Under 6.0 in.	$\pm 0.015$ in.	10.0 in. and under	0.010 in.	20.0 in. and under	0.0015 in. per inch of outside diameter.
6.0 to 12.0 in.	$\pm 0.020$ in.	For each additional inch of outside diameter, add 0.0005 in.			
Over 12.0 in.	$\pm 0.040$ in.			For each additional inch of outside diameter, add 0.0005 in.	

<sup>a</sup> Total indicator reading.  
All dimensions in inches.

**Horsepower Ratings:** The horsepower ratings for light duty V-belts can be calculated from the following formulas:

$$3L \quad \text{HP} = r \left( \frac{0.2164d^{0.91}}{r^{0.09}} - 0.2324 - 0.0001396r^2d^3 \right)$$

$$4L \quad \text{HP} = r \left( \frac{0.4666d^{0.91}}{r^{0.09}} - 0.7231 - 0.0002286r^2d^3 \right)$$

$$5L \quad \text{HP} = r \left( \frac{0.7748d^{0.91}}{r^{0.09}} - 1.727 - 0.0003641r^2d^3 \right)$$

where  $d = d_0 - 2a$ ;  $d_0$  = effective outside diameter of small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000. The corrected horsepower rating is obtained by dividing the horsepower rating by the combined correction factor (Table 24), which accounts for drive geometry and service factor requirements.

**Table 24. Combined Correction Factors**

Type of Driven Unit	Speed Ratio	
	Less than 1.5	1.5 and Over
Fans and blowers	1.0	0.9
Domestic laundry machines	1.1	1.0
Centrifugal pumps	1.1	1.0
Generators	1.2	1.1
Rotary compressors	1.2	1.1
Machine tools	1.3	1.2
Reciprocating pumps	1.4	1.3
Reciprocating compressors	1.4	1.3
Woodworking machines	1.4	1.3

**V-Ribbed Belts ANSI/RMA IP-26.**—V-ribbed belts are a cross between flat belts and V-belts. The belt is basically flat with V-shaped ribs projecting from the bottom, which guide the belt and provide greater stability than that found in a flat belt. The ribs operate in grooved sheaves.

V-ribbed belts do not have the wedging action of a V-belt and thus operate at higher tensions. This design provides excellent performance in high-speed and serpentine applications, and in drives that utilize small diameter sheaves. The V-ribbed belt comes in five cross sections: H, J, K, L, and M, specified by effective length, cross section and number of ribs.

**Belt Cross Sections:** Nominal dimensions of the five cross sections are given in Table 25.

**Table 25. Nominal Dimensions of V-Ribbed Belt Cross Sections**  
ANSI/RMA IP-26, 1977

Cross Section	$h_b$	$S_g$	Standard Number of Ribs
H	0.12	0.063	...
J	0.16	0.092	4, 6, 10, 16, 20
K	0.24	0.140	...
L	0.38	0.185	6, 8, 10, 12, 14, 16, 18, 20
M	0.66	0.370	6, 8, 10, 12, 14, 16, 18, 20

All dimensions in inches.

**Table 26. V-Ribbed Belt Sheave and Groove Dimensions ANSI/RMAIP-26, 1977**

Cross Section	Minimum Recommended Outside Diameter	$\alpha$ Groove Angle $\pm 0.25$ (deg)	$S_g^a$	$r_f$ +0.005, -0.000	$2a$	$r_b$	$h_g$ (min)	$d_B$ $\pm 0.0005$	$S_c$
H	0.50	40	0.063 $\pm 0.001$	0.005	0.020	0.013 +0.000 -0.005	0.041	0.0469	0.080 +0.020 -0.010
J	0.80	40	0.092 $\pm 0.001$	0.008	0.030	0.015 +0.000 -0.005	0.071	0.0625	0.125 +0.030 -0.015
K	1.50	40	0.140 $\pm 0.002$	0.010	0.038	0.020 +0.000 -0.005	0.122	0.1093	0.125 +0.050 -0.000
L	3.00	40	0.185 $\pm 0.002$	0.015	0.058	0.015 +0.000 -0.005	0.183	0.1406	0.375 +0.075 -0.030
M	7.00	40	0.370 $\pm 0.003$	0.030	0.116	0.030 +0.000 -0.010	0.377	0.2812	0.500 +0.100 -0.040

<sup>a</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave shall not exceed  $\pm 0.010$  in.

Other Sheave Tolerances <sup>a</sup>					
Outside Diameter		Radial Runout <sup>b</sup>		Axial Runout <sup>b</sup>	
Outside Diameter:		Outside Diameter:		0.001 in. per inch of outside diameter	
Up through 2.9 in.	$\pm 0.010$ in.	Up through 2.9 in.	0.005 in.		
Over 2.9 in. to and including 8.0 in.	$\pm 0.020$ in.	Over 2.9 in. to and including 10.0 in.	0.010 in.		
For each additional inch of outside diameter over 8.0 in., add $\pm 0.0025$ in.		For each additional inch of outside diameter over 10.0 in., add 0.0005 in.			

<sup>a</sup> Variations in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 2.9 in. outside diameter and up through 6 grooves, 0.002 in. (add 0.001 in. for each additional groove); over 2.9 in. to and including 19.9 in. and up through 10 grooves, 0.005 in. (add 0.0002 in. for each additional groove); over 19.9 in. and up through 10 grooves, 0.010 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed in the grooves diametrically opposite each other. Comparing this "diameter-over-balls or -rods" measurement between grooves will give the variation in pitch diameter.

<sup>b</sup> Total indicator reading.

All dimensions in inches

**Belt Size Designation:** Belt sizes are identified by a standard belt number, which consists of belt effective length to the nearest tenth of an inch, a letter designating cross section, and the number of ribs. For example, 540L6 signifies a 54.0 in. effective length, L belt, 6 ribs wide.

**Sheave Dimensions:** Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Table 26, along with various tolerance values.

**Cross Section Selection:** Use the chart (Fig. 9) as a guide to the V-ribbed belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart. H and K cross sections are not included because of their specialized use. Belt manufacturers should be contacted for specific data.

Fig. 9. Selection of V-Ribbed Belt Cross Section

**Horsepower Ratings:** The horsepower rating formulas are:

$$\mathbf{J:HP} = d_p r \left[ \frac{0.1240}{(d_p r)^{0.09}} - \frac{0.08663}{d_p} - 0.2318 \times 10^{-4} (d_p r)^2 \right] + 0.08663r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{L:HP} = d_p r \left[ \frac{0.5761}{(d_p r)^{0.09}} - \frac{0.8987}{d_p} - 1.018 \times 10^{-4} (d_p r)^2 \right] + 0.8987r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{M:HP} = d_p r \left[ \frac{1.975}{(d_p r)^{0.09}} - \frac{6.597}{d_p} - 3.922 \times 10^{-4} (d_p r)^2 \right] + 6.597r \left[ 1 - \frac{1}{K_{SR}} \right]$$

In these equations,  $d_p$  = pitch diameter of the small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 30. These formulas give the maximum horsepower per rib recommended, corrected for the speed ratio. To obtain the horsepower per rib for an arc of contact other than 180 degrees, and for belts longer or shorter than the average length, multiply the horsepower obtained from these formulas by the length correction factor (Table 28) and the arc of contact correction factor (Table 29).

0.40	157	0.94
0.50	151	0.92
0.60	145	0.90
0.70	139	0.88
0.80	133	0.85
0.90	127	0.83
1.00	120	0.80
1.10	113	0.77
1.20	106	0.74
1.30	99	0.71
1.40	91	0.67
1.50	83	0.63

*Number of Ribs:* The number of ribs required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one rib.

Arc of contact on the small sheave may be determined by the following formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D_o - d_o}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D_o - d_o)60}{C}$$

$D_o$  = effective outside diameter of large sheave, inch;  $d_o$  = effective outside diameter of small sheave, inch; and,  $C$  = center distance, inch.

Over 1.12 to and incl. 1.18	1.0567
Over 1.18 to and incl. 1.24	1.0719
Over 1.24 to and incl. 1.34	1.0875
Over 1.34 to and incl. 1.51	1.1036
Over 1.51 to and incl. 1.99	1.1202
Over 1.99	1.1373

<sup>a</sup> $D_p/d_p$ , where  $D_p$  ( $d_p$ ) is the pitch diameter of the large (small) sheave.

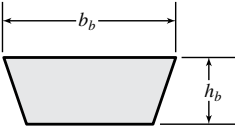

**Variable Speed Belts ANSI/ RMA IP-25.**—For drives that require more speed variation than can be obtained with conventional industrial V-belts, standard-line variable-speed drives are available. These drives use special wide, thin belts. Package units of standard-line variable-speed belts and sheaves, combined with the motor and output gearbox, are available in ranges from approximately  $1/2$  through 100 horsepower.

The speed ranges of variable-speed drives can be much greater than those drives using classical V-belts. Speed ranges up to 10:1 can be obtained on lower horsepower units.

This section covers 12 variable speed belt cross sections and sheave groove sizes designed 1422V, 1922V, 2322V, 1926V, 2926V, 3226V, 2530V, 3230V, 4430V, 4036V, 4436V, and 4836V. The industry supplies many other sizes that are not listed in this section.

**Belt Cross Sections and Lengths:** Nominal dimensions of the 12 cross sections are given in Table 31, and lengths in Table 32.

<sup>a</sup> The effective width ( $b_c$ ), a reference dimension, is the same as the ideal top width of closed variable-speed sheave ( $b_g$ ) and the ideal top width of the companion sheave ( $b_g$ ).

