function and a maximum safe preload is generally applied to it. However, if a low-strength fastener is replaced by one of higher strength, for the sake of convenience or standardization, the preload in the replacement should not be increased beyond that required in the original fastener.

To utilize the maximum amount of bolt strength, bolts are sometimes tightened to or beyond the yield point of the material. This practice is generally limited to ductile materials, where there is considerable difference between the yield strength and the ultimate (breaking) strength, because low-ductility materials are more likely to fail due to unexpected overloads when preloaded to yield. Joints designed for primarily static load conditions that use ductile bolts, with a yield strain that is relatively far from the strain at fracture, are often preloaded above the yield point of the bolt material. Methods for tightening up to and beyond the yield point include tightening by feel without special tools, and the use of electronic equipment designed to compare the applied torque with the angular rotation of the fastener and detect changes that occur in the elastic properties of fasteners at yield.

Bolt loads are maintained below the yield point in joints subjected to cyclic loading and in joints using bolts of high-strength material where the yield strain is close to the strain at fracture. For these conditions, the maximum preloads generally fall within the following ranges: 50 to 80 percent of the minimum tensile ultimate strength; 75 to 90 percent of the minimum tensile yield strength or proof load; or 100 percent of the observed proportional limit or onset of yield.

Bolt heads, driving recesses (in socket screws, for example), and the juncture of head and shank must be sufficiently strong to withstand the preload and any additional stress encountered during tightening. There must also be sufficient thread to prevent stripping (generally, at least three fully engaged threads). Materials susceptible to stress-corrosion cracking may require further preload limitations.

**Preload Adjustments.**—Preloads may be applied directly by axial loading or indirectly by turning of the nut or bolt. When preload is applied by turning of nuts or bolts, a torsion load component is added to the desired axial bolt load. This combined loading increases the tensile stress on the bolt. It is frequently assumed that the additional torsion load component dissipates quickly after the driving force is removed and, therefore, can be largely ignored. This assumption may be reasonable for fasteners loaded near to or beyond yield strength, but for critical applications where bolt tension must be maintained below yield, it is important to adjust the axial tension requirements to include the effects of the preload torsion. For this adjustment, the combined tensile stress (*von Mises* stress)  $F_{tc}$  in psi (MPa) can be calculated from the following:

$$F_{tc} = \sqrt{F_t^2 + 3F_s^2} \quad (3)$$

where  $F_t$  is the axial applied tensile stress in psi (MPa), and  $F_s$  is the shear stress in psi (MPa) caused by the torsion load application.

Some of the torsion load on a bolt, acquired when applying a preload, may be released by springback when the wrenching torque is removed. The amount of relaxation depends on the friction under the bolt head or nut. With controlled back turning of the nut, the torsional load may be reduced or eliminated without loss of axial load, reducing bolt stress and lowering creep and fatigue potential. However, calculation and control of the back-turn angle is difficult, so this method has limited application and cannot be used for short bolts because of the small angles involved.

For relatively soft work-hardenable materials, tightening bolts in a joint slightly beyond yield will work-harden the bolt to some degree. Back turning of the bolt to the desired tension will reduce embedment and metal flow and improve resistance to preload loss.

The following formula for use with single-start Unified inch screw threads calculates the combined tensile stress,  $F_{tc}$ :

$$F_{tc} = F_t \sqrt{1 + 3 \left( \frac{1.96 + 2.31\mu}{1 - 0.325P/d_2} - 1.96 \right)^2} \quad (4)$$

Single-start UNJ screw threads in accordance with MIL-S-8879 have a thread stress diameter equal to the bolt pitch diameter. For these threads,  $F_{tc}$  can be calculated from:

$$F_{tc} = F_t \sqrt{1 + 3 \left( \frac{0.637P}{d_2} + 2.31\mu \right)^2} \quad (5)$$

where  $\mu$  is the coefficient of friction between threads,  $P$  is the thread pitch ( $P = 1/n$ , and  $n$  is the number of threads per inch), and  $d_2$  is the bolt-thread pitch diameter in inches. Both Equations (2) and (3) are derived from Equation (1); thus, the quantity within the radical ( $\sqrt{\quad}$ ) represents the proportion of increase in axial bolt tension resulting from preload torsion. In these equations, tensile stress due to torsion load application becomes most significant when the thread friction,  $\mu$ , is high.

**Coefficients of Friction for Bolts and Nuts.**—Table 1 gives examples of coefficients of friction that are frequently used in determining torque requirements. Dry threads, indicated by the words “None added” in the Lubricant column, are assumed to have some residual machine oil lubrication. Table 1 values are not valid for threads that have been cleaned to remove all traces of lubrication because the coefficient of friction of these threads may be very much higher unless a plating or other film is acting as a lubricant.

**Table 1. Coefficients of Friction of Bolts and Nuts**

Bolt/Nut Materials	Lubricant	Coefficient of Friction, $\mu \pm 20\%$
Steel <sup>a</sup>	Graphite in petrolatum or oil	0.07
	Molybdenum disulfide grease	0.11
	Machine oil	0.15
Steel, <sup>a</sup> cadmium-plated	None added	0.12
Steel, <sup>a</sup> zinc-plated	None added	0.17
Steel <sup>b</sup> /bronze	None added	0.15
Corrosion-resistant steel or nickel-base alloys/silver-plated materials	None added	0.14
Titanium/steel <sup>a</sup>	Graphite in petrolatum	0.08
Titanium	Molybdenum disulfide grease	0.10

<sup>a</sup>"Steel" includes carbon and low-alloy steels but not corrosion-resistant steels.

Where two materials are separated by a slash (/), either may be the bolt material; the other is the nut material.

**Preload Relaxation.**—Local yielding, due to excess bearing stress under nuts and bolt heads (caused by high local spots, rough surface finish, and lack of perfect squareness of bolt and nut bearing surfaces), may result in preload relaxation after preloads are first applied to a bolt. Bolt tension also may be unevenly distributed over the threads in a joint, so thread deformation may occur, causing the load to be redistributed more evenly over the threaded length. Preload relaxation occurs over a period of minutes to hours after the application of the preload, so retightening after several minutes to several days may be required. As a general rule, an allowance for loss of preload of about 10 percent may be made when designing a joint.

Increasing the resilience of a joint will make it more resistant to local yielding, that is, there will be less loss of preload due to yielding. When practical, a joint-length to bolt-diameter ratio of 4 or more is recommended; for example, a 1/4-inch (6.35 mm) bolt and a 1-inch (25.4 mm) or greater joint length. Through bolts, far-side tapped holes, spacers, and washers can be used in the joint design to improve the joint-length to bolt-diameter ratio.

Over an extended period of time, preload may be reduced or completely lost due to vibration; temperature cycling, including changes in ambient temperature; creep; joint load; and other factors. An increase in the initial bolt preload or the use of thread-locking methods that prevent relative motion of the joint may reduce the problem of preload relaxation due to vibration and temperature cycling. Creep is generally a high-temperature effect, although some loss of bolt tension can be expected even at normal temperatures. Harder materials and creep-resistant materials should be considered if creep is a problem or high-temperature service of the joint is expected.

Mechanical properties of fastener materials vary significantly with temperature, and allowance must be made for these changes when ambient temperatures range beyond 30 to 200°F (–1 to 93°C). Mechanical properties that may change include tensile strength, yield strength, and modulus of elasticity. Where bolts and flange materials are generically dissimilar, such as carbon steel and corrosion-resistant steel, or steel and brass, differences in thermal expansion that might cause preload to increase or decrease must be taken into consideration.

**Methods of Applying and Measuring Preload.**—Depending on the tightening method, the accuracy of preload application may vary up to 25 percent or more. Care must be taken to maintain the calibration of torque and load indicators. Allowance should be made for uncertainties in bolt load to prevent overstressing the bolts or failing to obtain sufficient preload. The method of tensioning should be based on required accuracy and relative costs.

The most common methods of bolt tension control are indirect because it is usually difficult or impractical to measure the tension produced in each fastener during assembly. Table 2 lists the most frequently used methods of applying bolt preload and the approximate accuracy of each method. For many applications, fastener tension can be satisfactorily controlled within certain limits by applying a known torque to the fastener. Laboratory tests have shown that whereas a satisfactory torque tension relationship can be established for a given set of conditions, a change of any of the variables, such as fastener material, surface finish, and the presence or absence of lubrication, may severely alter the relationship. Because most of the applied torque is absorbed in intermediate friction, a change in the surface roughness of the bearing surfaces or a change in the lubrication will drastically affect the friction and thus the torque tension relationship. Regardless of the method or accuracy of applying the preload, tension will decrease in time if the bolt, nut, or washer seating faces deform under load, if the bolt stretches or creeps under tensile load, or if cyclic loading causes relative motion between joint members.

**Table 2. Accuracy of Bolt Preload Application Methods**

Method	Accuracy	Method	Accuracy
By feel	±35%	Computer-controlled wrench	
Torque wrench	±25%	below yield (turn-of-nut)	±15%
Turn-of-nut	±15%	yield-point sensing	±8%
Preload indicating washer	±10%	Bolt elongation	±3–5%
Strain gages	±1%	Ultrasonic sensing	±1%

Tightening methods using power drivers are similar in accuracy to equivalent manual methods.

**Elongation Measurement.**—Bolt elongation is directly proportional to axial stress when the applied stress is within the elastic range of the material. If both ends of a bolt are accessible, a micrometer measurement of bolt length made before and after the application of tension will ensure the required axial stress is applied. The elongation  $\delta$  in inches (mm) can be determined from the formula  $\delta = F_t \times L_B \div E$ , given the required axial stress  $F_t$  in psi (MPa), the bolt modulus of elasticity  $E$  in psi (MPa), and the effective bolt length  $L_B$  in inches (mm).  $L_B$ , as indicated in Fig. 2, includes the contribution of bolt area and ends (head and nut) and is calculated from:

$$L_B = \left(\frac{d_{ts}}{d}\right)^2 \times \left(L_s + \frac{H_B}{2}\right) + L_J - L_s + \frac{H_N}{2} \quad (6)$$

where  $d_{ts}$  is the thread stress diameter,  $d$  is the bolt diameter,  $L_s$  is the unthreaded length of the bolt shank,  $L_J$  is the overall joint length,  $H_B$  is the height of the bolt head, and  $H_N$  is the height of the nut.

Fig. 2. Effective Length Applicable in Elongation Formulas

The micrometer method is most easily and accurately applied to bolts that are essentially uniform throughout the bolt length, that is, threaded along the entire length or that have only a few threads in the bolt grip area. If the bolt geometry is complex, such as tapered or stepped, the elongation is equal to the sum of the elongations of each section with allowances made for transitional stresses in bolt head height and nut engagement length.

The direct method of measuring elongation is practical only if both ends of a bolt are accessible. Otherwise, if the diameter of the bolt or stud is sufficiently large, an axial hole can be drilled, as shown in Fig. 3, and a micrometer depth gage or other means used to determine the change in length of the hole as the fastener is tightened. A similar method uses a special indicating bolt that has a blind axial hole containing a pin fixed at the bottom. The pin is usually made flush with the bolt head surface before load application. As the bolt is loaded, the elongation causes the end of the pin to move below the reference surface. The displacement of the pin can be converted directly into unit stress by means of a calibrated gage. In some bolts of this type, the pin is set a distance above the bolt so that the pin is flush with the bolt head when the required axial load is reached.

Fig. 3. Hole Drilled to Measure Elongation When One End of Stud or Bolt Is Not Accessible

The *ultrasonic method* of measuring elongation uses a sound pulse, generated at one end of a bolt, that travels the length of a bolt, bounces off the far end, and returns to the sound generator in a measured period of time. The time required for the sound pulse to return depends on the length of the bolt and the speed of sound in the bolt material. The speed of sound in the bolt depends on the material, the temperature, and the stress level. The ultrasonic measurement system can compute the stress, load, or elongation of the bolt at any time by comparing the pulse travel time in the loaded and unstressed conditions. In a similar method, measuring round-trip transit times of longitudinal and shear wave sonic pulses allows calculation of tensile stress in a bolt without consideration of bolt length. This method permits checking bolt tension at any time and does not require a record of the ultrasonic characteristics of each bolt at zero load.

To ensure consistent results, the ultrasonic method requires that both ends of the bolt be finished square to the bolt axis. The accuracy of ultrasonic measurement compares favorably with strain gage methods, but is limited by sonic velocity variations between bolts of the same material and by corrections that must be made for unstressed portions of the bolt heads and threads.

The *turn-of-nut method* applies preload by turning a nut through an angle that corresponds to a given elongation. The elongation of the bolt is related to the angle turned by the formula:  $\delta_B = \theta \times l \div 360$ , where  $\delta_B$  is the elongation in inches (mm),  $\theta$  is the turn angle of the nut in degrees, and  $l$  is the lead of the thread helix in inches (mm). Substituting  $F_t \times L_B \div E$  for elongation  $\delta_B$  in this equation gives the turn-of-nut angle required to attain preload  $F_t$ :

$$\theta = 360 \frac{F_t L_B}{EI} \quad (7)$$

where  $L_B$  is given by Equation (6), and  $E$  is the modulus of elasticity.

Accuracy of the turn-of-nut method is affected by elastic deformation of the threads, by roughness of the bearing surfaces, and by the difficulty of determining the starting point for measuring the angle. The starting point is usually found by tightening the nut enough to seat the contact surfaces firmly, and then loosening it just enough to release

any tension and twisting in the bolt. The nut-turn angle will be different for each bolt size, length, material, and thread lead. The preceding method of calculating the nut-turn angle also requires elongation of the bolt without a corresponding compression of the joint material. The turn-of-nut method, as just outlined, is not valid for joints with compressible gaskets or other soft material, or if there is a significant deformation of the nut and joint material relative to that of the bolt. The nut-turn angle would then have to be determined empirically using a simulated joint and a tension-measuring device.

The Japanese Industrial Standards (JIS) Handbook, *Fasteners and Screw Threads*, indicates that the turn-of-nut tightening method is applicable in both elastic and plastic region tightening. Refer to JIS B 1083 for more detail on this subject.

Heating causes a bolt to expand at a rate proportional to its coefficient of expansion. When a hot bolt and nut are fastened in a joint and cooled, the bolt shrinks and tension is developed. The temperature necessary to develop an axial stress,  $F_t$  (when the stress is below the elastic limit) can be found as follows:

$$T = \frac{F_t}{Ee} + T_o \quad (8)$$

In this equation,  $T$  is the temperature in degrees Fahrenheit needed to develop the axial tensile stress  $F_t$  in psi,  $E$  is the bolt material modulus of elasticity in psi,  $e$  is the coefficient of linear expansion in in/in-°F, and  $T_o$  is the temperature in degrees Fahrenheit to which the bolt will be cooled.  $T - T_o$  is, therefore, the temperature change of the bolt. In finite-element simulations, heating and cooling are frequently used to preload mesh elements in tension or compression. Equation (8) can be used to determine required temperature changes in such problems.

*Example:* A tensile stress of 40,000 psi is required for a steel bolt in a joint operating at 70°F. If  $E$  is  $30 \times 10^6$  psi and  $e$  is  $6.2 \times 10^{-6}$  in/in-°F, determine the temperature of the bolt needed to develop the required stress on cooling.

$$T = \frac{40,000}{(30 \times 10^6)(6.2 \times 10^{-6})} + 70 = 285^\circ\text{F}$$

In practice, the bolt is heated slightly above the required temperature (to allow for some cooling while the nut is screwed down) and the nut is tightened snugly. Tension develops as the bolt cools. In another method, the nut is tightened snugly on the bolt, and the bolt is heated in place. When the bolt has elongated sufficiently, as indicated by inserting a thickness gage between the nut and the bearing surface of the joint, the nut is tightened. The bolt develops the required tension as it cools; however, preload may be lost if the joint temperature increases appreciably while the bolt is being heated.

**Calculating Thread Tensile-Stress Area.**—The tensile-stress area for Unified threads is based on a diameter equivalent to the mean of the pitch and minor diameters. The pitch and the minor diameters for Unified screw threads can be found from the major (nominal) diameter,  $d$ , and the screw pitch,  $P = 1/n$ , where  $n$  is the number of threads per inch, by use of the following formulas: the pitch diameter  $d_p = d - 0.649519 \times P$ ; the minor diameter  $d_m = d - 1.299038 \times P$ . The tensile stress area,  $A_s$ , for Unified threads can then be found as follows:

$$A_s = \frac{\pi}{4} \left( \frac{d_m + d_p}{2} \right)^2 \quad (9)$$

UNJ threads in accordance with MIL-S-8879 have a tensile thread area that is usually considered to be at the basic bolt pitch diameter; for these threads,  $A_s = (\pi d_p^2)/4$ . The tensile stress area for Unified screw threads is smaller than this area, so the required tightening torque for UNJ threaded bolts is greater than for an equally stressed Unified threaded bolt in an equivalent joint. To convert tightening torque for a Unified fastener to the equivalent torque required with a UNJ fastener, use the following relationship:

$$\text{UNJ}_{\text{torque}} = \left( \frac{d \times n - 0.6495}{d \times n - 0.9743} \right)^2 \times \text{Unified}_{\text{torque}} \quad (10)$$

where  $d$  is the basic thread major diameter, and  $n$  is the number of threads per inch.

The tensile stress area for metric threads is based on a diameter equivalent to the mean of the pitch diameter and a diameter obtained by subtracting  $1/6$  the height of the fundamental thread triangle from the external-thread minor diameter. The Japanese Industrial Standard JIS B 1082 (see also ISO 898/1) defines the stress area of metric screw threads as follows:

$$A_s = \frac{\pi}{4} \left( \frac{d_2 + d_3}{2} \right)^2 \quad (11)$$

In Equation (11),  $A_s$  is the stress area of the metric screw thread in  $\text{mm}^2$ ;  $d_2$  is the pitch diameter of the external thread in mm, given by  $d_2 = d - 0.649515 \times P$ ; and  $d_3$  is defined by  $d_3 = d_1 - H/6$ . Here,  $d$  is the nominal bolt diameter;  $P$  is the thread pitch;  $d_1 = d - 1.082532 \times P$  is the minor diameter of the external thread in mm; and  $H = 0.866025 \times P$  is the height of the fundamental thread triangle. Substituting the formulas for  $d_2$  and  $d_3$  into Equation (11) results in  $A_s = 0.7854(d - 0.9382P)^2$ .

The stress area,  $A_s$ , of Unified threads in  $\text{mm}^2$  is given in JIS B 1082 as:

$$A_s = 0.7854 \left( d - \frac{0.9743}{n} \times 25.4 \right)^2 \quad (12)$$

**Relation between Torque and Clamping Force.**—The Japanese Industrial Standard JIS B 1803 defines fastener tightening torque  $T_f$  as the sum of the bearing surface torque  $T_w$  and the shank (threaded) portion torque  $T_s$ . The relationship between the applied tightening torque and bolt preload  $F_f$  is as follows:  $T_f = T_s + T_w = K \times F_f \times d$ . In the preceding,  $d$  is the nominal diameter of the screw thread, and  $K$  is the torque coefficient defined as follows:

$$K = \frac{1}{2d} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' + \mu_w D_w \right) \quad (13)$$

where  $P$  is the screw thread pitch;  $\mu_s$  is the coefficient of friction between threads;  $d_2$  is the pitch diameter of the thread;  $\mu_w$  is the coefficient of friction between bearing surfaces;  $D_w$  is the equivalent diameter of the friction torque bearing surfaces; and  $\alpha'$  is the flank angle at the ridge perpendicular section of the thread ridge, defined by  $\tan \alpha' = \tan \alpha \cos \beta$ , where  $\alpha$  is the thread half angle ( $30^\circ$ , for example), and  $\beta$  is the thread helix, or lead, angle.  $\beta$  can be found from  $\tan \beta = l \div 2\pi r$ , where  $l$  is the thread lead, and  $r$  is the thread radius (i.e., one-half the nominal diameter  $d$ ). When the bearing surface contact area is circular,  $D_w$  can be obtained as follows:

$$D_w = \frac{2}{3} \times \frac{D_o^3 - D_i^3}{D_o^2 - D_i^2} \quad (14)$$

where  $D_o$  and  $D_i$  are the outside and inside diameters, respectively, of the bearing surface contact area.

The torques attributable to the threaded portion of a fastener,  $T_s$ , and bearing surfaces of a joint,  $T_w$ , are as follows:

$$T_s = \frac{F_f}{2} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' \right) \quad (15) \quad T_w = \frac{F_f}{2} \mu_w D_w \quad (16)$$

where  $F_f$ ,  $P$ ,  $\mu_s$ ,  $d_2$ ,  $\alpha'$ ,  $\mu_w$ , and  $D_w$  are as previously defined.

Table 3 and Table 4 give values of torque coefficient  $K$  for coarse- and fine-pitch metric screw threads corresponding to various values of  $\mu_s$  and  $\mu_w$ . When a fastener material yields according to the shearing-strain energy theory, the torque corresponding to the yield clamping force (see Fig. 4) is  $T_{fy} = K \times F_{fy} \times d$ , where the yield clamping force  $F_{fy}$  is given by:

$$F_{fy} = \frac{\sigma_y A_s}{\sqrt{1 + 3 \left[ \frac{2}{d_A} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' \right) \right]^2}} \quad (17)$$

**Table 3. Torque Coefficients  $K$  for Metric Hexagon Head Bolt and Nut Coarse Screw Threads**

Values in the table are average values of torque coefficient calculated using: Equations (13) and (14) for  $K$  and  $D_w$ ; diameters  $d$  of 4, 5, 6, 8, 10, 12, 16, 20, 24, 30, and 36 mm; and selected corresponding pitches  $P$  and pitch diameters  $d_2$  according to JIS B 0205 (ISO 724) thread standard. Dimension  $D_f$  was obtained for a Class 2 fit without chamfer from JIS B 1001, Diameters of Clearance Holes and Counterbores for Bolts and Screws (equivalent to ISO 273-1979). The value of  $D_o$  was obtained by multiplying the reference dimension from JIS B 1002, width across the flats of the hexagon head, by 0.95.

0.40	0.279	0.291	0.303	0.321	0.351	0.381	0.410	0.440	0.470	0.500	
0.45	0.306	0.318	0.330	0.348	0.378	0.408	0.437	0.467	0.497	0.527	

Values in the table are average values of torque coefficient calculated using Equations (13) and (14) for  $K$  and  $D_w$ ; diameters  $d$  of 8, 10, 12, 16, 20, 24, 30, and 36 mm; and selected respective pitches  $P$  and pitch diameters  $d_2$  according to JIS B 0207 thread standard (ISO 724). Dimension  $D_f$  was obtained for a Class 1 fit without chamfer from JIS B 1001, Diameters of Clearance Holes and Counterbores for Bolts and Screws (equivalent to ISO 273-1979). The value of  $D_o$  was obtained by multiplying the reference dimension from JIS B 1002 (small type series), width across the flats of the hexagon head, by 0.95.

In Equation (17),  $\sigma_y$  is the yield point or proof stress of the bolt,  $A_s$  is the stress area of the thread, and  $d_A = (4A_s/\pi)^{1/2}$  is the diameter of a circle having an area equal to the stress area of the thread. The other variables have been identified previously.

*Example:* Find the torque required to tighten a 10-mm coarse-threaded ( $P = 1.5$ ) grade 8.8 bolt to yield assuming that both the thread- and bearing-friction coefficients are 0.12.

*Solution:* From Equation (17), calculate  $F_{fy}$ , and then solve  $T_{fy} = KF_{fy}d$  to obtain the torque required to stress the bolt to the yield point.

$$\sigma_y = 640 \text{ N/mm}^2 \text{ (MPa) (minimum, based on 8.8 grade rating)}$$

$$A_s = 0.7854(10 - 0.9382 \times 1.5)^2 = 57.99 \text{ mm}^2$$

$$d_A = (4A_s/\pi)^{1/2} = 8.6 \text{ mm}$$

$$d_2 = 9.026 \text{ mm (see JIS B 0205 or ISO 724)}$$

Find  $\alpha'$  from  $\tan \alpha' = \tan \alpha \cos \beta$  using:

$$\alpha = 30^\circ; \tan \beta = l + 2\pi r; l = P = 1.5; \text{ and } r = d + 2 = 5 \text{ mm}$$

$$\tan \beta = 1.5 \div 10\pi = 0.0477, \text{ therefore } \beta = 2.73^\circ$$

$$\tan \alpha' = \tan \alpha \cos \beta = \tan 30^\circ \times \cos 2.73^\circ = 0.577, \text{ and } \alpha' = 29.97^\circ$$

Solving Equation (17) gives the yield clamping force as follows:

$$F_{fy} = \frac{640 \times 57.99}{\sqrt{1 + 3 \left[ \frac{2}{8.6} \left( \frac{1.5}{\pi} + 0.12 \times 9.026 \times \sec 29.97^\circ \right) \right]^2}} = 30,463 \text{ N}$$

$K$  can be determined from Table 3 (coarse thread) and Table 4 (fine thread) or from Equations (13) and (14). From Table 3, for  $\mu_s$  and  $\mu_w$  equal to 0.12,  $K = 0.164$ . The yield-point tightening torque can then be found from  $T_{fy} = K \times F_{fy} \times d = 0.164 \times 30,463 \times 10 = 49.9 \times 10^3 \text{ N}\cdot\text{mm} = 49.9 \text{ N}\cdot\text{m}$ .

**Obtaining Torque and Friction Coefficients.**—Given suitable test equipment, the torque coefficient  $K$  and friction coefficients between threads  $\mu_s$  or between bearing surfaces  $\mu_w$  can be determined experimentally as follows: Measure the value of the axial tightening

tension and the corresponding tightening torque at an arbitrary point in the 50 to 80 percent range of the bolt yield point or proof stress (for steel bolts, use the minimum value of the yield point or proof stress multiplied by the stress area of the bolt). Repeat this test several times and average the results. The tightening torque may be considered as the sum of the torque on the threads plus the torque on the bolt head- or nut-to-joint bearing surface. The torque coefficient can be found from  $K = T_f \div F_f \times d$ , where  $F_f$  is the measured axial tension, and  $T_f$  is the measured tightening torque.

To measure the coefficient of friction between threads or bearing surfaces, obtain the total tightening torque and that portion of the torque due to the thread or bearing surface friction. If only tightening torque and the torque on the bearing surfaces can be measured, then the difference between these two measurements can be taken as the thread-tightening torque. Likewise, if only the tightening torque and threaded-portion torque are known, the torque due to bearing can be taken as the difference between the known torques. The coefficients of friction between threads and bearing surfaces, respectively, can be obtained from the following:

$$\mu_s = \frac{2T_s \cos \alpha'}{d_2 F_f} - \cos \alpha' \tan \beta \quad (18) \qquad \mu_w = \frac{2T_w}{D_w F_f} \quad (19)$$

As before,  $T_s$  is the torque attributable to the threaded portion of the screw,  $T_w$  is the torque due to bearing,  $D_w$  is the equivalent diameter of friction torque on bearing surfaces according to Equation (14), and  $F_f$  is the measured axial tension.

**Torque-Tension Relationships.**—Torque is usually applied to develop an axial load in a bolt. To achieve the desired axial load in a bolt, the torque must overcome friction in the threads and friction under the nut or bolt head. In Fig. 5, the axial load  $P_B$  is a component of the normal force developed between threads. The normal-force component perpendicular to the thread helix is  $P_{N\beta}$  and the other component of this force is the torque load  $P_B \tan \beta$  that is applied in tightening the fastener. Assuming the turning force is applied at the pitch diameter of the thread, the torque  $T_1$  needed to develop the axial load is  $T_1 = P_B \times \tan \beta \times d_2/2$ . Substituting  $\tan \beta = l \div \pi d_2$  into the previous expression gives  $T_1 = P_B \times l \div 2\pi$ .

Fig. 5. Free Body Diagram of Thread Helix Forces

Fig. 6. Thread Friction Force

In Fig. 6, the normal-force component perpendicular to the thread flanks is  $P_{N\alpha}$ . With a coefficient of friction  $\mu_1$  between the threads, the friction load is equal to  $\mu_1 P_{N\alpha}$  or  $\mu_1 P_B \div \cos \alpha$ . Assuming the force is applied at the pitch diameter of the thread, the torque  $T_2$  to overcome thread friction is given by:

$$T_2 = \frac{d_2 \mu_1 P_B}{2 \cos \alpha} \quad (20)$$

With the coefficient of friction  $\mu_2$  between a nut or bolt-head pressure face and a component face, as in Fig. 7, the friction load is equal to  $\mu_2 P_B$ . Assuming the force is applied midway between the nominal (bolt) diameter  $d$  and the pressure-face diameter  $b$ , the torque  $T_3$  to overcome the nut or bolt underhead friction is:

$$T_3 = \frac{d+b}{4} \mu_2 P_B \quad (21)$$

The total torque,  $T$ , required to develop axial bolt load,  $P_B$ , is equal to the sum of the torques  $T_1$ ,  $T_2$ , and  $T_3$  as follows:

$$T = P_B \left( \frac{l}{2\pi} + \frac{d_2 \mu_1}{2 \cos \alpha} + \frac{(d+b) \mu_2}{4} \right) \quad (22)$$

For a fastener system with  $60^\circ$  threads,  $\alpha = 30^\circ$  and  $d_2$  is approximately  $0.92d$ . If no loose washer is used under the rotated nut or bolt head,  $b$  is approximately  $1.5d$  and Equation (22) reduces to:

$$T = P_B [0.159 \times l + d(0.531\mu_1 + 0.625\mu_2)] \quad (23)$$

In addition to the conditions of Equation (23), if the thread and bearing friction coefficients,  $\mu_1$  and  $\mu_2$ , are equal (which is not necessarily so), then  $\mu_1 = \mu_2 = \mu$ , and the previous equation reduces to:

$$T = P_B (0.159l + 1.156\mu d) \quad (24)$$

*Example:* Estimate the torque required to tighten a UNC  $\frac{1}{2}$ -13 grade 8 steel bolt to a pre-load equivalent to 55 percent of the minimum tensile bolt strength. Assume that the bolt is unlubed and both the thread and bearing friction coefficients equal 0.15.

*Solution:* The minimum tensile strength for SAE grade 8 bolt material is 150,000 psi (from page 1666). To use Equation (24), find the stress area of the bolt using Equation (9) with  $P = 1/13$ ,  $d_m = d - 1.2990P$ , and  $d_p = d - 0.6495P$ , and then calculate the necessary pre-load,  $P_B$ , and the applied torque,  $T$ .

$$A_s = \frac{\pi}{4} \left( \frac{0.4500 + 0.4001}{2} \right)^2 = 0.1419 \text{ in.}^2$$

$$P_B = \sigma_{\text{allow}} \times A_s = 0.55 \times 150000 \times 0.1419 = 11707 \text{ lb}_f$$

$$T = 11707 \left( \frac{0.159}{13} + 1.156 \times 0.15 \times 0.500 \right) = 1158 \text{ lb-in.} = 96.51 \text{ lb-ft}$$

Fig. 7. Nut or Bolt Head Friction Force

**Grade Marks and Material Properties for Bolts and Screws.**—Bolts, screws, and other fasteners are marked on the head with a symbol that identifies the grade of the fastener. The grade specification establishes the minimum mechanical properties that the fastener must meet. Additionally, industrial fasteners must be stamped with a registered head mark that identifies the manufacturer. The grade identification table identifies the grade markings and gives mechanical properties for some commonly used ASTM and SAE steel fasteners. Metric fasteners are identified by property grade marks, which are specified in ISO and SAE standards. These marks are discussed with metric fasteners.

#### Grade Identification Marks and Mechanical Properties of Bolts and Screws

Identifier	Grade	Size (in.)	Min. Strength (10 <sup>3</sup> psi)			Material & Treatment
			Proof	Tensile	Yield	
A	SAE Grade 1	¼ to 1½	33	60	36	1
	ASTM A307	¼ to 1½	33	60	36	3
	SAE Grade 2	¼ to ¾	55	74	57	1
		¾ to 1½	33	60	36	
B	SAE Grade 4	¼ to 1½	65	115	100	2, a
	SAE Grade 5, ASTM A449	¼ to 1	85	120	92	2, b
	ASTM A449	1½ to 1½	74	105	81	
C	SAE Grade 5.2	1¾ to 3	55	90	58	4, b
		¼ to 1	85	120	92	
D	ASTM A325, Type 1	½ to 1	85	120	92	2, b
		1½ to 1½	74	105	81	
E	ASTM A325, Type 2	½ to 1	85	120	92	4, b
		1½ to 1½	74	105	81	
F	ASTM A325, Type 3	½ to 1	85	120	92	5, b
		1½ to 1½	74	105	81	
G	ASTM A354, Grade BC	¼ to 2½	105	125	109	5, b
		2½ to 4	95	115	99	
H	SAE Grade 7	¼ to 1½	105	133	115	7, b
I	SAE Grade 8	¼ to 1½	120	150	130	7, b
	ASTM A354, Grade BD	¼ to 2½	120	150	130	6, b
		2½ to 4	105	140	115	
J	SAE Grade 8.2	¼ to 1	120	150	130	4, b
K	ASTM A490, Type 1	½ to 1½	120	150	130	6, b
L	ASTM A490, Type 3					5, b

Material Steel: 1—low or medium carbon; 2—medium carbon; 3—low carbon; 4—low-carbon martensite; 5—weathering steel; 6—alloy steel; 7—medium-carbon alloy. Treatment: a—cold drawn; b—quench and temper.

**Detecting Counterfeit Fasteners.**—Fasteners that have markings identifying them as belonging to a specific grade or property class are counterfeit if they do not meet the standards established for that class. Counterfeit fasteners may break unexpectedly at smaller loads than expected. Generally, these fasteners are made from the wrong material or they are not properly strengthened during manufacture. Either way, counterfeit fasteners can lead to dangerous failures in assemblies. The law now requires testing of fasteners used in some critical applications. Detection of counterfeit fasteners is difficult because the counterfeits look genuine. The only sure way to determine if a fastener meets its specification is to test it. However, reputable distributors will assist in verifying the authenticity of the fasteners they sell. For important applications, fasteners can be checked to determine whether they perform according to the standard. Typical laboratory checks used to detect fakes include testing hardness, elongation, and ultimate loading, and a variety of chemical tests.

**Mechanical Properties and Grade Markings of Nuts.**—Three grades of hex and square nuts designated Grades 2, 5, and 8 are specified by the SAE J995 standard covering nuts in the  $\frac{1}{4}$ - to  $1\frac{1}{2}$ -inch diameter range. Grades 2, 5, and 8 nuts roughly correspond to the SAE specified bolts of the same grade. Additional specifications are given for miscellaneous nuts such as hex jam nuts, hex slotted nuts, heavy hex nuts, etc. Generally speaking, use nuts of a grade equal to or greater than the grade of the bolt being used. Grade 2 nuts are not required to be marked, however, all Grades 5 and 8 nuts in the  $\frac{1}{4}$ - to  $1\frac{1}{2}$ -inch range must be marked in one of three ways: Grade 5 nuts may be marked with a dot on the face of the nut and a radial or circumferential mark at  $120^\circ$  counterclockwise from the dot; or a dot at one corner of the nut and a radial line at  $120^\circ$  clockwise from the nut, or one notch at each of the six corners of the nut. Grade 8 nuts may be identified by a dot on the face of the nut with a radial or circumferential mark at  $60^\circ$  counterclockwise from the dot; or a dot at one corner of the nut and a radial line at  $60^\circ$  clockwise from the nut, or two notches at each of the six corners of the nut.

**Working Strength of Bolts.**—When the nut on a bolt is tightened, an initial tensile load is placed on the bolt that must be taken into account in determining its safe working strength or external load-carrying capacity. The total load on the bolt theoretically varies from a maximum equal to the sum of the initial and external loads (when the bolt is absolutely rigid and the parts held together are elastic) to a minimum equal to either the initial or external loads, whichever is the greater (where the bolt is elastic and the parts held together are absolutely rigid). No material is absolutely rigid, so in practice the total load values fall somewhere between these maximum and minimum limits, depending upon the relative elasticity of the bolt and joint members.

Some experiments made at Cornell University to determine the initial stress due to tightening nuts on bolts sufficiently to make a packed joint steam-tight showed that experienced mechanics tighten nuts with a pull roughly proportional to the bolt diameter. It was also found that the stress due to nut tightening was often sufficient to break a  $\frac{1}{2}$ -inch (12.7-mm) bolt, but not larger sizes, assuming that the nut is tightened by an experienced mechanic. It may be concluded, therefore, that bolts smaller than  $\frac{5}{8}$  inch (15.9 mm) should not be used for holding cylinder heads or other parts requiring a tight joint. As a result of these tests, the following empirical formula was established for the working strength of bolts used for packed joints or joints where the elasticity of a gasket is greater than the elasticity of the studs or bolts.

$$W = S_t (0.55d^2 - 0.25d)$$

In this formula,  $W$  = working strength of bolt or permissible load, in pounds, after allowance is made for initial load due to tightening;  $S_t$  = allowable working stress in tension, pounds per square inch; and  $d$  = nominal outside diameter of stud or bolt, inches. A somewhat more convenient formula, and one that gives approximately the same results, is

$$W = S_t(A - 0.25d)$$

In this formula,  $W$ ,  $S_t$ , and  $d$  are as previously given, and  $A$  = area at the root of the thread, square inches.

*Example:* What is the working strength of a 1-inch bolt that is screwed tightly in a packed joint when the allowable working stress is 10,000 psi?

$$W = 10,000(0.55 \times 1^2 - 0.25 \times 1) = 3000 \text{ pounds approx.}$$

**Formulas for Stress Areas and Lengths of Engagement of Screw Threads.**—The critical areas of stress of mating screw threads are: 1) The effective cross-sectional area, or tensile-stress area, of the external thread; 2) the shear area of the external thread, which depends principally on the minor diameter of the tapped hole; and 3) the shear area of the internal thread, which depends principally on the major diameter of the external thread. The relation of these three stress areas to each other is an important factor in determining how a threaded connection will fail, whether by breakage in the threaded section of the screw (or bolt) or by stripping of either the external or internal thread.

If failure of a threaded assembly should occur, it is preferable for the screw to break rather than have either the external or internal thread strip. In other words, the length of engagement of mating threads should be sufficient to carry the full load necessary to break the screw without the threads stripping.

If mating internal and external threads are manufactured of materials having equal tensile strengths, then to prevent stripping of the external thread, the length of engagement should be not less than that given by [Formula \(1\)](#):

$$L_e = \frac{2 \times A_t}{3.1416K_n \max \left[ \frac{1}{2} + 0.57735n(E_s \min - K_n \max) \right]} \quad (1)$$

In this formula, the factor of 2 means that it is assumed that the area of the screw in shear must be twice the tensile-stress area to attain the full strength of the screw (this value is slightly larger than required and thus provides a small factor of safety against stripping);  $L_e$  = length of engagement, in inches;  $n$  = number of threads per inch;  $K_n \max$  = maximum minor diameter of internal thread;  $E_s \min$  = minimum pitch diameter of external thread for the class of thread specified; and  $A_t$  = tensile-stress area of screw thread given by [Formula \(2a\)](#) or [\(2b\)](#) or the thread tables for Unified threads, [Table 4a](#) through [Table 5h](#) starting on page 1978, which are based on [Formula \(2a\)](#).

For steels of up to 180,000 psi ultimate tensile strength,

$$A_t = 3.1416 \left( \frac{E}{2} - \frac{3H}{16} \right)^2 \quad \text{or} \quad A_t = 0.7854 \left( D - \frac{0.9743}{n} \right)^2 \quad (2a)$$

For steels of over 180,000 psi ultimate tensile strength,

$$A_t = 3.1416 \left( \frac{E_s \min}{2} - \frac{0.16238}{n} \right)^2 \quad (2b)$$

In these formulas,  $D$  = basic major diameter of the thread,  $E$  = basic pitch diameter, and the other symbols have the same meanings as before.

*Stripping of Internal Thread:* If the internal thread is made of material of lower strength than the external thread, stripping of the internal thread may take place before the screw breaks. To determine whether this condition exists, it is necessary to calculate the factor  $J$  for the relative strength of the external and internal threads given by [Formula \(3\)](#):

$$J = \frac{A_s \times \text{tensile strength of external thread material}}{A_n \times \text{tensile strength of internal thread material}} \quad (3)$$

If  $J$  is less than or equal to 1, the length of engagement determined by **Formula (1)** is adequate to prevent stripping of the internal thread; if  $J$  is greater than 1, the required length of engagement  $Q$  to prevent stripping of the internal thread is obtained by multiplying the length of engagement  $L_e$ , **Formula (1)**, by  $J$ :

$$Q = JL_e \tag{4}$$

In **Formula (3)**,  $A_s$  and  $A_n$  are the shear areas of the external and internal threads, respectively, given by **Formulas (5)** and **(6)**:

$$A_s = 3.1416nL_eK_n \max \left[ \frac{1}{2n} + 0.57735(E_s \min - K_n \max) \right] \tag{5}$$

$$A_n = 3.1416nL_eD_s \min \left[ \frac{1}{2n} + 0.57735(D_s \min - E_n \max) \right] \tag{6}$$

In these formulas,  $n$  = threads per inch;  $L_e$  = length of engagement from **Formula (1)**;  $K_n \max$  = maximum minor diameter of internal thread;  $E_s \min$  = minimum pitch diameter of the external thread for the class of thread specified;  $D_s \min$  = minimum major diameter of the external thread; and  $E_n \max$  = maximum pitch diameter of internal thread.

**Load to Break Threaded Portion of Screws and Bolts.**—The direct tensile load  $P$  to break the threaded portion of a screw or bolt (assuming that no shearing or torsional stresses are acting) can be determined from the following formula:

$$P = SA_t$$

where  $P$  = load in pounds to break screw;  $S$  = ultimate tensile strength of material of screw or bolt in pounds per square inch; and  $A_t$  = tensile-stress area in square inches from **Formula (2a)**, **(2b)**, or from the screw thread tables.

**Lock Wire Procedure Detail.**—Wire ties are frequently used as a locking device for bolted connections to prevent loosening due to vibration and loading conditions, or tampering. The use of safety wire ties is illustrated in **Fig. 1** and **Fig. 2** below. The illustrations assume the use of right-hand threaded fasteners and the following additional rules apply:

- 1) No more than three bolts may be tied together; 2) bolt heads may be tied as shown only when the female thread receiver is captive; 3) pre-drilled nuts may be tied in a fashion similar to that illustrated with the following conditions: a) Nuts must be heat treated; and b) nuts are factory drilled for use with lock wire; 4) lock wire must fill a minimum of 75 percent of the drilled hole provided for the use of lock wire; and 5) lock wire must be aircraft quality stainless steel of 0.508 mm (0.020 inch) diameter, 0.8128 mm (0.032 inch) diameter, or 1.067 mm (0.042 inch) diameter. Diameter of lock wire is determined by the thread size of the fastener to be safe-tied: a) Thread sizes of 6 mm (0.25 inch) and smaller use 0.508 mm (0.020 inch) wire; b) thread sizes of 6 mm (0.25 inch) to 12 mm (0.5 inch) use 0.8128 mm (0.032 inch) wire; c) thread sizes > 12 mm (0.5 inch) use 1.067 mm (0.042 inch) wire; and d) the larger wire may be used in smaller bolts in cases of convenience, but smaller wire must not be used in larger fastener sizes.

Fig. 1. Three Bolt Procedure

Fig. 2. Two Bolt Procedure

## INCH THREADED FASTENERS

Dimensions of bolts, screws, nuts, and washers used in machine construction are given here. For data on thread forms, see the section *SCREW THREAD SYSTEMS* starting on page 1940.

**American Square and Hexagon Bolts, Screws, and Nuts.**—The 1941 American Standard ASA B18.2 covered head dimensions only. In 1952 and 1955 the Standard was revised to cover the entire product. Some bolt and nut classifications were simplified by elimination or consolidation in agreements reached with the British and Canadians. In 1965 ASA B18.2 was redesignated into two standards: B18.2.1 covering square and hexagon bolts and screws including hexagon cap screws and lag screws and B18.2.2 covering square and hexagon nuts. In B18.2.1-1965, hexagon head cap screws and finished hexagon bolts were consolidated into a single product; heavy semifinished hexagon bolts and heavy finished hexagon bolts were consolidated into a single product; regular semifinished hexagon bolts were eliminated; a new tolerance pattern for all bolts and screws and a positive identification procedure for determining whether an externally threaded product should be designated as a bolt or screw were established. Also included in this standard are heavy hexagon bolts and heavy hexagon structural bolts. In B18.2.2-1965, regular semifinished nuts were discontinued; regular hexagon and heavy hexagon nuts in sizes  $\frac{1}{4}$  through 1 inch, finished hexagon nuts in sizes larger than  $1\frac{1}{2}$  inches, washer-faced semifinished style of finished nuts in sizes  $\frac{5}{8}$ -inch and smaller and heavy series nuts in sizes  $\frac{7}{16}$ -inch and smaller were eliminated.

Further revisions and refinements include the addition of a skew head bolts and hex head lag screws and the specifying of countersunk diameters for the various hex nuts. Heavy hex structural bolts and heavy hex nuts were moved to a new structural applications standard, ANSI/ASME B18.2.6-2019, *Fasteners for Use in Structural Applications*. Additionally, B18.2.1 has been revised to allow easier conformance to Public Law 101-592. All these changes are reflected in ANSI/ASME B18.2.1-2012, and ANSI/ASME B18.2.2-2015.

**Unified Square and Hexagon Bolts, Screws, and Nuts.**—Items that are recognized in the Standard as “unified” dimensionally with British and Canadian standards are shown in bold-face in certain tables.

The other items in the same tables are based on formulas accepted and published by the British for sizes outside the ranges listed in their standards which, as a matter of information, are BS 1768:1963 (obsolescent) for Precision (Normal Series) Unified Hexagon Bolts, Screws, Nuts (UNC and UNF Threads) and BS 1769 and amendments for Black (Heavy Series) Unified Hexagon Bolts, etc. Tolerances applied to comparable dimensions of American and British Unified bolts and nuts may differ because of rounding off practices and other factors.

**Differentiation between Bolt and Screw.**—A bolt is an externally threaded fastener designed for insertion through holes in assembled parts, and is normally intended to be tightened or released by torquing a nut.

A screw is an externally threaded fastener capable of being inserted into holes in assembled parts, of mating with a preformed internal thread or forming its own thread and of being tightened or released by torquing the head.

An externally threaded fastener which is prevented from being turned during assembly, and which can be tightened or released only by torquing a nut is a *bolt*. (Example: round head bolts, track bolts, plow bolts.)

An externally threaded fastener that has a thread form which prohibits assembly with a nut having a straight thread of multiple pitch length is a *screw*. (Example: wood screws, tapping screws.)

An externally threaded fastener that must be assembled with a nut to perform its intended service is a *bolt*. (Example: heavy hex structural bolt.)

An externally threaded fastener that must be torqued by its head into a tapped or other preformed hole to perform its intended service is a *screw*. (Example: square head set screw.)

Fig. 6. Hex Jam Nuts, Heavy Hex Jam Nuts (Table 7)

**Square and Hex Bolts, Screws, and Nuts.**—The dimensions for square and hex bolts and screws given in the following tables have been taken from American National Standard ANSI/ASME B18.2.1-2012 and for nuts from American National Standard ANSI/ASME B18.2.2-2015. Reference should be made to these Standards for information or data not found in the following text and tables:

*Designation:* Bolts and screws should be designated by the following data in the sequence shown: nominal size (fractional and decimal equivalent); threads per inch (omit for lag screws); product length for bolts and screws (fractional or two-place decimal equivalent); product name; material, including specification, where necessary; and protective finish, if required. Examples: (1)  $\frac{3}{8}$ -16  $\times$  1 $\frac{1}{2}$  Square Bolt, Steel, Zinc Plated; (2)  $\frac{1}{2}$ -13  $\times$  3 Hex Cap

Screw, SAE Grade 8 Steel; and (3)  $.75 \times 5.00$  Hex Lag Screw, Steel. (4)  $\frac{1}{2}$ -13 Square Nut, Steel, Zinc Plated; (5)  $\frac{3}{4}$ -16 Heavy Hex Nut, SAE J995 Grade 5 Steel; and (6) 1000-8 Hex Thick Slotted Nut, ASTM F594 (Alloy Group 1) Corrosion-Resistant Steel.

<sup>a</sup> The table has been included for reference only. Heavy hex structural bolts have been removed from ANSI/ASME B18.2.1 and are now included in ANSI/ASME B18.2.6.

All dimensions are in inches. **Bold type shows bolts unified dimensionally with British and Canadian Standards.** Threads, when rolled, shall be Unified Coarse, Fine, or 8-thread series (UNC, UNRF, or 8 UNR Series), Class 2A. Threads produced by other methods may be Unified Coarse, Fine, or 8-thread series (UNC, UNF, or 8 UN Series), Class 2A.

<sup>a</sup> *Nominal Size*: Where specifying nominal size in decimals, zeros preceding the decimal point and in the fourth decimal place are omitted.

<sup>b</sup> Thread lengths,  $L_T$ , shown are for bolt lengths 6 inches and shorter. For longer bolt lengths add 0.250 inch to thread lengths shown.

All dimensions are in inches.

**Bold type shows bolts unified dimensionally with British and Canadian Standards.**

*Threads*: Threads, when rolled, are Unified Coarse, Fine, or 8-thread series (UNRC, UNRF, or 8 UNR Series), Class 2A. Threads produced by other methods may be Unified Coarse, Fine or 8-thread series (UNC, UNF, or 8 UN Series), Class 2A.

*Body Diameter*: Bolts may be obtained in "reduced diameter body." Where "reduced diameter body" is specified, the body diameter may be reduced to approximately the pitch diameter of the thread. A shoulder of full body diameter under the head may be supplied at the option of the manufacturer.

*Material*: Unless otherwise specified, chemical and mechanical properties of steel bolts conform to ASTM A307, Grade A. Other materials are as agreed upon by manufacturer and purchaser.

<sup>a</sup> *Nominal Size*: Where specifying nominal size in decimals, zeros preceding the decimal and in the fourth decimal place are omitted.

<sup>b</sup> *Thread lengths, L<sub>T</sub>*, shown are for bolt lengths 6 inches and shorter. For longer bolt lengths add 0.250 inch to thread lengths shown.

<sup>c</sup> *Thread lengths, L<sub>T</sub>*, shown are for bolt lengths over 6 inches.

All dimensions are in inches.

**Unification: Bold type indicates product features unified dimensionally with British and Canadian Standards.** Unification of fine thread products is limited to sizes 1 inch and smaller.

**Bearing Surface:** Bearing surface is flat and washer faced. Diameter of bearing surface is equal to the maximum width across flats within a tolerance of minus 10 percent.

**Threads Series:** Threads, when rolled, are Unified Coarse, Fine, or 8-thread series (UNRC, UNRF, or 8UNR Series), Class 2A. Threads produced by other methods shall preferably be UNRC, UNRF or 8UNR but, at manufacturer's option, may be Unified Coarse, Fine or 8-thread series (UNC, UNF, or 8UN Series), Class 2A.

**Material:** Chemical and mechanical properties of steel screws normally conform to Grades 2, 5, or 8 of SAE J429, ASTM A449 or ASTM A354 Grade BD. Where specified, screws may also be made from brass, bronze, corrosion-resisting steel, aluminum alloy or other materials.

<sup>a</sup> When specifying decimal nominal size, zeros before decimal point and in fourth decimal place are omitted.

All dimensions in inches.

Minimum thread length is  $1/2$  length of screw plus 0.50 inch, or 6.00 inches, whichever is shorter. Screws too short for the formula thread length shall be threaded as close to the head as practicable.

Thread formulas: Pitch =  $1 +$  threads per inch. Flat at root =  $0.4305 \times$  pitch. Depth of single thread =  $0.385 \times$  pitch.

All dimensions are in inches.

**Bold type shows nuts unified dimensionally with British and Canadian Standards.**

Threads are Unified Coarse-, Fine-, or 8-thread series (UNC, UNF or 8UN), Class 2B. Unification of fine-thread nuts is limited to sizes 1 inch and under.

All dimensions are in inches.

**Bold type indicates nuts unified dimensionally with British and Canadian Standards.**

Threads are Unified Coarse-, Fine-, or 8-thread series (UNC, UNF, or 8UN), Class 2B.

Unification of fine-thread nuts is limited to sizes 1 inch and under.

All dimensions are in inches unless otherwise specified.

Threads are Unified Standard, Class 2A, UNC Series, in accordance with ANSI/ASME B1.1. For threads with additive finish, the maximum diameters of Class 2A shall apply before plating or coating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) shall apply to a bolt after plating or coating.

Bolts are designated in the sequence shown: nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name; material; and protective finish, if required.

i.e.: ½-13 × 3 Round Head Square Neck Bolt, Steel .375-16 × 2.50 Step Bolt, Steel, Zinc Plated

<sup>a</sup>These sizes pertain to 114 degree countersunk square neck bolts only. Dimensions given in last seven columns to the right are for these bolts only. All dimensions are in inches unless otherwise specified.

Threads are Unified Standard, Class 2A, UNC Series, in accordance with ANSI/ASME B1.1. For threads with additive finish, the maximum diameters of Class 2A shall apply before plating or coating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) shall apply to a bolt after plating or coating. Bolts are designated in the sequence shown: nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name; material; and protective finish, if required. For example

½-13 × 3 Round Head Square Neck Bolt, Steel .375-16 × 2.50 Step Bolt, Steel, Zinc Plated

**American National Standard Countersunk Bolts and Slotted Countersunk Bolts**

<sup>a</sup> Where specifying size in decimals, zeros preceding decimal and in fourth decimal place omitted.

<sup>b</sup> Flat on minimum diameter head calculated on minimum sharp and absolute minimum head diameters and 82° head angle.

<sup>c</sup> Maximum head height calculated on maximum sharp head diameter, basic bolt diameter, and 78° head angle.

<sup>d</sup> Minimum head height calculated on minimum sharp head diameter, basic bolt diameter, and 82° head angle.

All dimensions are given in inches. For thread information and method of bolt designation see footnotes to previous table. Heads are unslotted unless otherwise specified. For slot dimensions see [Table 1 in Slotted Head Cap Screws](#) on page 1812.

**Wrench Clearance Dimensions.**—Wrench openings for nuts are given in [Table 1](#), clearances for open end engineers wrenches in [Table 2](#), clearances for single and double hexagon socket wrenches in [Table 3a](#) (inch) and [Table 3b](#) (metric), clearances for 12-point box wrenches (inch and metric) are given in [Table 4](#). They are based on the dimensions across the flats of the fastener.

<sup>a</sup> Wrenches are marked with the "Nominal Size of Wrench," which is equal to the basic or maximum width across flats of the corresponding nut. Minimum wrench opening is (1.005W + 0.001). Tolerance on wrench opening is (0.005W + 0.004) from minimum, where W equals nominal size of wrench.

<sup>b</sup> Openings for 5/32 to 3/8 widths from old ASA B18.2-1960 and italic values are from former ANSI B18.2.2-1972.

All dimensions given in inches.

<sup>a</sup> B = arc radius created by the swing of the wrench.

<sup>b</sup> F = inside arc radius of part.

<sup>c</sup> H = thickness of wrench head. (Dimension line not shown.)

<sup>d</sup> J = torque that wrench will withstand in inch-pounds. Values updated from ANSI/ASME B107.100-2010, Wrenches.

<sup>a</sup> Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes.

<sup>b</sup> The 0.734-inch, 1.156-inch, and 1.469-inch outside diameters avoid washers which could be used in coin operated devices.

All dimensions are in inches.

Preferred sizes are for the most part from series previously designated "Standard Plate" and "SAE." Where common sizes existed in the two series, the SAE size is designated "N" (narrow) and the Standard Plate "W" (wide). These sizes as well as all other sizes of Type A Plain Washers are to be ordered by ID, OD, and thickness dimensions.

Additional selected sizes of Type A Plain Washers are shown in Table 1b.

**Table 1b. American National Standard Type A Plain Washers.—

<sup>a</sup> The 0.734-inch and 1.469-inch outside diameters avoid washers which could be used in coin operated devices.

All dimensions are in inches.

The above sizes are to be ordered by ID, OD, and thickness dimensions.

Preferred Sizes of Type A Plain Washers are shown in [Table 1a](#).

**ANSI Standard Plain Washers.**—The Type A plain washers were originally developed in a light, medium, heavy and extra heavy series. These series have been discontinued and the washers are now designated by their nominal dimensions.

The Type B plain washers are available in a narrow, regular and wide series with proportions designed to distribute the load over larger areas of lower strength materials.

Plain washers are made of ferrous or nonferrous metal, plastic or other material as specified. The tolerances indicated in the tables are intended for metal washers only.

<sup>a</sup> Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes.

<sup>b</sup> N indicates Narrow; R, Regular; and W, Wide Series.

<sup>c</sup> The 0.734-inch and 1.469-inch outside diameter avoids washers which could be used in coin operated devices.

All dimensions are in inches.

Inside and outside diameters shall be concentric within at least the inside diameter tolerance.

Washers shall be flat within 0.005-inch for basic outside diameters up through 0.875-inch and within 0.010 inch for larger outside diameters.

For 2 1/4-, 2 1/2-, 2 3/4-, and 3-inch sizes see ANSI/ASME B18.21.1-2009 (R2016).

**American National Standard Helical Spring and Tooth Lock Washers ANSI/ASME B18.21.1-2009 (R2016).**—This standard covers helical spring lock washers of carbon steel; boron steel; corrosion resistant steel, Types 302 and 305; aluminum-zinc alloy; phosphor-bronze; silicon-bronze; and K-Monel; in various series. Tooth lock washers of carbon steel having internal teeth, external teeth, and both internal and external teeth, of two constructions, designated as Type A and Type B. Washers intended for general industrial application are also covered. American National Standard Lock Washers (Metric Series) ANSI/ASME B18.21.2M-1999 (R2014) covers metric sizes for helical spring and tooth lock washers.

**Helical Spring Lock Washers:** These washers are used to provide: 1) good bolt tension per unit of applied torque for tight assemblies; 2) hardened bearing surfaces to create uniform torque control; 3) uniform load distribution through controlled radii—section—cut-off; and 4) protection against looseness resulting from vibration and corrosion.

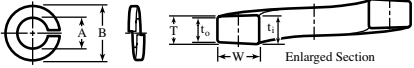

Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes. These washers are designated by the following data in the sequence shown: Product name; nominal size (number, fraction or decimal equivalent); series; material; and protective finish, if required. For example: Helical Spring Lock Washer, 0.375 Extra Duty, Steel, Phosphate Coated.

Helical spring lock washers are available in four series: Regular, heavy, extra duty and hi-collar as given in [Table 2](#) and [Table 1](#). Helical spring lock washers made of materials other than carbon steel are available in the regular series as given in [Table 2](#).

<sup>a</sup> T = mean section thickness = (t<sub>1</sub> + t<sub>0</sub>) ÷ 2.

All dimensions are given in inches.\*See ANSI/ASME B18.21.1-2009 (R2016) standard for sizes over 1½ to 3, inclusive, for regular and heavy helical spring lock washers and over 1½ to 2, inclusive, for extra-duty helical spring lock washers.

When carbon steel helical spring lock washers are to be hot-dipped galvanized for use with hot-dipped galvanized bolts or screws, they are to be coated to limits onto inch in excess of those specified in Table 2 and Table 1 for minimum inside diameter and maximum outside diameter. Galvanizing washers under ¼ inch nominal size are not recommended.

**Tooth Lock Washers:** These washers serve to lock fasteners, such as bolts and nuts, to the component parts of an assembly, or increase the friction between the fasteners and the assembly. They are designated in a manner similar to helical spring lock washers, and are available in carbon steel. Dimensions are given in Table 3 and Table 4.

**Table 3. American National Standard Internal-External Tooth Lock Washers**  
ANSI/ASME B18.21.1-2009 (R2016)

All dimensions are given in inches except whole numbers under "Size"

<sup>a</sup> Starting with #4, approx. O.D.'s are: 0.213, 0.289, 0.322, 0.354, 0.421, 0.454, 0.505, 0.599, 0.765, 0.867, and 0.976. All dimensions are given in inches.

**Fasteners for Use in Structural Applications**

The ANSI/ASME B18.2.6 standard covers the complete general and dimensional data for four products in the inch series recognized as American National Standard. Heavy hex nut thickness formulas and those for width across flats and width across corners are found in the Appendix of ANSI/ASME B18.2.2. The inclusion of dimensional data in this standard is not intended to imply that all products described herein are stock production sizes. Fasteners intended for use in structural applications and purchased for government use shall conform to this standard. All dimensions in ANSI/ASME B18.2.6 are in inches unless stated otherwise, and apply to unplated or uncoated product.

Symbols specifying geometric characteristics are in accord with ASME Y14.5, *Dimensioning and Tolerancing*. Standards for chemical and mechanical requirements for structural bolts are included in ASTM A325 and ASTM A490. Heavy hex nuts are included in ASTM A563. Hardened steel washers are included in ASTM F436, and compressible washer type direct tension indicators in ASTM F 959.

**Heavy Hex Structural Bolts.**—*Head Width Across Flats:* The width across flats of heads shall be the distance measured perpendicular to the axis of product, overall between two opposite sides of the head in accordance with the notes in the dimensional table.

*Head Height:* The head height shall be that overall distance measured parallel to the axis of the product from the top of the head to the bearing surface and shall include the thickness of the washer face. Raised grade and manufacturer's identification are excluded from head height.

*Bolt Length:* The bolt length shall be the distance measured parallel to the axis of the product from the bearing surface of the head to the extreme end of the bolt including point.

*Threads:* Threads shall be cut or rolled in accordance with ASME B 1.1. When specified, 8 thread series may be used on bolts over 1 inch in diameter. Structural bolts shall not be undersized to accommodate heavy coatings. Threads which have been hot-dipped or mechanically zinc coated shall meet the requirements specified in ASTM A325.

*Body Diameter:* The body diameter limits are shown in [Table 5](#).

*Finish:* Unless otherwise specified, bolts shall be supplied with a plain (as processed) finish. Bolts to ASTM A490 shall not be metallic coated.

*Materials:* Chemical and mechanical properties of steel bolts shall conform to ASTM A325 or ASTM A490.

*Workmanship:* Bolts shall be free from burrs, seams, laps, loose scale, irregular surfaces, and any defects affecting serviceability. When control of surface discontinuities is required, the purchaser shall specify conformance to ASTM F 788/F 788M, surface discontinuities of bolts, screws, and studs, inch and metric series.

*Designation:* Heavy hex structural bolts shall be designated by the following data in the sequence shown: product name, nominal size (fractional or decimal equivalent), threads per inch, material (including specification and type where necessary), and protective finish (if required). See example below:

*Example:* Heavy Hex Structural Bolt,  $\frac{3}{4}$ -10  $\times$  2  $\frac{1}{4}$ , ASTM A325, Type 1, hot dipped zinc coated.

*Identification Grade Symbols:* Each bolt shall be marked in accordance with the requirements of the applicable specification; ASTM A325 or ASTM A490 and requirements of [Table 5](#), Note (13).

(1) *Top of Head:* Top of head shall be full form and chamfered or rounded with the diameter of chamfer circle or start of rounding being equal to the maximum width across flats within a tolerance of  $-15\%$ .

(2) *Head Taper:* Maximum width across flats shall not be exceeded. No transverse section through the head between 25 and 75 percent of actual head height, as measured from the bearing surface, shall be less than the minimum width across flats.

(3) *Bearing Surface:* Bearing surface shall be flat and washer faced. Diameter of washer face shall be equal to the maximum width across flats within a tolerance of  $-10\%$ .

Thickness of the washer face shall be not less than 0.015 inch nor greater than 0.025 inch for bolt sizes  $\frac{3}{4}$  inch and smaller; and not less than 0.015 inch nor greater than 0.035 inch for sizes larger than  $\frac{3}{4}$  inch.

The plane of the bearing surface shall be perpendicular to the axis of the body within the FIM limits specified for total runout. Measurement of FIM shall extend as close to the periphery of the bearing surface as possible while the bolt is being held in a collet or other gripping device at a distance of one bolt diameter from the underside of the head.

(4) *True Position of Head:* The axis of the head shall be located at true position with respect to the axis of the body (determined over a distance under the head equal to one diameter) within a tolerance zone having a diameter equivalent to 6 percent of the maximum width across flats at maximum material condition.

(5) *Body Diameter:* Any swell or fin under the head or any die seam on the body should not exceed the basic bolt diameter by the following: 0.030 in. for sizes  $\frac{1}{2}$  inch; 0.050 inch for sizes  $\frac{5}{8}$  and  $\frac{3}{4}$  inch; 0.060 inch for sizes over  $\frac{3}{4}$  inch to 1 $\frac{1}{4}$  inch; 0.090 inch for sizes over 1 $\frac{1}{4}$  inch.

(6) *Point:* Point shall be chamfered or rounded at the manufacturer's option from approximately 0.016 inch below the minor diameter of the thread. The first full formed thread at major diameter is located a distance no greater than 2 times the pitch measured from the end of the screw. This distance is to be determined by measuring how far the point enters into a cylindrical NOT GO major diameter ring gage.

(7) *Straightness:* Shanks of bolts shall be straight within the following limits at MMC; for bolts with nominal lengths to and including 12 inches the maximum camber shall be 0.006 inch per inch (0.006L) of bolt length, and for bolts with nominal lengths over 12 inches to and including 24 inches the maximum camber shall be 0.008 inch per inch (0.008L) of length.

(8) *Bolt Length:* Bolts are normally supplied in  $\frac{1}{4}$  inch length increments, all lengths.

(9) *Length Tolerance:* Bolt length tolerances shall be as tabulated below:

Nominal Bolt Size	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$ through 1	1 $\frac{1}{8}$ through 1 $\frac{1}{2}$
Nominal Bolt Length	Tolerance of Length			
Through 6 inches	-0.12	-0.12	-0.19	-0.25
Over 6 inches	-0.19	-0.25	-0.25	-0.25

(10) *Thread Length:* The length of thread on bolts shall be controlled by the grip gaging length,  $L_G$ , max., and the body length,  $L_B$ , min., as follows.

Grip gaging length,  $L_G$ , max., is the distance measured parallel to the axis of bolt from the underhead bearing surface to the face of a noncounterbored or noncountersunk standard G0 thread ring gage assembled by hand as far as the thread will permit. It shall be used as the criterion for inspection. The maximum grip gaging length, as calculated and rounded to two decimal places for any bolt not threaded full length, shall be equal to the nominal bolt length minus the basic thread length ( $L_G$ , max. =  $L_{nom} - L_T$ ). For bolts which are threaded full length,  $L_G$ , max. defines the unthreaded length under the head and shall not exceed the length of 2.5 times the thread pitch for sizes up to and including 1 inch, and 3.5 times the thread pitch for sizes larger than 1 inch,  $L_G$ , max. represents the minimum design grip length of the bolt and may be used for determining thread availability when selecting bolt lengths even though usable threads may extend beyond this point.

Basic thread length,  $L_T$ , is a reference dimension, intended for calculation purposes only, which represents the distance from the extreme end of the bolt to the last complete (full form) thread.

Body length,  $L_B$ , min., is the distance measured parallel to the axis of bolt from the under-head bearing surface to the last scratch of thread or to the top of the extrusion angle. It shall be used as a criterion for inspection. The minimum body length, as calculated and rounded to two decimal places, shall be equal to the maximum grip gaging length minus the maximum transition thread length ( $L_{B, min} = L_{G, max} - Y_{max}$ ). Bolts of nominal lengths which have a calculated  $L_{B, min}$  length equal to or shorter than 2.5 times the thread pitch for sizes 1 inch and smaller, and 3.5 times the thread pitch for sizes larger than 1 inch shall be threaded for full length.

Transition thread length  $Y$  is a reference dimension, intended for calculation purposes only, which represents the length of incomplete threads and tolerance on grip gaging length.

(11) *Incomplete Thread Diameter*: The major diameter of incomplete thread shall not exceed the actual major diameter of the full form thread.

(12) *Threads*: Threads, when rolled, shall be in the Unified inch coarse or 8 thread series (UNRC or 8 UNR Series), Class 2A. Threads produced by other methods may be Unified inch coarse or 8 thread series (UNC or 8 UN Series), Class 2A. Acceptability of screw threads shall be determined based on System 21, ANSI/ASME B1.3, screw thread gaging systems for dimensional acceptability, unless otherwise specified.

(13) *Identification Symbols*: Identification marking symbols on the tops of heads for bolt sizes  $\frac{5}{8}$  inch and smaller shall project not less than 0.005 inch above the surface nor more than 0.015 inch over the specified maximum head height. Bolt sizes larger than  $\frac{5}{8}$  inch shall project not less than the equivalent in inches of 0.0075 times the basic bolt diameter above the surface nor more than 0.030 inch over the specified maximum head height.

(14) *Material*. Chemical and mechanical properties of steel bolts shall conform to ASTM A325 or ASTM A490.

(15) *Nominal Size*. Where specifying nominal size in decimals, zeros preceding the decimal and in the fourth decimal place shall be omitted.

(16) *Dimensional Conformance*. Heavy hex structural bolts shall have the following characteristics inspected to ANSI/ASME B18.18-2017 to the inspection level C: threads, width across comers, head height, grip length, visual.

If verifiable in-process inspection is used, see *Dimensional Characteristics* on page 1705.

*Identification Source Symbols*: Each bolt shall be marked to identify its source (manufacturer, or private label distributor) accepting the responsibility for conformance to this and other applicable specifications.

*Quality Assurance*: Unless otherwise specified, products shall be furnished in accordance with ANSI/ASME B18.18-2017 as noted as below.

*Dimensional Characteristics*: Bolts shall conform to the dimensions indicated in Table 5. The designated characteristics defined in Table 5, Note (16) shall be inspected in accordance with ANSI/ASME B18.18. For nondesignated characteristics, the provisions of ANSI/ASME B18.18 shall apply. Should a nondesignated dimension be determined to have a variance, it shall be deemed conforming to this Standard if the user, who is the installer, accepts the variance based on fit, form, and function considerations. Where verifiable in-process inspection is used in accordance with ANSI/ASME B18.18-2017, the final inspection level sample sizes of those respective standards shall apply.

**Heavy Hex Nuts.**—*Width Across Flats*: The width across flats of heavy hex nuts shall be the overall distance measured, perpendicular to the axis of the nut, between two opposite sides of the nut in accordance with the notes of Table 6. For milled-from-bar hex nuts, the nominal bar size used shall be the closest commercially available size to the specified basic width across flats of the nut.

**Table 6. Dimensions of Heavy Hex Nuts for Use with Structural Bolts ANSI/ASME B18.2.6-2019**

Note: Complete table included in B18.2.2 Square and Hex Nuts (Inch Sizes)

(1) *Unification*: Only the 7/16 size is not unified dimensionally with British and Canadian standards. Unification of fine thread products is limited to sizes 1 inch and under.

(2) *Tops and Bearing Surfaces of Nuts*: Nuts may be double chamfered or have washer faced bearing surface and chamfered top.

The diameter of chamfer circle on double chamfered nuts and diameter of washer face shall be within the limits of the maximum width across flats and 95 percent of the minimum width across flats.

The tops of washer faced nuts shall be flat and the diameter of chamfer circle shall be equal to the maximum width across flats within a tolerance of -15%. The length of chamfer at hex corners shall be 5 to 15 percent of the basic thread diameter. The surface of chamfer may be slightly convex or rounded.

Bearing surfaces shall be flat and, unless otherwise specified, shall be perpendicular to the axis of the threaded hole within the total runout (FIM) tabulated for the respective nut size, type, and strength level.

(3) *True Position of Tapped Hole*: At maximum material condition, the axis of nut body shall be located at true position with respect to the axis of the tapped hole within a tolerance zone having a diameter equivalent to 4 percent of the maximum width across flats for 1 1/2 inch nominal size nuts or smaller.

(4) *Countersink*: Tapped hole shall be countersunk on the bearing face or faces. The maximum countersink diameter shall be 1.08 times the thread basic (nominal) major diameter. No part of the threaded portion shall project beyond the bearing surface.

(5) *Corner Fill*: A rounding or lack of fill at junction of hex corners with chamfer shall be permissible provided the width across corners is within specified limits at and beyond a distance equal to 17.5% of the basic thread diameter from the chamfered faces.

(6) *Width Across Flats*: Maximum width across flats shall not be exceeded (see exception in *Heavy Hex Nuts.—Width Across Flats*). No transverse section through the nut between 25 and 75 percent of the actual nut thickness, as measured from the bearing surface, shall be less than the minimum width across flats. For milled-from-bar nuts, *Heavy Hex Nuts.—Width Across Flats*, pertaining to the nominal bar size to be used.

(7) *Threads*: Threads shall be UNC or 8 UN Class 2B in accordance with ANSI/ASME B1.1, Unified Inch Screw Threads. When specified, 8 thread series may be used on nuts over 1 inch in diameter.

(8) *Dimensional Conformance*: Heavy hex nuts shall have the following characteristics inspected to ANSI/ASME B18.18-2017 to the inspection levels as follows: Width across corners, inspection level C; Thickness, inspection level B; Visual, inspection level C.

If verifiable in-process inspection is used, see *Dimensional Characteristics* on page 1707.

*Nut Thickness*: The nut thickness shall be the overall distance measured parallel to the axis of nut, from the top of the nut to the bearing surface, and shall include the thickness of the washer face where provided.

*Threads*: Threads shall be in accordance with Table 6, Note (7).

*Thread Gaging*: Unless otherwise specified by the purchaser, gaging for screw thread dimensional acceptability shall be in accordance with Gaging System 21 as specified in ANSI/ASME B1.3 Screw Thread Gaging Systems for Acceptability: Inch and Metric Screw Threads (UN, UNR, UNJ, M, and MJ).

*Overtapping*: When nuts are zinc coated, they shall be overtapped after coating in accordance with the provisions of ASTM A563.

*Finish*: Unless otherwise specified, nuts shall be supplied with a plain (as-processed) finish, unlapped or uncoated.

*Materials*: Chemical and mechanical properties of heavy hex nuts shall conform to ASTM A563.

*Workmanship*: Nuts shall be free from burrs, seams, laps, loose scale, irregular surfaces, and any defects affecting their serviceability. When control of surface discontinuities is required, the purchaser shall specify conformance to ASTM F 812/F 812M, Surface Discontinuities of Nuts—Inch and Metric Series.

*Designation*: Nuts shall be designated by the following data in sequence shown: product name, nominal size (fraction or decimal), threads per inch, material (including specification where necessary), protective finish (if required). See example below:

*Example*: Heavy Hex Nut,  $\frac{1}{2}$ -13, ASTM A563 Grade C, Plain Finish

*Identification Grade Symbols*: Each nut shall be marked in accordance with the requirements of the applicable specification: ASTM A563 or ASTM A194.

*Identification Source Symbols*: Each nut shall be marked to identify its source (manufacturer, or private label distributor) accepting the responsibility for conformance to this and other applicable specifications.

*Quality Assurance*: Unless otherwise specified, products shall be furnished in accordance with ANSI/ASME B18.18 as noted in *Dimensional Characteristics*.

*Dimensional Characteristics*: Products shall conform to the dimensions indicated for the heavy hex nut in Table 6. The designated characteristics defined in Table 6, Note (8) shall be inspected in accordance with ANSI/ASME B18.18. For nondesignated characteristics, the provision of ANSI/ASME B18.18 shall apply. Should a nondesignated dimension be determined to have a variance, it shall be deemed conforming to this Standard if the user, who is the installer, accepts the variance based on fit, form, and function considerations. Where verifiable in-process inspection is used in accordance with ANSI/ASME B18.18-2017, the final inspection level sample sizes of those respective standards shall apply.

## Hardened Steel Washers

**Flat Washers.**—*Flat Washers Dimensions:* All circular and circular clipped washers shall conform to the dimensions shown in [Table 7](#).

**Table 7. Dimensions for Hardened Steel Circular and Circular Clipped Washers ANSI/ASME B18.2.6-2019**

Bolt Size or Nominal <sup>a</sup> Washer Size, Inch	Inside Diameter A			Outside Diameter B			Thickness C		Minimum Edge Distance E
	Basic Washer	Tolerance		Basic	Tolerance		Min.	Max.	
		Plus	Minus		Plus	Minus

1 1/2	1.625	0.0313	0	3.000	0.0313	0.0313	0.136	0.177	1.313

<sup>a</sup> Nominal washer sizes are intended for use with comparable nominal bolt diameters.

## General Notes:

(1) *Dimensional Conformance:* Circular and circular clipped washers shall have the following characteristics inspected to ANSI/ASME B18.18-2017 to the inspection levels as follows: Width across corners, inspection level B; Visual, inspection level C.

If verifiable in-process inspection is used, see *Dimensional Characteristics* on page 1709.

(2) Nominal washer sizes are intended for use with comparable nominal bolt diameters.

(3) Additional requirements are in *Beveled Washers* on page 1709.