Other Sheave Tolerances			
Outside Diameter	Radial Runout <sup>a</sup>		Axial Runout <sup>a</sup>
Up through 4.0 in. outside diameter	$\pm 0.020$ in.	Up through 10.0 in. outside diameter	0.010 in.
For each additional inch of outside diameter add $\pm 0.005$ in.		For each additional inch of outside diameter add 0.0005 in.	Up through 5.0 in. outside diameter
			0.005 in.
			For each additional inch of outside diameter add 0.001 in.

<sup>a</sup> Total indicator reading.

Surface Finish			
Machined Surface Area	Max Surface Roughness Height, $R_a$ (AA) ( $\mu$ in.)	Machined Surface Area	Max Surface Roughness Height, $R_a$ (AA) ( $\mu$ in.)
V-Sheave groove sidewalls	125	Straight bores with 0.002 in. or less total tolerance	125
Rim edges and ID, hub ends and OD	500	Taper and straight bores with total tolerance over 0.002 in.	250

All dimensions in inches, except where noted.

**Belt Size Designation:** Variable-speed belt sizes are identified by a standard belt number. The first two digits denote the belt top width in sixteenths of an inch; the third and fourth digits indicate the angle of the groove in which the belt is designed to operate. Letter V (for variable) follows the first four digits. The digits after the V indicate pitch length to the nearest 0.1 in. For example, 1422V450 is a belt of  $\frac{7}{8}$  in. ( $1\frac{1}{16}$  in.) nominal top width designed to operate in a sheave of 22 degree groove angle and having a pitch length of 45.0 in.

**Sheave Groove Data:** A variable speed sheave is an assembly of movable parts, designed to permit one or both flanges of the sheave to be moved axially causing a radial movement of the variable speed belt in the sheave groove. This radial movement permits stepless speed variation within the physical limits of the sheave and the belt. A companion sheave may be a solid sheave having a constant diameter and groove profile or another variable sheave. Variable speed sheave designs should conform to the dimensions in Table 33 and Fig. 10. The included angle of the sheaves, top width, and clearance are boundary dimensions. Groove angles and dimensions of companion sheaves should conform to Table 33 and Fig. 11. Various tolerance values are also given in Table 33.

Fig. 10. Variable Sheaves

**Variable-Speed Drive Design:** Variable-speed belts are designed to operate in sheaves that are an assembly of movable parts. The sheave design permits one or both flanges of the sheave to be moved axially, causing a radial movement of the variable-speed belt in the sheave groove. The result is a stepless speed variation within the physical limits of the sheave and the variable-speed belt. Therefore, besides transmitting power, variable-speed belt drives provide speed variation.

Fig. 11. Companion Sheaves

The factors that determine the amount of pitch diameter change on variable-speed sheaves are belt top width, belt thickness, and sheave angle. This pitch diameter change, combined with the selected operating pitch diameters for a sheave, determines the possible speed variation.

The range of output speeds from a variable-speed sheave drive is established by the companion sheave and is a function of the ratio of the pitch diameter of the companion sheave to the maximum and minimum pitch diameters of the variable sheave. Speed variation is usually obtained by varying the center distance between the two sheaves. This type of drive seldom exceeds a speed variation of 3:1.

For a single variable-speed sheave drive, the speed variation

$$\text{Speed variation} = \frac{\text{PD Max}}{\text{PD Min}} (\text{of variable sheave})$$

For a dual variable-speed sheave drive, which is frequently referred to as a compound drive because both sheaves are variable, the speed variation is

$$\text{Speed variation} = \frac{DR(DN)}{dr(dn)}$$

where  $DR$  = max driver PD

$DN$  = max driven PD

$dr$  = min driver PD

$dn$  = min driven PD

With this design, the center distance is generally fixed and speed variation is usually accomplished by mechanically altering the pitch diameter of one sheave. In this type of drive, the other sheave is spring loaded to make an opposite change in the pitch diameter and to provide the correct belt tension. Speed variations of up to 10:1 are common on this type of drive.

**Speed Ratio Adjustment:** All speed ratio changes must be made while the drives are running. Attempting to make adjustments while the unit is stopped creates unnecessary and possibly destructive forces on both the belt and sheaves. In stationary control drives, the belt tension should be released to allow the flanges to adjust without belt force interference.

**Cross Section Selection:** Selection of a variable speed belt cross section is based on the drive design horsepower and speed variation. Table 33 shows the maximum pitch diameter variation ( $2av$ ) that each cross section can attain.

**Horsepower Ratings:** The general horsepower formulas for variable-speed belts are:

$$1422V \text{ HP} = d_p r \left[ 0.4907(d_p r)^{0.09} - \frac{0.8378}{d_p} - 0.000337(d_p r)^2 \right] + 0.8378r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1922V \text{ HP} = d_p r \left[ 0.8502(d_p r)^{0.09} - \frac{1.453}{d_p} - 0.000538(d_p r)^2 \right] + 1.453r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2322V \text{ HP} = d_p r \left[ 1.189(d_p r)^{0.09} - \frac{2.356}{d_p} - 0.000777(d_p r)^2 \right] + 2.356r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1926V \text{ HP} = d_p r \left[ 1.046(d_p r)^{0.09} - \frac{1.833}{d_p} - 0.000589(d_p r)^2 \right] + 1.833r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2926V \text{ HP} = d_p r \left[ 1.769(d_p r)^{0.09} - \frac{4.189}{d_p} - 0.001059(d_p r)^2 \right] + 4.189r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3226V \text{ HP} = d_p r \left[ 2.073(d_p r)^{0.09} - \frac{5.236}{d_p} - 0.001217(d_p r)^2 \right] + 5.236r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2530V \text{ HP} = d_p r \left[ 2.395(d_p r)^{0.09} - \frac{6.912}{d_p} - 0.001148(d_p r)^2 \right] + 6.912r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3230V \text{ HP} = d_p r \left[ 2.806(d_p r)^{0.09} - \frac{7.854}{d_p} - 0.001520(d_p r)^2 \right] + 7.854r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4430V \text{ HP} = d_p r \left[ 3.454(d_p r)^{0.09} - \frac{7.854}{d_p} - 0.002196(d_p r)^2 \right] + 9.818r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4036V \text{ HP} = d_p r \left[ 3.566(d_p r)^{0.09} - \frac{9.687}{d_p} - 0.002060(d_p r)^2 \right] + 9.687r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4436V \text{ HP} = d_p r \left[ 4.041(d_p r)^{0.09} - \frac{11.519}{d_p} - 0.002297(d_p r)^2 \right] + 11.519r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4836V \text{ HP} = d_p r \left[ 4.564(d_p r)^{0.09} - \frac{13.614}{d_p} - 0.002634(d_p r)^2 \right] + 13.614r \left( 1 - \frac{1}{K_{SR}} \right)$$

In these equations,  $d_p$  = pitch diameter of small sheave, in.;  $r$  = rpm of faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 34. These formulas give the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower for arcs of contact other than 180 degrees and for belts longer or shorter than average length, multiply the horsepower obtained from these formulas by the arc of contact correction factor (Table 36) and the length correction factor (Table 35).

**Table 34. Speed Ratio Correction Factors**

Speed Ratio <sup>a</sup>	$K_{SR}$	Speed Ratio <sup>a</sup>	$K_{SR}$
1.00-1.01	1.0000	1.19-1.24	1.0719

**Rim Speed:** The material and design selected for sheaves must be capable of withstanding the high rim speeds that may occur in variable-speed drives. The rim speed is calculated as follows: Rim speed (fpm) =  $(\pi/12)(D_o)(\text{rpm})$ .

**Arc of Contact:** Arc of contact on the small sheave may be determined by the formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D-d}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D-d)60}{C}$$

where  $D$  = Pitch diameter of large sheave or flat pulley, inch or mm

$d$  = Pitch diameter of small sheave, inch or mm

$C$  = Center distance, inch or mm

**Table 36. Arc of Contact Correction Factors**

$\frac{D-d}{C}$	Arc of Contact, $\theta$ , on Small Sheave, (deg)	Correction Factor	$\frac{D-d}{C}$	Arc of Contact, $\theta$ , on Small Sheave, (deg)	Correction Factor

**60-Degree V-Belts.**—60-degree V-belts are ideal for compact drives. Their 60-degree angle and ribbed top are specifically designed for long life on small diameter sheaves. These belts offer extremely smooth operation at high speeds (in excess of 10,000 rpm) and can be used on drives with high speed ratios. They are available in 3M, 5M, 7M, and 11M (3, 5, 7, 11 mm) cross sections (top widths) and are commonly found in the joined configuration, which provides extra stability and improved performance. They are specified by cross section and nominal length; for example, a 5M315 designation indicates a belt having a 5 mm cross section and an effective length of 315 mm.

Industry standards have not yet been published for 60-degree V-belts. Belt manufacturers should be contacted for specific applications, specifications, and additional information.

**SAE Standard V-Belts.**—The data for V-belts and pulleys shown in Table 37 cover nine sizes, three of which — 0.250, 0.315, and 0.440 — were added in 1977 to conform to existing practice. This standard was reaffirmed in 1987.

V-belts are produced in a variety of constructions in a basic trapezoidal shape and are to be dimensioned in such a way that they are functional in pulleys dimensioned as described in the standard. Standard belt lengths are in increments of  $\frac{1}{2}$  inch (12.7 mm) up to and including 80 inches (203.2 cm). Standard lengths above 80 inches up to and including 100 inches (254 cm) are in increments of 1 inch (2.54 cm), without fractions. Standard belt length tolerances are based on the center distance and are as follows: For belt lengths of 50 inches (127 cm) or less,  $\pm 0.12$  inch; over 50 to 60 inches (127–152.4 cm), inclusive,  $\pm 0.16$  inch; over 60 to 80 inches (152.4–203.2 cm), inclusive,  $\pm 0.19$  inch; and over 80 to 100 inches (203.2–254 cm), inclusive,  $\pm 0.22$  inch.

**Belt Storage and Handling.**—To achieve maximum belt performance, proper belt storage procedures should always be practiced. If belts are not stored properly, their performance can be adversely affected. Four key rules are:

- 1) Do not store belts on floors unless they are protected by appropriate packaging.
- 2) Do not store belts near windows where the belts may be exposed to direct sunlight or moisture.

	Over 8.00	38				0.666		

All dimensions in inches.

<sup>a</sup> Pulley effective diameters below those recommended should be used with caution, because power transmission and belt life may be reduced.

<sup>b</sup> The X dimension is radial; 2X is to be subtracted from the effective diameter to obtain "pitch diameter" for speed ratio calculations.

<sup>c</sup> These values are intended for adjacent grooves of the same effective width (W). Choice of pulley manufacture or belt design parameter may justify variance from these values. The S dimension should be the same on all multiple groove pulleys in a drive using matched belts. © 1990, SAE, Inc.

3) Do not store belts near electrical devices that may generate ozone (transformers, electric motors, etc.).

4) Do not store belts in areas where solvents or chemicals are present in the atmosphere.

Belts should be stored in a cool, dry environment. When stacked on shelves, the stacks should be short enough to avoid excess weight on the bottom belts, which may cause distortion. When stored in containers, the container size and contents should be sufficiently limited to avoid distortion.

*V-Belts:* A common method is to hang the belts on pegs or pin racks. Very long belts stored this way should use sufficiently large pins or crescent-shaped "saddles" to prevent their weight from causing distortion.

*Joined V-belts, Synchronous Belts, V-Ribbed Belts:* Like V-belts, these belts may be stored on pins or saddles with precautions taken to avoid distortion. However, belts of this

The machines listed above are representative samples only. Select the group listed above whose load characteristics most closely approximate those of the machine being considered.

type up to approximately 120 inch (3.05 m) are normally shipped in a "nested" configuration and should be stored in the same manner. Nests are formed by laying a belt on its side on a flat surface and placing as many belts inside the first belt as possible without undue force. When the nests are tight and are stacked with each rotated 180° from the one below, they may be stacked without damage.

Belts of this type over 120 in. may be "rolled up" and tied for shipment. These rolls may be stacked for easy storage. Care should be taken to avoid small bend radii which could damage the belts.

**Variable Speed Belts:** Variable speed belts are more sensitive to distortion than most other belts, and should not be hung from pins or racks but stored on shelves in the sleeves in which they are shipped.

**Service Factors:** Service factors for V-belts are listed in [Table 38](#).

### Synchronous Belts

**Synchronous Belts ANSI/RMA IP-24.**—Synchronous belts are also known as timing or positive-drive belts. These belts have evenly spaced teeth on their surfaces, which mesh with teeth on pulleys or sprockets to produce a positive, no-slip transmission of power. Such designs should not be confused with molded notched V-belts, which transmit power by means of the wedging action of the V-shape. Synchronous belts are used where driven shaft speeds must be synchronized to the rotation of the driver shaft and to eliminate the noise and maintenance problems of chain drives.

*Standard Timing Belts:* Conventional trapezoidal, or rectangular tooth, timing belts come in six cross sections, which relate to the pitch of the belt. Pitch is the distance from center to center of the teeth. The six basic cross sections or pitches are MXL (mini extra light), XL (extra light), L (light), H (heavy), XH (extra heavy), and XXH (double extra heavy) (Fig. 12). Belts are specified by pitch length, cross section (pitch), and width.

Double-sided timing belts have identical teeth on both sides of the belt and are used where synchronization is required from each belt face. They are available in XL, L, and H cross sections.

*Size Designations:* Synchronous belt sizes are identified by a standard number. The first digits specify the belt length to 0.1 inch (2.54 mm) followed by the belt section (pitch) designation. The digits following the belt section designation represent the nominal belt width times 100. For example, an L section belt 30.000 inches pitch length and 0.75 inch in width would be specified as a 300L075 synchronous belt.

Fig. 12. Standard Synchronous Belt Sections

The RMA nomenclature for double-sided belts is the same as for single-sided belts with the addition of the prefix “D” in front of the belt section. However, some manufacturers use their own designation system for double-sided belts.

*Standard Sections:* Belt sections are specified in terms of pitch. Table 40 gives the Standard Belt Sections and their corresponding pitches.

**Table 39. Service Factors for Synchronous Belt Drives**

Synchronous belts will not slip, and therefore must be belted for the highest loadings anticipated in the system. A minimum service factor of 2.0 is recommended for equipment subject to chocking.

**Pitch Lengths:** Standard belt pitch lengths, belt length designations, and numbers of teeth are shown in Table 42. Belt length tolerances are also given in this table; these tolerances apply to all belt sections and represent the total manufacturing tolerance on belt length.

**Nominal Tooth Dimensions:** Table 40 shows the nominal tooth dimensions for each of the standard belt sections. Tooth dimensions for single- and double-sided belts are identical.

**Widths:** Standard belt widths, width designations, and width tolerances are shown in Table 43.

**Length Determination:** The pitch length of a synchronous belt is determined by placing the belt on a measuring fixture having two pulleys of equal diameter, a method of applying force, and a means of measuring the center distance between the two pulleys. The position of one of the two pulleys is fixed and the other is movable along a graduated scale.

**Synchronous Belt Pulley Diameters:** Table 44 lists the standard pulley diameters by belt section (pitch). Fig. 13 defines the pitch, pitch diameter, outside diameter and pitch line differential.

All dimensions in inches.

\* Usually not available in all widths — consult supplier.

**Widths:** Standard pulley widths for each belt section are shown in Table 41. The nominal pulley width is specified in terms of the maximum standard belt width the pulley will accommodate. The minimum pulley width, whether flanged or unflanged, is also shown in Table 41, along with flange dimensions and various pulley tolerances.

**Pulley Size Designation:** Synchronous belt pulleys are designated by the number of grooves, the belt section, and a number representing 100 times the nominal width. For example, a 30 groove L section pulley with a nominal width of 0.75 in. would be designated by 30L075. Pulley tolerances are shown in Table 45.

**Table 45. Pulley Tolerances (All Sections)**

Outside Diameter Range	Outside Diameter Tolerance	Pitch to Pitch Tolerance	
		Adjacent Grooves	Accumulative Over 90 Degrees
Up thru 1.000	+0.002 -0.000	±0.001	±0.003
Over 1.000 to and including 2.000	+0.003 -0.000	±0.001	±0.004
Over 2.000 to and including 4.000	+0.004 -0.000	±0.001	±0.005
Over 4.000 to and including 7.000	+0.005 -0.000	±0.001	±0.005
Over 7.000 to and including 12.000	+0.006 -0.000	±0.001	±0.006
Over 12.000 to and including 20.000	+0.007 -0.000	±0.001	±0.007
Over 20.000	+0.008 -0.000	±0.001	±0.008

Radial Runout <sup>a</sup>	Axial Runout <sup>a</sup>
For outside diameters 8.0 in. and under 0.005 in. For each additional inch of outside diameter add 0.0005 in.	For outside diameters 1.0 in. and under 0.001 in. For each additional inch of outside diameter up through 10.0 in., add 0.001 in. For each additional inch of outside diameter over 10.0 in., add 0.0005 in.

<sup>a</sup>Total indicator reading.

All dimensions in inches.

**Cross Section Selection:** The chart (Fig. 14) may be used as a guide to the selection of a synchronous belt for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may result in selection of a belt cross section different from that indicated in the chart. Belt manufacturers should be contacted for specific data.

**Torque Ratings:** It is customary to use torque load requirements rather than horsepower load when designing drives using the small pitch MXL section belts. These belts operate on small diameters resulting in relatively low belt speeds, so torque is essentially constant for all rpm. The torque rating formulas for MXL sections are:

$$Q_r = d[1.13 - 1.38 \times 10^{-3} d^2] \text{ for belt width} = 0.12 \text{ in.}$$

$$Q_r = d[1.88 - 2.30 \times 10^{-3} d^2] \text{ for belt width} = 0.19 \text{ in.}$$

$$Q_r = d[2.63 - 3.21 \times 10^{-3} d^2] \text{ for belt width} = 0.25 \text{ in.}$$

where  $Q_r$  = the maximum torque rating (lb-ft-in.) for a belt of specified width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Torque ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, inch.

Fig. 14. Selection of Synchronous Belt Cross Section

Table 46. Teeth in Mesh Factor

Teeth in Mesh	Factor $K_c$	Teeth in Mesh	Factor $K_c$
6 or more	1.00	3	0.40
5	0.80	2	0.20
4	0.60		

**Horsepower Rating Formulas:** The horsepower rating formulas for synchronous belts, other than the MLX section, are determined from the following formulas, where the number in parentheses is the belt width in inches.

$$XL(0.38) \text{ HP} = dr[0.0916 - 7.07 \times 10^{-5}(dr)^2]$$

$$L(1.00) \text{ HP} = dr[0.436 - 3.01 \times 10^{-4}(dr)^2]$$

$$H(3.00) \text{ HP} = dr[3.73 - 1.41 \times 10^{-3}(dr)^2]$$

$$XH(4.00) \text{ HP} = dr[7.21 - 4.68 \times 10^{-3}(dr)^2]$$

$$XXH(5.00) \text{ HP} = dr[11.4 - 7.81 \times 10^{-3}(dr)^2]$$

where  $HP$  = the maximum horsepower rating recommended for the specified standard belt width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Horsepower ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, inch;  $r$  = rpm of faster shaft divided by 1000. Total horsepower ratings are the same for double-sided as for single-sided belts. Contact manufacturers for percentage of horsepower available for each side of the belt.