*Flat Washers Tolerances:* Washer inside diameter, outside diameter, thickness, and edge distance shall be in accordance with [Table 7](#). The deviation from flatness shall not exceed 0.010 inch as the maximum deviation from a straight edge placed on the cut side. Circular runout of the outside diameter with respect to the hole shall not exceed 0.030 FIM. Burrs shall not project above immediately adjacent washer surface more than 0.010 inch.

*Finish:* Unless otherwise specified, washers shall be supplied with a plain (as processed) finish. If zinc coatings are required, they shall be in accordance with ASTM F 436.

*Materials:* Materials shall conform to the requirements established by ASTM F 436.

*Workmanship:* Washers shall be free from burrs, seams, laps, loose scale, irregular surfaces, and any defects affecting serviceability.

*Designation:* Washers shall be designated by the following data in the sequence shown: product name, nominal size (fraction or decimal), material specification, protective finish. See example below:

*Example:* Hardened Steel Circular Washer,  $1\frac{1}{8}$  ASTM F 436, Hot-Dip Galvanized in Accordance with ASTM A153 Class C.

*Identification Symbols:* Grade and source marking and symbols shall conform to the requirements of ASTM F436. The source marking is intended to identify the source accepting the responsibility for the conformance to this and other applicable specifications.

*Quality Assurance:* Unless otherwise specified, products shall be furnished in accordance with ANSI/ASME B18.18-2017 as noted in *Dimensional Characteristics*.

*Dimensional Characteristics:* Washers shall conform to the dimensions indicated in Table 7. The designated characteristics defined in Table 7, Note (1) shall be inspected in accordance with ANSI/ASME B18.18-2017. For nondesignated characteristics, the provisions of ANSI/ASME B18.18-2017 shall also apply. Should a nondesignated dimension be determined to have a variance, it shall be deemed conforming to this Standard if the user, who is the installer, accepts the variance based on fit, form, and function considerations. Where verifiable in-process inspection is used in accordance with ANSI/ASME B18.18-2017, the final inspection level sample sizes of those respective standards shall apply.

**Beveled Washers.**—*Dimensions:* All square beveled and clipped square beveled washers shall conform to the dimensions shown in Table 8.

*Tolerances:* Tolerances for inside diameter for beveled washers shall be in accordance with Table 8. The flatness shall not exceed 0.010 inch as the maximum deviation from a straight edge placed on the cut side. Burrs shall not project above immediately adjacent washer surface more than 0.010 inch.

*Finish:* Unless otherwise specified, washers shall be supplied with a plain (as-processed) finish. If zinc coatings are required, they shall be in accordance with ASTM F 436.

*Materials and Mechanical Properties:* Materials and properties shall conform to the requirements established by ASTM F 436.

*Workmanship:* Washers shall be free from burrs, seams, laps, loose scale, irregular surfaces, and any defects affecting serviceability.

*Designation:* Washers shall be designated by the following data in the sequence shown: product name, nominal washer size (fraction or decimal), material specification, protective finish. See example below:

*Example:* Square Beveled Washer,  $1\frac{1}{4}$  ASTM F 436, hot-dip galvanized in accordance with ASTM A153 Class C.

**Table 8. Dimensions for Hardened Beveled Washers with Slope or Taper in Thickness 1:6 ANSI/ASME B18.2.6-2019**

Nominal Washer Size [Note (3)]	Inside Diameter A				Minimum Side Length L	Thickness T	Minimum Edge Distance E
	Tolerance						
	Basic	Plus	Minus				
1/2	0.500	0.531	0.0313	0	1.750	0.313	0.438
5/8	0.625	0.688	0.0313	0	1.750	0.313	0.547
3/4	0.750	0.813	0.0313	0	1.750	0.313	0.656
7/8	0.875	0.938	0.0313	0	1.750	0.313	0.766
1	1.000	1.125	0.0313	0	1.750	0.313	0.875
1 1/8	1.125	1.250	0.0313	0	2.250	0.313	0.984
1 1/4	1.250	1.375	0.0313	0	2.250	0.313	1.094
1 3/8	1.375	1.500	0.0313	0	2.250	0.313	1.203
1 1/2	1.500	1.625	0.0313	0	2.250	0.313	1.313

**General notes for Table 8:**

(1) **Dimensional Conformance:** Beveled washers shall have the following characteristics inspected to ANSI/ASME B18.18-2017 to the inspection levels as follows: Width across corners, inspection level B; Visual, inspection level C.

If verifiable in-process inspection is used, see *Dimensional Characteristics* on page 1709.

(2) Nonclipped washers may be rectangular providing neither side dimension is less than L.

(3) Nominal washer sizes are intended for use with comparable nominal bolt diameters.

(4) Additional requirements are in *Beveled Washers* on page 1709.

**Identification Symbols:** Grade and source marking and symbols shall conform to the requirements of ASTM F 436. The source marking is intended to identify the source accepting the responsibility for conformance to this and other applicable specifications.

**Quality Assurance:** Unless otherwise specified, products shall be furnished in accordance with ANSI/ASME B18.18 as noted in *Dimensional Characteristics* on page 1710.

**Dimensional Characteristics:** Washers shall conform to the dimensions specified in Table 8. The designated characteristics defined in Table 8, Note (1) shall be inspected in accordance with ANSI/ASME B18.18. For nondesignated characteristics, the provisions of ANSI/ASME B18.18 shall apply. Should a nondesignated dimension be determined to have a variance, it shall be deemed conforming to this Standard if the user, who is the installer, accepts the variance based on fit, form, and function considerations. Where

verifiable in-process inspection is used in accordance with ANSI/ASME B18.18-2017, the final inspection level sample sizes of these respective standards shall apply.

**Compressible Washer-type Direct Tension Indicators.**—*Dimensions:* The dimensions for the two washer types of direct tension indicators, Type A 325 and A 490, shall be in accordance with [Table 9](#).

*Finish:* Unless otherwise specified, direct tension indicators shall be supplied with a plain (as-processed) finish, tinplated, or uncoated. If zinc coatings are required, they shall be in accordance with ASTM F 959.

*Materials and Performance:* Direct tension indicators shall conform to the requirements of ASTM F 959.

*Workmanship:* The workmanship shall be smooth and free of burrs, laps, seams, excess mill scale, and foreign material on bearing surfaces or in protrusion welds, or other defects which would make them unsuitable for intended application.

*Designation:* Compressible washer-type direct tension indicators shall be designated by the following data in the sequence shown: product name, nominal size (fractional or decimal equivalent), type (325 or 490), finish (plain, zinc, or epoxy). See example below:

*Example:* DTI,  $\frac{1}{2}$  Type 325, Plain Finish

*Identification Symbols:* Grade and source marking and symbols shall conform to the requirements of ASTM F 959.

*Lot Number:* Each direct tension indicator shall be marked with a lot number in accordance with ASTM F 959.

*Quality Assurance:* Unless otherwise specified, products shall be furnished in accordance with ANSI/ASME B18.18 as noted in *Dimensional Characteristics*.

*Dimensional Characteristics:* Direct tension indicators shall conform to the dimensions indicated in [Table 9](#). The designated characteristics defined in [Table 9](#), Note (1) shall be inspected in accordance with ANSI/ASME B18.18. For nondesignated characteristics, the provisions of ANSI/ASME B18.18 shall apply. Should a nondesignated dimension be determined to have a variance, it shall be deemed conforming to this Standard if the user, who is the installer, accepts the variance based on fit, form, and function considerations. Where verifiable in-process inspection is used in accordance with ANSI/ASME B18.18-2017, the final inspection level sample sizes of these respective standards shall apply.

Fig. 3. Compressible Washer Dimensions

**Table 9. Dimensions for Compressible Washer-Type Direct Tension Indicators ANSI/ASME B18.2.6-2019**

Bolt Size, inch	All Types					Type A 325			Type A 490		
	Inside Diameter, inch		Protrusion Tangential Diameter, inch B, Max.	Thickness, inch		Outside Diameter, inch C		Number of Protrusions (Equally Spaced)	Outside Diameter, inch		Number of Protrusions (Equally Spaced)
				Without Protrusion	With Protrusion						
	Min.	Max.	Min.	Max.	Min.	Max.	Min.	Max.			
1/2	0.520	0.527	0.788	0.104	0.180	1.031	1.187	4	1.031	1.375	5
5/8	0.651	0.658	0.956	0.126	0.220	1.281	1.375	4	1.281	1.625	5
3/4	0.783	0.790	1.125	0.126	0.240	1.437	1.625	5	1.437	1.750	6
7/8	0.914	0.921	1.294	0.142	0.260	1.718	1.875	5	1.718	2.000	6
1	1.043	1.052	1.463	0.158	0.270	1.937	2.000	6	1.937	2.250	7
1 1/8	1.174	1.183	1.631	0.158	0.280	2.187	2.250	6	2.187	2.500	7
1 1/4	1.306	1.315	1.800	0.158	0.280	2.437	2.500	7	2.437	2.750	8
1 3/8	1.437	1.446	1.969	0.158	0.280	2.687	2.750	7	2.687	3.000	8
1 1/2	1.568	1.577	2.138	0.158	0.280	2.937	3.000	8	2.937	3.250	9

**General Notes:**

(1) *Dimensional Conformance*: Direct tension indicators shall have the following characteristics inspected to ANSI/ASME B18.18-2017 to the inspection levels as follows: Inside diameter and Width across corners, inspection level B; Visual, inspection level C.

If verifiable in-process inspection is used, *Dimensional Characteristics* on page 1709.

(2) Nonclipped washers may be rectangular providing neither side dimension is less than *L*.

(3) Nominal washer sizes are intended for use with comparable nominal bolt diameters.

(4) Additional requirements are in *Compressible Washer-type Direct Tension Indicators* on page 1711.

## METRIC THREADED FASTENERS

A number of American National Standards covering metric bolts, screws, nuts, and washers have been established in cooperation with the Department of Defense in such a way that they could be used by the government for procurement purposes. Extensive information concerning these metric fasteners is given in the following text and tables, but for additional manufacturing and acceptance specifications reference should be made to the respective Standards which may be obtained by nongovernmental agencies from the American National Standards Institute, 25 West 43rd Street, New York, NY 10036, [www.ansi.org](http://www.ansi.org). These Standards are:

ANSI/ASME B18.2.3.1M-1999 (Withdrawn) Metric Hex Cap Screws	Table 1
ANSI/ASME B18.2.3.2M-2005 (Withdrawn) Metric Formed Hex Screws	Table 2
ANSI/ASME B18.2.3.3M-2007 (R2014) Metric Heavy Hex Screws	Table 3
ANSI/ASME B18.2.3.8M-1981 (Withdrawn) Metric Hex Lag Screws	Table 5
ANSI/ASME B18.3.3M-1986 (Withdrawn) Metric Socket Hd. Shldr. Screws	Table 6a
ASME B18.2.3.9M-2001 (R2014) Metric Heavy Hex Flange Screws	Table 7
ASME B18.2.3.4M-2001 (Withdrawn) Metric Hex Flange Screws	Table 8
ANSI/ASME B18.5.2.2M-1982 Metric Round Head Square Neck Bolts	Table 10
ANSI/ASME B18.2.3.6M-1979 (Withdrawn) Metric Heavy Hex Bolts	Table 11
ANSI/ASME B18.2.6M-2012 Metric Fasteners for Use in Structural Applications	Table 12
ASME B18.2.3.5M-1979 (R2016) Metric Hex Bolts	Table 13
ANSI/ASME B18.3.1M-1986 (Withdrawn) Socket Head Cap Screws (Metric Series)	Table 21
ANSI/ASME B18.2.6M-2012 Metric Fasteners for Use in Structural Applications (For section on Metric Hex Nuts, Style)	Table 25
ANSI/ASME B18.2.6-2019 Metric Hex Nuts, Style 2	Table 25
ANSI/ASME B18.2.4.3M-1979 (R2017) Metric Slotted Hex Nuts	Table 24
ANSI/ASME B18.2.4.4M-1982 (Withdrawn) Metric Hex Flange Nuts	Table 26
ANSI/ASME B18.16M-2004 (R2016) Prevailing-Torque Type Steel Metric Hex Nuts and Hex Flange Nuts	Table 29
ANSI/ASME B18.16M-2004 (R2016) Prevailing-Torque Type Steel Metric Hex Nuts and Hex Flange Nuts	Table 27
ANSI/ASME B18.2.6-2019 Metric Hex Jam Nuts	Table 28
ANSI/ASME B18.2.6M-2012 Metric Fasteners for Use in Structural Applications (For section on Metric Heavy Hex Nuts)	Table 28
ANSI/ASME B18.22M-1981 (R2017) Metric Plain Washers	Table 30

Manufacturers should be consulted concerning items and sizes in stock production.

**Comparison with ISO Standards.**—American National Standards for metric bolts, screws and nuts have been coordinated to the extent possible with the comparable ISO Standards or proposed Standards. The dimensional differences between the ANSI and the comparable ISO Standards or proposed Standards are few, relatively minor, and none will affect the functional interchangeability of bolts, screws, and nuts manufactured to the requirements of either.

Where no comparable ISO Standard had been developed, as was the case when the ANSI Standards for Metric Heavy Hex Screws, Metric Heavy Hex Bolts, and Metric Hex Lag Screws were adopted, nominal diameters, thread pitches, body diameters, widths across flats, head heights, thread lengths, thread dimensions, and nominal lengths are in accord with ISO Standards for related hex head screws and bolts. At the time of ANSI adoption (1982) there was no ISO Standard for round head square neck bolts.

The following functional characteristics of hex head screws and bolts are in agreement between the respective ANSI Standard and the comparable ISO Standard or proposed Standard: diameters and thread pitches, body diameters, widths across flats (see exception below), bearing surface diameters (except for metric hex bolts), flange diameters (for metric hex flange screws), head heights, thread lengths, thread dimensions, and nominal lengths.

**Table 1. American National Standard Metric Hex Cap Screws**  
ANSI/ASME B18.2.3.1M-1999 (Withdrawn)

<sup>a</sup> This size with width across flats of 15 mm is not standard. M10 screws with 15 mm width across flats are commonly produced in United States and other countries. The width across flats for all M10's should be specified. All sizes except the following are included in ISO 4014 and ISO 4017: M10 × 1.5 with 15 mm width across flats, and M72 through M100.

All dimensions are in millimeters.

Basic thread lengths,  $B$ , are the same as given in Table 13.

Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the ANSI/ASME B18.2.3.1M-1999 (Withdrawn).

<sup>a</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 formed hex screws with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

† Basic thread lengths,  $B$ , are the same as given in Table 13.

‡ Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on the grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the Standard.

Socket head cap screws ANSI/ASME B18.3.1M-1986 (Withdrawn) are functionally interchangeable with screws which conform to ISO R861-1968 or ISO 4762-1977. However, the thread lengths specified in the ANSI Standard are equal to or longer than required by either ISO Standard. Consequently the grip lengths also vary on screws where the North American thread length practice differs. Minor variations in head diameter, head height, key engagement and wall thickness are due to diverse tolerancing practice and will be found documented in the ANSI Standard.

One exception with respect to width across flats for metric hex cap screws, formed hex screws, and hex bolts is the M10 size. These are currently being produced in the United States with a width across flats of 15 mm. This size, however, is not an ISO Standard. Unless these M10 screws and bolts with 15 mm width across flats are specifically ordered, the M10 size with 16 mm across flats will be furnished.

All dimensions are in millimeters.

Basic thread lengths,  $B$ , are the same as given in Table 13.

Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the Standard.

ANSI letter symbols designating dimensional characteristics are in accord with those used in ISO Standards except capitals have been used for data processing convenience instead of the lower case letters used in the ISO Standards.

**Metric Screw and Bolt Diameters.**—Metric screws and bolts are furnished with full diameter body within the limits shown in the respective dimensional tables, or are threaded to the head (see *Metric Screw and Bolt Thread Lengths* on page 1725) unless the purchaser specifies “reduced body diameter.” Metric formed hex screws (Table 4), hex flange screws (Table 4), hex bolts (Table 4), heavy hex bolts (Table 4), hex lag screws (Table 5), heavy hex flange screws (Table 7), and round head square neck bolts (Table 9) may be obtained with reduced diameter body, if so specified; however, formed hex screws, hex flange screws, heavy hex flange screws, hex bolts, or heavy hex bolts with nominal lengths shorter than  $4D$ , where  $D$  is the nominal diameter, are not recommended. Metric formed hex screws, hex flange screws, heavy hex flange screws, and hex lag screws with reduced body diameter will be furnished with a shoulder under the head. For metric hex bolts and heavy hex bolts this is optional with the manufacturer.

For bolts and lag screws there may be a reasonable swell, fin, or die seam on the body adjacent to the head not exceeding the nominal bolt diameter by: 0.50 mm for M5, 0.65 mm for M6, 0.75 mm for M8 through M14, 1.25 mm for M16, 1.50 mm for M20 through M30, 2.30 mm for M36 through M48, 3.00 mm for M56 through M72, and 4.80 mm for M80 through M100.

110.0											
120.0				130120	160120	200120	250120				

All dimensions are in millimeters.

*R*<sub>1</sub> rounded or chamfered; *R*<sub>1</sub> ≤ 0.15 mm for M5, M6, M10; *R*<sub>1</sub> ≤ 0.20 mm for M12, M16, M20 Unless specified otherwise, threads are metric coarse series in accordance with ANSI/ASME B1.13M, Metric Screw Threads - M Profile. Tolerances for threads are to ISO Tolerance Class 4g6g. Standard length and diameter combinations are shown in the lower chart. The government encourages the general use of the part number system (PIN) to achieve maximum parts standardization. For details not shown, including material and complete PIN system, see ANSI/ASME B18.3.3M-1986 (Withdrawn).

**Table 7. American National Standard Metric Heavy Hex Flange Screws ANSI/ASME B18.2.3.9M-2001 (R2014)**

The technical drawing illustrates the geometry of a metric heavy hex flange screw. It includes a top view of the hexagonal head with dimensions  $D_c$  (head diameter),  $S$  (width across flats), and  $E$  (width across corners). The head height is  $K$ , and the fillet radius is  $R$ . The drawing also shows the side view with dimensions  $L$  (total length),  $L_g$  (grip length),  $B$  (basic thread length),  $L_s$  (transition thread length),  $x$  (transition thread length including tolerances),  $D_s$  (body diameter),  $D_w$  (bearing circle diameter),  $C$  (flange edge thickness), and  $K_1$  (wrenching height). An optional indentation and configuration is shown on the head. A detail view 'X' shows the head profile with a  $15^\circ-30^\circ$  chamfer, a  $1.5^\circ$  maximum contour, and a fillet radius  $R$ . An optional point construction is also shown.

Nominal Screw Dia., $D$ , and Thread Pitch	Body Dia., $D_s$		Width Across Flats, $S$		Width Across Corners, $E$		Flange Dia., $D_c$	Bearing Circle Dia., $D_w$	Flange Edge Thickness, $C$	Head Height, $K$	Wrenching Height $K_1$	Fillet Radius, $R$

All dimensions are in millimeters. Basic thread lengths,  $B$ , are the same as given in Table 13. Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. This dimension is intended for calculation purposes only. For additional manufacturing and acceptance specifications, reference should be made to ANSI/ASME B18.2.3.4M-2001 standard.

All dimensions are in millimeters.

Table 10. American National Standard Metric Round Head Square Neck Bolts ANSI/ASME B18.5.2.2M-1982 (Withdrawn)

The drawing shows a side view and an end view of a square neck bolt. The side view labels include: (30° REF) for the chamfered edge, R for the chamfer radius, (R<sub>k</sub>) for the head radius, D<sub>s</sub> for the diameter of the full body, D<sub>w</sub> for the bearing surface diameter, D for the nominal diameter, C for the head edge thickness, F<sub>1</sub> for the square corner depth, F for the square depth, K for the head height, L<sub>g</sub> for the grip gaging length, and L for the basic thread length. The end view labels include V for the square width across flats and D<sub>c</sub> for the square width across corners.

<sup>a</sup> Basic thread length, *B*, is a reference dimension.<sup>b</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 hex bolts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

For additional manufacturing and acceptance specifications, reference should be made to the ASME B18.2.3.5M-1979 (R2016) standard.

**Materials and Mechanical Properties.**—Unless otherwise specified, steel metric screws and bolts, with the exception of heavy hex structural bolts, hex lag screws, and socket head cap screws, conform to the requirements specified in SAE J1199 or ASTM F568. Steel heavy hex structural bolts conform to ASTM A325M or ASTM A490M. Alloy steel socket head cap screws conform to ASTM A574M, property class 12.9, where the numeral 12 represents approximately one-hundredth of the minimum tensile strength in megapascals and the decimal .9 approximates the ratio of the minimum yield stress to the minimum tensile stress. This is in accord with ISO designation practice. Screws and bolts

of other materials, and all materials for hex lag bolts, have properties as agreed upon by the purchaser and the manufacturer.

Except for socket head cap screws, metric screws and bolts are furnished with a natural (as processed) finish, unplated or uncoated unless otherwise specified.

Alloy steel socket head cap screws are furnished with an oiled black oxide coating (thermal or chemical) unless a protective plating or coating is specified by the purchaser.

**Metric Screw and Bolt Identification Symbols.**—Screws and bolts are identified on the top of the head by property class symbols and manufacturer's identification symbol.

**Metric Screw and Bolt Designation.**—Metric screws and bolts with the exception of socket head cap screws are designated by the following data, preferably in the sequence shown: product name, nominal diameter and thread pitch (except for hex lag screws), nominal length, steel property class or material identification, and protective coating, if required.

*Example:* Hex cap screw, M10 × 1.5 × 50, class 9.8, zinc plated

Heavy hex structural bolt, M24 × 3 × 80, ASTM A490M

Hex lag screw, 6 × 35, silicon bronze.

Socket head cap screws (metric series) are designated by the following data in the order shown: ANSI Standard number, nominal size, thread pitch, nominal screw length, name of product (may be abbreviated SHCS), material and property class (alloy steel screws are supplied to property class 12.9 as specified in ASTM A574M; corrosion-resistant steel screws are specified to the property class and material requirements in ASTM F837M), and protective finish, if required.

*Example:* B18.3.1M—6 × 1 × 20 Hexagon Socket Head Cap Screw, Alloy Steel

B18.3.1M—10 × 1.5 × 40 SHCS, Alloy Steel Zinc Plated.

**Metric Screw and Bolt Thread Lengths.**—The length of thread on metric screws and bolts (except for metric lag screws) is controlled by the grip gaging length,  $L_g$  max. This is the distance measured parallel to the axis of the screw or bolt, from under the head bearing surface to the face of a noncounterbored or noncountersunk standard GO thread ring gage assembled by hand as far as the thread will permit. The maximum grip gaging length, as calculated and rounded to one decimal place, is equal to the nominal screw length,  $L$ , minus the basic thread length,  $B$ , or in the case of socket head cap screws, minus the minimum thread length  $L_T$ .  $B$  and  $L_T$  are reference dimensions intended for calculation purposes only and will be found in Table 13 and Table 15, respectively.

**Table 14. Basic Thread Lengths for Metric Round Head Square Neck Bolts**  
ANSI/ASME B18.5.2.2M-1982 (R2010)

Nom. Bolt Dia., $D$ and Thread Pitch	Bolt Length, $L$			Nom. Bolt Dia., $D$ and Thread Pitch	Bolt Length, $L$		
	≤ 125	> 125 and ≤ 200	> 200		≤ 125	> 125 and ≤ 200	> 200
	Basic Thread Length, $B$				Basic Thread length, $B$		
M5 × 0.8	16	22	35	M14 × 2	34	40	53
M6 × 1	18	24	37	M16 × 2	38	44	57
M8 × 1.25	22	28	41	M20 × 2.5	46	52	65
M10 × 1.5	26	32	45	M24 × 3	54	60	73
M12 × 1.75	30	36	49	...	...	...	...

All dimensions are in millimeters

Basic thread length  $B$  is a reference dimension intended for calculation purposes only.

**Table 15. Socket Head Cap Screws (Metric Series)—Length of Complete Thread**  
*ANSI/ASME B18.3.1M-1986 (Withdrawn)*

Nominal Size	Length of Complete Thread, $L_T$	Nominal Size	Length of Complete Thread, $L_T$	Nominal Size	Length of Complete Thread, $L_T$
M1.6	15.2	M6	24.0	M20	52.0
M2	16.0	M8	28.0	M24	60.0
M2.5	17.0	M10	32.0	M30	72.0
M3	18.0	M12	36.0	M36	84.0
M4	20.0	M14	40.0	M42	96.0
M5	22.0	M16	44.0	M48	108.0

Grip length,  $L_G$  equals screw length,  $L$ , minus  $L_T$ . Total length of thread  $L_{TT}$  equals  $L_T$  plus 5 times the pitch of the coarse thread for the respective screw size. Body length  $L_B$  equals  $L$  minus  $L_{TT}$ .

The minimum thread length for hex lag screws is equal to one-half the nominal screw length plus 12 mm, or 150 mm, whichever is shorter. Screws too short for this formula to apply are threaded as close to the head as practicable.

**Metric Screw and Bolt Diameter-Length Combinations.**—For a given diameter, the recommended range of lengths of metric cap screws, formed hex screws, heavy hex screws, hex flange screws, and heavy hex flange screws can be found in Table 17, for heavy hex structural bolts in Table 18, for hex lag screws in Table 16, for round head square neck bolts in Table 19, and for socket head cap screws in Table 20. No recommendations for diameter-length combinations are given in the Standards for hex bolts and heavy hex bolts.

Hex bolts in sizes M5 through M24 and heavy hex bolts in sizes M12 through M24 are standard only in lengths longer than 150 mm or  $10D$ , whichever is shorter. When shorter lengths of these sizes are ordered, hex cap screws are normally supplied in place of hex bolts and heavy hex screws in place of heavy hex bolts. Hex bolts in sizes M30 and larger and heavy hex bolts in sizes M30 and M36 are standard in all lengths; however, at manufacturer's option, hex cap screws may be substituted for hex bolts and heavy hex screws for heavy hex bolts for any diameter-length combination.

<sup>a</sup> Lengths in parentheses are not recommended. Recommended lengths of formed hex screws, hex flange screws, and heavy hex flange screws do not extend above 150 mm. Recommended lengths of heavy hex screws do not extend below 20 mm. Standard sizes for government use. Recommended diameter-length combinations are indicated by the symbol ●. Screws with lengths above heavy cross lines are threaded full length.

<sup>b</sup> Does not apply to hex flange screws and heavy hex flange screws.

All dimensions are in millimeters.

For available diameters of each type of screw, see respective dimensional table.

All dimensions are in millimeters. Screws with lengths above heavy cross lines are threaded full length. Diameter-length combinations are indicated by the symbol ●. Standard sizes for government use. In addition to the lengths shown, the following lengths are standard: 3, 4, 5, 6, 8, 10, 12, and 16 mm. No diameter-length combinations are given in the Standard for these lengths. Screws larger than M24 with lengths equal to or shorter than  $L_{TT}$  (see Table 15 footnote) are threaded full length.

<sup>a</sup> See also Table 23.<sup>b</sup> The M14 × 2 size is not recommended for use in new designs.

All dimensions are in millimeters

*L<sub>G</sub>* is grip length and *L<sub>B</sub>* is body length (see Table 15). For length of complete thread, see Table 15.

For additional manufacturing and acceptance specifications, see ANSI/ASME B18.3.1M (Withdrawn).

**Table 22. Drilled Head Dimensions for Metric Hex Socket Head Cap Screws**

Nominal Size or Basic Screw Diameter	Hole Center Location, W		Drilled Hole Diameter, X		Hole Alignment Check Plug Diameter
	Max.	Min.	Max.	Min.	Basic
M3	1.20	0.80	0.95	0.80	0.75
M4	1.60	1.20	1.35	1.20	0.90
M5	2.00	1.50	1.35	1.20	0.90
M6	2.30	1.80	1.35	1.20	0.90
M8	2.70	2.20	1.35	1.20	0.90
M10	3.30	2.80	1.65	1.50	1.40
M12	4.00	3.50	1.65	1.50	1.40
M16	5.00	4.50	1.65	1.50	1.40
M20	6.30	5.80	2.15	2.00	1.80
M24	7.30	6.80	2.15	2.00	1.80
M30	9.00	8.50	2.15	2.00	1.80
M36	10.50	10.00	2.15	2.00	1.80

All dimensions are in millimeters.

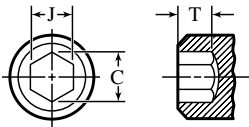

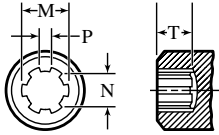

Drilled head metric hexagon socket head cap screws normally are not available in screw sizes smaller than M3 nor larger than M36. The M3 and M4 nominal screw sizes have two drilled holes spaced 180 degrees apart. Nominal screw sizes M5 and larger have six drilled holes spaced 60 degrees apart unless the purchaser specifies two drilled holes. The positioning of holes on opposite sides of the socket should be such that the hole alignment check plug will pass completely through the head without any deflection. When so specified by the purchaser, the edges of holes on the outside surface of the head will be chamfered 45 degrees to a depth of 0.30 to 0.50 mm.

### Metric Nuts

The American National Standards covering metric nuts have been established in cooperation with the Department of Defense in such a way that they could be used by the government for procurement purposes. Extensive information concerning these nuts is given in the following text and tables, but for more complete manufacturing and acceptance specifications, reference should be made to the respective Standards, which may be obtained by non-governmental agencies from the American National Standards Institute, 25 West 43rd Street, New York, NY 10036, [www.ansi.org](http://www.ansi.org). Manufacturers should be consulted concerning items and sizes which are in stock production.

**Comparison with ISO Standards.**—American National Standards for metric nuts have been coordinated to the extent possible with comparable ISO Standards or proposed Standards, thus: ANSI B18.2.4.1M Metric Hex Nuts, Style 1 with ISO 4032; B18.2.4.2M Metric Hex Nuts, Style 2 with ISO 4033; B18.2.4.4M Metric Hex Flange Nuts with ISO 4161; B18.2.4.5M Metric Hex Jam Nuts with ISO 4035; and B18.2.4.3M Metric Slotted Hex Nuts, B18.2.4.6M Metric Heavy Hex Nuts in sizes M12 through M36, and B18.16M Prevailing-Torque Type Steel Metric Hex Nuts and Hex Flange Nuts with comparable draft ISO Standards. The dimensional differences between each ANSI Standard and the comparable ISO Standard or draft Standard are very few, relatively minor, and none will affect the interchangeability of nuts manufactured to the requirements of either.

7.391	7.5692	7.5184	6.4516	6.4008	1.7272	2.6764

<sup>a</sup> The tabulated dimensions represent direct metric conversions of the equivalent inch size spline sockets shown in American National Standard Socket Cap, Shoulder and Set Screws.—Inch Series ANSI/ASME B18.3. Therefore, the spline keys and bits shown therein are applicable for wrenching the corresponding size metric spline sockets.

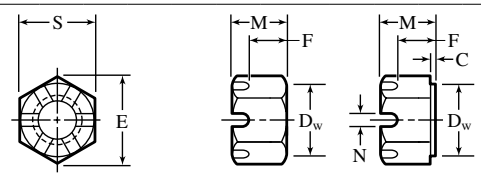

At its meeting in Varna, May 1977, ISO/TC2 studied several technical reports analyzing design considerations influencing determination of the best series of widths across flats for hex bolts, screws, and nuts. A primary technical objective was to achieve a logical ratio between under head (nut) bearing surface area (which determines the magnitude of compressive stress on the bolted members) and the tensile stress area of the screw thread (which governs the clamping force that can be developed by tightening the fastener). The series of widths across flats in the ANSI Standards agree with those which were selected by ISO/TC2 to be ISO Standards.

One exception for width across flats of metric hex nuts, styles 1 and 2, metric slotted hex nuts, metric hex jam nuts, and prevailing-torque metric hex nuts is the M10 size. These nuts in M10 size are currently being produced in the United States with a width across flats of 15 mm. This width, however, is not an ISO Standard. Unless these M10 nuts with width across flats of 15 mm are specifically ordered, the M10 size with 16 mm width across flats will be furnished.

In ANSI Standards for metric nuts, letter symbols designating dimensional characteristics are in accord with those used in ISO Standards, except capitals have been used for data processing convenience instead of lower case letters used in ISO Standards.

**Metric Nut Tops and Bearing Surfaces.**—Metric hex nuts, styles 1 and 2, slotted hex nuts, and hex jam nuts are double chamfered in sizes M16 and smaller and in sizes M20 and larger may either be double chamfered or have a washer-faced bearing surface and a chamfered top at the option of the manufacturer. Metric heavy hex nuts are optional either way in all sizes. Metric hex flange nuts have a flange bearing surface and a chamfered top and prevailing-torque type metric hex nuts have a chamfered bearing surface. Prevailing-torque type metric hex flange nuts have a flange bearing surface. All types of metric nuts have the tapped hole countersunk on the bearing face and metric slotted hex nuts, hex flange nuts, and prevailing-torque type hex nuts and hex flange nuts may be countersunk on the top face.

**Table 24. American National Standard Metric Slotted Hex Nuts**

<sup>a</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 slotted hex nuts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

**Materials and Mechanical Properties.**—Non-heat-treated carbon steel metric hex nuts, style 1 and slotted hex nuts conform to material and property class requirements specified for property class 5 nuts; hex nuts, style 2 and hex flange nuts to property class 9 nuts; hex jam nuts to property class 4 nuts, and non-heat-treated carbon and alloy steel heavy hex nuts to property classes 5, 9, 8S, or 8S3 nuts; all as covered in ASTM A563M. Carbon steel metric hex nuts, style 1 and slotted hex nuts that have specified heat treatment conform to material and property class requirements specified for property class 10 nuts; hex nuts, style 2 to property class 12 nuts; hex jam nuts to property class 05 nuts; hex flange nuts to property classes 10 and 12 nuts; and carbon or alloy steel heavy hex nuts to property classes 10S, 10S3, or 12 nuts, all as covered in ASTM A563M. Carbon steel prevailing-torque type hex nuts and hex flange nuts conform to mechanical and property class requirements as given in ANSI/ASME B18.16M-2004 (R2016).

<sup>a</sup> The width across flats shall be the distance, measured perpendicular to the axis of the nut, between two opposite wrenching flats.

<sup>b</sup> A rounding or lack of fill at the junction of hex corners with the chamfer shall be permissible.

<sup>c</sup> The nut thickness shall be the overall distance, measured parallel to the axis of the nut, from the top of the nut to the bearing surface, and shall include the thickness of the washer face where provided.

<sup>d</sup> M16 and smaller nuts shall be double chamfered. M20 and larger nuts shall be either double chamfered or have a washer faced bearing surface and a chamfered top.

<sup>e</sup> Dimensional requirements shown in bold type are in addition to or differ from ISO 4032.

<sup>f</sup> When M10 hex nuts are ordered, nuts with 16 mm width across flats shall be furnished unless 15 mm width across flats is specified.

**Table 26. American National Standard Metric Hex Flange Nuts**

M20 × 2.5	30.00	29.16	34.64	32.95	42.8	39.9	3.0	20.00	18.90	1.2

All dimensions are in millimeters.

Metric nuts of other materials, such as stainless steel, brass, bronze, and aluminum alloys, have properties as agreed upon by the manufacturer and purchaser. Properties of nuts of several grades of nonferrous materials are covered in ASTM F467M.

Unless otherwise specified, metric nuts are furnished with a natural (unprocessed) finish, unplated or uncoated.

**Metric Nut Thread Series.**—Metric nuts have metric coarse threads with class 6H tolerances in accordance with ANSI/ASME B1.13M (see *Metric Screw and Bolt Diameter-Length Combinations* on page 1726). For prevailing-torque type metric nuts this condition applies before introduction of the prevailing torque feature. Nuts intended for use with externally threaded fasteners which are plated or coated with a plating or coating thickness (e.g., hot dip galvanized) requiring overtapping of the nut thread to permit assembly, have over-tapped threads in conformance with requirements specified in ASTM A563M.

**Types of Metric Prevailing-Torque Type Nuts.**—There are three basic designs for prevailing-torque type nuts:

- 1) All-metal, one-piece construction nuts which derive their prevailing-torque characteristics from controlled distortion of the nut thread and/or body.
- 2) Metal nuts which derive their prevailing-torque characteristics from addition or fusion of a nonmetallic insert, plug or patch in their threads.

3) Top insert, two-piece construction nuts which derive their prevailing-torque characteristics from an insert, usually a full ring of non-metallic material, located and retained in the nut at its top surface.

The first two designs are designated in Table 29 and Table 27 as “all-metal” type and the third design as “top-insert” type.

**Table 27. American National Standard Prevailing-Torque Metric Hex Flange Nuts ANSI/ASME B18.16M-2004 (R2016)**

Note: Size, Shape and Location of the Prevailing Torque Element Optional

<sup>a</sup> Also includes metal nuts with nonmetallic inserts, plugs, or patches in their threads.

All dimensions are in millimeters.

**Metric Nut Identification Symbols.**—Carbon steel hex nuts, styles 1 and 2, hex flange nuts, and carbon and alloy steel heavy hex nuts are marked to identify the property class and manufacturer in accordance with requirements specified in ASTM A563M. The aforementioned nuts when made of other materials, as well as slotted hex nuts and hex jam nuts, are marked to identify the property class and manufacturer as agreed upon by manufacturer and purchaser. Carbon steel prevailing-torque type hex nuts and hex flange nuts are marked to identify property class and manufacturer as specified in ANSI/ASME B18.16M. Prevailing-torque type nuts of other materials are identified as agreed upon by the manufacturer and purchaser.

**Metric Nut Designation.**—Metric nuts are designated by the following data, preferably in the sequence shown: product name, nominal diameter and thread pitch, steel property class or material identification, and protective coating, if required. (Note: It is common practice in ISO Standards to omit thread pitch from the product designation when the nut threads are the metric coarse thread series, e.g., M10 stands for M10 × 1.5).

*Example:* Hex nut, style 1, M10 × 1.5, ASTM A563M class 10, zinc plated

Heavy hex nut, M20 × 2.5, silicon bronze, ASTM F467, grade 651

Slotted hex nut, M20, ASTM A563M class 10.

<sup>a</sup> Also includes metal nuts with non-metallic inserts, plugs, or patches in their threads.

<sup>b</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 slotted hex nuts with 16 mm width across flats will be furnished. All dimensions are in millimeters.

### Metric Washers

**Metric Plain Washers.**—American National Standard ANSI/ASME B18.22M-1981 (R2017) covers general specifications and dimensions for flat, round-hole washers, both soft (as fabricated) and hardened, intended for use in general-purpose applications. Dimensions are given in the following table. Manufacturers should be consulted for current information on stock sizes.

**Comparison with ISO Standards.**—The washers covered by this ASME Standard are nominally similar to those covered in various ISO documents. Outside diameters were selected, where possible, from ISO/TC2/WG6/N47 “General Plan for Plain Washers for Metric Bolts, Screws, and Nuts.” The thicknesses given in the ASME Standard are similar to the nominal ISO thicknesses, however the tolerances differ. Inside diameters also differ.

ISO metric washers are currently covered in ISO 887, “Plain Washers for Metric Bolts, Screws, and Nuts - General Plan.”

**Types of Metric Plain Washers.**—Soft (as fabricated) washers are generally available in nominal sizes 1.6 mm through 36 mm in a variety of materials. They are normally used in low-strength applications to distribute bearing load, to provide a uniform bearing surface, and to prevent marring of the work surface.

Hardened steel washers are normally available in sizes 6 mm through 36 mm in the narrow and regular series. They are intended primarily for use in high-strength joints to minimize embedment, to provide a uniform bearing surface, and to bridge large clearance holes and slots.

**Metric Plain Washer Materials and Finish.**—Soft (as fabricated) washers are made of nonhardened steel unless otherwise specified by the purchaser. Hardened washers are made of through-hardened steel tempered to a hardness of 38 to 45 RC (Rockwell C scale).

Unless otherwise specified, washers are furnished with a natural (as fabricated) finish, unplated or uncoated with a light film of oil or rust inhibitor.

**Metric Plain Washer Designation.**—When specifying metric plain washers, the designation should include the following data in the sequence shown: description, nominal size, series, material type, and finish, if required.

*Example:* Plain washer, 6 mm, narrow, soft, steel, zinc plated

Plain washer, 10 mm, regular, hardened steel.

**Table 30. American National Standard Metric Plain Washers**  
*ANSI/ASME B18.22M-1981 (R2017)*

36	Narrow	38.92	38.30	66.00	64.80	5.60	4.50
	Regular	38.92	38.30	90.00	88.60	6.40	5.00
	Wide	38.92	38.30	110.00	108.60	8.50	7.00

<sup>a</sup> Nominal washer sizes are intended for use with comparable screw and bolt sizes.

<sup>b</sup> The 18.80/18.37 and 25.40/24.48 mm outside diameters avoid washers which could be used in coin-operated devices.

All dimensions are in millimeters.

### Clearance Holes for Bolts, Screws, and Studs

The Standard ANSI/ASME B18.2.8-1999 (R2017) covers the recommended clearance hole sizes for #0 through 1.5 inch and M1.6 through M100 metric fasteners in three classes of clearance using a close-, normal-, and loose-fit category.

The clearance hole tolerances for both inch and metric holes are based on ISO 286, *ISO System of Limits and Fits*, using tolerance class H12 for close-fit, H13 for normal-fit, and H14 for loose-fit clearance holes. The clearances provided by the three classes of fit are based on regularly stepped clearances as listed in [Table 1a](#) for inch and [Table 2b](#) for metric.

**Inch Fasteners.**—The hole sizes for inch fasteners are patterned after US common usage and the general clearances translated from the metric standard. The hole tolerances are based on the *ISO System of Limits and Fits*, as required by ISO 273.

The tabulated drill and hole sizes, [Table 1a](#), lists the inch fastener clearance hole recommendations. The recommended drill sizes for inch fasteners are tabulated by nominal drill designation as letter, numbers, or fractional sizes. The drill sizes were selected to provide as nearly as practical a step-patterned clearance size for the minimum recommended hole ([Table 1b](#)). The maximum recommended hole size is based on standard hole tolerances.

**Table 1a. Clearance Holes for Inch Fasteners ANSI/ASME B18.2.8-1999 (R2017)**

**Table 1b. Inch Clearance Hole Allowances**

Nominal Screw Size	Fit Classes			Nominal Screw Size	Fit Classes		
	Normal	Close	Loose		Normal	Close	Loose
#0 - #4	1/64	0.008	1/32	1	3/32	1/32	5/32
#5 - 7/16	1/32	1/64	3/64	1 1/8, 1 1/4	3/32	1/32	3/16
1/2, 5/8	1/16	1/32	7/64	1 3/8, 1 1/2	1/2	1/16	15/64
3/4, 7/8	1/16	1/32	5/32	...	...	...	...

Dimensions are in inches.

**Metric Fasteners.**—The recommended drill and hole sizes for metric fasteners are tabulated in [Table 2a](#). The minimum recommended hole is the drill size and the maximum recommended hole size is based on standard tolerances. The hole sizes for metric fasteners are in agreement with ISO 273, *Fasteners-Clearance Holes for Bolts and Screws*, except that ISO 273 covers fastener sizes M1 through M150.

**Close Clearance:** Close clearance should be specified only for square holes in very thin and/or soft material, or for slots, or where conditions such as critical alignment of assembled parts, wall thickness, or other limitations necessitate use of a minimal hole. Allowable swell or fins on the bolt body and/or fins on the corners of the square neck may interfere with close clearance round or square holes.

**Normal Clearance:** Normal clearance hole sizes are preferred for general purpose applications and should be specified unless special design considerations dictate the need for either a close or loose clearance hole.

**Loose Clearance:** Loose clearance hole sizes should be specified only for applications where maximum adjustment capability between components being assembled is necessary. Loose clearance square hole or slots may not prevent bolt turning during wrenching.

All dimensions are in millimeters. Source: ANSI/ASME B18.5.2.2M-1982, Appendix II

<sup>a</sup> *Countersink*: It is considered good practice to countersink or break the edges of holes which are smaller than  $B$  Max. (see Table 21, page 1730) in parts having a hardness which approaches, equals, or exceeds the screw hardness. If such holes are not countersunk, the heads of screws may not seat properly or the sharp edges on holes may deform the fillets on screws, thereby making them susceptible to fatigue in applications involving dynamic loading. The countersink or corner relief, however, should not be larger than is necessary to ensure that the fillet on the screw is cleared. Normally, the diameter of countersink does not have to exceed  $B$  Max. Countersinks or corner reliefs in excess of this diameter reduce the effective bearing area and introduce the possibility of embedment where the parts to be fastened are softer than the screws or of brinelling or flaring the heads of the screws where the parts to be fastened are harder than the screws.

<sup>b</sup> *Close Fit*: The close fit is normally limited to holes for those lengths of screws which are threaded to the head in assemblies where only one screw is to be used or where two or more screws are to be used and the mating holes are to be produced either at assembly or by matched and coordinated tooling.

<sup>c</sup> *Normal Fit*: The normal fit is intended for screws of relatively long length or for assemblies involving two or more screws where the mating holes are to be produced by conventional tolerancing methods. It provides for the maximum allowable eccentricity of the longest standard screws and for certain variations in the parts to be fastened, such as: deviations in hole straightness, angularity between the axis of the tapped hole and that of the hole for shank, differences in center distances of the mating holes, etc.

All dimensions are in millimeters.

## HELICAL COIL SCREW THREAD INSERTS

## Introduction

The ANSI/ASME B18.29.2M standard delineates the dimensional, mechanical, and performance data for the metric series helical coil screw thread insert and threaded hole into which it is installed. Appendices that describe insert selection, STI (screw thread insert) taps, insert installation, and removal tooling are also included.

Helical coil inserts are screw thread bushings coiled from wire of diamond-shape cross section. Inserts are screwed into STI-tapped holes to form nominal size internal threads. Inserts are installed by torquing through a diametral tang. This tang is notched for removal after installation. In the free state, they are larger in diameter than the tapped hole into which they are installed. In the assembly operation, the torque applied to the tang reduces the diameter of the leading coil and permits it to enter the tapped thread. The remaining coils are reduced in diameter as they, in turn, are screwed into the tapped hole. When the torque or rotation is stopped, the coils expand with a spring-like action anchoring the insert in place against the tapped hole.

**Dimensions.**—Dimensions in this standard are in millimeters and apply before any coating. Symbols specifying geometric characteristics are in accordance with ASME Y14.5.

**Tolerance Classes 4H5H and 5H.**—Because helical coil inserts are flexible, the class of fit of the final assembly is a function of the size of the tapped hole. Helical coil STI taps are available for both tolerance class 4H5H (or class 4H6H) and class 5H tapped holes. Tolerance class 5H tapped holes provide maximum production tolerances but result in lower locking torques when screw-locking inserts are used. The higher and more consistent torques given in Table 5 are met by the screw-locking inserts when assembled and tested in tolerance class 4H5H (or class 4H6H) tapped holes.

**Compatibility.**—Assembled helical coil inserts will mate properly with items that have M Profile external threads in accordance with ANSI/ASME B1.13M. Also, due to the radius on the crest of the insert at the minor diameter, the assembled insert will mate with MJ Profile externally threaded parts with controlled radius root threads per ANSI/ASME B1.21M.

**Types of Inserts.**—*Free-running* inserts provides a smooth, hard, and free-running thread. *Screw-locking* inserts provides a resilient locking thread produced by a series of chords on one or more of the insert coils.

**STI-Tapped Hole.**—The tapped hole into which the insert is installed shall be in accordance with ANSI/ASME B1.13M, except that diameters are larger to accommodate the wire cross section of the insert (See Fig. 1). Dimensions of the STI-tapped hole are shown in Table 1 and are calculated per General Note (c) to Table 1.

*Screw Thread Designation for Tapped Hole:* The drawing note for the STI-threaded hole per Table 1 to accept the helical coil insert shall be in accordance with the following:

*Example 1:* MS  $\times$  1.25-5H STI; 23.5 T per ANSI/ASME B18.29.2M.

*Designation for a Helical Coil Insert:* Helical coil inserts shall be designated by the following data, in the sequence shown:

a) product name; b) designation of the standard; c) nominal diameter and thread pitch (4) nominal length; and d) insert type (free-running or screw-locking).

*Example 2:* Helical Coil insert, ANSI/ASME B18.29.2M, M8  $\times$  1.25  $\times$  12.0 free-running.  
Helical Coil insert, ANSI/ASME B18.29.2M, M5  $\times$  0.8  $\times$  7.5 screw-locking.

The recommended B18 part number (PIN) code system for helical coil inserts is included in ANSI/ASME B18.24. This system may be used by user needing definitive part-numbering.

Fig. 1. Tapping Depth

**Designation for STI-Threaded Hole Including Installed Helical Coil Insert:** The drawing note for the STI-threaded hole per [Table 1](#) having a helical coil insert installed shall be in accordance with this example.

*Example 3:* M8 × 1.25 STI 23.5 deep;

Helical Coil insert, ANSI/ASME B18.29.2M, M8 × 1.25 × 12.0, free running

**Gages and Gaging:** Acceptance of the threaded hole is determined by gaging with STI GO, NOT GO (HI), and plain cylindrical gages designed and applied in accordance with System 21 of ANSI/ASME B1.3 and with ANSI/ASME B1.16M.

### Helical Coil Insert

**Material.**—Chemical composition of the inserts is austenitic corrosion-resistant (stainless) steel material within the limits of [Table 2](#).

**Properties.**—Wire, before coiling into inserts, shall have tensile strength not lower than 1035 MPa, determined in accordance with ASTM A370. Wire shall withstand, without cracking, bending in accordance with ASTM E 290 at room temperature through an angle of 180° around a diameter equal to twice the cross-sectional dimension of the wire in the plane of the bend. The formed wire shall be of uniform quality and temper; it shall be smooth, clean, and free from kinks, waviness, splits, cracks, laps, seams, scale, segregation, and other defects that may impair the serviceability of the insert.

**Coatings.**—At the option of the user, dry film lubricant coating can be applied to helical coil inserts. The color of dry film-lubricated inserts is dark gray to black. Lubricant shall meet requirements of Aerospace Standard SAE AS5272, type I, lubricant, solid film heat cured, and corrosion inhibiting. Coating shall be uniformly deposited on the insert with the minimum thickness being complete coverage. Maximum thickness shall be the avoidance of bridging between coils. Slight fill in between closely wound coils, which immediately separates as the coils are axially pulled apart by hand, shall not be considered bridging.

**Configuration and Dimensions.**—Insert configurations shall be in accordance with [Fig. 2](#), and dimensions shall be in accordance with [Table 3](#) and [Table 4](#). Each nominal insert size is standardized in five lengths, which are multiples of the insert's nominal diameter. These are 1, 1.5, 2, 2.5, and 3 times nominal diameter. Each nominal length is the minimum through-hole length (material thickness), without countersink, into which that insert can be installed. The nominal insert length is a reference value and cannot be measured. Actual assembled length of the insert equals nominal length minus 0.5 pitch to minus 0.75 pitch, with insert installed in a basic STI threaded hole. Assembled length cannot be measured in the insert's free state.

**Notes:**

(1) The minimum drilling depths allow for  
a) countersinking the drilled hole to prevent a feather edge at the start of the tapped hole.

b) 0.75 to 1.5 pitch of insert set-down to allow for maximum production tolerance.

c) Dimensions are shown for both plug and bottoming taps. Plug taps 8 mm and smaller have a male center, and the drilled hole depth dimensions allow for this length (one-half of the diameter of the bolt). Calculation of minimum drilling depth dimension *G* is as follows:

Plug taps 8 mm and smaller,  $G = \text{insert nominal length} + 0.5 \times \text{nominal bolt diameter} + 4 \text{ pitches for tap chamfer} + 1 \text{ pitch for tap end clearance} + 1 \text{ pitch allowance for countersink and maximum insert set-down.}$

Plug taps larger than 8 mm,  $G = \text{insert nominal length} + 4 \text{ pitches for tap chamfer} + 1 \text{ pitch for tap end clearance} + 1 \text{ pitch allowance for countersink and maximum insert set-down.}$

Bottoming taps,  $G = \text{insert nominal length} + 2 \text{ pitches for tap chamfer} + 1 \text{ pitch for tap end clearance} + 1 \text{ pitch allowance for countersink and maximum insert set-down.}$

(2) The minimum tapping depth (dimension *T*) is the minimum for countersink holes with insert set-down of 1.5 pitch maximum (See Fig. 1). The dimension  $T = \text{insert nominal length} + 1 \text{ pitch.}$

(3) Thread diameters are calculated as follows:

Pitch diameter, min. = Pitch diameter, min. of nominal thread +  $2 \times H_{\max}$

Pitch diameter, max. = Pitch diameter, max. of nominal thread +  $2 \times H_{\min}$

Major diameter, min. = Pitch diameter, min. +  $0.649519 \times P$

Minor diameter, min. = Pitch diameter min. –  $0.433013 \times P$

Minor diameter, max. = Minor diameter min. + tolerance

where  $H_{\max}$  and  $H_{\min}$  are from Table 14, and tolerance is selected from the appropriate table in ANSI/ASME B1.13M with basic major diameter equal to the minimum major diameter of the STI thread.

Fig. 2. Insert Configuration

**General Notes for Fig. 2:**

- (a) Assembled length of insert to be measured from notch.
- (b) Dimensions apply before supplementary coating (see Table 3 and Table 4).
- (c) Surface texture; symbols per ASME Y14.35, requirements per ANSI/ASME B46.1.
- (d) Dimensions and tolerancing; ASME Y14.5.

**Notes:**

- (1) Number of locking coils, spacing of locking coils, number of locking deformations, shape and orientation optional locking feature for 1, 1.5, and 2 diam. length inserts symmetrically positioned about the center of insert, and for 2.5 and 3 diam. length inserts at 1 diam. from tang end of insert.
- (2) Number of free coils to be counted from notch.

**Inspection and Quality Assurance**

The inspection of inserts shall be in accordance with ANSI/ASME B18.18, with inspection level 3 for the 15 cycle torque test.

**Inspection (Nondestructive).**—Inserts shall be visually examined for conformance with drawings and workmanship requirements in accordance with ANSI/ASME B18.18.

**Threads:** The inserts, when assembled in STI threaded holes conforming to Table 1, shall form threads conforming to ANSI/ASME B1.13M tolerance class 4H5H or 5H except for the locking feature of screw-locking inserts. The assembled insert, both types, shall accept and function with parts having external MJ threads per ANSI/ASME B1.21M.

**Table 2. Screw Thread Insert Chemical Composition**  
ANSI/ASME B18.29.2M-2005 (R2017)

Element	Analysis, %	Check Analysis	
		Under, Min.	Over, Max.
Carbon	0.15 max.	...	0.01
Manganese	2.00 max.	...	0.04
Silicon	1.00 max.	...	0.05
Phosphorous	0.045 max.	...	0.01
Sulphur	0.035 max.	...	0.005
Chromium	17.00 to 20.00	0.20	0.20
Nickel	8.00 to 10.50	0.15	0.15
Molybdenum	0.75 max.	...	0.05
Copper	0.75 max.	...	0.05
Iron	Remainder	...	...

The accuracy of the finished thread when the insert is installed depends on the accuracy of the tapped hole. If the finished tapped hole gages satisfactorily, the installed insert will be within the thread tolerance when the insert meets the requirements of the Standard. It is, therefore, not necessary to gage the installed insert. After the insert is installed, the GO thread plug gage may not enter freely because the insert may not have been fully seated in the tapped hole. However, the insert should become seated after a bolt or screw is installed and tightened.

**Tang Removal Notch:** The tang removal notch shall be located as shown in Fig. 2 and of such depth that the part may be installed without failure of the tang and that the tang may be removed, after assembly, without affecting the function of the installed insert.

**Torque Test Bolts:** Assembled screw-locking inserts shall be torque tested with bolts in accordance with ANSI/ASME B1.13M or ANSI/ASME B1.21M, cadmium plated, or having other coating with a similar coefficient of friction and hardness of 36 to 44 RC (Rockwell C scale). The bolts selected for this test shall be of sufficient length so the thread runout does not enter the insert and that a minimum of one full thread extends past the end of the insert when the bolt is fully seated. Acceptability of bolt threads shall be determined based on System 22 of ANSI/ASME B1.3.

Until a replacement for cadmium plating on the torque test bolts is found, and test data completed, an alternate coating/lubricant can be used to perform the torque test.

**Self-Locking Torque (Destructive).**—The screw-locking insert, when assembled in threaded holes conforming to Table 1 and tested in accordance with the following paragraphs, shall provide a frictional lock to retain the bolt threads within the torque limits specified in Table 5.

**Torque Test Block and Spacer:** The insert to be tested shall be installed in a tolerance class 4H5H or 4H6H threaded hole conforming to Table 1 in a test block made from 2024-T4 (SAE AMS4120 or ASTM B209M) aluminum alloy. After installation, the tang shall be removed. The surface of the test block from which the insert is assembled shall be marked "TOP" and shall be marked to indicate the radial location where the assembled insert begins. A steel spacer meeting the requirements of Fig. 3 and Table 6 shall be used for developing the bolt load.

**Torque Test Method:** The torque test shall consist of a 15-cycle, room temperature test. A new bolt or screw and new tapped hole shall be used for each complete 15-cycle test. For each of the 15 cycles, bolts shall be assembled and seated to the assembly torque specified in Table 5. Bolts shall be completely disengaged from the locking coils of the insert at the end of each cycle. The test shall be run at less than 40 rpm to yield a dependable measure of torque and avoid heating of the bolt.

**Maximum Locking Torque:** Maximum locking torque shall be the highest torque value encountered on any installation or removal cycle and shall not exceed the values specified in Table 5. Maximum locking torque readings shall be taken on the first and seventh installation cycles before the assembly torque is applied and on the 15th removal cycle.

**Table 5. Self-Locking Torque ANSI/ASME B18.29.2M-2005 (R2017)**

...	...	...	M39 × 2	150	20
...	...	...	M39 × 3	150	20

**Minimum Breakaway Torque:** Minimum breakaway torque shall be the torque required to overcome static friction when 100 percent of the locking feature is engaged and the bolt or screw is not seated (no axial load). It shall be recorded at the start of the 15th removal cycle. The torque value for any cycle shall be not less than the applicable value shown in Table 5.

**Acceptance:** The inserts shall be considered to have failed if, at the completion of any of the tests and inspection, any of the following conditions exist:

- any break or crack in the insert
- installation or removal torque exceeds the maximum locking torque value in Table 5
- breakaway torque less than the values in Table 5
- movement of the insert beyond 90° relative to the top surface when installing or removing the test bolt
- seizure or galling of the insert or test bolt
- tang not broken off, which interferes with the test bolt at installation
- tang breaks off during insert installation

**Table 6. Torque Test Spacer Dimensions** *ANSI/ASME B18.29.2M-2005 (R2017)*

Nominal Insert Size	Minimum Diameter or Width	Hole Diameter		Countersink Diameter		Minimum Thickness

### Insert Length Selection

**Engaged Length of Bolt.**—Normally, the engaged length of bolt in an insert is determined by strength considerations.

**Material Strengths.**—The standard engineering practice of balancing the tensile strength of the bolt material against the shear strength of the parent or boss material also applies to helical coil inserts. [Table 7](#) and [Table 8](#) will aid in developing the full load value of the bolt rather than stripping the parent or tapped material.

In using this table, the following factors must be considered:

a) The parent material shear strengths are for room temperature. Elevated temperatures call for significant shear value reductions; compensation should be made when required. Shear values are appropriate because the parent material is subject to shearing stress at the major diameter of the tapped threads.

b) When parent material shear strength falls between two tabulated values, use the lower of the two.

c) Bolt thread length; overall length, insert length, and full tapped thread depth must be adequate to ensure full-thread engagement when assembled to comply with its design function.

**Table 7. Insert Length Selection ANSI/ASME B18.29.2M-2005 (R2017)**

Parent Material Shear Strength, MPa	Bolt Property Class						
	4.6	4.8	5.8	8.8	9.8	10.9	12.9
	Insert Length in Terms of Diameters						
70	3	3	3	...	...	...	...
100	2	2	2	3	...	...	...
150	1.5	1.5	1.5	2	2.5	2.5	3
200	1.5	1.5	1.5	2	2	2	2
250	1	1	1	1.5	1.5	1.5	1.5
300	1	1	1	1.5	1.5	1.5	1.5
350	1	1	1	1	1	1.5	1.5

**Table 8. Hardness Number Conversion ANSI/ASME B18.29.2M-2005 (R2017)**

Bolt Property Class	Max. Rockwell Hardness	Max. Tensile Strength, MPa	Bolt Property Class	Max. Rockwell Hardness	Max. Tensile Strength, MPa
4.6	95 RB	705	9.8	36 RC	1115
4.8	95 RB	705	10.9	39 RC	1215
5.8	95 RB	705	12.9	44 RC	1435
8.8	34 RC	1055			

Bolt strength upon which insert length recommendations are based is developed by taking the maximum hardness per ASTM F568M *Carbon and Alloy Steel Externally Threaded Metric Fasteners* and the equivalent tensile strength from SAE J417 *Hardness Tests and Hardness Number Conversions*.

**Screw Thread Insert Taps.**—ANSI/ASME B94.9 covers design and dimensions for taps for producing Metric Series STI-threaded holes required for the installation of helical coil screw thread inserts. Threaded hole dimensions are shown in [Table 1](#) of this standard. Helical coil screw thread insert taps are identified by the designation STI. Various types and styles of STI taps are available. General dimensions and tolerances are in accordance with ANSI/ASME B94.9.

*Tap Thread Limits:* Ground thread taps are recommended for screw thread inserts. Tap thread limits are in accordance with ANSI/ASME B94.9. Basic pitch diameter used for determining values is the “Pitch Diameter, min.” from [Table 1](#).

*Marking:* Taps are marked in accordance with ANSI/ASME B94.9.

*Example:* M6 × 1 STI HS G H2.

## BRITISH FASTENERS

**British Standard Square and Hexagon Bolts, Screws and Nuts.**—Important dimensions of precision hexagon bolts, screws and nuts (BSW and BSF threads) as covered by British Standard 1083:1965 are given in [Table 1](#) and [Table 2](#). The use of fasteners in this standard will decrease as fasteners having Unified inch and ISO metric threads come into increasing use.

Dimensions of Unified precision hexagon bolts, screws and nuts (UNC and UNF threads) are given in BS 1768:1963 (obsolescent); of Unified black hexagon bolts, screws and nuts (UNC and UNF threads) in BS 1769:1951 (obsolescent); and of Unified black square and hexagon bolts, screws and nuts (UNC and UNF threads) in BS 2708:1956 (withdrawn). Unified nominal and basic dimensions in these British Standards are the same as the comparable dimensions in the American Standards, but the tolerances applied to these basic dimensions may differ because of rounding-off practices and other factors. For Unified dimensions of square and hexagon bolts and nuts as given in ANSI/ASME B18.2.1-2012 and ANSI/ASME B18.2.2-2015 see [Table 1](#) through [Table 4](#) starting on page [1672](#), and [Table 7](#) to [Table 10](#) starting on page [1677](#).

ISO metric precision hexagon bolts, screws and nuts are specified in the British Standard BS 3692:1967 (obsolescent) (see *British Standard ISO Metric Precision Hexagon Bolts, Screws and Nuts* starting on page [1766](#)), and ISO metric black hexagon bolts, screws and nuts are covered by British Standard BS 4190:1967 (obsolescent).

See the section *MACHINE SCREWS AND NUTS* starting on page [1775](#) for information on British Standard metric, Unified, Whitworth, and BSF machine screws and nuts.

**British Standard Screwed Studs.**—General purpose screwed studs are covered in British Standard 2693: Part 1:1956. The aim in this standard is to provide for a stud having tolerances which would not render it expensive to manufacture and which could be used in association with standard tapped holes for most purposes. Provision has been made for the use of both Unified Fine threads, Unified Coarse threads, British Standard Fine threads, and British Standard Whitworth threads as shown in the table on page [1761](#).

*Designations:* The *metal end* of the stud is the end which is screwed into the component. The *nut end* is the end of the screw of the stud which is not screwed into the component. The *plain portion* of the stud is the unthreaded length.

*Recommended Fitting Practices for Metal End of Stud:* It is recommended that holes tapped to Class 3B limits (see [Table 3](#), page [1951](#)) in accordance with BS 1580 “Unified Screw Threads” or to Close Class limits in accordance with BS 84 “Screw Threads of Whitworth Form” as appropriate, be used in association with the metal end of the stud specified in this standard. Where fits are not critical, however, holes may be tapped to Class 2B limits (see table on page [1951](#)) in accordance with BS 1580 or Normal Class limits in accordance with BS 84.

It is recommended that the B.A. stud specified in this standard be associated with holes tapped to the limits specified for nuts in BS 93, 1919 edition. Where fits for these studs are not critical, holes may be tapped to limits specified for nuts in the current edition of BS 93.

In general, it will be found that the amount of oversize specified for the studs will produce a satisfactory fit in conjunction with the standard tapping as above. Even when interference is not present, locking will take place on the thread runout which has been carefully controlled for this purpose. Where it is considered essential to assure a true interference fit, higher grade studs should be used. It is recommended that standard studs be used even under special conditions where selective assembly may be necessary.

### British Standard Whitworth (BSW) and Fine (BSF) Precision Hexagon Bolts, Screws, and Nuts

For dimensions, see Table 1 and Table 2.

<sup>a</sup> Sizes shown in parentheses are non-preferred.

All dimensions are in millimeters. For illustration of hexagon slotted nuts and castle nuts see [Table 3](#).

After several years of use of BS 2693:Part 1:1956 (obsolescent), it was recognized that it would not meet the requirements of all stud users. The thread tolerances specified could result in clearance of interference fits because locking depended on the run-out threads. Thus, some users felt that true interference fits were essential for their needs. As a result, the British Standards Committee has incorporated the Class 5 interference fit threads specified in American Standard ASA B1.12 into the BS 2693:Part 2:1964, "Recommendations for High Grade Studs."

**British Standard ISO Metric Precision Hexagon Bolts, Screws and Nuts.**—This British Standard BS 3692:1967 (obsolescent) gives the general dimensions and tolerances of precision hexagon bolts, screws and nuts with ISO metric threads in diameters from 1.6 to 68 mm. It is based on the following ISO recommendations and draft recommendations: R 272, R 288, DR 911, DR 947, DR 950, DR 952 and DR 987. Mechanical properties are given only with respect to carbon or alloy steel bolts, screws and nuts, which are not to be used for special applications such as those requiring weldability, corrosion resistance or ability to withstand temperatures above 300°C or below -50°C. The dimensional requirements of this standard also apply to nonferrous and stainless steel bolts, screws and nuts.

*Finish:* Finishes may be dull black which results from the heat-treating operation or may be bright finish, the result of bright drawing. Other finishes are possible by mutual agreement between purchaser and producer. It is recommended that reference be made to BS 3382 "Electroplated Coatings on Threaded Components" in this respect.

*General Dimensions:* The bolts, screws and nuts conform to the general dimensions given in Table 3, Table 4, Table 5 and Table 6.

*Nominal Lengths of Bolts and Screws:* The nominal length of a bolt or screw is the distance from the underside of the head to the extreme end of the shank including any chamfer or radius. Standard nominal lengths and tolerances thereon are given in Table 7.

**Table 7. British Standard ISO Metric Bolt and Screw Nominal Lengths**  
BS 3692:1967 (obsolescent)

(22)	±0.42	80	±0.60	170	±0.80	475	±1.25
25	±0.42	85	±0.70	180	±0.80	500	±1.25
(28)	±0.42	...	...	190	±0.925	...	...

<sup>a</sup> Nominal lengths shown in parentheses are non-preferred.  
All dimensions are in millimeters.

*Bolt and Screw Ends:* The ends of bolts and screws may be finished with either a 45-degree chamfer to a depth slightly exceeding the depth of thread or a radius approximately equal

to  $1\frac{1}{4}$  times the nominal diameter of the shank. With rolled threads, the lead formed at the end of the bolt by the thread rolling operation may be regarded as providing the necessary chamfer to the end; the end being reasonably square with the center line of the shank.

*Screw Thread Form:* The form of thread and diameters and associated pitches of standard ISO metric bolts, screws, and nuts are in accordance with BS 3643:Part 1:1981 (2004), "Principles and Basic Data." The screw threads are made to the tolerances for the medium class of fit (6H/6g) as specified in BS 3643:Part 2:1981 (1998), "Specification for Selected Limits of Size."

*Length of Thread on Bolts:* The length of thread on bolts is the distance from the end of the bolt (including any chamfer or radius) to the leading face of a screw ring gage which has been screwed as far as possible onto the bolt by hand. Standard thread lengths of bolts are  $2d + 6$  mm for a nominal length of bolt up to and including 125 mm,  $2d + 12$  mm for a nominal bolt length over 125 mm up to and including 200 mm, and  $2d + 25$  mm for a nominal bolt length over 200 mm. Bolts that are too short for minimum thread lengths are threaded as screws and designated as screws. The tolerance on bolt thread lengths are plus two pitches for all diameters.

*Length of Thread on Screws:* Screws are threaded to permit a screw ring gage being screwed by hand to within a distance from the underside of the head not exceeding two and a half times the pitch for diameters up to and including 52 mm and three and a half times the pitch for diameters over 52 mm.

*Angularity and Eccentricity of Bolts, Screws and Nuts:* The axis of the thread of the nut is square to the face of the nut subject to the "squareness tolerance" given in Table 5.

In gaging, the nut is screwed by hand onto a gage, having a truncated taper thread, until the thread of the nut is tight on the thread of the gage. A sleeve sliding on a parallel extension of the gage, which has a face of diameter equal to the minimum distance across the flats of the nut and exactly at 90 degrees to the axis of the gage, is brought into contact with the leading face of the nut. With the sleeve in this position, it should not be possible for a feeler gage of thickness equal to the "squareness tolerance" to enter anywhere between the leading nut face and sleeve face.

The hexagon flats of bolts, screws and nuts are square to the bearing face, and the angularity of the head is within the limits of 90 degrees, plus or minus 1 degree. The eccentricity of the hexagon flats of nuts relative to the thread diameter should not exceed the values given in Table 5 and the eccentricity of the head relative to the width across flats and eccentricity between the shank and thread of bolts and screws should not exceed the values given in Table 4.

*Chamfering, Washer Facing and Countersinking:* Bolt and screw heads have a chamfer of approximately 30 degrees on their upper faces and, at the option of the manufacturer, a washer face or full bearing face on the underside. Nuts are countersunk at an included angle of 120 degrees plus or minus 10 degrees at both ends of the thread. The diameter of the countersink should not exceed the nominal major diameter of the thread plus 0.13 mm up to and including 12 mm diameter, and plus 0.25 mm above 12 mm diameter. This stipulation does not apply to slotted, castle or thin nuts.

*Strength Grade Designation System for Steel Bolts and Screws:* This Standard includes a strength grade designation system consisting of two figures. The first figure is one tenth of the minimum tensile strength in  $\text{kgf/mm}^2$ , and the second figure is one tenth of the ratio between the minimum yield stress (or stress at permanent set limit,  $R_{0.2}$ ) and the minimum tensile strength, expressed as a percentage. For example with the strength designation grade 8.8, the first figure 8 represents  $\frac{1}{10}$  the minimum tensile strength of 80  $\text{kgf/mm}^2$  and the second figure 8 represents  $\frac{1}{10}$  the ratio

$$\frac{\text{stress at permanent set limit } R_{0.2}\%}{\text{minimum tensile strength}} = \frac{1}{10} \times \frac{64}{80} \times \frac{100}{1}$$

the numerical values of stress and strength being obtained from the accompanying table.

### Strength Grade Designations of Steel Bolts and Screws

Strength Grade Designation	4.6	4.8	5.6	5.8	6.6	6.8	8.8	10.9	12.9	14.9
Tensile Strength ( $R_m$ ), Min.	40	40	50	50	60	60	80	100	120	140
Yield Stress ( $R_e$ ), Min.	24	32	30	40	36	48	...	...	...	...
Stress at Permanent Set Limit ( $R_{0.2}$ ), Min.	...	...	...	...	...	...	64	90	108	126
All stress and strength values are in kgf/mm <sup>2</sup> units.										

**Strength Grade Designation System for Steel Nuts:** The strength grade designation system for steel nuts is a number which is one-tenth of the specified proof load stress in kgf/mm<sup>2</sup>. The proof load stress corresponds to the minimum tensile strength of the highest grade of bolt or screw with which the nut can be used.

### Strength Grade Designations of Steel Nuts

Strength Grade Designation	4	5	6	8	12	14
Proof Load Stress (kgf/mm <sup>2</sup> )	40	50	60	80	120	140

### Recommended Bolt and Nut Combinations

Grade of Bolt	4.6	4.8	5.6	5.8	6.6	6.8	8.8	10.9	12.9	14.9
Recommended Grade of Nut	4	4	5	5	6	6	8	12	12	14
<i>Note:</i> Nuts of a higher strength grade may be substituted for nuts of a lower strength grade.										

**Marking:** The marking and identification requirements of this Standard are only mandatory for steel bolts, screws and nuts of 6 mm diameter and larger; manufactured to strength grade designations 8.8 (for bolts or screws) and 8 (for nuts) or higher. Bolts and screws are identified as ISO metric by either of the symbols "ISO M" or "M", embossed or indented on top of the head. Nuts may be indented or embossed by alternative methods depending on their method of manufacture.

**Designation:** Bolts 10 mm diameter, 50 mm long manufactured from steel of strength grade 8.8, would be designated:

"Bolts M10 × 50 to BS 3692.—8.8."

Brass screws 8 mm diameter, 20 mm long would be designated:

"Brass screws M8 × 20 to BS 3692."

Nuts 12 mm diameter, manufactured from steel of strength grade 6, cadmium plated could be designated:

"Nuts M12 to BS 3692.—6, plated to BS 3382: Part 1."

**Miscellaneous Information:** The Standard also gives mechanical properties of steel bolts, screws and nuts [i.e., tensile strengths; hardnesses (Brinell, Rockwell, Vickers); stresses (yield, proof load); etc.], material and manufacture of steel bolts, screws and nuts; and information on inspection and testing. Appendices to the Standard give information on gaging; chemical composition; testing of mechanical properties; examples of marking of bolts, screws and nuts; and a table of preferred standard sizes of bolts and screws, to name some.

All dimensions are in millimeters. Sizes shown in parentheses are nonpreferred and are not usually stock sizes.

**British Standard for Metric Series Metal Washers.**—BS 4320:1968 (1998) specifies bright and black metal washers for general engineering purposes.

**Bright Metal Washers:** These washers are made from either CS4 cold-rolled strip steel BS 1449:Part 3B or from CZ 108 brass strip BS 2870: 1980, both in the hard condition. However, by mutual agreement between purchaser and supplier, washers may be made available with the material in any other condition, or they may be made from another material, or may be coated with a protective or decorative finish to some appropriate British Standard. Washers are reasonably flat and free from burrs and are normally supplied unchamfered. They may, however, have a 30-degree chamfer on one edge of the external diameter. These washers are made available in two size categories, normal and large diameter, and in two thicknesses, normal (Form A or C) and light (Form B or D). The thickness of a light-range washer is from  $\frac{1}{2}$  to  $\frac{2}{3}$  the thickness of a normal range washer.

**Black Metal Washers:** These washers are made from mild steel, and can be supplied in three size categories designated normal, large, and extra large diameters. The normal-diameter series is intended for bolts ranging from M5 to M68 (Form E washers), the large-diameter series for bolts ranging from M8 to M39 (Form F washers), and the extra large series for bolts from M5 to M39 (Form G washers). A protective finish can be specified by the purchaser in accordance with any appropriate British Standard.

**Washer Designations:** The Standard specifies the details that should be given when ordering or placing an inquiry for washers. These details are the general description, namely, bright or black washers; the nominal size of the bolt or screw involved, for example, M5; the designated form, for example, Form A or Form E; the dimensions of any chamfer required on bright washers; the number of the Standard BS 4320:1968 (1998), and coating information if required, with the number of the appropriate British Standard and the coating thickness needed. As an example, in the use of this information, the designation for a chamfered, normal-diameter series washer of normal-range thickness to suit a 12-mm diameter bolt would be: Bright washers M12 (Form A) chamfered to BS 4320.

## MACHINE SCREWS AND NUTS

## American National Standard Machine Screws and Machine Screw Nuts

This Standard ANSI/ASME B18.6.3 covers both slotted and recessed head machine screws. Dimensions of various types of slotted machine screws, machine screw nuts, and header points are given in Table 1 through Table 12. The Standard also covers flat trim head, oval trim head and drilled fillister head machine screws and gives cross recess dimensions and gaging dimensions for all types of machine screw heads. Information on metric machine screws B18.6.7M (Withdrawn) is given beginning on page 1790.

**Threads.**—Except for sizes 0000, 000, and 00, machine screw threads may be either Unified Coarse (UNC) and Fine thread (UNF) Class 2A (see *American Standard for Unified Screw Threads* starting on page 1947) or UNRC and UNRF Series, at option of manufacturer. Thread dimensions for sizes 0000, 000, and 00 are given in Table 7 on page 1780.

Threads for hexagon machine screw nuts may be either UNC or UNF, Class 2B, and for square machine screw nuts are UNC Class 2B.