**Finding the Required Belt Width:** The belt width should not exceed the small pulley diameter or excessive side thrust will result.

**Torque Rating Method (MXL Section):** Divide the design torque by the teeth in mesh factor to obtain the corrected design torque. Compare the corrected design torque with the torque rating given in Table 47 for the pulley diameter being considered. Select the narrowest belt width that has a torque rating equal to or greater than the corrected design torque.

**Table 47. Torque Rating for MXL Section (0.080 in. Pitch)**

Belt Width, (in.)	Rated Torque (lbf-in.) for Small Pulley (Number of Grooves and Pitch Diameter, in.)									
	10MXL 0.255	12MXL 0.306	14MXL 0.357	16MXL 0.407	18MXL 0.458	20MXL 0.509	22MXL 0.560	24MXL 0.611	28MXL 0.713	30MXL 0.764
0.12	0.29	0.35	0.40	0.46	0.52	0.57	0.63	0.69	0.81	0.86
0.19	0.48	0.58	0.67	0.77	0.86	0.96	1.05	1.15	1.34	1.44
0.25	0.67	0.80	0.94	1.07	1.20	1.34	1.47	1.61	1.87	2.01

**Horsepower Rating Method (XL, L, H, XH, and XXH Sections):** Multiply the horsepower rating for the widest standard belt of the selected section by the teeth in mesh factor to obtain the corrected horsepower rating. Divide the design horsepower by the corrected horsepower rating to obtain the required belt width factor. Compare the required belt width factor with those shown in Table 48. Select the narrowest belt width that has a width factor equal to or greater than the required belt width factor.

**Table 48. Belt Width Factor**

Belt Section	Belt Width (in.)											
	0.12	0.19	0.25	0.38	0.50	0.75	1.00	1.50	2.00	3.00	4.00	5.00
MXL (0.080)	0.43	0.73	1.00	...	...	...	...	...	...	...	...	...
XL (0.200)	...	...	0.62	1.00	...	...	...	...	...	...	...	...
L (0.375)	...	...	...	...	0.45	0.72	1.00	...	...	...	...	...
H (0.500)	...	...	...	...	...	0.21	0.29	0.45	0.63	1.00	...	...
XH (0.875)	...	...	...	...	...	...	...	...	0.45	0.72	1.00	...
XXH (1.250)	...	...	...	...	...	...	...	...	0.35	0.56	0.78	1.00

**Drive Selection:** Information on design and selection of synchronous belt drives is available in engineering manuals published by belt manufacturers. Manufacturers should be consulted on such matters as preferred stock sizes, desirable speeds, center distances, etc.

**Minimum Pulley Size:** The recommended minimum pulley size depends on the rpm of the faster shaft. Minimum sheave diameters for each belt cross section are listed in Table 44.

**Selection of Flanged Pulleys:** To determine when to use flanged pulleys, consider the following conditions:

- 1) On all two-pulley drives, the minimum flanging requirements are two flanges on one pulley, or one flange on each pulley on opposite sides.
- 2) On drives where the center distance is more than eight times the diameter of the small pulley, both pulleys should be flanged on both sides.
- 3) On vertical shaft drives, one pulley should be flanged on both sides and other pulleys in the system should be flanged on the bottom side only.
- 4) On drives with more than two pulleys, the minimum flanging requirements are two flanges on every other pulley, or one flange on every pulley, alternating sides around the system.

**Service Factors:** Service factors for synchronous belts in Table 39.

**Gravity Idler.**—The gravity type of idler used in conjunction with many belt drives, consists of a weighted idler pulley, so pivoted from a long arm that the idler runs near the small pulley against the loose side of the belt, in such a way as to increase the arc of contact of the belt on this pulley. These idlers are of special value on difficult drives where there is a large difference in the diameter of the driver and driven pulleys.

## TRANSMISSION CHAINS

## Types of Chains

In addition to the standard roller and inverted tooth types, a wide variety of drive chains of different construction is available. Such chains are manufactured to various degrees of precision ranging from unfinished castings or forgings to chains having certain machined parts. Practically all of these chains as well as standard roller chains can be equipped with attachments to fit them for conveyor use. A few such types are briefly described in the following paragraphs. Detailed information about them can be obtained from the manufacturers.

**Types of Chains.**—*Detachable Chains:* The links of this type of chain, which are identical, are easily detachable. Each has a hook-shaped end in which the bar of the adjacent link articulates. These chains are available in malleable iron or pressed steel. The chief advantage is the ease with which any link can be removed.

*Cast Roller Chains:* Cast roller chains are constructed, wholly or partly, of cast metal parts and are available in various styles. In general the rollers and side bars are accurately made castings without machine finish. The links are usually connected by means of forged pins secured by nuts or cotters. Such chains are used for slow speeds and moderate loads, or where the precision of standard roller chains is not required.

*Pintle Chains:* Unlike the roller chain, the pintle chain is composed of hollow-cored cylinders cast or forged integrally with two offset side bars and each link identical. The links are joined by pins inserted in holes in the ends of the side bars and through the cored holes in the adjacent links. Lugs prevent turning of the pins in the side bars ensuring articulation of the chain between the pin and the cored cylinder, allowing for greater force and power transmission.

## Standard Roller Transmission Chains

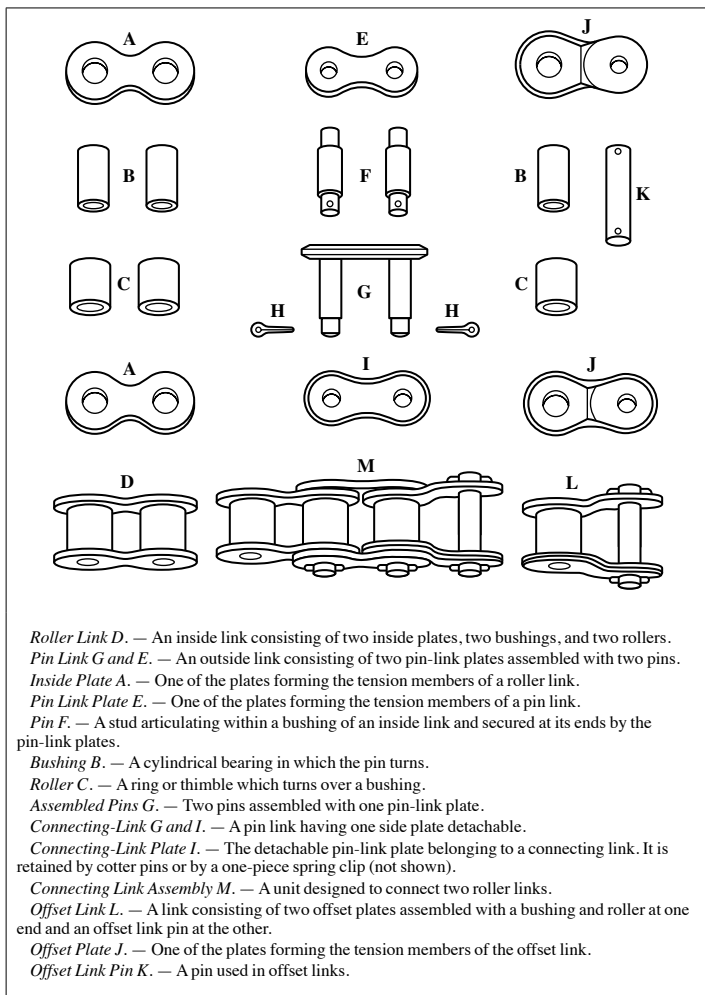

A roller chain is made up of two kinds of links: roller links and pin links alternately spaced throughout the length of the chain as shown in [Table 1](#).

Roller chains are manufactured in several types, each designed for the particular service required. All roller chains are so constructed that the rollers are evenly spaced throughout the chain. The outstanding advantage of this type of chain is the ability of the rollers to rotate when contacting the teeth of the sprocket. Two arrangements of roller chains are in common use: the single-strand type and the multiple-strand type. In the latter type, two or more chains are joined side by side by means of common pins which maintain the alignment of the rollers in the different strands.

**Types of Roller Chains.**—*Standard roller chains* are manufactured to the specifications in the American National Standard for precision power transmission roller chains, attachments, and sprockets ANSI/ASME B29.1-2011 (R2016) and, where indicated, the data in the subsequent tables have been taken from this standard. These roller chains and sprockets are commonly used for the transmission of power in industrial machinery, machine tools, motor trucks, motorcycles, tractors, and similar applications. In tabulating the dimensional information in ANSI/ASME B29.1-2011 (R2016), customary inch-pound units were used. Metric (SI) units are given in separate tabulations in the ANSI/ASME standard.

*Nonstandard roller chains*, developed individually by various manufacturers prior to the adoption of the ANSI/ASME standard, are similar in form and construction to standard roller chains but do not conform dimensionally to standard chains. Some sizes are maintained from the originating manufacturers for replacement on existing equipment. They are not recommended for new installations, since their manufacture may be discontinued without ongoing support.