**Length of Thread.**—Machine screws of sizes No. 5 and smaller with nominal lengths equal to 3 diameters and shorter have full form threads extending to within 1 pitch (thread) of the bearing surface of the head, or closer, if practicable. Nominal lengths greater than 3 diameters, up to and including  $1\frac{1}{8}$  inch, have full form threads extending to within two pitches (threads) of the bearing surface of the head, or closer, if practicable. Unless otherwise specified, screws of longer nominal length have a minimum length of full form thread of 1.00 inch. Machine screws of sizes No. 6 and larger with nominal length equal to 3 diameters and shorter have full form threads extending to within 1 pitch (thread) of the bearing surface of the head, or closer, if practicable. Nominal lengths greater than 3 diameters, up to and including 2 inches, have full form threads extending to within 2 pitches (threads) of the bearing surface of the head, or closer, if practicable. Screws of longer nominal length, unless otherwise specified, have a minimum length of full form thread of 1.50 inches.

$\frac{3}{8}$	0.3750	$\frac{3}{8}$	0.625	0.607	0.884	0.833	0.722	0.692	0.257	0.239

All dimensions in inches. Hexagon machine screw nuts have tops flat and chamfered. Diameter of top circle should be the maximum width across flats within a tolerance of minus 15 percent. Bottoms are flat but may be chamfered if so specified. Square machine screw nuts have tops and bottoms flat without chamfer.

**Diameter of Body.**—The diameter of machine screw bodies is not less than Class 2A thread minimum pitch diameter nor greater than the basic major diameter of the thread. Cross-recessed trim head machine screws not threaded to the head have an 0.062 in. minimum length shoulder under the head with diameter limits as specified in the dimensional tables in the standard.

**Designation.**—Machine screws are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name, including head type and driving provision; header point, if desired; material; and protective finish, if required. For example:

$\frac{1}{4}$  – 20  $\times$  1 $\frac{1}{4}$  Slotted Pan Head Machine Screw, Steel, Zinc Plated

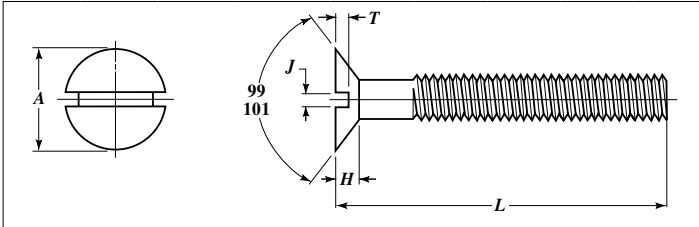

6 – 32  $\times$   $\frac{3}{4}$  Type IA Cross Recessed Fillister Head Machine Screw, Brass

Machine screw nuts are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); threads per inch; product name; material; and protective finish, if required. For example:

10 – 24 Hexagon Machine Screw Nut, Steel, Zinc Plated

0.138 – 32 Square Machine Screw Nut, Brass

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> There is no allowance provided on the external threads.

<sup>c</sup> The minor diameter limits for internal threads are not specified, they being determined by the amount of thread engagement necessary to satisfy the strength requirements and tapping performance in the intended application.

All dimensions are in inches.

All dimensions are in inches.

<sup>1</sup> Where specifying nominal size in decimals, zeros preceding decimal points and in the fourth decimal place are omitted.

<sup>2</sup> Drilled hole shall be approximately perpendicular to the axis of slot and may be permitted to break through bottom of the slot. Edges of the hole shall be free from burrs.

<sup>3</sup> A slight rounding of the edges at periphery of head is permissible provided the diameter of the bearing circle is equal to no less than 90 percent of the specified minimum head diameter.

<sup>a</sup> When specifying nominal size in decimals, zeros preceding decimal point and in the fourth decimal place are omitted.

All dimensions are in inches.

Not recommended, use Pan Head machine screws.

**Machine Screw Cross Recesses.**—Four cross recesses, Types I, IA, II, and III, may be used in lieu of slots in machine screw heads. Dimensions for recess diameter  $M$ , width  $N$ , and depth  $T$  (not shown above) together with recess penetration gaging depths are given in American National Standard ANSI/ASME B18.6.3-2013 for machine screws, and in ANSI/ASME B18.6.7M-1999 (Withdrawn) for metric machine screws.

#### ANSI/ASME Cross Recesses for Machine Screws and Metric Machine Screw

Type I Cross Recess

Type IA Cross Recess

Type II Cross Recess

Type III Square Center

## Slotted Head Miniature Screws

The ASA B18.11 standard establishes head types, their dimensions, and lengths of slotted head miniature screws, threaded in conformance with American Standard Unified Miniature Screw Threads, ASA B1.10. The standard covers threads of a nominal diameter from 0.0118 inch (0.3 mm) to 0.0551 inch (1.4 mm). Preferred diameter pitch combinations for general use are shown in bold type in the tables.

**Head Types.—Fillister Head:** The fillister head has a flat top surface (oval crown optional) with cylindrical sides and a flat bearing surface. The head proportions are given in [Table 1](#).

**Pan Head:** The pan head has a flat top surface, cylindrical sides, and a flat bearing surface. The head height is less than the fillister but the head diameter is slightly larger. Head proportions are given in [Table 2](#).

**Flat Head:** The flat head has a flat top surface and a conical bearing surface with an included angle of approximately 100°. Head proportions are given in [Table 3](#).

**Binding Head:** The head height is less than the pan head but the head diameter is greater, and is intended for applications which would otherwise require washers. Head proportions are given in [Table 4](#).

Bold face type indicates preferred sizes. See [Notes for Table 1 through Table 4](#) on page 1786.

<sup>a</sup> T measured from bearing surface.

<sup>b</sup> Relative to maximum major diameter.

**Notes for Table 1 through Table 4**

**Material:**

Corrosion resistant steels: ASTM Designation A276  
 CLASS 303, COND A  
 CLASS 416, COND A, heat treat to approx 120,000–150,000 PSI (28–34 on Rockwell C scale)  
 CLASS 420, COND A, heat treat to approx 220,000–240,000 PSI (50–53 on Rockwell C scale)

Brass: Temper half hard ASTM Designation B16  
 Nickel Silver: Temper hard ASTM Designation B151, Alloy C

**Machine Finish:**

Machined surface roughness of heads shall be approximately 63  $\mu\text{in.}$  arithmetical average determined by visual comparison.

**Applied coatings:**

Corrosion resistant steel: passivate; Brass: bare, black oxide, or nickel flash.  
 Nickel silver: none

**Notes:**

- 1) The diameter of the unthreaded body shall not be more than the maximum major diameter nor less than the minimum pitch diameter of the thread.
- 2) For screw lengths four times the major diameter or less, thread length ( $L_T$ ) shall extend to within two threads of the head bearing surface. Screws of greater length shall have complete threads for a minimum of four major diameters.
- 3) Screws shall be free of all projecting burrs, observed at 3 $\times$  magnification.
- 4) All dimensions are in inches.

<sup>a</sup> Bold face type indicates preferred sizes. See *Notes for Table 1 through Table 4* on page 1786.

<sup>b</sup> Relative to maximum major diameter.

**Specifications.—Head Height:** The head heights given in the dimensional tables represent the metal measurement (after slotting).

**Depth of Slots:** The depth of slots on fillister, pan and binding head screws is measured from the bearing surface to the intersection of the bottom of the slot with the head diameter. On heads with a conical bearing surface, the depth of slots is measured parallel to the axis of the screw from the flat top surface to the intersection of the bottom of the slot with the bearing surface. The maximum permissible concavity of the slot shall not exceed 3 percent of the mean head diameter.

**Bearing Surface:** The bearing surface of fillister, pan and binding head screws shall be at right angles to the axis of the body within 2°.

**Eccentricity:** Eccentricity is defined as one half of the total indicator reading.

**Head Eccentricity:** The heads of miniature fastening screws shall not be eccentric with the screw bodies by more than 2 percent of the maximum head diameter or 0.001 inch, whichever is the greater.

**Eccentricity of Slots:** Slots in miniature fastening screw heads shall not be eccentric with screw bodies by more than 5 percent of the nominal body diameter.

Bold face type indicates preferred sizes. See Notes for Table 1 through Table 4 below.

<sup>a</sup> *T* measured from bearing surface.

**Underhead Fillets:** The radius of the fillet under perpendicular bearing surface type heads shall not exceed  $\frac{1}{2}$  times the pitch of the thread. The radius of the fillet under conical bearing surface type heads shall not exceed 2 times the pitch of the thread. The radius of the fillet under the binding head is given in Table 4.

**Unthreaded Diameter:** On miniature fastening screws not threaded to the head, the diameter of the unthreaded body shall not be more than the maximum major diameter of the thread nor less than the minimum pitch diameter of the thread.

**Length:** The length of miniature screws having perpendicular bearing surface type heads shall be measured from the bearing surface to the extreme end in a line parallel to the axis of the screw. The length of screws with conical bearing surface type heads shall be measured from the top of the head to the extreme end in a line parallel to the axis of the screw. Preferred lengths are those listed in Table 5.

**Tolerance on Length:** The length tolerance of miniature screws shall conform to the limits given in Table 5.

**Length of Thread:** On all miniature screws having a length four times the nominal body diameter or less the threaded length shall extend to within two threads of the bearing surface of the head. Screws of greater length shall possess complete threads for a minimum of four diameters.

<sup>a</sup> Sizes 30 UNM and 35 UNM are not specified for Binding Head.

<sup>b</sup> Does not apply to 100° Flat Head.

Bold face type indicates preferred sizes. Sizes surrounded by heavy line apply to 100° Flat Head only.

*End of Body:* Miniature fastening screws shall be regularly supplied with flat ends having a chamfer of approximately 45° extending to the minor diameter of the thread as a minimum depth.

*Thread Series and Tolerances:* The screw threads of miniature screws shall be in conformance with American Standard Unified Miniature Screw Threads, ASA B1.10-1958.

*Material and Finish:* Miniature screws are generally supplied in ferrous and nonferrous materials, coatings, and heat treatments which must be specified by the user. Coatings, when required, are limited to those of electro-plating or chemical oxidation.

*Designation:* Screws in conformance with this standard shall be identified by the designation for thread size in conformance with American Standard ASA B1.10 followed by the nominal length in units of  $\frac{1}{1000}$  inch (omitting the decimal point) and the head type. Typical examples are:

60 UNM×040 FIL HD

100 UNM×080 PAN HD

120 UNM×120 FLAT HD

140 UNM×250 BIND HD

*Machined Finish:* Roughness of the machined surfaces of heads shall not exceed 63 micro-inches arithmetical average (per ASA B46.1, Surface Texture) determined by visual comparison with roughness comparison specimens.

### American National Standard Metric Machine Screws

This Standard B18.6.7M (Withdrawn) covers metric flat and oval countersunk and slotted and recessed pan head machine screws and metric hex head and hex flange head machine screws. Dimensions are given in [Table 1](#) through [Table 4](#) and [Table 5](#).

*Threads:* Threads for metric machine screws are coarse M profile threads, as given in ANSI/ASME B1.13M (see page [2012](#)), unless otherwise specified.

*Length of Thread:* The lengths of threads on metric machine screws are given in [Table 1](#) for the applicable screw type, size, and length. Also see [Table 6](#).

*Diameter of Body:* The body diameters of metric machine screws are within the limits specified in the dimensional tables ([Table 3](#) through [Table 4](#) and [Table 5](#)).

*Designation:* Metric machine screws are designated by the following data in the sequence shown: Nominal size and thread pitch; nominal length; product name, including head type and driving provision; header point if desired; material (including property class, if steel); and protective finish, if required. For example:

M8 × 1.25 × 30 Slotted Pan Head Machine Screw, Class 4.8 Steel, Zinc Plated

M3.5 × 0.6 × 20 Type IA Cross Recessed Oval Countersunk Head Machine Screw,  
Header Point, Brass

It is common ISO practice to omit the thread pitch from the product size designation when screw threads are the metric coarse thread series, e.g., M10 stands for M10 × 1.5.

**Table 1. American National Standard Thread Lengths for Metric Machine Screws**  
*ANSI/ASME B18.6.7M-1999 (Withdrawn)*

M4 × 0.7	12	1.8	0.7	12	50	1.8	1.4	50	38.0
M5 × 0.8	15	2.0	0.8	15	50	2.0	1.6	50	38.0
M6 × 1	18	2.5	1.0	18	50	2.5	2.0	50	38.0
M8 × 1.25	24	3.1	1.2	24	50	3.1	2.5	50	38.0
M10 × 1.5	30	3.8	1.5	30	50	3.8	3.0	50	38.0
M12 × 1.75	36	4.4	1.8	36	50	4.4	3.5	50	38.0

<sup>a</sup> The length tolerances for metric machine screws are: up to 3 mm, incl., ± 0.2 mm; over 3 to 10 mm, incl., ± 0.3 mm; over 10 to 16 mm, incl., ± 0.4 mm; over 16 to 50 mm, incl., ± 0.5 mm; over 50 mm, ± 1.0 mm.

<sup>b</sup> Unthreaded lengths  $L_U$  and  $L_{US}$  represent the distance, measured parallel to the axis of screw, from the underside of the head to the face of a nonchamfered or noncounterbored standard GO thread ring gage assembled by hand as far as the thread will permit.

<sup>c</sup> Refer to the illustrations for respective screw head styles.

<sup>d</sup> The  $L_{US}$  values apply only to heat-treated recessed flat countersunk head screws.

<sup>e</sup> The  $L_U$  values apply to all screws except heat-treated recessed flat countersunk head screws.

All dimensions in millimeters.

<sup>a</sup> All recessed head heat-treated steel screws of property class 9.8 or higher strength have the Style B head form. Recessed head screws other than those specifically designated to be Style B have the Style A head form. The underhead shoulder on the Style B head form is mandatory and all other head dimensions are common to both the Style A and Style B head forms.

<sup>b</sup> This size is not specified for Type III square recessed flat countersunk heads; Type II cross recess is not specified for any size.

All dimensions in millimeters.

For dimension *B*, see Table 1.

For dimension *L*, see Table 6.

<sup>a</sup> Dimensions across flats and across corners of the head are measured at the point of maximum metal. Taper of sides of head (angle between one side and the axis) shall not exceed 2° or 0.10 mm, whichever is greater, the specified width across flats being the large dimension.

<sup>b</sup> The contour of the edge at periphery of flange is optional provided the minimum flange thickness is maintained at the minimum flange diameter. The top surface of flange may be straight or slightly rounded (convex) upward.

All dimensions in millimeters.

A slight rounding of all edges of the hexagon surfaces of indented hex heads is permissible provided the diameter of the bearing circle is not less than the equivalent of 90 percent of the specified minimum width across flats dimension.

Heads may be indented, trimmed, or fully upset at the option of the manufacturer.

For dimension  $B$ , see Table 1.

For dimension  $L$ , see Table 6.

**Table 6. Recommended Nominal Screw Lengths for Metric Machine Screws**

60							A	A	A	H
65								A	A	H
70								A	A	H
80								A	A	H
90									A	H

All dimensions in millimeters.

<sup>1</sup>The nominal screw lengths included between the heavy lines are recommended for the respective screw sizes and screw head styles as designated by the symbols.

A—Signifies screws of all head styles covered in this standard.

P—Signifies pan head screws.

H—Signifies hex and hex flange head screws.

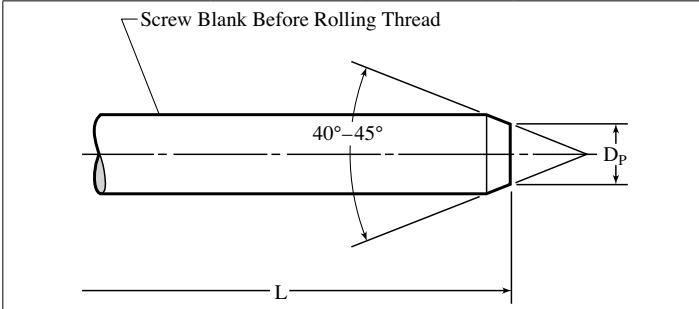

**Table 7. Clearance Holes for Metric Machine Screws**  
*ANSI/ASME B18.6.7M-1999 (Withdrawn), Appendix*

Nominal Screw Size	Basic Clearance Hole Diameter <sup>a</sup>		
	Close Clearance <sup>b</sup>	Normal Clearance (Preferred) <sup>b</sup>	Loose Clearance <sup>b</sup>
M2	2.20	2.40	2.60
M2.5	2.70	2.90	3.10
M3	3.20	3.40	3.60
M3.5	3.70	3.90	4.20
M4	4.30	4.50	4.80
M5	5.30	5.50	5.80
M6	6.40	6.60	7.00
M8	8.40	9.00	10.00
M10	10.50	11.00	12.00
M12	13.00	13.50	14.50

<sup>a</sup> The values given in this table are minimum limits. The recommended plus tolerances are as follows: for clearance hole diameters over 1.70 to and including 5.80 mm, plus 0.12, 0.20, and 0.30 mm for close, normal, and loose clearances, respectively; for clearance hole diameters over 5.80 to 14.50 mm, plus 0.18, 0.30, and 0.45 mm for close, normal, and loose clearances, respectively.

<sup>b</sup> Normal clearance hole sizes are preferred. Close clearance hole sizes are for situations such as critical alignment of assembled components, wall thickness, or other limitations which necessitate the use of a minimal hole. Countersinking or counterboring at the fastener entry side may be necessary for the proper seating of the head. Loose clearance hole sizes are for applications where maximum adjustment capability between the components being assembled is necessary.

All dimensions in millimeters.

**Table 8. American National Standard Header Points for Metric Machine Screws Before Threading ANSI/ASME B18.6.7M-1999 (Withdrawn)**

The diagram shows a cylindrical screw blank with a conical header point at one end. The angle of the cone is labeled as 40°-45°. The diameter of the point is labeled as D<sub>p</sub>, and the length of the blank is labeled as L.

Nominal Screw Size and Thread Pitch	D <sub>p</sub>		L <sup>a</sup>
	Point Diameter		Nominal Screw Length
	Max.	Min.	Max.
M2 × 0.4	1.33	1.21	13
M2.5 × 0.45	1.73	1.57	13
M3 × 0.5	2.12	1.93	16
M3.5 × 0.6	2.46	2.24	20
M4 × 0.7	2.80	2.55	25
M5 × 0.8	3.60	3.28	30
M6 × 1	4.25	3.85	40
M8 × 1.25	5.82	5.30	40
M10 × 1.5	7.36	6.71	40
M12 × 1.75	8.90	8.11	45

<sup>a</sup> Header points apply to these nominal lengths or shorter. The pointing of longer lengths may require machining to the dimensions specified.

All dimensions in millimeters.

The edge of the point may be rounded and the end of point need not be flat nor perpendicular to the axis of screw shank.

### British Machine Screws

Many of these classifications of fasteners are covered in British Standards BS 57:1951, "B.A. Screws, Bolts and Nuts"; BS 450:1958 (obsolescent), "Machine Screws and Machine Screw Nuts (BSW and BSF Threads)"; BS 1981:1953, "Unified Machine Screws and Machine Screw Nuts"; BS 2827:1957 (obsolescent):1957, "Machine Screw Nuts, Pressed Type (B.A. and Whitworth Form Threads)"; BS 3155:1960, "American Machine Screws and Nuts in Sizes Below 1/4 inch Diameter"; and BS 4183:1967 (obsolescent), "Machine Screws and Machine Screw Nuts, Metric Series." At a conference organized by the British Standards Institution in 1965 at which the major sectors of British industry were represented, a policy statement was approved that urged British firms to regard the traditional screw thread systems—Whitworth, B.A. and BSF—as obsolescent, and to make the internationally-agreed ISO metric thread their first choice (with ISO Unified thread as second choice) for all future designs. It is recognized that some sections of British industry already using ISO inch (Unified) screw threads may find it necessary, for various reasons, to continue with their use for some time: Whitworth and B.A. threads should, however, be superseded by ISO metric threads in preference to an

intermediate change to ISO inch threads. Fasteners covered by BS 57, BS 450 and BS 2827:1957 (obsolescent) eventually would be superseded and replaced by fasteners specified by BS 4183.

**British Standard Whitworth (BSW) and Fine (BSF) Machine Screws.**—British Standard BS 450:1958 (obsolescent) covers machine screws and nuts with British Standard Whitworth and British Standard Fine threads. All the various heads in common use in both slotted and recessed forms are covered. Head shapes are shown on page 1809 and dimensions on page 1811. It is intended that this standard will eventually be superseded by BS 4183, “Machine Screws and Machine Screw Nuts, Metric Series.”

**British Standard Machine Screws and Machine Screw Nuts, Metric Series.**—British Standard BS 4183:1967 (obsolescent) gives dimensions and tolerances for: countersunk head, raised countersunk head, and cheese head slotted head screws in a diameter range from M1 (1 mm) to M20 (20 mm); pan head slotted head screws in a diameter range from M2.5 (2.5 mm) to M10 (10 mm); countersunk head and raised countersunk head recessed head screws in a diameter range from M2.5 (2.5 mm) to M12 (12 mm); pan head recessed head screws in a diameter range from M2.5 (2.5 mm) to M10 (10 mm); and square and hexagon machine screw nuts in a diameter range from M1.6 (1.6 mm) to M10 (10 mm). Mechanical properties are also specified for steel, brass and aluminum alloy machine screws and machine screw nuts in this standard.

*Material:* The materials from which the screws and nuts are manufactured have a tensile strength not less than the following: steel, 40 kgf/mm<sup>2</sup> (392 N/mm<sup>2</sup>); brass, 32 kgf/mm<sup>2</sup> (314 N/mm<sup>2</sup>); and aluminum alloy, 32 kgf/mm<sup>2</sup> (314 N/mm<sup>2</sup>). The unit, kgf/mm<sup>2</sup> is in accordance with ISO DR 911 and the unit in parentheses has the relationship, 1 kgf = 9.80665 newtons. These minimum strengths are applicable to the finished products. Steel machine screws conform to the requirements for strength grade designation 4.8. The strength grade designation system for machine screws consists of two figures, the first is  $\frac{1}{10}$  of the minimum tensile strength in kgf/mm<sup>2</sup>, the second is  $\frac{1}{10}$  of the ratio between the yield stress and the minimum tensile strength expressed as a percentage:  $\frac{1}{10}$  minimum tensile strength of 40 kgf/mm<sup>2</sup> gives the symbol “4”;  $\frac{1}{10}$  ratio  $\frac{\text{yield stress}}{\text{minimum tensile strength}} \times 100 = \frac{1}{10} \times \frac{32}{40} \times 100/1 = “8”$ ; giving the strength grade designation “4.8.” Multiplication of these two figures gives the minimum yield stress in kgf/mm<sup>2</sup>.

*Coating of Screws and Nuts:* It is recommended that the coating comply with the appropriate part of BS 3382. “Electroplated Coatings on Threaded Components.”

*Screw Threads:* Screw threads are ISO metric coarse pitch series threads in accordance with BS 3643. “ISO Metric Screw Threads,” Part 1, “Thread Data and Standard Thread Series.” The external threads used for screws conform to tolerance Class 6g limits (medium fit) as given in BS 3643, “ISO Metric Screw Threads,” Part 2, “Limits and Tolerances for Coarse Pitch Series Threads.” The internal threads used for nuts conform to tolerance Class 6H limits (medium fit) as given in BS 3643: Part 2.

*Nominal Lengths of Screws:* For countersunk head screws the nominal length is the distance from the upper surface of the head to the extreme end of the shank, including any chamfer, radius, or cone point. For raised countersunk head screws the nominal length is the distance from the upper surface of the head (excluding the raised portion) to the extreme end of the shank, including any chamfer, radius, or cone point. For pan and cheese head screws the nominal length is the distance from the underside of the head to the extreme end of the shank, including any chamfer, radius, or cone point. Standard nominal lengths and tolerances are given in Table 5.

*Lengths of Thread on Screws:* The length of thread is the distance from the end of the screw (including any chamfer, radius, or cone point) to the leading face of a nut without countersink which has been screwed as far as possible onto the screw by hand. The minimum thread length is shown in the following table:

Nominal Thread Dia., $d^a$	M1	M1.2	(M1.4)	M1.6	M2	(M2.2)	M2.5	M3	(M3.5)	M4
Thread Length $b$ (Min.)	<sup>b</sup>	<sup>b</sup>	<sup>b</sup>	15	16	17	18	19	20	22
Nominal Thread Dia., $d^a$	(M4.5)	M5	M6	M8	M10	M12	(M14)	M16	(M18)	M20
Thread Length $b$ (Min.)	24	25	28	34	40	46	52	58	64	70

<sup>a</sup> Items shown in parentheses are non-preferred.

<sup>b</sup> Threaded up to the head.

All dimensions are in millimeters.

Screws of nominal thread diameter M1, M1.2 and M1.4 and screws of larger diameters that are too short for the above thread lengths are threaded as far as possible up to the head.

In these screws the length of unthreaded shank under the head does not exceed  $1\frac{1}{2}$  pitches for lengths up to twice the diameter and 2 pitches for longer lengths, and is defined as the distance from the leading face of a nut that has been screwed as far as possible onto the screw by hand to: 1) the junction of the basic major diameter and the countersunk portion of the head on countersunk and raised countersunk heads; and 2) the underside of the head on other types of heads.

*Diameter of Unthreaded Shank on Screws:* The diameter of the unthreaded portion of the shank on screws is not greater than the basic major diameter of the screw thread and not less than the minimum effective diameter of the screw thread. The diameter of the unthreaded portion of shank is closely associated with the method of manufacture; it will generally be nearer the major diameter of the thread for turned screws and nearer the effective diameter for those produced by cold heading.

*Radius Under the Head of Screws:* The radius under the head of pan and cheese head screws runs smoothly into the face of the head and shank without any step or discontinuity. A true radius is not essential providing that the curve is smooth and lies wholly within the maximum radius. Any radius under the head of countersunk head screws runs smoothly into the conical bearing surface of the head and the shank without any step or discontinuity. The radius values given in Table 1 and Table 2 are regarded as the maximum where the shank diameter is equal to the major diameter of the thread and minimum where the shank diameter is approximately equal to the effective diameter of the thread.

**Table 1. British Standard Slotted Countersunk Head Machine Screws—Metric Series BS 4183:1967 (obsolescent)**

<sup>a</sup> Nominal sizes shown in parentheses are non-preferred.<sup>b</sup> See *Radius Under the Head of Screws* description in text.<sup>c</sup> See text following table in *Lengths of Thread on Screws* description in text.<sup>d</sup> Threaded up to head.

All dimensions are given in millimeters. For dimensional notation see diagram on page 1804. Recessed head screws are also standard and available. For dimensions see British Standard.

*Ends of Screws:* When screws are made with rolled threads, the “lead” formed by the thread rolling operation is normally regarded as providing the necessary chamfer and no other machining is necessary. The ends of screws with cut threads are normally finished with a chamfer conforming to the dimension in Fig. 1a through Fig. 1d. At the option of the manufacturer, the ends of screws smaller than M6 (6-mm diameter) may be finished with a radius approximately equal to  $1\frac{1}{4}$  times the nominal diameter of the shank. When cone point ends are required, they should have the dimensions given in Fig. 1a through Fig. 1d.

Fig. 1c. Cut Thread Radiused End (Permissible on Sizes Below M6 Diameter)

Fig. 1d. Cone Pointed End (Permissible on Cut or Rolled Thread Screws, but Regarded as “Special”)

*Dimensions of 90-Degree Countersunk Head Screws:* One of the appendices to this British Standard states that countersunk head screws should fit into the countersunk hole with as great a degree of flushness as possible. To achieve this condition, it is necessary for the dimensions of both the head of the screw and the countersunk hole to be controlled within prescribed limits. The maximum or design size of the head is controlled by a theoretical diameter to a sharp corner and the minimum head angle of 90 degrees. The minimum head size is controlled by a minimum head diameter, the maximum head angle of 92 degrees and a flushness tolerance (see Fig. 2). The edge of the head may be flat or rounded, as shown in Fig. 3.

							M8	13.0	12.73	18.4
							M10	17.0	16.73	24.0

<sup>a</sup> Nominal sizes and lengths shown in parentheses are non-preferred.

All dimensions are given in millimeters. For dimensional notation, see diagram on page 1804.

**General Dimensions:** The general dimensions and tolerances for screws and nuts are given in the accompanying tables. Although slotted screw dimensions are given, recessed head screws are also standard and available. Dimensions of recessed head screws are given in BS 4183:1967 (obsolescent).

**British Unified Machine Screws and Nuts.**—British Standard BS 1981:1953 covers certain types of machine screws and machine screw nuts for which agreement has been reached with the United States and Canada as to general dimensions for interchangeability. These types are: countersunk, raised-countersunk, pan, and raised-cheese head screws with slotted or recessed heads; small hexagon head screws; and precision and pressed nuts. All have Unified threads. Head shapes are shown on page 1809 and dimensions are given on page 1810.

**Identification:** As revised by Amendment No. 1 in February 1955, this standard now requires that the above-mentioned screws and nuts that conform to this standard should have a distinguishing feature applied to identify them as Unified. All recessed head screws are to be identified as Unified by a groove in the form of four arcs of a circle in the upper surface of the head. All hexagon head screws are to be identified as Unified by: 1) a circular recess in the upper surface of the head; 2) a continuous line of circles indented on one or more of the flats of the hexagon and parallel to the screw axis; and 3) at least two contiguous circles indented on the upper surface of the head. All *machine screw* nuts of the pressed type shall be identified as Unified by means of the application of a groove indented in one face of the nut approximately midway between the major diameter of the thread and flats of the square or hexagon. *Slotted head screws* shall be identified as Unified either by a circular recess or by a circular platform or raised portion on the upper surface of the head. *Machine screw nuts* of the *precision type* shall be identified as Unified by either a groove indented on one face of the front approximately midway between the major diameter of the thread and the flats of the hexagon or a continuous line of circles indented on one or more of the flats of the hexagon and parallel to the nut axis.

Identification Markings for British Standard Unified Machine Screws

## British Standard Machine Screws and Nuts

BS 450:1958 (obsolescent) and BS 1981:1953

\*Countersinks to suit the screws should have a maximum angle of 80° (Unified) or 90° (BSF and BSW) with a negative tolerance.

†Unified countersunk and raised countersunk head screws 2 inches long and under are threaded right up to the head. Other Unified, BSW and BSF machine screws 2 inches long and under have an unthread shank equal to twice the pitch. All Unified, BSW and BSF machine screws longer than 2 inches have a minimum thread length of 1¼ inches.

<sup>a</sup> All dimensions, except *J*, given for the 1/8- through 3/8- inch sizes also apply to all the 90° Raised Countersunk Head Screw dimensions given in the Standard.

<sup>b</sup> These screws are also available with recessed heads; dimensions of recess are not given here but may be found in the Standard.

<sup>c</sup> Non-preferred size; avoid use whenever possible.

<sup>d</sup> By arrangement may also be 0.309.

<sup>e</sup> By arrangement may also be 0.468.

All dimensions in inches.

See diagram on page 1809 for a pictorial representation of screws and letter dimensions.

## CAPANDESET SCREWS

**Slotted Head Cap Screws.**—American National Standard ANSI/ASME B18.6.2-1998 (R2010) is intended to cover the complete general and dimensional data for the various styles of slotted head cap screws as well as square head and slotted headless set screws (see page 1819). Reference should be made to this Standard for information or data not found in the following text or tables.

**Length of Thread:** The length of complete (full form) thread on cap screws is equal to twice the basic screw diameter plus 0.250 in. with a plus tolerance of 0.188 in. or an amount equal to  $2\frac{1}{2}$  times the pitch of the thread, whichever is greater. Cap screws of lengths too short to accommodate the minimum thread length have full form threads extending to within a distance equal to  $2\frac{1}{2}$  pitches (threads) of the head.

**Designation:** Slotted head cap screws are designated by the following data in the sequence shown: Nominal size (fraction or decimal equivalent); threads per inch; screw length (fraction or decimal equivalent); product name; material; and protective finish, if required. Examples:  $\frac{1}{2}$ -13  $\times$  3 Slotted Round Head Cap Screw, SAE Grade 2 Steel, Zinc Plated. .750-16  $\times$  2.25 Slotted Flat Countersunk Head Cap Screw, Corrosion Resistant Steel.

<sup>a</sup> Key engagement depths are minimum. Spline socket sizes are nominal.

<sup>b</sup> Spline driven fasteners are removed from the latest revision. For additional information on these fasteners, see ANSI/ASME B18.3-1998.

All dimensions in inches. The body length  $L_B$  of the screw is the length of the unthreaded cylindrical portion of the shank. The length of thread,  $L_T$ , is the distance from the extreme point to the last complete (full form) thread. Standard length increments for screw diameters up to 1 inch are 1/16 inch for lengths 1/8 inch through 1/4 inch, 1/8 inch for lengths 1/4 inch through 1 inch, 1/4 inch for lengths 1 through 3 1/2 inches, 1/2 inch for lengths 3 1/2 through 7 inches, 1 inch for lengths 7 through 10 inches and for diameters over 1 inch are 1/2 inch for lengths 1 through 7 inches, 1 inch for lengths 7 through 10 inches, and 2 inches for lengths over 10 inches.

Heads may be plain or knurled, and chamfered to an angle  $E$  of 30 to 45 degrees with the surface of the flat. The thread conforms to the Unified Standard with radius root, Class 3A UNRC and UNRF for screw sizes No. 0 through 1 inch inclusive, Class 2A UNRC and UNRF for over 1 inch through 1 1/2 inches inclusive, and Class 2A UNRC for larger sizes. Socket dimensions are given in Table 11. For details not shown, including materials, see ANSI/ASME B18.3-2012 and ANSI/ASME B18.3-1998 (for Spline driven fasteners).

2	2.0000	21/32	2.031	2 1/16	2.062	3 1/8	2.180

<sup>a</sup> **Countersink:** It is considered good practice to countersink or break the edges of holes which are smaller than ( $D_{Max} + 2F_{Max}$ ) in parts having a hardness which approaches, equals or exceeds the screw hardness. If such holes are not countersunk, the heads of screws may not seat properly or the sharp edges on holes may deform the fillets on screws thereby making them susceptible to fatigue in applications involving dynamic loading. The countersink or corner relief, however, should not be larger than is necessary to insure that the fillet on the screw is cleared.

<sup>b</sup> **Close Fit:** The close fit is normally limited to holes for those lengths of screws which are threaded to the head in assemblies where only one screw is to be used or where two or more screws are to be used and the mating holes are to be produced either at assembly or by matched and coordinated tooling.

<sup>c</sup> **Normal Fit:** The normal fit is intended for screws of relatively long length or for assemblies involving two or more screws where the mating holes are to be produced by conventional tolerancing methods. It provides for the maximum allowable eccentricity of the longest standard screws and for certain variations in the parts to be fastened, such as: deviations in hole straightness, angularity between the axis of the tapped hole and that of the hole for the shank, differences in center distances of the mating holes, etc.

All dimensions in inches.

<sup>a</sup> Spline driven fasteners are removed from the latest revision. For additional information on these fasteners, see ANSI/ASME B18.3-1998.

All dimensions in inches.

The body of the screw is the unthreaded cylindrical portion of the shank where not threaded to the head; the shank being the portion of the screw from the point of juncture of the conical bearing surface and the body to the flat of the point. The length of thread *L<sub>T</sub>* is the distance measured from the extreme point to the last complete (full form) thread.

Standard length increments of No. 0 through 1-inch sizes are as follows: 1/16 inch for nominal screw lengths of 1/8 inch through 1/4 inch; 1/8 inch for lengths of 1/4 inch through 1 inch; 1/4 inch for lengths of 1 inch through 3 1/2 inches; 1/2 inch for lengths of 3 1/2 through 7 inches; and 1 inch for lengths of 7 through 10 inches, incl. For screw sizes over 1 inch, length increments are: 1/2 inch for nominal screw lengths of 1 inch through 7 inches; 1 inch for lengths of 7 through 10 inches; and 2 inches for lengths over 10 inches.

Threads shall be Unified external threads with radius root; Class 3A UNRC and UNRF series for sizes No. 0 through 1 inch and Class 2A UNRC and UNRF series for sizes over 1 inch to 1 1/2 inches, incl.

For manufacturing details not shown, including materials, see American National Standard ANSI/ASME B18.3-2012 and ANSI/ASME B18.3-1998 (for Spline driven fasteners). Socket dimensions are given in Table 11.

**Table 7. American National Standard Hexagon Socket and Spline Socket Button Head Cap Screws ANSI/ASME B18.3-2012**

<sup>a</sup> Socket dimensions are given in Table 11.

<sup>b</sup> Spline driven fasteners are removed from the latest revision. For additional information on these fasteners, see ANSI/ASME B18.3-1998.

All dimensions in inches.

These cap screws have been designed and recommended for light fastening applications. They are not suggested for use in critical high-strength applications where socket head cap screws should normally be used.

Standard length increments for socket button head cap screws are as follows: 1/16 inch for nominal screw lengths of 1/8 through 1/4 inch, 1/8 inch for nominal screw lengths of 1/4 through 1 inch, and 1/4 inch for nominal screw lengths of 1 inch through 2 inches. Tolerances on lengths are -0.03 inch for lengths up to 1 inch inclusive. For lengths from 1 through 2 inches, inclusive, length tolerances are -0.04 inch.

The thread conforms to the Unified standard, Class 3A, with radius root, UNRC and UNRF.

To prevent interference, American National Standard ANSI/ASME B18.3.4M-1986 gives metric dimensional and general requirements for a lower head profile hexagon socket button head cap screw. Because of its design, wrenchability and other design factors are reduced; therefore, B18.3.4M should be reviewed carefully. Available only in metric sizes and with metric threads.

For manufacturing details, including materials, not shown, see American National Standard ANSI/ASME B18.3-2012 and ANSI/ASME B18.3-1998 (for Spline driven fasteners).

**Table 8. American National Standard Hexagon Socket Head Shoulder Screws**

2	1.089	1.059	0.286	1.728	0.125	0.072	0.066	0.080	1
2	1.307	1.277	0.333	1.978	0.125	0.102	0.096	0.090	1¼

All dimensions are in inches. The shoulder is the enlarged, unthreaded portion of the screw. Standard length increments for shoulder screws are: ⅛ inch for nominal screw lengths of ¼ through ¾ inch; ¼ inch for lengths above ¾ through 5 inches; and ½ inch for lengths over 5 inches. The thread conforms to the Unified Standard Class 3A, UNC. Hexagon socket sizes for the respective shoulder screw sizes are the same as for set screws of the same nominal size (see Table 7) except for shoulder screw size 1 inch, socket size is ½ inch, for screw size 1 ½ inches, socket size is ⅞ inch, and for screw size 2 inches, socket size is 1 ¼ inches. For details not shown, including materials, see ANSI/ASME B18.3-2012.

<sup>a</sup> When specifying a nominal size in decimals a zero preceding the decimal point or any zero in the fourth decimal place is omitted.

All dimensions are in inches.

**Crown Radius, *I*:** The crown radius has the same value as the basic screw diameter to three decimal places.

**Oval Point Radius, *R*:** Values of the oval point radius according to nominal screw size are: For a screw size of 0, a radius of .045; 1, .055; 2, .064; 3, .074; 4, .084; 5, .094; 6, .104; 8, .123; 10, .142; 12, .162; 1/4, .188; 5/16, .234; 3/8, .281; 7/16, .328; 1/2, .375; 9/16, .422; 5/8, .469; and for 3/4, .562.

**Cone Point Angle, *Y*:** The cone point angle is 90° ± 2° for the following nominal lengths, or longer, shown according to screw size: For nominal size 0, a length of 3/64; 1, 3/32; 2, 7/64; 3, 1/8; 4, 3/32; 5, 3/16; 6, 3/16; 8, 1/4; 10, 1/4; 12, 5/16; 1/4, 5/16; 3/8, 3/8; 7/16, 7/16; 1/2, 1/2; 9/16, 9/16; 5/8, 5/8; 3/4, and for 3/4, 7/8. For shorter screws, the cone point angle is 118° ± 2°.

**Point Angle *X*:** The point angle is 45°, + 5°, - 0°, for screws of nominal lengths, or longer, as given just above for cone point angle, and 30°, min. for shorter screws.

**Threads:** are Unified Standard Class 2A; UNC and UNF Series or UNRC and UNRF Series.

<sup>a</sup> Spline driven fasteners are removed from the latest revision. For additional information on these fasteners, see ANSI/ASME B18.3-1998.

All dimensions are in inches.

\* Socket depths, *T*, for various screw types are given in the standard but are not shown here.

Where sockets are chamfered, the depth of chamfer shall not exceed 10 percent of the nominal socket size for sizes up to and including 1/16 inch for hexagon sockets and 0.060 for spline sockets, and 7.5 percent for larger sizes.

1 1/2	1.5000	.926	.886	1.125	1.105	.760	.740	.385	.365	1.125

All dimensions are in inches.

\*Threads: Threads are Unified Standard Class 2A; UNC, UNF and 8 UN Series or UNRC, UNRF and 8 UNR Series.

Length of Thread: Square head set screws have complete (full form) threads extending over that portion of the screw length which is not affected by the point. For the respective constructions, threads extend into the neck relief, to the conical underside of head, or to within one thread (as measured with a thread ring gage) from the flat underside of the head. Threads through angular or crowned portions of points have fully formed roots with partial crests.

\* When specifying a nominal size in decimals, the zero preceding the decimal point is omitted as is any zero in the fourth decimal place.

**Designation:** Square head set screws are designated by the following data in the sequence shown: Nominal size (number, fraction or decimal equivalent); threads per inch; screw length (fraction or decimal equivalent); product name; point style; material; and protective finish, if required. Examples:  $\frac{1}{4}$  - 20 x  $\frac{3}{4}$  Square Head Set Screw, Flat Point, Steel, Cadmium Plated. .500 - 13 x 1.25 Square Head Set Screw, Cone Point, Corrosion Resistant Steel.

**Cone Point Angle, Y:** For the following nominal lengths, or longer, shown according to nominal size, the cone point angle is  $90^\circ \pm 2^\circ$ : For size No. 10,  $\frac{1}{4}$ ,  $\frac{1}{4}$ ,  $\frac{5}{16}$ ,  $\frac{3}{16}$ ,  $\frac{3}{8}$ ,  $\frac{7}{16}$ ,  $\frac{1}{2}$ ,  $\frac{1}{2}$ ,  $\frac{9}{16}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$ ,  $\frac{3}{4}$ ,  $\frac{7}{8}$ ,  $\frac{7}{8}$ , 1, 1,  $1\frac{1}{8}$ ,  $1\frac{1}{8}$ ,  $1\frac{1}{4}$ ,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$ ,  $1\frac{3}{8}$ ,  $1\frac{3}{8}$ ; and for  $1\frac{1}{2}$ ,  $1\frac{3}{4}$ . For shorter screws the cone point angle is  $118^\circ \pm 2^\circ$ .

**Point Types:** Unless otherwise specified, square head set screws are supplied with cup points. Cup points as furnished by some manufacturers may be externally or internally knurled. Where so specified by the purchaser, screws have cone, dog, half-dog, flat or oval points as given on the following page.

**Point Angle, X:** The point angle is  $45^\circ + 5^\circ - 0^\circ$  for screws of the nominal lengths, or longer, given just above for cone point angle, and  $30^\circ$  min. for shorter lengths.

<sup>a</sup> Reference should be made to the Standard for shortest optimum nominal lengths to which the minimum key engagement depths  $T_H$  and  $T_S$  apply.

<sup>b</sup> Cone point angle  $Y$  is 90 degrees plus or minus 2 degrees for these nominal lengths or longer and 118 degrees plus or minus 2 degrees for shorter nominal lengths.

All dimensions are in inches. The thread conforms to the Unified Standard, Class 3A, UNC and UNF series. The socket depth  $T$  is included in the Standard and some are shown here. The nominal length  $L$  of all socket type set screws is the total or overall length. For nominal screw lengths of 1/16 through 3/16 inch (0 through 3 sizes incl.) the standard length increment is 0.06 inch; for lengths 1/8 through 1 inch the increment is 1/8 inch; for lengths 1 through 2 inches the increment is 1/4 inch; for lengths 2 through 6 inches the increment is 1/2 inch; for lengths 6 inches and longer the increment is 1 inch. Socket dimensions are given in Table 11.

**Length Tolerance:** The allowable tolerance on length  $L$  for all set screws of the socket type is  $\pm 0.01$  inch for set screws up to 3/8 inch long;  $\pm 0.02$  inch for screws over 3/8 to 2 inches long;  $\pm 0.03$  inch for screws over 2 to 6 inches long and  $\pm 0.06$  inch for screws over 6 inches long. Socket dimensions are given in Table 11.

For manufacturing details, including materials, not shown, see American National Standard ANSI/ASME B18.3-2012 and ANSI/ASME B18.3-1998 (for Spline driven fasteners).

**British Standard Hexagon Socket Screws—Metric Series.**—The first five parts of British Standard BS 4168:1981 provide specifications for hexagon socket head cap screws and hexagon socket set screws.

*Hexagon Socket Head Cap Screws:* The dimensional data in [Table 1](#) are based upon BS 4168: Part 1: 1981. These screws are available in stainless steel and alloy steel, the latter having class 12.9 properties as specified in BS 6104:Part 1. When ordering these screws, the designation “Hexagon socket head cap screw BS 4168 M5 × 20-12.9” would mean, as an example, a cap screw having a thread size of  $d = M5$ , nominal length  $l = 20$  mm, and property class 12.9. Alloy steel cap screws are furnished with a black oxide finish (thermal or chemical); stainless steel cap screws with a plain finish. Combinations of thread size, nominal length, and length of thread are shown in [Table 2](#); the screw threads in these combinations are in the ISO metric coarse pitch series specified in BS 3643 with tolerances in the 5g6g class. (See Metric Screw Threads in Index.)

*Hexagon Socket Set Screws:* Part 2 of BS 4168:1981 specifies requirements for hexagon socket set screws with flat point having ISO metric threads, and diameters from 1.6 mm up to and including 24 mm. The dimensions of these set screws along with those of cone-point, dog-point, and cup-point set screws in accord, respectively, with Parts 3, 4, and 5 of the Standard are given in [Table 3](#) and the accompanying illustration. All of these set screws are available in either steel processed to mechanical properties class 45H BS 6104:Part 3; or stainless steel processed to mechanical properties described in BS 6105. Steel set screws are furnished with black oxide (thermal or chemical) finish; stainless steel set screws are furnished plain. The tolerances applied to the threads of these set screws are for ISO product grade A, based on ISO 4759/1-1978 “Tolerances for fasteners.—Part 1: Bolts, screws, and nuts with thread diameters greater than or equal to 1.6 mm and less than or equal to 150 mm and product grades A, B, and C.”

Hexagon socket set screws are designated by the type, the thread size, nominal length, and property class. As an example, for a flat-point set screw of thread size  $d = M6$ , nominal length  $l = 12$  mm, and property class 45H:

Hexagon socket set screw flat point BS 4168 M6 × 12-45H

*British Standard Hexagon Socket Countersunk and Button Head Screws.—Metric Series:* British Standard BS 4168:1967 provides a metric series of hexagon socket countersunk and button head screws. The dimensions of these screws are given in [Table 4](#). The revision of this Standard will constitute Parts 6 and 8 of BS 4168.

*British Standards for Mechanical Properties of Fasteners:* BS 6104: Part 1:1981 specifies mechanical properties for bolts, screws, and studs with nominal diameters up to and including 39 mm of any triangular ISO thread and made of carbon or alloy steel. It does not apply to set screws and similar threaded fasteners. Part 2 of this Standard specifies the mechanical properties of set screws and similar fasteners, not under tensile stress, in the range from M1.6 up to and including M39 and made of carbon or alloy steel.

BS 6105:1981 provides specifications for bolts, screws, studs, and nuts made from austenitic, ferritic, and martensitic grades of corrosion-resistant steels. This Standard applies only to fastener components after completion of manufacture with nominal diameters from M1.6 up to and including M39. These Standards are not described further here. Copies may be obtained from the British Standards Institution, 389 Chiswick High Road, London, W4 4AL, [www.bsigroup.com](http://www.bsigroup.com), and also from the American National Standards Institute, 25 West 43rd Street, New York, NY 10036, [www.ansi.org](http://www.ansi.org).

All dimensions are in millimeters.

The popular lengths are those between the stepped solid lines. Lengths above the shaded areas are threaded to the head within 3 pitch lengths (3*P*). Lengths within and below the shaded areas have values of *L<sub>g</sub>* and *L<sub>s</sub>* (see Table 1) given by the formulas: *L<sub>g</sub>*max = *L* nom - *b* ref, and *L<sub>s</sub>*min = *L<sub>g</sub>*max - 5*P*.

<sup>a</sup> The smaller of the two *t* min. values applies to certain short-length set screws. These short-length screws are those whose length is approximately equal to the diameter of the screw. The larger *t* min. values apply to longer-length screws.

<sup>b</sup> A dog point set screw having a nominal length equal to or less than the length shown in the (\*) column of the table is supplied with length *z* shown in the short dog column. For set screws of lengths greater than shown in the (\*) column, *z* for long dogs applies.

All dimensions are in millimeters. For dimensional notation, see diagram, page 1831.

All dimensions are given in millimeters.

**British Standard Hexagon Socket Set Screws.—Metric Series**  
*BS 4168:Parts 2, 3, 4, and 5:1994*

\*The 120° angle is mandatory for short-length screws shown in the Standard. Short-length screws are those whose length is, approximately, equal to the diameter of the screw.

\*\*The 45° angle applies only to that portion of the point below the root diameter,  $d_f$ , of the thread.

\*\*\*The cone angle applies only to the portion of the point below the root diameter,  $d_f$ , of the thread and shall be 120° for certain short lengths listed in the Standard. All other lengths have a 90° cone angle.

†The popular length ranges of these set screws are listed in Table 3. These lengths have been selected from the following nominal lengths: 2, 2.5, 3, 4, 6, 8, 10, 12, 16, 20, 25, 30, 35, 40, 45, 50, 55, and 60 millimeters.

**Holding Power of Set Screws.**—While the amount of power a set screw of given size will transmit without slipping (when used for holding a pulley, gear, or other part from turning relative to a shaft) varies somewhat according to the physical properties of both set screw and shaft and other variable factors, experiments have shown that the safe holding force in pounds for different diameters of set screws should be approximately as follows: For  $\frac{1}{4}$ -inch (6.35 mm) diameter set screws the safe holding force is 100 pounds (445 N), for  $\frac{3}{8}$ -inch (9.5 mm) diameter set screws the safe holding force is 250 pounds (1112 N), for

$\frac{1}{2}$ -inch (12.7 mm) diameter set screws the safe holding force is 500 pounds (2224 N), for  $\frac{3}{4}$ -inch (19 mm) diameter set screws the safe holding force is 1300 pounds (5783 N), and for 1-inch (25.4 mm) diameter set screws the safe holding force is 2500 pounds (11121 N).

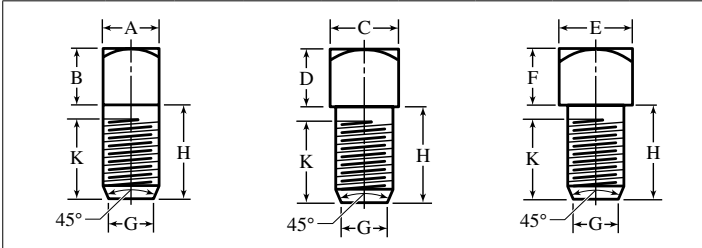

The power or torque that can be safely transmitted by a set screw may be determined from the formulas,  $P = (DNd^{2.3}) \div 50$ ; or  $T = 1250Dd^{2.3}$  in which  $P$  is the horsepower transmitted;  $T$  is the torque in inch-pounds transmitted;  $D$  is the shaft diameter in inches;  $N$  is the speed of the shaft in revolutions per minute; and  $d$  is the diameter of the set screw in inches.

*Example:* How many  $\frac{1}{2}$ -inch diameter set screws would be required to transmit 3 horsepower at a shaft speed of 1000 rpm if the shaft diameter is 1 inch?

Using the first formula given above, the power transmitted by a single  $\frac{1}{2}$ -inch diameter set screw is determined:  $P = [1 \times 1000 \times (\frac{1}{2})^{2.3}] \div 50 = 4.1$  hp. Therefore a single  $\frac{1}{2}$ -inch diameter set screw is sufficient.

*Example:* In the previous example, how many  $\frac{3}{8}$ -inch diameter set screws would be required?  $P = [1 \times 1000 \times (\frac{3}{8})^{2.3}] \div 50 = 2.1$  hp. Therefore two  $\frac{3}{8}$ -inch diameter set screws are required.

**Table 5. British Standard Whitworth (BSW) and British Standard Fine (BSF) Bright Square Head Set Screws (With Flat Chamfered Ends)**

\* Depth of Head  $B, D$  and  $F$  same as for Width Across Flats, No. 1 Standard.

Dimensions  $A, B, C, D, E,$  and  $F$  are in inches.

## SELF-THREADING SCREWS

**ANSI Standard Sheet Metal, Self-Tapping, and Metallic Drive Screws.**—Table 1 shows the various types of “self-tapping” screw threads covered by the ANSI/ASME B18.6.3-2013 standard. (Metric thread forming and thread cutting tapping screws are discussed beginning on page 1848). ANSI designations are also shown. Types A, AB, B, BP and C when turned into a hole of proper size form a thread by a displacing action. Types D, F, G, T, BF and BT when turned into a hole of proper size form a thread by a cutting action. Type U when driven into a hole of proper size forms a series of multiple threads by a displacing action. These screws have the following descriptions and applications:

*Type A:* Spaced-thread screw with gimlet point primarily for use in light sheet metal, resin-impregnated plywood, and asbestos compositions. This type is no longer recommended. Use Type AB in new designs and whenever possible substitute for Type A in existing designs.

*Type AB:* Spaced-thread screw with same pitches as Type B but with gimlet point, primarily for similar uses as for Type A.

*Type B:* Spaced-thread screw with a blunt point with pitches generally somewhat finer than Type A. Used for thin metal, nonferrous castings, plastics, resin-impregnated plywood, and asbestos compositions.

*Type BP:* Spaced-thread screw, the same as Type B but having a conical point extending beyond incomplete entering threads. Used for piercing fabrics or in assemblies where holes are misaligned.

*Type C:* Screws having machine screw diameter-pitch combinations with threads approximately Unified Form and with blunt tapered points. Used where a machine screw thread is preferable to the spaced-thread types of thread forming screws. Also useful when chips from machine screw thread-cutting screws are objectionable. In view of the declining use of Type C screws, which in general require high driving torques, in favor of more efficient designs of thread tapping screws, they are not recommended for new designs.

*Types D, F, G, and T:* Thread-cutting screws with threads approximating machine screw threads, with blunt point, and with tapered entering threads having one or more cutting edges and chip cavities. The tapered threads of the Type F may be complete or incomplete at the producer's option; all other types have incomplete tapered threads. These screws can be used in materials such as aluminum, zinc, and lead die castings; steel sheets and shapes; cast iron; brass; and plastics.

*Types BF and BT:* Thread-cutting screws with spaced threads as in Type B, with blunt points, and one or more cutting grooves. Used in plastics, asbestos, and other similar compositions.

*Type U:* Multiple-threaded drive screw with large helix angle, having a pilot point, for use in metal and plastics. This screw is forced into the work by pressure and is intended for making permanent fastenings.

**ANSI Standard Head Types for Tapping and Metallic Drive Screws:** Many of the head types used with “self-tapping” screw threads are similar to the head types of American National Standard machine screws shown in the section with that heading.

*Round Head:* The round head has a semi-elliptical top surface and a flat bearing surface. Because of the superior slot driving characteristics of pan head screws over round head screws, and the overlap in dimensions of cross recessed pan heads and round heads, it is recommended that pan head screws be used in new designs and wherever possible substituted in existing designs.

*Undercut Flat and Oval Countersunk Heads:* For short lengths, 82-degree and oval countersunk head tapping screws have heads undercut to 70 percent of normal side height to afford greater length of thread on the screws.

*Flat Countersunk Head:* The flat countersunk head has a flat top surface and a conical bearing surface with a head angle for one design of approximately 82 degrees and for another design of approximately 100 degrees. Because of its limited usage and in the interest of curtailing product varieties, the 100-degree flat countersunk head is considered non-preferred.

*Oval Countersunk Head:* The oval countersunk head has a rounded top surface and a conical bearing surface with a head angle of approximately 82 degrees.

*Flat and Oval Countersunk Trim Heads:* Flat and oval countersunk trim heads are similar to the 82-degree flat and oval countersunk heads except that the size of head for a given size screw is one (large trim head) or two (small trim head) sizes smaller than the regular flat and oval countersunk head size. Oval countersunk trim heads have a definite radius where the curved top surface meets the conical bearing surface. Trim heads are furnished only in cross recessed types.

*Pan Head:* The slotted pan head has a flat top surface rounded into cylindrical sides and a flat bearing surface. The recessed pan head has a rounded top and a flat bearing surface. This head type is now preferred to the round head.

*Fillister Head:* The fillister head has a rounded top surface, cylindrical sides, and a flat bearing surface.

*Hex Head:* The hex head has a flat or indented top surface, six flat sides, and a flat bearing surface. Because the slotted hex head requires a secondary operation in manufacture which often results in burrs at the extremity of the slot that interfere with socket wrench engagement and the wrenching capability of the hex far exceeds that of the slot, it is not recommended for new designs.

*Hex Washer Head:* The hex washer head has an indented top surface and six flat sides formed integrally with a flat washer that projects beyond the sides and provides a flat bearing surface. Because the slotted hex washer head requires a secondary operation in manufacture, which often results in burrs at the extremity of the slot that often interferes with socket wrench engagement, and because the wrenching capability of the hex far exceeds that of the slot in the indented head, it is not recommended for new designs.

*Truss Head:* The truss head has a low rounded top surface with a flat bearing surface, the diameter of which for a given screw size is larger than the diameter of the corresponding round head. In the interest of product simplification and recognizing that the truss head is an inherently weak design, it is not recommended for new designs.

**Method of Designation.**—Tapping screws are designated by the following data in the sequence shown: Nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); point type; product name, including head type and driving provision; material; and protective finish, if required. Examples:

$\frac{1}{4}$ -14  $\times$  1 $\frac{1}{2}$  Type AB Slotted Pan Head Tapping Screw, Steel, Nickel Plated

6-32  $\times$   $\frac{3}{4}$  Type T, Type 1A Cross Recessed Pan Head Tapping Screw, Corrosion Resistant Steel

0.375-16  $\times$  1.50 Type D, Washer Head Tapping Screw, Steel

*Metallic Drive Screws:* Type U metallic drive screws are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); nominal length (fraction or decimal equivalent); product name, including head type; material; and protective finish, if required. Examples:

10  $\times$   $\frac{5}{16}$  Round Head Metallic Drive Screw, Steel

0.312  $\times$  0.50 Round Head Metallic Drive Screw, Steel, Zinc Plated

**Table 1. ANSI Standard Threads and Points for Thread Forming Self-Tapping Screws ANSI/ASME B18.6.3-2013**

See Table 3, Table 5, and Table 6 for thread data.

**Table 2. ANSI Standard Threads and Points for Thread Cutting Self-Tapping Screws ANSI/ASME B18.6.3-2013**

See Table 5 and Table 7 for thread data.

**Cross Recesses.**—Type I cross recess has a large center opening, tapered wings, and blunt bottom, with all edges relieved or rounded. Type IA cross recess has a large center opening, wide straight wings, and blunt bottom, with all edges relieved or rounded. Type II consists of two intersecting slots with parallel sides converging to a slightly truncated apex at the bottom of the recess. Type III has a square center opening, slightly tapered side walls, and a conical bottom, with top edges relieved or rounded.

**Table 3. ANSI Standard Cross Recesses for Self-Tapping Screws ANSI/ASME B18.6.3-2013 and Metric Thread Forming and Thread Cutting Tapping Screws ANSI/ASME B18.6.5M-2000 (Withdrawn)**

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The width of flat at crest of thread shall not exceed 0.004 inch for sizes up to No. 8, inclusive, and 0.006 inch for larger sizes.

<sup>c</sup> Point diameters specified apply to screw threads before roll threading.

<sup>d</sup> Points of screws are tapered and fluted or slotted. The flute on Type BT screws has an included angle of 90 to 95 degrees and the thread cutting edge is located above the axis of the screw. Flutes and slots extend through first full form thread beyond taper except for Type BF screw on which tapered threads may be complete at manufacturer's option and flutes may be one pitch short of first full form thread.

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The tabulated values apply to screw blanks before roll threading.

<sup>c</sup> Screws of these nominal lengths and shorter shall have point taper length specified above for short screws. Longer lengths shall have point taper length specified for long screws.

All dimensions are in inches. See Table 1 for thread diagrams. Type C is not recommended for new designs.

Tapered threads shall have unfinished crests.

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The tabulated values apply to screw blanks before roll threading.

<sup>c</sup> Screws of these nominal lengths and shorter shall have point taper length specified above for short screws. Longer lengths shall have point taper length specified for long screws.

All dimensions are in inches. See [Table 2](#) for thread diagrams.

“Type D” otherwise designated “Type 1.”

“Type T” otherwise designated “Type 23.”

<sup>a</sup> For Types B and BP only; for Type AB see concluded Table 12b following.

Since conditions differ widely, it may be necessary to vary the hole size to suit a particular application. Hole sizes for metal thicknesses above 0.075 inch are for Types B and BP only.

**Table 12b. Supplementary Data for Types AB Thread Forming Screws in Steel, Stainless Steel, Monel Metal, and Brass Sheet Metal**

Screw Size	Metal Thickness	Hole Size	Drill Size	Screw Size	Metal Thickness	Hole Size	Drill Size	Screw Size	Metal Thickness	Hole Size	Drill Size
In Steel, Stainless Steel, Monel Metal, and Brass Sheet Metal

14	125	...	...	...	...	...	...	...	...

Torsional strength data are in pound-inches.

**Self-Tapping Thread Inserts.**—Self-tapping screw thread inserts are essentially hard bushings with internal and external threads. The internal threads conform to Unified and American standard classes 2B and 3B, depending on the type of insert used. The external thread has cutting edges on the end that provide the self-tapping feature. These inserts may be used in magnesium, aluminum, cast iron, zinc, plastics, and other materials. Self-tapping inserts are made of case-hardened carbon steel, stainless steel, and brass, the brass type being designed specifically for installation in wood.

**Screw Thread Inserts.**—Screw thread inserts are helically formed coils of diamond-shaped stainless steel or phosphor bronze wire that screw into a threaded hole to form a mating internal thread for a screw or stud. These inserts provide a convenient means of repairing stripped-out threads and are also used to provide stronger threads in soft materials such as aluminum, zinc die castings, wood, magnesium, etc. than can be obtained by direct tapping of the base metal involved.

According to the Heli-Coil Corp., conventional design practice in specifying boss diameters or edge distances can usually be applied since the major diameter of a hole tapped to receive a thread insert is not much larger than the major diameter of thread the insert provides.

Screw thread inserts are available in thread sizes from 4-40 to 1<sup>1</sup>/<sub>2</sub>-6 inch National and Unified Coarse Thread Series and in 6-40 to 1<sup>1</sup>/<sub>2</sub>-12 sizes in the fine-thread series. When used in conjunction with appropriate taps and gages, screw thread inserts will meet requirements of 2, 2B, 3, and 3B thread classes.

**ANSI Standard Metric Thread Forming and Thread Cutting Tapping Screws.**—Table 1 shows the various types of metric thread forming and thread cutting screw threads covered by the standard ANSI/ASME B18.6.5M-2000 (Withdrawn). The designations of the American National Standards Institute are shown.

**Table 1. ANSI Standard Threads and Points for Metric Thread Forming and Thread Cutting Tapping Screws ANSI/ASME B18.6.5M-2000 (Withdrawn)**

See Table 3 and Table 4 for thread data.

**Thread Forming Tapping Screws:** These types are generally for application in materials where large internal stresses are permissible or desirable, to increase resistance to loosening. These screws have the following descriptions and applications:

*Type AB:* Spaced thread screw with gimlet point primarily intended for use in thin metal, resin impregnated plywood, and asbestos compositions.

*Type B:* Spaced thread screw with a blunt point that has tapered entering threads with unfinished crests and same pitches as Type AB. Used for thin metal, nonferrous castings, resin impregnated plywood, certain resilient plastics, and asbestos compositions.

*Thread Cutting Tapping Screws:* These screws are generally for application in materials where disruptive internal stresses are undesirable or where excessive driving torques are encountered with thread forming tapping screws. These screws have the following descriptions and applications:

*Types BF and BT:* Spaced threads with blunt point and tapered entering threads having unfinished crests, as on Type B, with one or more cutting edges or chip cavities, intended for use in plastics, asbestos compositions, and other similar materials.

*Types D, F, and T:* Tapping screws with threads of machine screw diameter-pitch combinations (metric coarse thread series) approximating a 60 degree basic thread form (not necessarily conforming to any standard thread profile) with a blunt point and tapered entering threads with unfinished crests and having one or more cutting edges and chip cavities, intended for use in materials such as aluminum, zinc, and lead die castings; steel sheets and shapes; cast iron; brass; and plastics.

**ANSI Standard Head Types for Metric Thread Forming and Cutting Tapping Screws.**—The head types covered by ANSI/ASME B18.6.5M-2000 (Withdrawn) include those commonly applicable to metric tapping screws and are described as follows:

*Flat Countersunk Head:* The flat countersunk head has a flat top surface and a conical bearing surface with a head angle of 90 to 92 degrees.

*Oval Countersunk Head:* The oval countersunk head has a rounded top surface and a conical bearing surface with a head angle of 90 to 92 degrees.

*Pan Head:* The slotted pan head has a flat top surface rounding into cylindrical sides and a flat bearing surface. The recessed pan head has a rounded top surface blending into cylindrical sides and a flat bearing surface.

*Hex Head:* The hex head has a flat or indented top surface, six flat sides, and a flat bearing surface.

*Hex Flange Head:* The hex flange head has a flat or indented top surface and six flat sides formed integrally with a frustoconical or slightly rounded (convex) flange that projects beyond the sides and provides a flat bearing surface.

**Method of Designation.**—Metric tapping screws are designated with the following data, preferably in the sequence shown: Nominal size; thread pitch; nominal length; thread and point type; product name, including head style and driving provision; material; and protective finish, if required.

*Examples:*

6.3 × 1.8 × 30 Type AB, Slotted Pan Head Tapping Screw, Steel, Zinc Plated

6 × 1 × 20 Type T, Type 1A Cross Recessed Pan Head Tapping Screw, Corrosion Resistant Steel

4.2 × 1.4 × 13 Type BF, Type 1 Cross Recessed Oval Countersunk Head Tapping Screw, Steel, Chromium Plated

10 × 1.5 × 40 Type D, Hex Flange Head Tapping Screw, Steel

<sup>a</sup> The body diameter (unthreaded portion) is not less than the minimum minor diameter nor greater than the maximum major diameter of the thread.

<sup>b</sup> The tabulated values shall apply to screw blanks prior to roll threading.

<sup>c</sup> The tabulated maximum limits are equal to approximately two times the thread pitch.

<sup>d</sup> Lengths shown are theoretical minimums and are intended to assist the user in the selection of appropriate short screw lengths. Refer to Table 2 for recommended diameter-length combinations.

<sup>e</sup> Basic screw diameter and basic thread pitch shall be used for calculation purposes wherever these factors appear in formulations for dimensions.

<sup>f</sup> The minimum effective grip length on Type AB tapping screws shall be determined by subtracting the point length factor from the minimum screw length.

All dimensions are in millimeters. See Table 1 for thread diagrams.

<sup>7</sup> Pan, hex, and hex flange heads.

<sup>8</sup> Flat and oval countersunk heads.

6 × 1	6.00	5.79	4.69	4.55	5.21	3.5	2.5	4.5	3.5	9	12		
8 × 1.25	8.00	7.76	6.40	6.24	7.04	4.4	3.1	5.6	4.4	11	16		
10 × 1.5	10.00	9.73	8.08	7.88	8.86	5.3	3.8	6.8	5.3	13	18		

<sup>a</sup> Minimum limits for body diameter (unthreaded portion) are tabulated for convenient reference. For Types BF and BT, the body diameter is not less than the minimum minor diameter nor greater than the maximum major diameter of the thread.

<sup>b</sup> Long screws are screws of nominal lengths equal to or longer than those listed under L.

All dimensions are in millimeters. See Table 1 for thread diagrams.

**Material and Heat Treatment.**—Tapping screws are normally fabricated from carbon steel and are suitably processed to meet the performance and test requirements outlined in the standard, B18.6.5M. Tapping screws may also be made from corrosion resistant steel, Monel, brass, and aluminum alloys. The materials, properties, and performance characteristics applicable to such screws should be mutually agreed upon between the manufacturer and the purchaser.

5.5 × 1.8	5.90	6.10	6.50	5 × 0.8	5.30	5.50	5.80
6.3 × 1.8	6.70	6.90	7.30	6 × 1	6.40	6.60	7.00
8 × 2.1	8.40	9.00	10.00	8 × 1.25	8.40	9.00	10.00
9.5 × 2.1	10.00	10.50	11.50	10 × 1.5	10.50	11.00	12.00

<sup>a</sup> The values given in this table are minimum limits. The recommended plus tolerances are as follows: for clearance hole diameters over 1.70 to and including 5.80 mm, plus 0.12, 0.20, and 0.30 mm for close, normal, and loose clearances, respectively; over 5.80 to and including 14.50 mm, plus 0.18, 0.30, and 0.45 mm for close, normal, and loose clearances, respectively.

<sup>b</sup> Normal clearance hole sizes are preferred. Close clearance hole sizes are for situations such as critical alignment of assembled components, wall thickness, or other limitations that necessitate the use of a minimal hole. Countersinking or counterboring at the fastener entry side may be necessary for the proper seating of the head. Loose clearance hole sizes are for applications where maximum adjustment capability between the components being assembled is necessary.

All dimensions are in millimeters.

**Approximate Installation Hole Sizes for Metric Tapping Screws.**—The approximate hole sizes given in Table 7 through Table 9 provide general guidance in selecting holes for installing the respective types of metric thread forming and thread cutting tapping screws in various commonly used materials. Types AB, B, BF, and BT metric tapping screws are covered in these tables; hole sizes for Types D, F, and T metric thread cutting tapping screws are still under development.

**Table 6. Approximate Pierced or Extruded Hole Sizes for Steel Types AB and B Metric Thread Forming Tapping Screws**

Nominal Screw Size and Thread Pitch	Metal Thickness	Hole Size	Nominal Screw Size and Thread Pitch	Metal Thickness	Hole Size	Nominal Screw Size and Thread Pitch	Metal Thickness	Hole Size

<sup>a</sup> Customary drill size references have been retained where the metric hole sizes are direct conversions of their decimal inch equivalents.

All dimensions are in millimeters except drill sizes.

The finish (plating or coating) on metric tapping screws and the material composition and hardness of the mating component are factors that affect assembly torques in individual applications. Although the recommended installation hole sizes given in [Table 7](#) through [Table 9](#) were based on the use of plain unfinished carbon steel metric tapping screws, experience has shown that the specified holes are also suitable for screws having most types of commercial finishes. However, owing to various finishes providing different degrees of lubricity, some adjustment of installation torques may be necessary to suit individual applications. Also, where exceptionally heavy finishes are involved or screws are to be assembled into materials of higher hardness, some deviation from the specified hole sizes may be required to provide optimum assembly. The necessity and extent of such deviations can best be determined by experiment in the particular assembly environment.

## T-SLOTS, BOLTS, AND NUTS

**Table 1. American National Standard T-Slots ANSI/ASME B5.1M-1985 (R2014)**

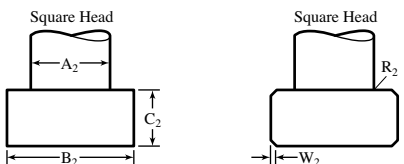

Nominal T-Bolt Size <sup>a</sup>		Width of Throat $A_1$ <sup>b</sup>		Width of Headspace $B_1$				Depth of Headspace $C_1$				Depth of Throat $D_1$				Rounding or Breaking of Corners <sup>c</sup>

	48		54			90	95			40	44			50	66					1.5	2.5	2	

<sup>a</sup> Width of tongue (tenon) to be used with the above T-Slots will be found in the complete standard, B5.1M.

<sup>b</sup> Throat dimensions are basic. When slots are intended to be used for holding only, tolerances can be 0.0 + 0.010 inch or H12 Metric (ISO/R286); when intended for location, tolerance can be 0.0 + 0.001 inch or H8 Metric (see page 665).

<sup>c</sup> Corners of T-Slots may be square or may be rounded or broken to the indicated maximum dimensions at the manufacturer's option.

For the dimensions of tongue seats, inserted tongues, and solid tongues refer to the complete standard, B5.1M.

<sup>a</sup> T-slot dimensions to fit the above nuts will be found in Table 1.<sup>b</sup> For tolerances of inch threads see page 1951.<sup>c</sup> No tolerances are given for "Total Thickness" or "Nut Length" as they need not be held to close limits.<sup>d</sup> Metric tapped thread grade and tolerance position is 5H (see page 2019).

## RIVETS AND RIVETED JOINTS

## Riveted Joint Design

**Classes and Types of Riveted Joints.**—Riveted joints may be classified by application as: 1) pressure vessel; 2) structural; and 3) machine member.

For information and data concerning joints for pressure vessels such as boilers, reference should be made to standard sources such as the ASME Boiler Code. The following sections will cover only structural and machine-member riveted joints.

Basically there are two kinds of riveted joints, the *lap-joint* and the *butt-joint*. In the ordinary *lap-joint*, the plates overlap each other and are held together by one or more rows of rivets. In the *butt-joint*, the plates being joined are in the same plane and are joined by means of a cover plate or butt strap, which is riveted to both plates by one or more rows of rivets. The term *single riveting* means one row of rivets in a lap-joint or one row on each side of a butt-joint; *double riveting* means two rows of rivets in a lap-joint or two rows on each side of the joint in butt riveting. Joints are also triple and quadruple riveted. Lap-joints may also be made with inside or outside cover plates. Types of lap and butt joints are illustrated in the tables on starting at page 1865.

**General Design Considerations for Riveted Joints.**—Factors to be considered in the design or specification of a riveted joint are: type of joint; spacing of rivets; type and size of rivet; type and size of hole; and rivet material.

*Spacing of Rivets:* The spacing between rivet centers is called *pitch* and between row center lines, *back pitch* or *transverse pitch*. The distance between centers of rivets nearest each other in adjacent rows is called *diagonal pitch*. The distance from the edge of the plate to the center line of the nearest row of rivets is called *margin*.

Examination of a riveted joint made up of several rows of rivets will reveal that after progressing along the joint a given distance, the rivet pattern or arrangement is repeated. (For a butt joint, the length of a *repeating section* is usually equal to the *long pitch* or pitch of the rivets in the outer row, that is the row farthest from the edge of the joint.) For structural and machine-member joints, the proper pitch may be determined by making the tensile strength of the plate over the length of the repeating section, that is the distance between rivets in the outer row, equal to the total shear strength of the rivets in the repeating section. Minimum pitch and diagonal pitch are also governed by the clearance required for the hold-on (Dolly bar) and rivet set. Dimensions for different sizes of hold-ons and rivet sets are given in the table on page 1870.

When fastening thin plate, it is particularly important to maintain accurate spacing to avoid buckling.

*Size and Type of Rivets:* The rivet diameter  $d$  commonly falls between  $d = 1.2\sqrt{t}$  and  $d = 1.4\sqrt{t}$ , where  $t$  is the thickness of the plate. Dimensions for various types of American Standard large ( $\frac{1}{2}$ -inch diameter and up) rivets and small solid rivets are shown in tables that follow. It may be noted that countersunk heads are not as strong as other types.

*Size and Type of Hole:* Rivet holes may be punched, punched and reamed, or drilled. Rivet holes are usually made  $\frac{1}{16}$  inch (1.6 mm) larger in diameter than the nominal diameter of the rivet although in some classes of work in which the rivet is driven cold, as in automatic machine riveting, the holes are reamed to provide minimum clearance so that the rivet fills the hole completely.

When holes are punched in heavy steel plate, there may be considerable loss of strength unless the holes are reamed to remove the inferior metal immediately surrounding them. This results in the diameter of the punched hole being increased by from  $\frac{1}{16}$  to  $\frac{1}{8}$  inch (1.6 to 3.2 mm). Annealing after punching tends to restore the strength of the plate in the vicinity of the holes.

**Rivet Material:** Rivets for structural and machine-member purposes are usually made of wrought iron or soft steel, but for aircraft and other applications where light weight or resistance to corrosion is important, copper, aluminum alloy, Monel, Inconel, etc., may be used as rivet material.