**Table 1. Nomenclature for Roller Chain Parts**  
ANSI/ASME B29.1-2011 (R2016)

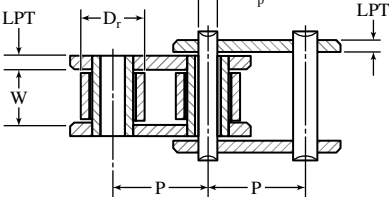

*Standard double-pitch roller chains* are like standard roller chains, except that their link plates have twice the pitch of the corresponding standard-pitch chain. Their design conforms to specifications in the ANSI/ASME standard for double-pitch power transmission roller chains and sprockets ANSI/ASME B29.100-2011 (R2016). They are especially useful for low speeds, moderate loads, or long center distances.

## Transmission Roller Chain

**Standard Roller Chain Nomenclature, Dimensions and Loads.**—Standard nomenclature for roller chain parts are given in Table 1. Dimensions for Standard Series and Heavy Series roller chain are given in Table 2.

Table 2. Roller Chain Dimensions ANSI/ASME B29.1-2011 (R2016)

Pitch $P$	Max. Roller Diameter $D_r$	Standard Series					Heavy Series
		Standard Chain No.	Width $W$	Pin Diameter $D_p$	Thickness of Link Plates $LPT$	Measuring Load, <sup>a</sup> lb	
0.250	<sup>b</sup> 0.130	25	0.125	0.0905	0.030	18	...
0.375	<sup>b</sup> 0.200	35	0.188	0.141	0.050	18	...

2.500	1.562	200	1.500	0.781	0.312	781	0.375
3.000	1.875	240	1.875	0.937	0.375	1000	0.500

<sup>a</sup> For single-strand chain.

<sup>b</sup> Bushing diameter. This size chain has no rollers.

All dimensions are in inches.

Roller Diameters  $D_r$  are approximately  $\frac{5}{8}P$ .

The width  $W$  is defined as the distance between the link plates. It is approximately  $\frac{5}{8}$  of the chain pitch.

Pin Diameters  $D_p$  are approximately  $\frac{5}{16}P$  or  $\frac{1}{2}$  of the roller diameter.

Thickness  $LPT$  of Inside and Outside Link Plates for the Standard Series is approximately  $\frac{1}{8}P$ .

Thickness of Link Plates for the Heavy Series of any pitch is approximately that of the next larger pitch Standard Series chain.

Maximum Height of Roller Link Plates =  $0.95P$ .

Maximum Height of Pin Link Plates =  $0.82P$ .

Maximum Pin Diameter = nominal pin diameter + 0.0005 inch.

Minimum Hole in Bushing = nominal pin diameter + 0.0015 inch.

Maximum Width of Roller Link = nominal width of chain +  $(2.12 \times \text{nominal link plate thickness})$ .

Minimum Distance between Pin Link Plates = maximum width of roller link + 0.002 inch.

**Chain Pitch:** Distance in inches between centers of adjacent joint members. Other dimensions are proportional to the pitch.

**Tolerances for Chain Length:** New chains, under standard measuring load, must not be underlength. Overlength tolerance is  $0.001/(\text{pitch in inches})^2 + 0.015$  inch per foot. Length measurements are to be taken over a length of at least 12 inches.

**Measuring Load:** The load in pounds under which a chain should be measured for length. It is equal to 1 percent of the ultimate tensile strength, with a minimum of 18 pounds and a maximum of 1000 pounds for both single and multiple-strand chain.

**Minimum Ultimate Tensile Strength:** For single-strand chain, equal to or greater than  $12,500 \times (\text{pitch in inches})^2$  pounds. The minimum tensile strength or breaking strength of a multiple-strand chain is equal to that of a single-strand chain multiplied by the number of strands. Minimum ultimate tensile strength is indicative only of the tensile strength quality of the chain, not the maximum load that can be applied.

**Standard Roller Chain Numbers.**—The right-hand figure in the chain number is zero for roller chains of the usual proportions, 1 for a lightweight chain, and 5 for a rollerless bushing chain. The numbers to the left of the right-hand figure denote the number of  $\frac{1}{8}$  inches in the pitch. The letter *H* following the chain number denotes the heavy series; thus the number 80*H* denotes a 1-inch pitch heavy chain. The hyphenated number 2 suffixed to the chain number denotes a double strand, 3 a triple strand, 4 a quadruple strand chain and so on.

**Heavy Series:** These chains, made in  $\frac{3}{4}$ -inch and larger pitches, have thicker link plates than those of the regular standard. Their value is only in the acceptance of higher loads at lower speeds.

**Light-weight Machinery Chain:** This chain is designated as No. 41. It is  $\frac{1}{2}$  inch pitch;  $\frac{1}{4}$  inch wide; has 0.306-inch diameter rollers and a 0.141-inch pin diameter. The minimum ultimate tensile strength is 1500 pounds.

**Multiple-strand Chain:** This is essentially an assembly of two or more single-strand chains placed side by side with pins that extend through the entire width to maintain alignment of the different strands.

**Types of Sprockets.**—Four different designs or types of roller-chain sprockets are shown by the sectional views, Fig. 1. Type *A* is a plain plate; type *B* has a hub on one side only; type *C*, a hub on both sides; and type *D*, a detachable hub. Also used are shear pin and slip clutch sprockets designed to prevent damage to the drive or to other equipment caused by overloads or stalling.

Fig. 1. Types of Sprockets

**Attachments.**—Modifications to standard chain components to adapt the chain for use in conveying, elevating, and timing operations are known as “attachments.” The components commonly modified are: 1) the link plates, which are provided with extended lugs which may be straight or bent; and 2) the chain pins, which are extended in length so as to project substantially beyond the outer surface of the pin link plates.

Hole diameters, thicknesses, hole locations and offset dimensions for straight link and bent link plate extensions and lengths and diameters of extended pins are given in **Table 3**.

**Table 3. Straight and Bent Link Plate Extensions and Extended Pin Dimensions**  
ANSI/ASME B29.1-2011 (R2016)

Chain No.	Straight Link Plate Extension			Bent Link Plate Extension				Extended Pin	
	<i>B</i> min.	<i>D</i>	<i>F</i>	<i>B</i> min.	<i>C</i>	<i>D</i>	<i>F</i>	<i>D<sub>p</sub></i> Nominal	<i>L</i>
35	0.102	0.375	0.050	0.102	0.250	0.375	0.050	0.141	0.375
40	0.131	0.500	0.060	0.131	0.312	0.500	0.060	0.156	0.375
50	0.200	0.625	0.080	0.200	0.406	0.625	0.080	0.200	0.469
60	0.200	0.719	0.094	0.200	0.469	0.750	0.094	0.234	0.562
80	0.261	0.969	0.125	0.261	0.625	1.000	0.125	0.312	0.750
100	0.323	1.250	0.156	0.323	0.781	1.250	0.156	0.375	0.938
120	0.386	1.438	0.188	0.386	0.906	1.500	0.188	0.437	1.125
140	0.448	1.750	0.219	0.448	1.125	1.750	0.219	0.500	1.312
160	0.516	2.000	0.250	0.516	1.250	2.000	0.250	0.562	1.500
200	0.641	2.500	0.312	0.641	1.688	2.500	0.312	0.781	1.875

All dimensions are in inches.

**Sprocket Classes.**—The American National Standard ANSI/ASME B29.1-2011 (R2016) provides for two classes of sprockets designated as Commercial and Precision. The selection of either is a matter of drive application judgment. The usual moderate to slow speed commercial drive is adequately served by Commercial sprockets. Where extreme high speed in combination with high load is involved, or where the drive involves fixed centers, critical timing, or register problems, or close clearance with outside interference, then the use of Precision sprockets may be more appropriate.

As a general guide, drives requiring Type A or Type B lubrication (see page 2638) would be served by Commercial sprockets. Drives requiring Type C lubrication may require Precision sprockets; the manufacturer should be consulted.

**Keys, Keyways, and Set Screws.**—To secure sprockets to the shaft, both keys and set screws should be used. The key is used to prevent rotation of the sprocket on the shaft. Keys should be fitted carefully in the shaft and sprocket keyways to eliminate all backlash, especially on the fluctuating loads. A set screw should be located over a flat key to secure it against longitudinal displacement.

Where a set screw is to be used with a parallel key, the following sizes are recommended by the American Chain Association. For a sprocket bore and shaft diameter in the range of:

- $\frac{1}{2}$  through  $\frac{7}{8}$  inch, a  $\frac{1}{4}$ -inch set screw
- $\frac{15}{16}$  through  $1\frac{3}{4}$  inches, a  $\frac{3}{8}$ -inch set screw
- $1\frac{13}{16}$  through  $2\frac{1}{4}$  inches, a  $\frac{1}{2}$ -inch set screw
- $2\frac{5}{16}$  through  $3\frac{1}{4}$  inches, a  $\frac{5}{8}$ -inch set screw
- $3\frac{3}{8}$  through  $4\frac{1}{2}$  inches, a  $\frac{3}{4}$ -inch set screw
- $4\frac{3}{4}$  through  $5\frac{1}{2}$  inches, a  $\frac{7}{8}$ -inch set screw
- $5\frac{3}{4}$  through  $7\frac{3}{8}$  inches, a 1-inch set screw
- $7\frac{1}{2}$  through  $12\frac{1}{2}$  inches, a  $1\frac{1}{4}$ -inch set screw

**Sprocket Diameters.**—The various diameters of roller chain sprockets are shown in Fig. 2. These are defined as follows.