**Simplified Design Assumptions:** In the design of riveted joints, a simplified treatment is frequently used in which the following assumptions are made:

- 1) The load is carried equally by the rivets.
- 2) No combined stresses act on a rivet to cause failure.
- 3) The shearing stress in a rivet is uniform across the cross section under question.
- 4) The load that would cause failure in single shear would have to be doubled to cause failure in double shear.
- 5) The bearing stress of rivet and plate is distributed equally over the projected area of the rivet.
- 6) The tensile stress is uniform in the section of metal between the rivets.

**Failure of Riveted Joints.**—Rivets may fail by:

- 1) Shearing through one cross section (single shear)
- 2) Shearing through two cross sections (double shear)
- 3) Crushing

Plates may fail by:

- 4) Shearing along two parallel lines extending from opposite sides of the rivet hole to the edge of the plate
- 5) Tearing along a single line from middle of rivet hole to edge of plate
- 6) Crushing
- 7) Tearing between adjacent rivets (tensile failure) in the same row or in adjacent rows

Types 4 and 5 failures are caused by rivets being placed too close to the edge of the plate. These types of failure are avoided by placing the center of the rivet at a minimum of one and one-half times the rivet diameter away from the edge.

Types of Rivet and Plate Failure

Failure due to tearing on a diagonal between rivets in adjacent rows when the pitch is four times the rivet diameter or less is avoided by making the transverse pitch one and three-quarters times the rivet diameter.

**Theoretical versus Actual Riveted Joint Failure:** If it is assumed that the rivets are placed the suggested distance from the edge of the plate and each row the suggested distance from another row, then the failure of a joint is most likely to occur as a result of shear failure of the rivets, bearing failure (crushing) of the plate or rivets, or tensile failure of the plate, alone or in combination depending on the makeup of the joints.

Joint failure in actuality is more complex than this. Rivets do not undergo pure shear especially in lap-joints where rivets are subjected to single shear. The rivet, in this instance,

would be subject to a combination of tensile and shearing stresses and it would fail because of combined stresses, not a single stress. Furthermore, the shearing stress is usually considered to be distributed evenly over the cross section, which is also not the case.

Rivets that are usually driven hot contract on cooling. This contraction in the length of the rivet draws the plates together and sets up a stress in the rivet estimated to be equal in magnitude to the yield point of the rivet steel. The contraction in the diameter of the rivet results in a little clearance between the rivet and the hole in the plate. The tightness in the plates caused by the contraction in length of the rivet gives rise to a condition in which quite a sizeable frictional force would have to be overcome before the plates would slip over one another and subject the rivets to a shearing force. It is European practice to design joints for resistance to this slipping. It has been found, however, that the strength-basis designs obtained in American and English practice are not very different from European designs.

**Allowable Stresses.**—The design stresses for riveted joints are usually set by codes, practices, or specifications. The American Institute of Steel Construction issues specifications for the design, fabrication, and erection of structural steel for buildings in which the allowable stress permitted in tension for structural steel and rivets is specified at 20,000 pounds per square inch, the allowable bearing stress for rivets is 40,000 psi in double shear and 32,000 psi in single shear, and the allowable shearing stress for rivets is 15,000 psi. The American Society of Mechanical Engineers in its Boiler Code lists the following ultimate stresses: tensile, 55,000 psi; shearing, 44,000 psi; compressive or bearing, 95,000 psi. The design stresses usually are one-fifth of these, that is tensile, 11,000 psi; shearing, 8800 psi; compressive or bearing, 19,000 psi. In machine design work, values close to these or somewhat lower are commonly used.

**Analysis of Joint Strength.**—The following examples and strength analyses of riveted joints are based on the six previously outlined *Simplified Design Assumptions*.

*Example 1:* Consider a 12-inch section of single-riveted lap-joint made up with plates of  $\frac{1}{4}$ -inch thickness and six rivets,  $\frac{5}{8}$  inch in diameter. Assume that rivet holes are  $\frac{1}{16}$  inch larger in diameter than the rivets. In this joint, the entire load is transmitted from one plate to the other by means of the rivets. Each plate and the six rivets carry the entire load. The safe tensile load  $L$  and the efficiency  $\eta$  may be determined in the following way: Design stresses of 8500 psi for shear, 20,000 psi for bearing, and 10,000 psi for tension are arbitrarily assigned and it is assumed that the rivets will not tear or shear through the plate to the edge of the joint.

a) The safe tensile load  $L$  based on single shear of the rivets is equal to the number of rivets  $n$  times the cross-sectional area of one rivet  $A_r$  times the allowable shearing stress  $S_s$  or

$$L = n \times A_r \times S_s = 6 \times \frac{\pi}{4} (0.625)^2 \times 8500 = 15,647 \text{ pounds}$$

b) The safe tensile load  $L$  based on bearing stress is equal to the number of rivets  $n$  times the projected bearing area of the rivet  $A_b$  (diameter times thickness of plate) times the allowable bearing stress  $S_c$  or

$$L = n \times A_b \times S_c = 6 \times (0.625 \times 0.25) \times 20,000 = 18,750 \text{ pounds}$$

c) The safe load  $L$  based on the tensile stress is equal to the net cross-sectional area of the plate between rivet holes  $A_p$  times the allowable tensile stress  $S_t$  or

$$L = A_p \times S_t = 0.25 [12 - 6(0.625 + 0.0625)] \times 10,000 = 19,688 \text{ pounds}$$

The safe tensile load for the joint would be the least of the three loads just computed or 15,647 pounds, and the efficiency  $\eta$  would be equal to this load divided by the tensile strength of the section of plate under consideration if it were unperforated, or

$$\eta = \frac{15,647}{12 \times 0.25 \times 10,000} \times 100 = 52.2 \text{ percent}$$

*Example 2:* Under consideration is a 12-inch section of double-riveted butt-joint with main plates  $\frac{1}{2}$  inch thick and two cover plates each  $\frac{5}{16}$  inch thick. There are 3 rivets in the inner row and 2 on the outer and their diameters are  $\frac{7}{8}$  inch. Assume that the diameter of

the rivet holes is  $\frac{1}{16}$  inch larger than that of the rivets. The rivets are so placed that the main plates will not tear diagonally from one rivet row to the others nor will they tear or fail in shear out to their edges. The safe tensile load  $L$  and the efficiency  $\eta$  may be determined in the following way: Design stresses for 8500 psi for shear, 20,000 psi for bearing, and 10,000 psi for tension are arbitrarily assigned.

a) The safe tensile load  $L$  based on double shearing of the rivets is equal to the number of rivets  $n$  times the number of shearing planes per rivet times the cross-sectional area of one rivet  $A_r$  times the allowable shearing stress  $S_s$ , or

$$L = n \times 2 \times A_r \times S_s = 5 \times 2 \times \frac{\pi}{4} (0.875)^2 \times 8500 = 51,112 \text{ pounds}$$

b) The safe tensile load  $L$  based on bearing stress is equal to the number of rivets  $n$  times the projected bearing area of the rivet  $A_b$  (diameter times thickness of plate) times the allowable bearing stress  $S_c$  or  $L = n \times A_b \times S_c = 5 \times (0.875 \times 0.5) \times 20,000 = 43,750$  pounds.

(Cover plates are not considered since their combined thickness is  $\frac{1}{4}$  inch greater than the main plate thickness.)

c) The safe tensile load  $L$  based on the tensile stress is equal to the net cross-sectional area of the plate between the two rivets in the outer row  $A_p$  times the allowable tensile stress  $S_t$  or  $L = A_p \times S_t = 0.5[12 - 2(0.875 + 0.0625)] \times 10,000 = 50,625$  pounds.

In completing the analysis, the sum of the load that would cause tearing between rivets in the three-hole section plus the load carried by the two rivets in the two-hole section is also investigated. The sum is necessary because if the joint is to fail, it must fail at both sections simultaneously. The least safe load that can be carried by the two rivets of the two-hole section is based on the bearing stress (see the foregoing calculations).

1) The safe tensile load  $L$  based on the bearing strength of two rivets of the two-hole section is  $L = n \times A_b \times S_c = 2 \times (0.875 \times 0.5) \times 20,000 = 17,500$  pounds.

2) The safe tensile load  $L$  based on the tensile strength of the main plate between holes in the three-hole section is  $L \times A_p \times S_t = 0.5[12 - 3(0.875 + 0.0625)] \times 10,000 = 45,938$  pounds.

The total safe tensile load based on this combination is  $17,500 + 45,938 = 63,438$  pounds, which is greater than any of the other results obtained.

The safe tensile load for the joint would be the least of the loads just computed or 43,750 pounds and the efficiency  $\eta$  would be equal to this load divided by the tensile strength of the section of plate under consideration if it were unperforated or

$$\eta = \frac{43,750}{0.5 \times 12 \times 10,000} \times 100 = 72.9 \text{ percent}$$

**Formulas for Riveted Joint Design.**—A riveted joint may fail by shearing through the rivets (single or double shear), crushing the rivets, tearing the plate between the rivets, crushing the plate or by a combination of two or more of the foregoing causes. Rivets placed too close to the edge of the plate may tear or shear the plate out to the edge but this type of failure is avoided by placing the center of the rivet 1.5 times the rivet diameter away from the edge.

The efficiency of a riveted joint is equal to the strength of the joint divided by the strength of the unriveted plate, expressed as a percentage.

In the following formulas, let

$d$  = diameter of holes       $t$  = thickness of plate       $t_c$  = thickness of cover plates

$p$  = pitch of inner row of rivets       $P$  = pitch of outer row of rivets

$S_s$  = shear stress for rivets       $S_t$  = tensile stress for plates

$S_c$  = compressive or bearing stress for rivets or plates

In the joint examples that follow, dimensions are usually specified in inches and stresses in pounds per square inch. See page 1863 for a discussion of allowable stresses that may be used in calculating the strengths given by the formulas. The design stresses are usually set by codes, practices, or specifications.

#### Single-Riveted Lap-Joint

- (1) Resistance to shearing one rivet =  $\frac{\pi d^2}{4} S_s$
- (2) Resistance to tearing plate between rivets =  $(p - D)tS_t$
- (3) Resistance to crushing rivet or plate =  $dtS_c$

#### Double-Riveted Lap-Joint

- (1) Resistance to shearing two rivets =  $\frac{2\pi d^2}{4} S_s$
- (2) Resistance to tearing between two rivets =  $(p - D)tS_t$
- (3) Resistance to crushing in front of two rivets =  $2dtS_c$

#### Single-Riveted Lap-Joint with Inside Cover Plate

- (1) Resistance to tearing between outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to tearing between inner row of rivets, and shearing outer row of rivets =  $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$
- (3) Resistance to shearing three rivets =  $\frac{3\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of three rivets =  $3tdS_c$
- (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row =  $(P - 2D)tS_t + tdS_c$

#### Double-Riveted Lap-Joint with Inside Cover Plate

- (1) Resistance to tearing at outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to shearing four rivets =  $\frac{4\pi d^2}{4} S_s$
- (3) Resistance to tearing at inner row and shearing outer row of rivets =  $(P - 1\frac{1}{2}D)tS_t + \frac{\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of four rivets =  $4tdS_c$
- (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet =  $(P - 1\frac{1}{2}D)tS_t + tdS_c$

*Double-Riveted Butt-Joint*

- |   |  |
|---|--|
| (1) Resistance to tearing at outer row of rivets =  | $(P - D)tS_t$                          |
| (2) Resistance to shearing two rivets in double shear and one in single shear =                     | $\frac{5\pi d^2}{4} S_s$               |
| (3) Resistance to tearing at inner row of rivets and shearing one rivet of the outer row =          | $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$ |
| (4) Resistance to crushing in front of three rivets =   | $3tdS_c$                               |
| (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row = | $(P - 2D)tS_t + tdS_c$                 |

*Triple-Riveted Butt-Joint*

- |  |  |
|--|--|
| (1) Resistance to tearing at outer row of rivets =                               | $(P - D)tS_t$                          |
| (2) Resistance to shearing four rivets in double shear and one in single shear = | $\frac{9\pi d^2}{4} S_s$               |
| (3) Resistance to tearing at middle row of rivets and shearing one rivet =       | $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$ |
| (4) Resistance to crushing in front of four rivets and shearing one rivet =      | $4dtS_c + \frac{\pi d^2}{4} S_s$       |
| (5) Resistance to crushing in front of five rivets =                             | $4dtS_c + dt_cS_c$                     |

**American National Standard Rivets**

Standards for rivets published by the American National Standards Institute and the British Standards Institution are as follows:

**American National Standard Large Rivets.**—The types of rivets covered by this standard, ANSI/ASME B18.1.2-1972 (R2016), are shown on pages 1868, 1869, and 1870. It may be noted, however, that when specified, the swell neck included in this standard is applicable to all standard large rivets except the flat countersunk head and oval countersunk head types. Also shown are the hold-on (dolly bar) and rivet set impression dimensions (see page 1870). All standard large rivets have fillets under the head not exceeding a 0.062-inch radius. The length tolerances for these rivets are given as follows: through 6 inches in length,  $\frac{1}{2}$ - and  $\frac{5}{8}$ -inch diameters,  $\pm 0.03$  inch;  $\frac{3}{4}$ - and  $\frac{7}{8}$ -inch diameters,  $\pm 0.06$ -inch; and 1- through  $1\frac{3}{4}$ -inch diameters,  $\pm 0.09$  inch. For rivets over 6 inches in length,  $\frac{1}{2}$ - and  $\frac{5}{8}$ -inch diameters,  $\pm 0.06$  inch;  $\frac{3}{4}$ - and  $\frac{7}{8}$ -inch diameters,  $\pm 0.12$  inch; and 1- through  $1\frac{3}{4}$ -inch diameters,  $\pm 0.19$  inch. Steel and wrought iron rivet materials appear in ASTM Specifications A31, A131, A152, and A502.

**American National Standard Small Solid Rivets.**—The types of rivets covered by this standard, ANSI/ASME B18.1.1-1972 (R2016), are shown on pages 1871 through 1873. In addition, the standard gives the dimensions of 60-degree flat countersunk head rivets used to assemble ledger plates and guards for mower cutter bars, but these are not shown. As the heads of standard rivets are not machined or trimmed, the circumference may be somewhat irregular and edges may be rounded or flat. Rivets other than countersunk types are furnished with a definite fillet under the head, whose radius should not exceed 10 percent of the maximum shank diameter or 0.03 inch, whichever is the smaller. With regard to head dimensions, tolerances shown in the dimensional tables are applicable to rivets produced by the normal cold heading process. Unless otherwise specified, rivets should have plain sheared ends that should be at right angles within 2 degrees to the axis of the rivet and be reasonably flat. When so specified by the user, rivets may have the standard header points shown on page 1868. Rivets may be made of ASTM Specification A31, Grade A steel; or may adhere to SAE Recommended Practice, Mechanical and Chemical Requirements for Nonthreaded Fasteners—SAE J430, Grade 0. When specified, rivets may be made of other materials.

1 5/8	1.625	1.665	1.588	3.019	2.878	0.831	0.309	3.656
1 3/4	1.750	1.790	1.713	3.262	3.121	0.901	0.332	3.938

<sup>a</sup> All dimensions are given in inches. Basic dimension as manufactured. For tolerances see table footnote on page 1866. The following formulas give basic dimensions for manufactured shapes: *Flat Countersunk Head*,  $A = 1.810D$ ;  $H = 1.192(\text{Max } A - D)/2$ ; included angle  $Q$  of head = 78 degrees. *Oval Countersunk Head*,  $A = 1.810D$ ;  $H = 1.192(\text{Max } A - D)/2$ ; included angle of head = 78 degrees. Length  $L$  is measured parallel to the rivet axis, from the extreme end to the intersection of the head top surface with the head diameter for countersunk head-type rivets.

<sup>b</sup> Sharpedged head.

<sup>c</sup> Rounded or flat edged irregularly shaped head (heads are not machined or trimmed).

ANSI/ASME B18.1.3M-1983 (R2016), Metric Small Solid Rivets, provides data for small, solid rivets with flat, round, and flat countersunk heads in metric dimensions. The main series of rivets has body diameters, in millimeters, of 1.6, 2, 2.5, 3, 4, 5, 6, 8, 10, and 12. A secondary series (nonpreferred) consists of sizes, 1, 1.2, 1.4, 3.5, 7, 9, and 11 millimeters.

### British Standard Rivets

**British Standard Rivets for General Engineering.**—Dimensions in metric units of rivets for general engineering purposes are given in this British Standard, BS 4620:1970, which is based on ISO Recommendation ISO/R 1051. The snap head rivet dimensions of 14 millimeters and above are taken from the German Standard DIN 124, Round Head Rivets for Steel Structures. The shapes of heads have been restricted to those in common use in the United Kingdom. Table 3b shows the rivet dimensions. Table 3a shows a tentative range of preferred nominal lengths as given in an appendix to the Standard. It is stated that these lengths will be reviewed in the light of usage. The rivets are made by cold or hot forging methods from mild steel, copper, brass, pure aluminum, aluminum alloys, or other suitable metal. It is stated that the radius under the head of a rivet shall run smoothly into the face of the head and shank without step or discontinuity.

<sup>a</sup> Tolerance for diameter of body is plus and minus from nominal and for  $\frac{1}{2}$ -in. size equals +0.020, -0.022; for sizes  $\frac{5}{8}$  to 1-in., incl., equals +0.030, -0.025; for sizes  $1\frac{1}{8}$  and  $1\frac{1}{4}$ -in. equals +0.035; -0.027; for sizes  $1\frac{3}{8}$  and  $1\frac{1}{2}$ -in. equals +0.040, -0.030; for sizes  $1\frac{5}{8}$  and  $1\frac{3}{4}$ -in. equals +0.040, -0.037.

<sup>b</sup> Note 1. Basic dimensions of head as manufactured. All dimensions are given in inches. The following formulas give the basic dimensions for manufactured shapes: *Button Head*,  $A = 1.750D$ ;  $H = 0.750D$ ;  $G = 0.885D$ . *High Button Head*,  $A = 1.500D + 0.031$ ;  $H = 0.750D + 0.125$ ;  $F = 0.750D + 0.281$ ;  $G = 0.750D - 0.281$ . *Cone Head*,  $A = 1.750D$ ;  $B = 0.938D$ ;  $H = 0.875D$ . *Pan Head*,  $A = 1.600D$ ;  $B = 1.000D$ ;  $H = 0.700D$ . Length  $L$  is measured parallel to the rivet axis, from the extreme end to the bearing surface plane for flat bearing surface head type rivets, or to the intersection of the head top surface with the head diameter for countersunk head-type rivets.

<sup>c</sup> Note 2. Dimensions of manufactured head after driving and also of driven head.

<sup>d</sup> Note 3. Slight flat permissible within the specified head-height tolerance.

1 3/4	1.750	1.790	1.713	1.813	1.773	0.875

<sup>a</sup> The swell neck is applicable to all standard forms of large rivets except the flat countersunk and oval countersunk head types.

<sup>b</sup> All dimensions are given in inches. The following formulas give basic dimensions for manufactured shapes: *Swell Neck*,  $E = D + 0.063$ ;  $K = 0.500D$ . Length  $L$  is measured parallel to the rivet axis, from the extreme end to the bearing surface plane for flat bearing surface head-type rivets. Basic dimension as manufactured. For tolerances see table footnote on page 1866.

<sup>a</sup> All dimensions in inches. Length tolerance of all rivets is plus or minus 0.016 inch. Approximate proportions of rivets: flat head,  $A = 2.00 \times D$ ,  $H = 0.33 D$ ; flat countersunk head,  $A = 1.850 \times D$ ,  $H = 0.425 \times D$ ; button head,  $A = 1.750 \times D$ ,  $H = 0.750 \times D$ ,  $R = 0.885 \times D$ ; pan head,  $A = 1.720 \times D$ ,  $H = 0.570 \times D$ ,  $R1 = 0.314 \times D$ ,  $R2 = 0.850 \times D$ ,  $R3 = 3.430 \times D$ . Note: ANSI Small Solid Rivets may be obtained with or without points. Point proportions are given in the diagram in Table 2a.

<sup>b</sup> Given for reference purposes only. Variations in this dimension are controlled by the head and shank diameters and the included angle of the head.

<sup>c</sup> Tabulated maximum values calculated on basic diameter of rivet and  $92^\circ$  included angle extended to a sharp edge.

<sup>d</sup> Minimum of rounded or flat-edged irregularly shaped head. Rivet heads are not machined or trimmed and the circumference may be irregular and edges rounded or flat.

In this Standard, **Table 3a** and **Table 3b**, the following definitions apply: 1) *Nominal diameter*: The diameter of the shank; 2) *Nominal length of rivets other than countersunk or raised countersunk rivets*: The length from the underside of the head to the end of the shank; 3) *Nominal length of countersunk and raised countersunk rivets*: The distance from the periphery of the head to the end of the rivet measured parallel to the axis of the rivet; and 4) *Manufactured head*: The head on the rivet as received from the manufacturer.

All dimensions are in millimeters.

Note: Sizes and lengths shown in parenthesis are nonpreferred and should be avoided if possible.

**British Standard Small Rivets for General Purposes.**—Dimensions of small rivets for general purposes are given in British Standard 641:1951 and are shown in **Table 4** on page 1876. In addition, the standard lists the standard lengths of these rivets, gives the dimensions of washers to be used with countersunk head rivets (140°), indicates that the rivets may be made from mild steel, copper, brass, and a range of aluminum alloys and pure aluminum specified in BS 1473, and gives the dimensions of Coopers' flat head rivets 1/2 inch in diameter and below, in an appendix. In all types of rivets, except those with countersunk heads, there is a small radius or chamfer at the junction of the head and the shank.

**British Standard Dimensions of Rivets (1/2 to 1 3/4 inch diameter).**—The dimensions of rivets covered in BS 275:1927 (obsolescent) are given on page 1877 and do not apply to boiler rivets. With regard to this standard the terms "nominal diameter" and "standard diameter" are synonymous. The term "tolerance" refers to the variation from the nominal diameter of the rivet and not to the difference between the diameter under the head and the diameter near the point.

<sup>a</sup> All dimensions in inches unless specified otherwise.

<sup>b</sup> Gage numbers are British Standard Wire Gage (S.W.G.) numbers.

**Head Dimensions and Diameters of British Standard Rivets**  
*BS 275:1927 (obsolescent)*

<sup>a</sup> All dimensions that are tabulated are given in inches. This standard does not apply to Boiler Rivets

<sup>b</sup> Tolerances of the rivet diameter are as follows: at position X, plus 1/32 inch, minus zero; at position Y, plus zero, minus 1/64 inch; at position Z, minus 1/64 inch but in no case shall the difference between the diameters at positions X and Y exceed 1/32 inch, nor shall the diameter of the shank between positions X and Y be less than the minimum diameter specified at position Y.

<sup>c</sup> The location of positions Y and Z are as follows: Position Y is located 1/2 D from the end of the rivet for rivet lengths 5 diameters long and under. For longer rivets, position Y is located 4 1/2 D from the head of the rivet. Position Z (found only on rivets longer than 5D) is located 1/2 D from the end of the rivet.

<sup>d</sup> At the recommendation of the British Standards Institution, these sizes are to be dispensed with wherever possible.

<sup>a</sup> Lengths tabulated are intended for use with standard clevises, without spacers. When other lengths are required, it is recommended that they be limited wherever possible to nominal lengths in 0.06-inch increments.

All dimensions are in inches. For sizes, greater than 1-inch, refer to ANSI/ASME B18.8.1-2014.

**Dowel-Pins.**—Dowel-pins are used either to retain parts in a fixed position or to preserve alignment. Under normal conditions a properly fitted dowel-pin is subjected solely to shearing strain, and this strain occurs only at the junction of the surfaces of the two parts which are being held by the dowel-pin. It is seldom necessary to use more than two dowel-pins for holding two pieces together and frequently one is sufficient. For parts that have to be taken apart frequently, and where driving out of the dowel-pins would tend to wear the holes, and also for very accurately constructed tools and gages that have to be taken apart, or that require to be kept in absolute alignment, the taper dowel-pin is preferable. The taper dowel-pin is most commonly used for average machine work, but the straight type is given the preference on tool and gage work, except where extreme accuracy is required, or where the tool or gage is to be subjected to rough handling.

The size of the dowel-pin is governed by its application. For locating nests, gage plates, etc., pins from  $\frac{1}{8}$  to  $\frac{3}{16}$  inch (3.2–4.8 mm) in diameter are satisfactory. For locating dies, the diameter of the dowel-pin should never be less than  $\frac{1}{4}$  inch (6.35 mm); the general rule is to use dowel-pins of the same size as the screws used in fastening the work. The length of the dowel-pin should be about  $1\frac{1}{2}$  to 2 times its diameter in each plate or part to be doweled.

When hardened cylindrical dowel-pins are inserted in soft parts, ream the hole about 0.001 inch (0.025 mm) smaller than the dowel-pin. If the doweled parts are hardened, grind (or lap) the hole 0.0002 to 0.0003 inch (0.005–0.0076 mm) under size. The hole should be ground or lapped straight, that is, without taper or “bell-mouth.”

*Assembly with Dowel Pins* starting on page 1885.

**British Standard for Metric Series Dowel Pins.**—Steel parallel dowel pins specified in British Standard 1804:Part 2:1968 are divided into three grades which provide different degrees of pin accuracy.

*Grade 1* is a precision ground pin made from En 32A or En 32B low carbon steel (BS 970) or from high carbon steel to BS 1407 or BS 1423. Pins below 4 mm diameter are unhardened. Those of 4 mm diameter and above are hardened to a minimum of 750 HV 30 in accordance with BS 427, but if they are made from steels to BS 1407 or BS 1423 then the hardness shall be within the range 600 to 700 HV 30, in accordance with BS 427. The values of other hardness scales may be used in accordance with BS 860.

*Grade 2* is a ground pin made from any of the steels used for Grade 1. The pins are normally supplied unhardened, unless a different condition is agreed on between the purchaser and supplier.

*Grade 3* pins are made from En 1A free cutting steel (BS 970) and are supplied with a machined, bright rolled or drawn finish. They are normally supplied unhardened unless a different condition is agreed on between the purchaser and supplier.

Pins of any grade may be made from different steels in accordance with BS 970, by mutual agreement between the purchaser and manufacturer. If steels other than those in the standard range are used, the hardness of the pins shall also be decided on by mutual agreement between purchaser and supplier. As shown in the illustration at the head of the accompanying table, one end of each pin is chamfered to provide a lead. The other end may be similarly chamfered, or domed.

If a dowel pin is driven into a blind hole where no provision is made for releasing air, the worker assembling the pin may be endangered, and damage may be caused to the associated component, or stresses may be set up. The appendix of the Standard describes one method of overcoming this problem by providing a small flat surface along the length of a pin to permit the release of air.

For purposes of marking, the Standard states that each package or lot of dowel pins shall bear the manufacturer's name or trademark, the BS number, and the grade of pin.

24	30	+17	+8	0	-21	0	-130

<sup>a</sup> The limits of tolerance for grades 1 and 2 dowel pins have been chosen to provide satisfactory assembly when used in standard reamed holes (H7 and H8 tolerance zones). If the assembly is not satisfactory, refer to BS 1916: Part 1, Limits and Fits for Engineering, and select a different class of fit.

<sup>b</sup> This tolerance is larger than that given in BS 1916, and has been included because the use of a closer tolerance would involve precision grinding by the manufacturer, which is uneconomic for a grade 2 dowel pin.

The tolerance limits on the overall length of all grades of dowel pin up to and including 50 mm long are +0.5, -0.0 mm, and for pins over 50 mm long are +0.8, -0.0 mm. The Standard specifies that the roughness of the cylindrical surface of grades 1 and 2 dowel pins, when assessed in accordance with BS 1134, shall not be greater than 0.4 μm CLA (16 CLA).

**American National Standard Hardened Ground Machine Dowel Pins.**—Hardened ground machine dowel pins are furnished in two diameter series: Standard Series having basic diameters 0.0002 inch over the nominal diameter, intended for initial installations; and Oversize Series having basic diameters 0.001 inch over the nominal diameter, intended for replacement use.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which these pins are normally available are given in [Table 1](#). Other sizes and lengths are produced as required by the purchaser.

*Effective Length:* The effective length,  $L_e$ , must not be less than 75 percent of the overall length of the pin.

*Shear Strength:* Single shear strength values are listed in [Table 1](#). Prior versions of ANSI/ASME B18.8.2-2000 (R2010) had listed double shear load minimum values and had specified a minimum single shear strength of 130,000 psi. See ANSI/ASME B18.8.2-2000 (R2010), Appendix B for a description of the double shear test.

*Designation:* These pins are designated by the following data in the sequence shown: Product name (noun first), including pin series, nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

*Examples:* Pins, Hardened Ground Machine Dowel.—Standard Series,  $\frac{3}{8} \times 1\frac{1}{2}$ , Steel, Phosphate Coated.

Pins, Hardened Ground Machine Dowel.—Oversize Series,  $0.625 \times 2.500$ , Steel

*Installation Precaution:* Pins should not be installed by striking or hammering and when installing with a press, a shield should be used and safety glasses worn.

**American National Standard Hardened Ground Production Dowel Pins.**—Hardened ground production dowel pins have basic diameters that are 0.0002 inch over the nominal pin diameter.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which these pins are available are given in [Table 2](#). Other sizes and lengths are produced as required by the purchaser.

*Shear Strength:* Single shear strength values are listed in [Table 2](#). Prior versions of ANSI/ASME B18.8.2-2000 (R2010) had listed double shear load minimum values and had specified a minimum single shear strength of 102,000 psi. See ANSI/ASME B18.8.2-2000 (R2010), Appendix B for a description of the double shear test.

*Ductility:* These standard pins are sufficiently ductile to withstand being pressed into holes 0.0005 inch smaller than the nominal pin diameter in hardened steel without cracking or shattering.

*Designation:* These pins are designated by the following data in the sequence shown: Product name (noun first), nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

*Examples:* Pins, Hardened Ground Production Dowel,  $\frac{1}{8} \times \frac{3}{4}$ , Steel, Phosphate Coated

Pins, Hardened Ground Production Dowel,  $0.375 \times 1.500$ , Steel

<sup>a</sup> Where specifying nominal size as basic diameter, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/16-inch steps up to 3/8 inch, in 1/8-inch steps from 3/8 inch to 1 inch, in 1/4-inch steps from 1 inch to 2 1/2 inches, and in 1/2-inch steps above 2 1/2 inches. Tolerance on length is ±0.010 inch.

<sup>c</sup> These hole sizes have been commonly used for press fitting Standard Series machine dowel pins into materials such as mild steels and cast iron. In soft materials such as aluminum or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

<sup>d</sup> Nonpreferred sizes, not recommended for use in new designs.

All dimensions are in inches.

<sup>a</sup> Where specifying nominal pin size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/16-inch steps up to 1 inch, in 1/8-inch steps from 1 inch to 2 inches; and then are 2 1/4, 2 1/2, and 3 inches.

<sup>c</sup> These hole sizes have been commonly used for press fitting production dowel pins into materials such as mild steels and cast iron. In soft materials such as aluminum or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

All dimensions are in inches.

**American National Standard Unhardened Ground Dowel Pins.**—Unhardened ground dowel pins are normally produced by grinding the outside diameter of commercial wire or rod material to size. Consequently, the maximum diameters of the pins, as specified in Table 3, are below the minimum commercial stock sizes by graduated amounts from 0.0005 inch on the 1/16-inch nominal pin size to 0.0028 inch on the 1-inch nominal pin size.

**Preferred Lengths and Sizes:** The preferred lengths and sizes in which unhardened ground pins are normally available are given in Table 3. Other sizes and lengths are produced as required by the purchaser.

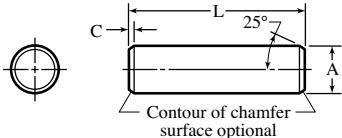

**Shear Strength:** These pins must have a single shear strength of 64,000 psi minimum for pins made from steel and 40,000 psi minimum for pins made from brass and must be capable of withstanding the minimum double shear loads given in Table 3 when tested in accordance with the procedure outlined in ANSI/ASME B18.8.2-2000 (R2010), Appendix B.

**Designation:** These pins are designated by the following data in the order shown: Product name (noun first), nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

**Examples:** Pins, Unhardened Ground Dowel, 1/8 × 3/4, Steel

Pins, Unhardened Ground Dowel, 0.250 × 2.500, Steel, Zinc Plated

<sup>a</sup> Where specifying pin size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/16-inch increments from 1/4 to 1 inch, in 1/8-inch increments from 1 inch to 2 inches, and in 1/4-inch increments from 2 to 2 1/2 inches, and in 1/2-inch increments from 2 1/2 to 4 inches.

<sup>c</sup> These hole sizes have been found to be satisfactory for press fitting pins into mild steel and cast and malleable irons. In soft materials such as aluminum alloys or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

<sup>d</sup> Nonpreferred size, not recommended for use in new designs.

All dimensions are in inches.

**Assembly with Dowel Pins.**—Hardened and ground dowel pins are made to a high degree of accuracy. Dowel pins are used to position and align machine components, provide a positive stop, add structural rigidity to an assembly, or to create a part nest.

When components are assembled with dowel pins, the dowel is a very close fit with its mating part. Machines or tools made with dowel pin construction can be disassembled for maintenance, engineering changes or repair, and reassembled, maintaining the original positional accuracy. Holes for dowel pins are carefully produced to obtain either a close sliding fit or a press fit for the dowel. When using dowels with fasteners, proper machine shop practice dictates that the sizes should be the same whenever possible. For example, if  $\frac{3}{8}$ -inch socket head cap screws are used,  $\frac{3}{8}$ -inch diameter dowels should also be used.

Fig. 1.

Fig. 1 is a typical example of an assembly using socket head cap screws and dowels. The fasteners and dowels are positioned as far apart as possible for rigidity and locational stability. Engineering drawings often show dowel locations as a circle with a partly filled-in cross. The dowel holes on this assembly are relieved in the top plate and have a smaller knockout hole in the bottom plate. The hole for the socket head cap screw is counterbored deep enough so that the screw is recessed 0.03 inch below the surface of the plate. Making dimension "A" different from dimension "B" prevents the plates from being assembled backwards.

When dowels are used for positioning:

- Position dowel pins as far apart as possible.
- Length of engagement for the dowel should be twice the dowel diameter in each component.
- Avoid pressing a dowel into a blind hole. If options are limited, pull dowels have a threaded hole that can be used to remove the dowel from a blind hole.
- Avoid pressing a dowel into a hardened part.
- Provide a knock out hole.
- Relieve deep holes.
- Dowels should be a press fit in one component and a slip fit in the other.

Fig. 2 shows a cross section of two plates with four different assembly possibilities for dowels.

Fig. 2. Four Options for Dowel Pin Installation

*Option A:* In the lower plate the dowel is a light press fit which means that there is 0.0002 to 0.0005 inch interference between the dowel and the hole. The hole in the bottom part of the lower plate is made 0.03 inch smaller than the dowel hole to prevent the dowel from falling out while providing a knockout hole for a punch. The top plate also has a stepped hole that is 0.0002 to 0.0005 inch larger than the dowel for a slip fit, and a larger diameter for a relief. The relief is 0.03 inch larger than the dowel. It is a good practice to relieve portions of the hole that are not used for locating. Dowels should be installed with two times their diameter as a bearing surface. In other words, a  $\frac{3}{8}$ -inch diameter dowel should contact the hole for  $\frac{3}{4}$  of its length in each component. A  $\frac{1}{4}$ -inch dowel should contact each plate for  $\frac{1}{2}$  inch of the dowel's length in each component.

*Option B:* In this example the design does not permit the dowel hole to go through the lower plate. Since pressing dowels into blind (dead end) holes is not recommended, the dowel is a slip fit in the lower plate and a press fit in the top plate. Again, the top plate is relieved allowing the dowel the proper amount of effective engagement.

*Option C:* This example is the opposite of Option B. A knockout hole which is 0.03 inch smaller than the dowel is provided in the lower plate. The press fit is in the lower plate, the slip fit is in the top plate because it is very difficult to remove a dowel that is pressed in a blind hole.

*Option D:* In the event that through holes are not permitted in either plate, both sides are made to a slip fit for the dowel.

**American National Standard Straight Pins.**—The diameter of both chamfered and square end straight pins is that of the commercial wire or rod from which the pins are made. The tolerances shown in Table 4 are applicable to carbon steel and some deviations in the diameter limits may be necessary for pins made from other materials.

**Table 4. American National Standard Chamfered and Square End Straight Pins**

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

<sup>b</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

All dimensions are in inches.

**Length Increments:** Lengths are as specified by the purchaser; however, it is recommended that nominal pin lengths be limited to increments of not less than 0.062 inch.

**Material:** Straight pins are normally made from cold drawn steel wire or rod having a maximum carbon content of 0.28 percent. Where required, pins may also be made from corrosion resistant steel, brass, or other metals.

**Designation:** Straight pins are designated by the following data, in the sequence shown: Product name (noun first), nominal size (fraction or decimal equivalent), material, and protective finish, if required.

**Examples:** Pin, Chamfered Straight, 1/8 × 1.500, Steel

Pin, Square End Straight, 0.250 × 2.250, Steel, Zinc Plated

**American National Standard Taper Pins.**—Taper pins have a uniform taper over the pin length with both ends crowned. Most sizes are supplied in commercial and precision classes, the latter having generally tighter tolerances and being more closely controlled in manufacture.

**Diameters:** The major diameter of both commercial and precision classes of pins is the diameter of the large end and is the basis for pin size. The diameter at the small end is computed by multiplying the nominal length of the pin by the factor 0.02083 and subtracting the result from the basic pin diameter. See also [Table 5](#).

**Taper:** The taper on commercial class pins is 0.250 ± 0.006 inch per foot and on the precision class pins is 0.250 ± 0.004 inch per foot of length.

**Materials:** Unless otherwise specified, taper pins are made from SAE 1211 steel or cold drawn SAE 1212 or 1213 steel or equivalents, and no mechanical property requirements apply.

**Hole Sizes:** Under most circumstances, holes for taper pins require taper reaming. Sizes and lengths of taper pins for which standard reamers are available are given in [Table 6](#). Drilling specifications for taper pins are given below.

**Designation:** Taper pins are designated by the following data in the sequence shown: Product name (noun first), class, size number (or decimal equivalent), length (fraction or three-place decimal equivalent), material, and protective finish, if required.

**Examples:** Pin, Taper (Commercial Class) No.  $0 \times \frac{3}{4}$ , Steel

Pin, Taper (Precision Class)  $0.219 \times 1.750$ , Steel, Zinc Plated

**Drilling Specifications for Taper Pins.**—When helically fluted taper pin reamers are used, the diameter of the through hole drilled prior to reaming is equal to the diameter at the small end of the taper pin. (See Table 5.) However, when straight fluted taper reamers are to be used, it may be necessary, for long pins, to step drill the hole before reaming, the number and sizes of the drills to be used depending on the depth of the hole (pin length).