**Pitch Diameter:** The pitch diameter is the diameter of the pitch circle that passes through the centers of the link pins as the chain is wrapped on the sprocket.

Fig. 2. Sprocket Diameters

Because the chain pitch is measured on a straight line between the centers of adjacent pins, the chain pitch lines form a series of chords of the sprocket pitch circle. Sprocket pitch diameters for one-inch pitch and for 9 to 108 teeth are given in Table 4. For lower (5 to 8) or higher (109 to 200) numbers of teeth use the following formula in which  $P$  = pitch,  $N$  = number of teeth: Pitch Diameter =  $P \div \sin(180^\circ \div N)$ .

**Bottom Diameter:** The bottom diameter is the diameter of a circle tangent to the curve (called the seating curve) at the bottom of the tooth gap. It equals the pitch diameter minus the diameter of the roller.

**Table 4. Roller Chain Sprocket Diameters ANSI/ASME B29.1-2011 (R2016)**

These diameters and caliper factors apply only to chain of 1-inch pitch. For any other pitch, multiply the values given below by the pitch.										
Caliper Dia. (even teeth) = Pitch Diameter – Roller Dia.										
Caliper Dia. (odd teeth) = Caliper factor × Pitch – Roller Dia.										
See Table 5 for tolerances on Caliper Diameters.

<sup>a</sup> For 5-8 and 109-200 teeth see text, pages 2621, 2623.

**Caliper Diameter:** The caliper diameter is the same as the bottom diameter for a sprocket with an even number of teeth. For a sprocket with an odd number of teeth, it is defined as the distance from the bottom of one tooth gap to that of the nearest opposite tooth gap. The caliper diameter for an even tooth sprocket is equal to pitch diameter-roller diameter. The caliper diameter for an odd tooth sprocket is equal to caliper factor-roller diameter. Here, the caliper factor =  $PD \cos(90^\circ \div N)$ , where  $PD$  = pitch diameter and  $N$  = number of teeth. Caliper factors for 1-in. pitch and sprockets having 9–108 teeth are given in Table 4. For other tooth numbers use above formula. Caliper diameter tolerances are minus only and are equal to  $0.002P\sqrt{N} + 0.006$  inch for the Commercial sprockets and  $0.001P\sqrt{N} + 0.003$  inch for Precision sprockets. Tolerances are given in Table 5.

**Table 5. Minus Tolerances on the Caliper Diameters of Precision Sprockets**  
ANSI/ASME B29.1-2011 (R2016)

3.000	0.027	0.030	0.033	0.036	0.039

Minus tolerances for Commercial sprockets are twice those shown in this table.

**Outside Diameter:** OD is the diameter over the tips of teeth. Sprocket ODs for 1-in. pitch and 9–108 teeth are given in Table 4. For other tooth numbers the OD may be determined by the following formulas in which  $O$  = approximate OD;  $P$  = pitch of chain;  $N$  = number of sprocket teeth:  $O = P[0.6 + \cot(180^\circ \div N)]$ , for turned sprocket;  $O =$  pitch diameter – roller diameter +  $2 \times$  whole depth of topping hob cut, for topping hob cut sprocket.\*

\*This dimension was added in 1984 as a desirable goal for the future. It should in no way obsolete existing tools or sprockets. The whole depth  $WD$  is found from the formula:  $WD = \frac{1}{2}D_r + P[0.3 - \frac{1}{2} \tan(90 \text{ deg} \div N_a)]$ , where  $N_a$  is the intermediate number of teeth for the topping hob. For teeth range 5,  $N_a = 5$ ; 6, 6; 7-8, 7.47; 9-11, 9.9; 12-17, 14.07; 18-34, 23.54; 35 and over, 56.

**Table 6. Roller Chain Sprocket Flange Thickness and Tooth Section Profile Dimension ANSI/ASME B29.1-2011 (R2016)**

Flange chamfer may be either as in Section "A" or Section "B" or anything in between

Formulas for Dimensions of Single and Multiple Sprockets

$H = 0.375 + \frac{D}{6} + 0.01 PD$        $E = 0.625P + 0.93W$   
 $L = 4H$  for semi-steel castings       $F = 0.150 + 0.25P$   
 $C = 0.5P$        $G = 2T$   
 $C' = 0.9P$        $R = 0.4P$  for single-strand sprockets  
 $R = 0.5T$  for multiple-strand sprockets

All dimensions in inches. Where  $P$  = chain pitch and  $W$  = nominal chain width.

**Table 8. Typical Proportions of Roller Chain Bar-steel Sprockets**

$H = Z + D/6 + 0.01PD$   
 For  $PD$  up to 2 inches,  $Z = 0.125$  inch; for 2-4 inches,  $Z = 0.187$  inch; for 4-6 inches,  $Z = 0.25$  inch; and for over 6 inches,  $Z = 0.375$  inch.  
 Hub length  $L = 3.3H$ , normally, with a minimum of  $2.6H$ .  
 Hub diameter  $HD = D + 2H$ , but not more than the maximum hub diameter  $MHD$  given by the formula:  

$$MHD = P \left( \cot \frac{180^\circ}{N} - 1 \right) - 0.030$$
 where  
 $P$  = Chain pitch, in inches;  $N$  = Number of sprocket teeth

When sprocket wheels are designed with spokes, the usual assumptions made in order to determine suitable proportions are as follows: 1) that the maximum torque load acting on a sprocket is the chain tensile strength times the sprocket pitch radius; 2) that the torque load is equally divided between the arms by the rim; and 3) that each arm acts as a cantilever beam.

The arms are generally elliptical in cross section, the major axis twice the minor axis.

**Selection of Chain and Sprockets.**—The smallest applicable pitch of roller chain is desirable for quiet operation and high speed. The horsepower capacity varies with the chain pitch as shown in Table 9 for 1/4, 3/8, and 1/2 in pitch designs. However, short pitch with high working load can often be obtained by the use of multiple-strand chain.

The small sprocket selected must be large enough to accommodate the shaft. Table 10 gives maximum bore and hub diameters consistent with commercial practice for sprockets with up to 25 teeth.

After selecting the small sprocket, the number of teeth in the larger sprocket is determined by the desired ratio of the shaft speed. Overemphasis on the exactness in the speed ratio may result in a cumbersome and expensive installation. In most cases, satisfactory operation can be obtained with a minor change in speed of one or both shafts.

**Table 9. Horsepower Ratings for Roller Chain, ANSI/ASME B29.1-2011 (R2016)**

To properly use this table the following factors must be taken into consideration:														
1) Service factors														
2) Multiple Strand Factors														
3) Lubrication														
Service Factors: See Table 15.														
Multiple Strand Factors: For two strands, the multiple strand factor is 1.7; for three strands, it is 2.5; and for four strands, it is 3.3.														
Lubrication:														
Required type of lubrication is indicated at the bottom of each roller chain size section of the table. For a description of each type of lubrication, see page 2638.														
Type A — Manual or Drip Lubrication														
Type B — Bath or Disc Lubrication														
Type C — Oil Stream Lubrication														
To find the required horsepower table rating, use the following formula:														
$\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple} - \text{Strand Factor}}$

**Center Distance between Sprockets.**—The center-to-center distance between sprockets, as a general rule, should not be less than  $1\frac{1}{2}$  times the diameter of the larger sprocket and not less than 30 times the pitch nor more than about 50 times the pitch, although much depends upon the speed and other conditions. A center distance equivalent to 80 pitches may be considered an approved maximum. Very long center distances result in catenary tension in the chain. If roller-chain drives are designed correctly, the center-to-center distance for some transmissions may be so short that the sprocket teeth nearly touch each other, assuming that the load is not too great and the number of teeth is not too

small. To avoid interference of the sprocket teeth, the center distance must, of course, be somewhat greater than one-half the sum of the outside diameters of the sprockets. The chain should extend around at least 120 degrees of the pinion circumference, and this minimum amount of contact is obtained for all center distances provided the ratio is less than  $3\frac{1}{2}$  to 1. Other things being equal, a fairly long chain is recommended in preference to the shortest one allowed by the sprocket diameters, because the rate of chain elongation due to natural wear is inversely proportional to the length, and also because the greater elasticity of the longer strand tends to absorb irregularities of motion and to decrease the effect of shocks.

If possible, the center distance should be adjustable in order to take care of slack due to elongation from wear and this range of adjustment should be at least one and one-half pitches. A little slack is desirable as it allows the chain links to take the best position on the sprocket teeth and reduces the wear on the bearings. Too much sag or an excessive distance between the sprockets may cause the chain to whip up and down — a condition detrimental to smooth running and very destructive to the chain. The sprockets should run in a vertical plane, the sprocket axes being approximately horizontal, unless an idler is used on the slack side to keep the chain in position. The most satisfactory results are obtained when the slack side of the chain is on the bottom.

**Center Distance for a Given Chain Length.**—When the distance between the driving and driven sprockets can be varied to suit the length of the chain, this center distance for a tight chain may be determined by the following formula, in which  $c$  = center-to-center distance in inches;  $L$  = chain length in pitches;  $P$  = pitch of chain;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket.

$$c = \frac{P}{8} (2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2})$$

This formula is approximate, but the error is less than the variation in the length of the best chains. The length  $L$  in pitches should be an even number for a roller chain, so that the use of an offset connecting link will not be necessary.