To determine the number and sizes of step drills required: Find the length of pin to be used at the top of the chart on page 1889 and follow this length down to the intersection with that heavy line which represents the size of taper pin (see taper pin numbers at the right-hand end of each heavy line). If the length of pin falls between the first and second dots, counting from the left, only one drill is required. Its size is indicated by following the nearest horizontal line from the point of intersection (of the pin length) on the heavy line over to the drill diameter values at the left. If the intersection of pin length comes between the second and third dots, then two drills are required. The size of the smaller drill then corresponds to the intersection of the pin length and the heavy line and the larger is the corresponding drill diameter for the intersection of one-half this length with the heavy line. Should the pin length fall between the third and fourth dots, three drills are required. The smallest drill will have a diameter corresponding to the intersection of the total pin length with the heavy line, the next in size will have a diameter corresponding to the intersection of two-thirds of this length with the heavy line, and the largest will have a diameter corresponding to the intersection of one-third of this length with the heavy line. Where the intersection falls between two drill sizes, use the smaller.

Chart to Facilitate Selection of Number and Sizes of Drills for Step-Drilling Prior to Taper Reaming

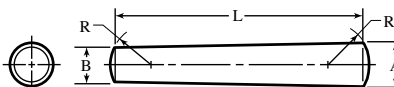

*Examples:* For a No. 10 taper pin 6-inches long, three drills would be used, of the sizes and for the depths shown in the accompanying diagram.

For a No. 10 taper pin 3-inches long, two drills would be used because the 3-inch length falls between the second and third dots. The first or through drill will be 0.6406 inch and the second drill, 0.6719 inch for a depth of  $1\frac{1}{2}$  inches.

<sup>a</sup> When specifying nominal pin size in decimals, zeros preceding the decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in  $1/8$ -inch steps up to 1 inch and in  $1/4$ -inch steps above 1 inch.

<sup>c</sup> Standard reamers are available for pin lengths in this column.

All dimensions are in inches.

For nominal diameters, B, see Table 5.

**American National Standard Grooved Pins.**—These pins have three equally spaced longitudinal grooves and an expanded diameter over the crests of the ridges formed by the material displaced when the grooves are produced. The grooves are aligned with the axes of the pins. There are seven types of grooved pins as shown in the illustration on page 1892.

*Standard Sizes and Lengths:* The standard sizes and lengths in which grooved pins are normally available are given in Table 7.

*Materials:* Grooved pins are normally made from cold drawn low carbon steel wire or rod. Where additional performance is required, carbon steel pins may be supplied surface hardened and heat treated to a hardness consistent with the performance requirements. Pins may also be made from alloy steel, corrosion resistant steel, brass, Monel and other nonferrous metals having chemical properties as agreed upon between manufacturer and purchaser.

*Performance Requirements:* Grooved pins are required to withstand the minimum double shear loads given in Table 7 for the respective materials shown, when tested in accordance with the Double Shear Testing of Pins as set forth in ANSI/ASME B18.8.2-2000 (R2010), Appendix B.

*Hole Sizes:* To obtain maximum product retention under average conditions, it is recommended that holes for the installation of grooved pins be held as close as possible to the limits shown in Table 7. The minimum limits correspond to the drill size, which is the same as the basic pin diameter. The maximum limits are generally suitable for length-diameter ratios of not less than 4 to 1 nor greater than 10 to 1. For smaller length-to-diameter ratios, the hole should be held closer to the minimum limits where retention is critical. Conversely for larger ratios where retention requirements are less important, it may be desirable to increase the hole diameters beyond the maximum limits shown.

*Designation:* Grooved pins are designated by the following data in the sequence shown: Product name (noun first) including type designation, nominal size (number, fraction or decimal equivalent), length (fraction or decimal equivalent), material, including specification or heat treatment where necessary, protective finish, if required.

*Examples:* Pin, Type A Grooved,  $\frac{3}{32} \times \frac{3}{4}$ , Steel, Zinc Plated

Pin, Type F Grooved,  $0.250 \times 1.500$ , Corrosion Resistant Steel

**American National Standard Grooved T-Head Cotter Pins and Round Head Grooved Drive Studs.**—The cotter pins have a T-head and the studs a round head. Both pins and studs have three equally spaced longitudinal grooves and an expanded diameter over the crests of the raised ridges formed by the material displaced when the grooves are formed.

*Standard Sizes and Lengths:* The standard sizes and range of standard lengths are given in Table 8 and Table 9.

*Material:* Unless otherwise specified these pins are made from low carbon steel. Where so indicated by the purchaser they may be made from corrosion resistant steel, brass or other nonferrous alloys.

*Hole Sizes:* To obtain optimum product retention under average conditions, it is recommended that holes for the installation of grooved T-head cotter pins and grooved drive studs be held as close as possible to the limits tabulated. The minimum limits given correspond to the drill size, which is equivalent to the basic shank diameter. The maximum limits shown are generally suitable for length-diameter ratios of not less than 4 to 1 and not greater than 10 to 1. For smaller length-to-diameter ratios, the holes should be held closer to minimum limits where retention is critical. Conversely, for larger length-to-diameter ratios or where retention requirements are not essential, it may be desirable to increase the hole diameter beyond the maximum limits shown.

*Designation:* Grooved T-head cotter pins and round head grooved drive studs are designated by the following data, in the order shown: Product name (noun first), nominal size (number, fraction or decimal equivalent), length (fraction or decimal equivalent), material including specification or heat treatment where necessary, and protective finish, if required.

*Examples:* Pin, Grooved T-Head Cotter,  $\frac{1}{4} \times 1\frac{1}{4}$ , Steel, Zinc Plated

Drive Stud, Round Head Grooved, No.  $10 \times \frac{1}{2}$ , Corrosion Resistant Steel

Types of American National Standard Grooved Pins, ANSI/ASME B18.8.2-2000 (R2010) (For notes see bottom of Table 7.)

**Table 7. American National Standard Grooved Pins ANSI/ASME B18.8.2-2000 (R2010)**

Nominal Size or Basic Pin Diameter	Pin Diameter, <sup>a</sup> A		Pilot Length, <sup>c</sup> C	Chamfer Length, <sup>b</sup> D	Crown Height, <sup>b</sup> E		Crown Radius, <sup>b</sup> F		Neck Width, <sup>b</sup> G		Shoulder Length, <sup>b</sup> H		Neck Radius, <sup>b</sup> J	Neck Diameter, <sup>b</sup> K		Range of Standard Lengths <sup>e</sup>

<sup>a</sup> For expanded diameters, *B*, see ANSI/ASME B18.8.2-2000 (R2010).

<sup>b</sup> Pins in 1/32- and 3/64-inch sizes of any length and all sizes of 1/4-inch nominal length or shorter are not crowned or chamfered.

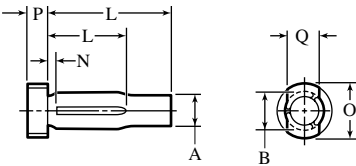

<sup>c</sup> Standard lengths increase in 1/8-inch steps from 1/8 to 1 inch, and in 1/4-inch steps above 1 inch. Standard lengths for the 1/32-, 3/64-, 1/16-, and 5/64-inch sizes and the 1/4-inch length for the 3/32-, 7/64-, and 1/8-inch sizes do not apply to Type G grooved pins.

<sup>d</sup> Non-stock items, not recommended for new designs.

Pin Material	Nominal Pin Size															
	1/32	3/64	1/16	5/64	3/32	7/64	1/8	5/32	3/16	7/32	1/4	5/16	3/8	7/16	1/2

<sup>a</sup> When specifying nominal size in decimals, zeros preceding decimal point and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/8-inch steps from 3/4 to 1 1/4 inch and in 1/2-inch steps above 1 1/4 inches. For groove length, *M*, dimensions see ANSI/ASME B18.8.2-2000 (R2010).

All dimensions are in inches.

For expanded diameter, *B*, dimensions, see ANSI/ASME B18.8.2-2000 (R2010).

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

<sup>b</sup> Length increments are 1/16 inch from 1/8 to 1 inch; 1/8 from 1 inch to 2 inches; and 1/4 inch from 2 inches to 6 inches.

All dimensions are in inches.

**American National Standard Spring Pins.**—These pins are made in two types: one type has a slot throughout its length; the other is shaped into a coil.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which these pins are normally available are given in [Table 10](#) and [Table 11](#).

*Materials:* Spring pins are normally made from SAE 1070-1095 carbon steel, SAE 6150H alloy steel, SAE types 51410 through 51420, 30302 and 30304 corrosion resistant steels, and beryllium copper alloy, heat treated or cold-worked to attain the hardness and performance characteristics set forth in ANSI/ASME B18.8.2-2000 (R2010).

*Designation:* Spring pins are designated by the following data in the sequence shown:

*Examples:* Pin, Coiled Spring, 1/4 × 1 1/4, Standard Duty, Steel, Zinc Plated

Pin, Slotted Spring, 1/2 × 3, Steel, Phosphate Coated

**Table 11. American National Standard Coiled-Type Spring Pins ANSI/ASME B18.8.2-2000 (R2010)**

<sup>a</sup> Sizes 1/32 inch through 0.052 inch are not available in SAE 1070-1095 carbon steel.

<sup>b</sup> Sizes 3/8 inch and larger are produced from SAE 6150H alloy steel, not SAE 1070-1095 carbon steel. Practical lengths, *L*, for sizes 1/32 through 0.052 inch are 1/8 through 3/8 inch and for the 3/64-inch size, 1/4 through 1 1/4 inches. For lengths of other sizes see [Table 10](#).

All dimensions are in inches.

## RETAINING RINGS

**Retaining Rings.**—The purpose of a retaining ring is to act as an artificial shoulder that will retain an object in a housing (internal ring), as shown in Fig. 1, or on a shaft (external ring). Two types of retaining ring are common, the stamped ring and the spiral-wound ring. The stamped-type of retaining ring, or snap ring, is stamped from tempered sheet metal and has a nonuniform cross section. The typical spiral-wound retaining ring has a uniform cross section and is made up of two or more turns of coiled, spring-tempered steel, although one-turn spiral-wound rings are common. Spiral-wound retaining rings provide a continuous gapless shoulder to a housing or shaft. Most stamped rings can only be installed at or near the end of a shaft or housing. The spiral-wound design generally requires installation from the end of a shaft or housing. Both types, stamped and spiral, are usually installed into grooves on the shaft or housing.

Fig. 1. Typical Retaining Ring Installation Showing Maximum Total Radius or Chamfer (Courtesy Spirolox Retaining Rings)

In the section that follows, Table 1 through Table 6 give dimensions and data on general-purpose tapered and reduced-cross-section metric retaining rings (stamped-type) covered by ANSI/ASME B27.7-1977 (R2017). Table 1 and Table 4 cover Type 3AM1 tapered external retaining rings, Table 2 and Table 5 cover Type 3BM1 tapered internal rings, and Table 3 and Table 6 cover Type 3CM1 reduced-cross-section external rings. Table 7 through Table 10 cover inch sizes of internal and external spiral retaining rings corresponding to MIL-R-27426 Types A (external) and B (internal), Class 1 (medium duty) and Class 2 (heavy duty). Table 11 through Table 17 cover stamped retaining rings in inch sizes.

All dimensions are in millimeters. Sizes -4, -5, and -6 are available in beryllium copper only.

These rings are designated by series symbol and shaft diameter, thus: for a 4 mm diameter shaft, 3AM1-4; for a 20 mm diameter shaft, 3AM1-20; etc.

**Ring Free Diameter Tolerances:** For ring sizes -4 through -6, +0.05, -0.10 mm; for sizes -7 through -12, +0.05, -0.15 mm; for sizes -13 through -26, +0.15, -0.25 mm; for sizes -27 through -38, +0.25, -0.40 mm; for sizes -40 through -50, +0.35, -0.50 mm; for sizes -52 through -62, +0.35, -0.65 mm; and for sizes -65 through -100, +0.50, -0.75 mm.

**Groove Diameter Tolerances:** For ring sizes -4 through -6, -0.08 mm; for sizes -7 through -10, -0.10 mm; for sizes -11 through -15, -0.12 mm; for sizes -16 through -26, -0.15 mm; for sizes -27 through -36, -0.20 mm; for sizes -38 through -55, -0.30 mm; and for sizes -57 through -100, -0.40 mm.

**Groove Diameter F.I.M. (full indicator movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes -4 through -6, 0.03 mm; for ring sizes -7 through -12, 0.05 mm; for sizes -13 through -28, 0.10 mm; for sizes -30 through -55, 0.15 mm; and for sizes -57 through -100, 0.20 mm.

**Groove Width Tolerances:** For ring size -4, +0.05 mm; for sizes -5 and -6, +0.10 mm, for sizes -7 through -38, +0.15 mm; and for sizes -40 through -100, +0.20 mm.

**Groove Maximum Bottom Radii, R:** For ring sizes -4 through -6, none; for sizes -7 through -18, 0.1 mm; for sizes -19 through -30, 0.2 mm; for sizes -32 through -50, 0.3 mm; and for sizes -52 through -100, 0.4 mm. For manufacturing details not shown, including materials, see ANSI/ASME B27.7-1977 (R2017).

All dimensions are in millimeters.

These rings are designated by series symbol and shaft diameter, thus: for a 9 mm diameter shaft, 3BM1-9; for a 22 mm diameter shaft, 3BM1-22; etc.

**Ring Free Diameter Tolerances:** For ring sizes -8 through -20, +0.25, -0.13 mm; for sizes -21 through -26, +0.40, -0.25 mm; for sizes -27 through -38, +0.65, -0.50 mm; for sizes -40 through

−50, +0.90, −0.65 mm; for sizes −52 through −75, +1.00, −0.75 mm; for sizes −78 through −92, +1.40, −1.40 mm; for sizes −95 through −155, +1.65, −1.65 mm; for sizes −160 through −180, +2.05, −2.05 mm; and for sizes −185 through −250, +2.30, −2.30 mm.

**Groove Diameter Tolerances:** For ring sizes −8 and −9, +0.06 mm; for sizes −10 through −18, +0.10 mm; for sizes −19 through −28, +0.15 mm; for sizes −30 through −50, +0.20 mm; for sizes −52 through −98, +0.30; for sizes −100 through −160, +0.40 mm; and for sizes −165 through −250, +0.50 mm.

**Groove Diameter F.I.M. (Full Indicator Movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes −8 through −10, 0.03 mm; for sizes −11 through −15, 0.05 mm; for sizes −16 through −25, 0.10 mm; for sizes −26 through −45, 0.15 mm; for sizes −46 through −80, 0.20 mm; for sizes −82 through −150, 0.25 mm; and for sizes −155 through −250, 0.30 mm.

**Groove Width Tolerances:** For ring size −8, +0.10 mm; for sizes −9 through −38, +0.15 mm; for sizes −40 through −130, +0.20 mm; and for sizes −135 through −250, +0.25 mm.

**Groove Maximum Bottom Radii:** For ring sizes −8 through −17, 0.1 mm; for sizes −18 through −30, 0.2 mm; for sizes −32 through −55, 0.3 mm; and for sizes −56 through −250, 0.4 mm.

For manufacturing details not shown, including materials, see ANSI/ASME B27.7-1977 (R2017).

All dimensions are in millimeters. Size −1 is available in beryllium copper only.

These rings are designated by series symbol and shaft diameter, thus: for a 2 mm diameter shaft, 3CMI-2; for a 13 mm shaft, 3CMI-13; etc.

**Ring Free Diameter Tolerances:** For ring sizes −1 through −7, +0.03, −0.08 mm; for sizes −8 through −13, +0.05, −0.10 mm; and for sizes −15 through −25, +0.10, −0.15 mm.

**Groove Diameter Tolerances:** For ring sizes −1 and −2, −0.05 mm; for sizes −3 through −6, −0.08; for sizes −7 through −11, −0.10 mm; for sizes −12 through −18, −0.15 mm; and for sizes −20 through −25, −0.20 mm.

**Groove Diameter F.I.M. (Full Indicator Movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes −1 through −3, 0.04 mm; for −4 through −6, 0.05 mm; for −7 through −10, 0.08 mm; for −11 through −25, 0.10 mm.

**Groove Width Tolerances:** For ring sizes −1 and −2, +0.05 mm; for size −3, +0.10 mm; and for sizes −4 through −25, +0.15 mm.

**Groove Maximum Bottom Radii:** For ring sizes −1 and −2, 0.05 mm; for −3 through −7, 0.15 mm; for −8 through −13, 0.25 mm; and for −15 through −25, 0.4 mm.

For manufacturing details not shown, including materials, see ANSI/ASME B27.7-1977 (R2017).

<sup>a</sup> For checking when ring is seated in groove.

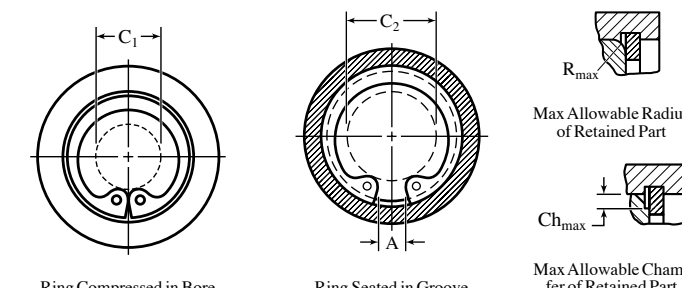

<sup>b</sup> These values have been calculated for steel rings.

<sup>c</sup> These values apply to rings made from SAE 1060-1090 steels and PH 15-7 Mo stainless steel used on shafts hardened to 50 RC minimum, with the exception of sizes -4, -5, and -6 which are supplied in beryllium copper only. Values for other sizes made from beryllium copper can be calculated by multiplying the listed values by 0.75. The values listed include a safety factor of 4.

<sup>d</sup> These values are for all standard rings used on low carbon steel shafts. They include a safety factor of 2.

Maximum allowable assembly loads with  $R$  max or  $Ch$  max are: For rings sizes -4, 0.2 kN; for sizes -5 and -6, 0.5 kN; for sizes -7 through -12, 2.1 kN; for sizes -13 through -17, 4.0 kN; for sizes -18 through -26, 6.0 kN; for sizes -27 through -38, 8.6 kN; for sizes -40 through -50, 13.2 kN; for sizes -52 through -68, 22.0 kN; for sizes -70 through -85, 32 kN; and for sizes -88 through -100, 47 kN.

-25	37.9	12.2	10.1	2.4	1.9	5 000

<sup>a</sup> These values have been calculated for steel rings.

<sup>b</sup> These values apply to rings made from SAE 1060-1090 steels and PH 15-7 Mo stainless steel used on shafts hardened to 50 RC minimum, with the exception of size -1 which is supplied in beryllium copper only. Values for other sizes made from beryllium copper can be calculated by multiplying the listed values by 0.75. The values listed include a safety factor of 4.

<sup>c</sup> These values apply to all standard rings used on low carbon steel shafts. They include a safety factor of 2.

Maximum allowable assembly loads with *R* max or *Ch* max are as follows:

Ring Size No.	Maximum Allowable Load, kN	Ring Size No.	Maximum Allowable Load, kN	Ring Size No.	Maximum Allowable Load, kN
-1	0.06	-8	1.4	-16	6.6
-2	0.13	-9	3.0	-18	8.7
-3	0.3	-10	3.4	-20	9.8
-4	0.7	-11	3.7	-22	10.8
-5	0.9	-12	4.9	-25	12.2
-6	1.1	-13	5.4	...	...
-7	1.2	-15	6.2	...	...

Source: Spirolox Retaining Rings, RR Series. All dimensions are in inches. Depth of groove  $d = (C - A)/2$ . Standard material: carbon spring steel (SAE 1070-1090).

**Ring Thickness, F:** For shaft sizes 0.500 through 0.718, 0.025; for sizes 0.750 through 0.938, 0.031; for sizes 0.968 through 1.156, 0.037; for sizes 1.188 through 1.500, 0.043; for sizes 1.562 through 2.952, 0.049; for sizes 3.000 through 4.562, 0.061; for sizes 4.625 through 6.000, 0.072; for sizes 6.125 through 11.000, 0.086.

**Ring Free Diameter Tolerances:** For housing sizes 0.500 through 1.031, +0.013, -0.000; for sizes 1.062 through 1.500, +0.015, -0.000; for sizes 1.562 through 2.047, +0.020, -0.000; for sizes 2.062 through 3.000, +0.025, -0.000; for sizes 3.062 through 4.063, +0.030, -0.000; for sizes 4.125 through 5.125, +0.035, -0.000; for sizes 5.250 through 6.125, +0.045, -0.000; for sizes 6.250 through 7.125, +0.055, -0.000; for sizes 7.250 through 11.000, +0.065, -0.000.

**Ring Thickness Tolerances:** Thickness indicated is for unplated rings; add 0.002 to upper thickness tolerance for plated rings. For housing sizes 0.500 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 4.562,  $\pm 0.003$ ; for sizes 4.625 through 11.000,  $\pm 0.004$ .

**Groove Diameter Tolerances:** For housing sizes 0.500 through 0.750,  $\pm 0.002$ ; for sizes 0.777 through 1.031,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.047,  $\pm 0.005$ ; for sizes 2.062 through 5.125,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.125 through 11.000,  $\pm 0.008$ .

**Groove Width Tolerances:** For housing sizes 0.500 through 1.156, +0.003, -0.000; for sizes 1.188 through 2.952, +0.004, -0.000; for sizes 3.000 through 6.000, +0.005, -0.000; for sizes 6.125 through 11.000, +0.006, -0.000.

Source: Spirolox Retaining Rings, RS Series. All dimensions are in inches.

Depth of groove  $d = (A - C)/2$ . Standard material: carbon spring steel (SAE 1070-1090).

Ring Thickness,  $F$ : For shaft sizes 0.500 through 0.718, 0.025; for sizes 0.750 through 0.937, 0.031; for sizes 0.968 through 1.156, 0.037; for sizes 1.188 through 1.500, 0.043; for sizes 1.562 through 2.952, 0.049; for sizes 3.000 through 4.500, 0.061; for sizes 4.562 through 6.000, 0.072; for sizes 6.125 through 11.000, 0.086.

Ring Free Diameter Tolerances: For shaft sizes 0.500 through 1.031, +0.000, +0.000, -0.013; for sizes 1.062 through 1.500, +0.000, -0.015; for sizes 1.562 through 2.125, +0.000, -0.020; for sizes 2.156 through 2.688, +0.000, -0.025; for sizes 2.750 through 3.437, +0.000, -0.030; for sizes 3.500 through 5.125, +0.000, -0.040; for sizes 5.250 through 6.125, +0.000, -0.050; for sizes 6.250 through 7.375, +0.000, -0.060; for sizes 7.500 through 11.000, +0.000, -0.070.

Ring Thickness Tolerances: Thickness indicated is for unplated rings; add 0.002 to upper tolerance for plated rings. For shaft sizes 0.500 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 4.500,  $\pm 0.003$ ; for sizes 4.562 through 11.000,  $\pm 0.004$ .

Groove Diameter Tolerances: For shaft sizes 0.500 through 0.562,  $\pm 0.002$ ; for sizes 0.594 through 1.031,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.000,  $\pm 0.005$ ; for sizes 2.062 through 5.125,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.125 through 11.000,  $\pm 0.008$ .

Groove Width Tolerances: For shaft sizes 0.500 through 1.156, +0.003, -0.000; for sizes 1.188 through 2.952, +0.004, -0.000; for sizes 3.000 through 6.000, +0.005, -0.000; for sizes 6.125 through 11.000, +0.006, -0.000.

Source: Spirolox Retaining Rings, RSN Series. All dimensions are in inches. Depth of groove  $d = (A - C)/2$ . Thickness indicated is for unplated rings; add 0.002 to upper tolerance for plated rings. Standard material: carbon spring steel (SAE 1070-1090).

**Ring Thickness, F:** For shaft size 0.469, 0.025; for sizes 0.500 through 0.669, 0.035; for sizes 0.688 through 1.023, 0.042; for sizes 1.062 through 1.500, 0.050; for sizes 1.562 through 2.000, 0.062; for sizes 2.062 through 2.687, 0.078; for sizes 2.750 through 3.437, 0.093; for sizes 3.500 through 5.000, 0.111; for sizes 5.250 through 6.000, 0.127; for sizes 6.250 through 7.250, 0.156; for sizes 7.500 through 15.000, 0.187.

**Ring Free Diameter Tolerances:** For shaft sizes 0.469 through 1.500, +0.000, -0.013; for sizes 1.562 through 2.000, +0.000, -0.020; for sizes 2.062 through 2.687, +0.000, -0.025; for sizes 2.750 through 3.437, +0.000, -0.030; for sizes 3.500 through 5.000, +0.000, -0.035; for sizes 5.250 through 6.000, +0.000, -0.050; for sizes 6.250 through 7.000, +0.000, -0.060; for sizes 7.250 through 10.000, +0.000, -0.070; for sizes 10.250 through 12.500, +0.000, -0.090; for sizes 12.750 through 15.000, +0.000, -0.110.

**Ring Thickness Tolerances:** For shaft sizes 0.469 through 1.500, ±0.002; for sizes 1.562 through 5.000, ±0.003; for sizes 5.250 through 6.000, ±0.004; for sizes 6.250 through 15.000, ±0.005.

**Groove Diameter Tolerances:** For shaft sizes 0.469 through 0.562, ±0.002; for sizes 0.594 through 1.023, ±0.003; for sizes 1.062 through 1.500, ±0.004; for sizes 1.562 through 2.000, ±0.005; for sizes 2.062 through 5.000, ±0.006; for sizes 5.250 through 6.000, ±0.007; for sizes 6.250 through 10.000, ±0.008; for sizes 10.250 through 12.500, ±0.010; for sizes 12.750 through 15.000, ±0.012.

**Groove Width Tolerances:** For shaft sizes 0.469 through 1.023, +0.003, -0.000; for sizes 1.062 through 2.000, +0.004, -0.000; for sizes 2.062 through 5.000, +0.005, -0.000; for sizes 5.250 through 6.000, +0.006; -0.000; for sizes 6.250 through 7.250, +0.008, -0.000; for sizes 7.500 through 15.000, +0.008, -0.000.

**Thrust Load Capacity:** The most important criterion in determining which ring is best suited for a specific application is thrust load capacity. The strength of the retaining ring and groove must both be considered when analyzing the thrust load capacity of an application to determine whether the groove or the retaining ring is likely to fail first. When a retaining ring application fails, the fault will usually be with the groove, unless the groove material is of very high strength.

**Ring Material:** The standard materials for spiral-wound retaining rings are SAE 1070 to 1090 carbon spring steels and 18-8 type 302 stainless steels. The 1070 to 1090 carbon spring steels provide high-strength retaining rings at low cost. Type 302 stainless steel withstands ordinary rusting. Other materials are used for specialized applications, such as the type 316 stainless frequently used in the food industry. For high-temperature use, superalloy A286 rings can be used at up to 900°F (482 °C) and Inconel X-750 at up to 1200°F (649 °C). Other materials, such as 316 stainless steel, 17-7PH and Inconel stainless steels are sometimes used for special-purpose and custom-made rings. Standard ring are typically supplied uncoated, however, special finishes such as cadmium, phosphate, zinc, or black oxide coatings for carbon spring steel rings and passivation of stainless steel rings are available.

**Table 11. Important Dimensions of Inch Series External Retaining Rings**  
MS 16624

Lugs: D = 0.125 to 0.236      Lugs: D = 4.25 to 8.00

*Source:* Industrial Retaining Rings, 3100 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Thickness indicated is for unplated rings; for most plated rings, the maximum ring thickness will not exceed the minimum groove width (W) minus 0.002 inch. Standard material: carbon spring steel (SAE 1060-1090).

*Ring Free Diameter Tolerances:* For shaft sizes 0.125 through 0.250, +0.002, -0.004; for sizes 0.276 through 0.500, +0.002, -0.005; for sizes 0.551 through 1.023, +0.005, -0.010; for sizes 1.062 through 1.500, +0.010, -0.015; for sizes 1.562 through 2.000, +0.013, -0.020; for sizes 2.062 through 2.500, +0.015, -0.025; for sizes 2.559 through 5.000, +0.020, -0.030; for sizes 5.250 through 6.000, +0.020, -0.040; for sizes 6.250 through 6.750, +0.020, -0.050; for sizes 7.000 and 7.500, +0.050, -0.130.

*Ring Thickness Tolerances:* For shaft sizes 0.125 and 0.156,  $\pm 0.001$ ; for sizes 0.188 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 5.000,  $\pm 0.003$ ; for sizes 5.250 through 6.000,  $\pm 0.004$ ; for sizes 6.250 through 7.500,  $\pm 0.005$ .

*Groove Diameter Tolerances:* For shaft sizes 0.125 through 0.250,  $\pm 0.0015$ ; for sizes 0.276 through 0.562,  $\pm 0.002$ ; for sizes 0.594 through 1.023,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.000,  $\pm 0.005$ ; for sizes 2.062 through 5.000,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.250 through 7.500,  $\pm 0.008$ .

*Groove Width Tolerances:* For shaft sizes 0.125 through 0.236, +0.002, -0.000; for sizes 0.250 through 1.023, +0.003, -0.000; for sizes 1.062 through 2.000, +0.004, -0.000; for sizes 2.062 through 5.000, +0.005, -0.000; for sizes 5.250 through 6.000, +0.006, -0.000; for sizes 6.250 through 7.500, +0.008, -0.000.

<sup>a</sup> Thrust Load Safety Factors: Ring, 4; groove, 2. Groove wall thrust loads are for grooves machined in cold-rolled steel with a tensile yield strength of 45,000 psi; for other shaft materials, the thrust load varies proportionally with the yield strength.

Source: Industrial Retaining Rings, 2000 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Standard material: carbon spring steel (SAE 1060-1090). Thickness indicated is for unplated rings; for most plated rings with shaft sizes less than 1.000 inch, the maximum thickness will not exceed the minimum groove width (W) minus 0.0002 inch; for larger rings, the ring thickness may increase by 0.002 inch.

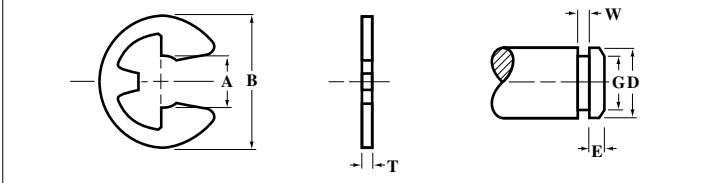

Groove Maximum Bottom Radii: For shaft diameters less than 0.500 inch, 0.005 inch; for shaft sizes 0.500 through 1.000 inch, 0.010 inch; all larger sizes, 0.015 inch.

Ring Free Diameter Tolerances: For shaft sizes 0.125 through 0.188, +0.002, -0.004; for sizes 0.219 through 0.437, +0.003, -0.005; for sizes 0.500 through 0.625, ±0.006; for sizes 0.687 through 1.000, ±0.007; for sizes 1.125 through 1.500, ±0.008; for sizes 1.750 and 2.000, ±0.010.

Ring Thickness Tolerances: For shaft sizes 0.125 through 1.500, ±0.002; for sizes 1.750 and 2.000, ±0.003.

Groove Diameter Tolerances: For shaft sizes 0.125 through 0.188, ±0.0015; for sizes 0.219 through 0.437, ±0.002; for sizes 0.500 through 1.000, ±0.003; for sizes 1.125 through 1.500, ±0.004; for sizes 1.750 and 2.000, ±0.005.

Groove Width Tolerances: For shaft sizes 0.125 through 0.188, +0.002, -0.000; for sizes 0.219 through 1.000, +0.003, -0.000; for sizes 1.125 through 2.000, +0.004, -0.000.

\* Thrust Load Safety Factors: Ring, 3; groove, 2.

Source: Industrial Retaining Rings, 1200 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Standard material: carbon spring steel (SAE 1060-1090). Thickness indicated is for unplated rings; for most plated rings the maximum thickness will not exceed the minimum groove width (W) minus 0.0002 inch.

**Groove Maximum Bottom Radii:** For shaft sizes 0.250 and smaller, 0.005 inch; for sizes 0.312 through 0.438, 0.010 inch; for sizes 0.500 and 0.562, 0.015 inch. **Ring Free Diameter Tolerances:** For shaft sizes 0.094 through 0.156, +0.001, -0.003; for sizes 0.188 through 0.312, ±0.003; for sizes 0.375 through 0.562, ±0.004. **Ring Thickness Tolerances:** For all shaft sizes, ±0.002. **Groove Diameter Tolerances:** For shaft sizes 0.094 through 0.188, +0.002, -0.000; for sizes 0.219 and 0.250, ±0.002; for sizes 0.312 through 0.562, ±0.003. **Groove Width Tolerances:** For shaft sizes 0.094 and 0.125, +0.002, -0.000; for sizes 0.156 through 0.562, +0.003, -0.000.

**Thrust Load Capacity:** The thrust load capacities shown in the tables of this section include safety factors. Usually, a safety factor of 2 is used for groove thrust load calculations when the load is applied through a retained part and groove with both having sharp corners and where the minimum side clearance exists between the retained part and the shaft or bore. Groove thrust load values in the tables of this section are based on these conditions. A safety factor of 3 is usual for calculations of thrust load capacity based on ring shear.

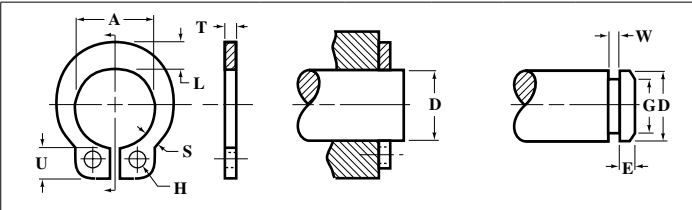

Ideally, the corner of a retained part in contact with a retaining ring should have square corners and contact the ring as closely as possible to the shaft or housing. The tabulated thrust capacities assume that minimum clearances exist between the retained part and shaft or housing, that the groove and retained part have square corners, and that contact between the retained part and the ring occurs close to the shaft or housing. If these conditions apply, the tabulated thrust loads apply. If the application does not meet the previous conditions but the side clearances, radii, and chamfers are less than the maximum total radius or chamfer of Fig. 1, then the thrust load capacity must be reduced by dividing the tabulated value by 2. The maximum total radius is given by  $0.5(b - d)$  and the maximum total chamfer by  $0.375(b - d)$ , where  $b$  is the radial wall thickness, and  $d$  is the groove depth. The recommended maximum total radius or chamfer specifications are

intended to be used as guidelines by the designer, and to ensure the ring application will withstand published and calculated values of static thrust loads.

In analyzing the retaining ring loading conditions, a static, uniformly applied load is usually assumed. Dynamic and eccentric loads, however, are frequently encountered. Eccentric loading occurs when the load is concentrated on a small portion of the ring, such as may be caused by incorrectly machined surfaces, cocking of the retained part, and axial misalignment of parts. Conditions leading to eccentric loading on the ring should be avoided. In addition to the factors that affect the static thrust capacity, applications in which shock or impact loading occurs must be evaluated very carefully and tested in service to assess the effect of the mass and velocity of the retained part striking the ring. Vibration caused by impact loading can also cause the ring to fail if the resonant frequency of the system (retaining ring application) coincides with the resonant frequency of the retaining ring.

**Table 16. Dimensions of Inch Series Self-Locking External Retaining Rings**

Shaft Diameter		Ring		Optical Groove			*Static Thrust Load (lb)

Source: Industrial Retaining Rings, 6000 Series (internal) and 6100 Series (external). All dimensions are in inches, thrust loads are in pounds. Thickness indicated is for unplated rings. Standard material: carbon spring steel (SAE 1060-1090).

**Internal Rings:** Thrust loads are for rings made of standard material inserted into cold-rolled, low-carbon housing. **Ring Thickness Tolerances:** For housing sizes 0.311 through 0.627,  $\pm 0.001$ ; for sizes 0.748 through 1.502,  $\pm 0.002$ . **Ring Diameter Tolerances:** For housing sizes 0.311 through 0.439,  $\pm 0.005$ ; for sizes 0.498 through 1.502,  $\pm 0.010$ .

**External Rings:** Thrust loads are for rings made of standard material installed onto cold-rolled, low-carbon shafts. **Ring Thickness Tolerances:** For shaft sizes 0.093 through 0.220,  $\pm 0.001$ ; for size 0.239,  $\pm 0.002$ ; for sizes 0.249 through 0.376,  $\pm 0.001$ ; for sizes 0.437 through 1.002,  $\pm 0.002$ . **Ring Diameter Tolerances:** For shaft sizes 0.093 through 0.502,  $\pm 0.005$ ; for sizes 0.560 through 1.002,  $\pm 0.010$ .

**Centrifugal Capacity:** Proper functioning of a retaining ring depends on the ring remaining seated on the groove bottom. External rings "cling" to the groove bottom because the ring ID is slightly smaller than the diameter at the bottom of the groove. Ring speed should be kept below the allowable steady-state speed of the ring, or self-locking rings specially designed for high-speed applications should be used, otherwise an external ring can lose its grip on the groove. Applications of large retaining rings that tend to spin in their grooves when subjected to sudden acceleration or deceleration of the retained part can benefit from a ring with more "cling" (i.e., a smaller interior diameter) as long as the stress of installation is within permissible limits. Special rings are also available that lock into a hole in the bottom of the groove, thereby preventing rotation. The following equation can be used to determine the allowable steady-state speed  $N$  of an external spiral retaining ring:

$$N = \sqrt{\frac{0.466C_1 E^3 \times 10^{12}}{R_n^3 (1 + C_1)(R_o^3 - R_i^3)}} \quad (1)$$

where the speed  $N$  is in revolutions per minute,  $C_1$  is the minimum ring cling to groove bottom,  $E$  is the ring radial wall,  $R_n$  is the free neutral ring radius,  $R_o$  is the free outside ring radius, and  $R_i$  is the free inside ring radius, all in inches. For external spiral rings, the minimum ring cling is given by:  $C_1 = (C - G)/G$ , where  $C$  is the mean groove diameter in inches, and  $G$  is the maximum ring free ID in inches.

**Rotation between Parts:** The use of spiral-wound rings to retain a rotating part should be limited to applications with rotation in only one direction. The ring should be matched so that the rotation tends to wind the spring into the groove. External rings should be wound in the direction of rotation of the retained part but internal rings should be wound against the direction of rotation of the rotating part. Failure to observe these precautions will cause the ring to wind out of the groove. Spiral-wound rings can be obtained with either right-hand (normal rotation) or left-hand (reverse rotation) wound configurations. Stamped retaining rings do not have these limitations, and may be used for applications that require rotation of the retained part, regardless of the direction of rotation.