**Idler Sprockets.**—When sprockets have a fixed center distance or are non-adjustable, it may be advisable to use an idler sprocket for taking up the slack. The idler should preferably be placed against the slack side between the two strands of the chain. When a sprocket is applied to the tight side of the chain to reduce vibration, it should be on the lower side and so located that the chain will run in a straight line between the two main sprockets. A sprocket will wear excessively if the number of teeth is too small and the speed too high, because there is impact between the teeth and rollers even though the idler carries practically no load.

**Length of Driving Chain.**—The total length of a block chain should be given in multiples of the pitch, whereas for a roller chain, the length should be in multiples of twice the pitch, because the ends must be connected with an outside and inside link. The length of a chain can be calculated accurately enough for ordinary practice by the use of the following formula, in which  $L$  = chain length in pitches;  $C$  = center distance in pitches;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left( \frac{N-n}{2\pi} \right)^2 \times \frac{1}{C}$$

Hobs designed for a given roller diameter ( $D_r$ ) and chain pitch ( $P$ ) will cut any number of teeth.

$P$  = Pitch of Chain

$P_n$  = Normal Pitch of Hob =  $1.011P$  inches

$D_s$  = Minimum Diameter of Seating Curve =  $1.005D_r + 0.003$  inches

$F$  = Radius Center for Arc  $GK$ ;  $TO = OU = P_n + 2$

$H = 0.27P$   $E = 0.03P$  = Radius of Fillet Circle

$Q$  is located on line passing through  $F$  and  $J$ . Point  $J$  is intersection of line  $XY$  with circle of diameter  $D_s$ .  $R$  is found by trial and the arc of this radius is tangent to arc  $GK$  at  $K$  and to fillet radius.

$OD$  = Outside Diameter =  $1.7(\text{Bore} + D_r + 0.7P)$  approx.

$D_n$  = Pitch Diameter =  $OD - D_s$ ;  $M$  = Helix Angle;  $\sin M = P_n + \pi D_n$

$L$  = Lead =  $P_n + \cos M$ ;  $W$  = Width = Not less than  $2 \times \text{Bore}$ , or  $6D_r$ , or  $3.2P$

To the length obtained by this formula, add enough to make a whole number (and for a roller chain, an even number) of pitches. If a roller chain has an odd number of pitches, it will be necessary to use an offset connecting link.

Another formula for obtaining chain length in which  $D$  = distance between centers of shafts;  $R$  = pitch radius of large sprocket;  $r$  = pitch radius of small sprocket;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket;  $P$  = pitch of chain and sprockets; and  $l$  = required chain length in inches, is:

$$l = \frac{180^\circ + 2\alpha}{360^\circ} NP + \frac{180^\circ - 2\alpha}{360^\circ} nP + 2D \cos \alpha \text{ where } \sin \alpha = \frac{R - r}{D}$$

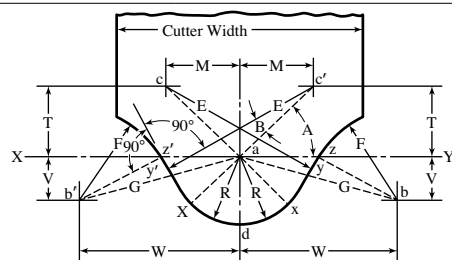

**Cutting Standard Sprocket Tooth Form.**—The proportions and seating curve data for the standard sprocket tooth form for roller chain are given in Table 11. Either formed or generating types of sprocket cutters may be employed.

**Hobs:** Only one hob will be required to cut any number of teeth for a given pitch and roller diameter. All hobs should be marked with pitch and roller diameter to be cut. Formulas and data for standard hob design are given in Table 12.

**Space Cutters:** Five cutters of this type will be required to cut from 7 teeth up for any given roller diameter. The ranges are, respectively, 7–8, 9–11, 12–17, 18–34, and 35 teeth and over. If less than 7 teeth is necessary, special cutters conforming to the required number of teeth should be used.

The regular cutters are based upon an intermediate number of teeth  $N_a$ , equal to  $2N_1N_2 \div (N_1 + N_2)$  in which  $N_1$  = minimum number of teeth and  $N_2$  = maximum number of teeth for which cutter is intended; but the topping curve radius  $F$  (see diagram in Table 13) is designed to produce adequate tooth height on a sprocket of  $N_2$  teeth. The values of  $N_a$  for the several cutters are, respectively, 7.47, 9.9, 14.07, 23.54, and 56. Formulas and construction data for space cutter layout are given in Table 13 and recommended cutter sizes are given in Table 14.

**Table 13. Standard Space Cutters for Roller-Chain Sprockets**

Data for Laying Out Space Cutter				
Range of Teeth	M	T	W	V
7–8	$0.5848D_r$	$0.5459D_r$	$1.2790D_r$	$0.5694D_r$
9–11	$0.6032D_r$	$0.5255D_r$	$1.3302D_r$	$0.4365D_r$
12–17	$0.6194D_r$	$0.5063D_r$	$1.3694D_r$	$0.2911D_r$
18–34	$0.6343D_r$	$0.4875D_r$	$1.3947D_r$	$0.1220D_r$
35 up	$0.6466D_r$	$0.4710D_r$	$1.4000D_r$	0
Range of Teeth	F	Chord $xy$	$yz$	Angle $Yab$
7–8	$0.8686D_r - 0.0015$	$0.2384D_r + 0.0003$	$0.0618D_r$	$24^\circ$
9–11	$0.8554D_r - 0.0015$	$0.2800D_r + 0.0003$	$0.0853D_r$	$18^\circ 10'$
12–17	$0.8364D_r - 0.0015$	$0.3181D_r + 0.0004$	$0.1269D_r$	$12^\circ$
18–34	$0.8073D_r - 0.0015$	$0.3540D_r + 0.0004$	$0.1922D_r$	$5^\circ$
35 up	$0.7857D_r - 0.0015$	$0.3850D_r + 0.0004$	$0.2235D_r$	$0^\circ$

$E$  (same for all ranges) =  $1.3025D_r + 0.0015$ ;  $G$  (same for all ranges) =  $1.4D_r$

See Table 14 for recommended cutter sizes.

Angle  $Yab$  is equal to  $180^\circ \div N$  when the cutter is made for a specific number of teeth. For the design of cutters covering a range of teeth, angle  $Yab$  was determined by layout to ensure chain roller clearance and to avoid pointed teeth on the larger sprockets of each range. It has values as given below for cutters covering the range of teeth shown. The following formulas are for cutters covering the standard ranges of teeth where  $N_a$  equals intermediate values given on page 2635.

$$W = 1.4D_r \cos(Yab) \quad V = 1.4D_r \sin(Yab)$$

$$yz = D_r \left[ 1.4 \sin \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 0.8 \sin \left( 18^\circ - \frac{56^\circ}{N_a} \right) \right]$$

$$F = D_r \left[ 0.8 \cos \left( 18^\circ - \frac{56^\circ}{N_a} \right) + 1.4 \cos \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 1.3025 \right] - 0.0015 \text{ in.}$$

For other points, use the value of  $N_a$  for  $N$  in the standard formulas in Table 11.

Where the same roller diameter is commonly used with chains of two different pitches it is recommended that stock cutters be made wide enough to cut sprockets for both chains.

*Marking of Cutters.*—All cutters are to be marked, giving pitch, roller diameter and range of teeth to be cut.

*Bores for Sprocket Cutters* (recommended practice) are approximately as calculated from the formula:

$$\text{Bore} = 0.7 \sqrt{(\text{Width of Cutter} + \text{Roller Diameter} + 0.7 \text{ Pitch})}$$

and are equal to 1 inch for 3/4- through 3/8-inch pitches; 1 1/4 inches for 1- through 1 1/2-inch for 1 3/4- through 2 1/4-inch pitches; 1 3/4 inches for 2 1/2-inch pitch; and 2 inches for 3-inch pitch.

*Minimum Outside Diameters of Space Cutters* for 35 teeth and over (recommended practice) are approximately as calculated from the formula:

$$\text{Outside Diameter} = 1.2(\text{Bore} + \text{Roller Diameter} + 0.7 \text{ Pitch}) + 1 \text{ in.}$$

**Shaper Cutters:** Only one will be required to cut any number of teeth for a given pitch and roller diameter. The manufacturer should be referred to for information concerning the cutter form design to be used.

**Sprocket Manufacture.**—Cast sprockets have cut teeth, and the rim, hub face, and bore are machined. The smaller sprockets are generally cut from steel bar stock, and are finished all over. Sprockets are often made from forgings or forged bars. The extent of finishing depends on the particular specifications that are applicable. Many sprockets are made by welding a steel hub to a steel plate. This process produces a one-piece sprocket of desired proportions and one that can be heat treated.

**Sprocket Materials.**—For large sprockets, cast iron is commonly used, especially in drives with large speed ratios, since the teeth of the larger sprocket are subjected to fewer chain engagements in a given time. For severe service, cast steel or steel plate is preferred.

The smaller sprockets of a drive are usually made of steel. With this material the body of the sprocket can be heat treated to produce toughness for shock resistance, and the tooth surfaces can be hardened to resist wear.

Stainless steel or bronze may be used for corrosion resistance, and Formica, nylon or other suitable plastic materials for special applications.

**Roller Chain Drive Ratings.**—In 1961, under auspices of The American Sprocket Chain Manufacturers Association (now called American Chain Association), a joint research program was begun to study pin-bushing interaction at high speeds and to gain further data on the phenomenon of chain joint galling among other research areas. These studies have shown that a separating film of lubricant is formed in chain joints in a manner similar to that found in journal bearings. These developments appear in ANSI/ASME B29.1-2011 (R2016), and are contained in Table 9. The ratings shown in Table 9 are below the galling range.

The horsepower ratings in Table 9 apply to lubricated, single-pitch, single-strand roller chains, both ANSI Standard and Heavy series. To obtain ratings of multiple-strand chains, a multiple-strand factor is applied.

The ratings in Table 9 are based upon: 1) a service factor of 1; 2) a chain length of approximately 100 pitches; 3) use of recommended lubrication methods; and 4) a drive arrangement where two aligned sprockets are mounted on parallel shafts in a horizontal plane.

Under these conditions, approximately 15,000 hours of service life at full load operation may be expected.

**Table 15. Roller Chain Drive Service Factors**

Type of Driven Load	Type of Input Power		
	Internal Combustion Engine with Hydraulic Drive	Electric Motor or Turbine	Internal Combustion Engine with Mechanical Drive
Smooth	1.0	1.0	1.2
Moderate Shock	1.2	1.3	1.4
Heavy Shock	1.4	1.5	1.7

Substantial increases in rated speed loads can be utilized, as when a service life of less than 15,000 hours is satisfactory, or when full load operation is encountered only during a portion of the required service life. Chain manufacturers should be consulted for assistance with any special application requirements.

The horsepower ratings shown in Table 9 relate to the speed of the smaller sprocket and drive selections are made on this basis, whether the drive is speed reducing or speed increasing. Drives with more than two sprockets, idlers, composite duty cycles, or other unusual conditions often require special consideration. Where quietness or extra smooth operation are of special importance, small-pitch chain operating over large diameter sprockets will minimize noise and vibration.

When making drive selection, consideration is given to the loads imposed on the chain by the type of input power and the type of equipment to be driven. Service factors are used to compensate for these loads and the *required* horsepower rating of the chain is determined by the following formula:

$$\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple} - \text{Strand Factor}}$$

*Service Factors:* The service factors in Table 15 are for normal chain loading. For unusual or extremely severe operating conditions not shown in this table, it is desirable to use larger service factors.

*Multiple-Strand Factors:* The horsepower ratings for multiple-strand chains equal single-strand ratings multiplied by these factors: for two strands, a factor of 1.7; for three strands, 2.5; and for four strands, 3.3.

**Lubrication.**—It has been shown that a separating wedge of fluid lubricant is formed in operating chain joints much like that formed in journal bearings. Therefore, fluid lubricant must be applied to ensure an oil supply to the joints and minimize metal-to-metal contact. If supplied in sufficient volume, lubrication also provides effective cooling and impact damping at higher speeds. For this reason, it is important that lubrication recommendations be followed. *The ratings in Table 9 apply only to drives lubricated in the manner specified in this table.*

Chain drives should be protected against dirt and moisture and the oil supply kept free of contamination. Periodic oil change is desirable. A good grade of non-detergent petroleum base oil is recommended. Heavy oils and greases are generally too stiff to enter and fill the chain joints. The following lubricant viscosities are recommended: For temperatures of 20° to 40°F, use SAE 20 lubricant; for 40° to 100°, use SAE 30; for 100° to 120°, use SAE 40; and for 120° to 140°, use SAE 50.

There are three basic types of lubrication for roller chain drives. The recommended type shown in Table 9 as Type A, Type B, or Type C is influenced by the chain speed and the amount of power transmitted. These are *minimum* lubrication requirements and the use of a better type (for example, Type C instead of Type B) is acceptable and may be beneficial. Chain life can vary appreciably depending upon the way the drive is lubricated. The better the chain lubrication, the longer the chain life. For this reason, it is important that the lubrication recommendations be followed when using the ratings given in Table 9. The types of lubrication are as follows:

*Type A — Manual or Drip Lubrication:* In manual lubrication, oil is applied copiously with a brush or spout can at least once every 8 hours of operation. Volume and frequency should be sufficient to prevent overheating of the chain or discoloration of the chain joints. In drip lubrication, oil drops from a drip lubricator are directed between the link plate edges. The volume and frequency should be sufficient to prevent discoloration of the lubricant in the chain joints. Precautions must be taken against misdirection of the drops by windage.

*Type B — Bath or Disc Lubrication:* In bath lubrication, the lower strand of the chain runs through a sump of oil in the drive housing. The oil level should reach the pitch line of the chain at its lowest point while operating. In disc lubrication, the chain operates above the oil level. The disc picks up oil from the sump and deposits it onto the chain, usually by means of a trough. The diameter of the disc should be such as to produce rim speeds of between 600 and 8000 feet per minute.

*Type C — Oil Stream Lubrication:* The lubricant is usually supplied by a circulating pump capable of supplying each chain drive with a continuous stream of oil. The oil should be applied inside the chain loop evenly across the chain width, and directed at the slack strand.

The chain manufacturer should be consulted when it appears desirable to use a type of lubricant other than that recommended.

**Installation and Alignment.**—Sprockets should have the tooth form, thickness, profile, and diameters conforming to ANSI/ASME B29.1. For maximum service life small sprockets operating at moderate to high speeds, or near the rated horsepower, should have hardened teeth. Normally, large sprockets should not exceed 120 teeth.

In general a center distance of 30 to 50 chain pitches is most desirable. The distance between sprocket centers should provide at least a 120 degree chain wrap on the smaller sprocket. Drives may be installed with either adjustable or fixed center distances. Adjustable centers simplify the control of chain slack. Sufficient housing clearance must always be provided for the chain slack to obtain full chain life.

Accurate alignment of shafts and sprocket tooth faces provides uniform distribution of the load across the entire chain width and contributes substantially to optimum drive life.

Shafting, bearings, and foundations should be suitable to maintain the initial alignment. Periodic maintenance should include an inspection of alignment.

**Example of Roller Chain Drive Design Procedure.**—The selection of a roller chain and sprockets for a specific design requirement is best accomplished by a systematic step-by-step procedure such as is used in the following example.

*Example:* Select a roller chain drive to transmit 10 horsepower from a countershaft to the main shaft of a wire drawing machine. The countershaft is  $1\frac{15}{16}$ -inches diameter and operates at 1000 rpm. The main shaft is also  $1\frac{15}{16}$ -inches diameter and must operate between 378 and 382 rpm. Shaft centers, once established, are fixed and by initial calculations must be approximately  $22\frac{1}{2}$  inches. The load on the main shaft is uneven and presents “peaks,” which place it in the heavy shock load category. The input power is supplied by an electric motor. The driving head is fully enclosed and all parts are lubricated from a central system.

*Step 1. Service Factor:* From Table 15 the service factor for heavy shock load and an electric motor drive is 1.5.

*Step 2. Design Horsepower:* The horsepower upon which the chain selection is based (design horsepower) is equal to the specified horsepower multiplied by the service factor,  $10 \times 1.5 = 15$  hp.

*Step 3. Chain Pitch and Small Sprocket Size for Single-Strand Drive:* In Table 9 under 1000 rpm, a  $\frac{5}{8}$ -inch pitch chain with a 24-tooth sprocket or a  $\frac{3}{4}$ -inch pitch chain with a 15-tooth sprocket are possible choices.

*Step 4. Check of Chain Pitch and Sprocket Selection:* From Table 10 it is seen that only the 24-tooth sprocket in Step 3 can be bored to fit the  $1\frac{15}{16}$ -inch diameter main shaft. In Table 9 a  $\frac{5}{8}$ -pitch chain at a small sprocket speed of 1000 rpm is rated at 15.5 hp for a 24-tooth sprocket.

*Step 5. Selection of Large Sprocket:* Since the driver is to operate at 1000 rpm and the driven at a minimum of 378 rpm, the speed ratio  $1000/378 = 2.646$ . Therefore, the large sprocket should have  $24 \times 2.646 = 63.5$  (use 63) teeth.

This combination of 24 and 63 teeth will produce a main drive shaft speed of 381 rpm which is within the limitation of 378 to 382 rpm established in the original specification.

*Step 6. Computation of Chain Length:* Since the 24- and 63-tooth sprockets are to be placed on  $22\frac{1}{2}$ -inch centers, the chain length is determined from the formula:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left( \frac{N-n}{2\pi} \right)^2 \times \frac{1}{C}$$

where  $L$  = chain length in pitches;  $C$  = shaft center distance in pitches;  $N$  = number of teeth in large sprocket; and  $n$  = number of teeth in small sprocket.

$$L = 2 \times 36 + \frac{63 + 24}{2} + \left( \frac{63 - 24}{6.28} \right)^2 \times \frac{1}{36} = 116.57 \text{ pitches}$$

*Step 7. Correction of Center Distance:* Since the chain is to couple at a whole number of pitches, 116 pitches will be used and the center distance recomputed based on this figure using the formula on page 2632 where  $c$  is the center distance in inches and  $P$  is the pitch.

$$\begin{aligned} c &= \frac{P}{8} (2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2}) \\ &= \frac{5}{64} (2 \times 116 - 63 - 24 + \sqrt{(2 \times 116 - 63 - 24)^2 - 0.810(63 - 24)^2}) \\ &= \frac{5}{64} (145 + 140.69) = 22.32 \text{ inches, say } 22\frac{3}{8} \text{ inches} \end{aligned}$$

## BALL AND ACME LEADSCREWS

### Leadscrew Overview

Leadscrew assemblies convert rotary motion into linear travel and are well suited to precise control using electric motors. Acme leadscrews, much like machine screws, are threaded to allow a mating nut to be pushed or pulled along the axis of the screw as the shaft is rotated. Ball screws are threaded to allow ball bearings to support the attached nut. The nut has raceways that allow the ball bearings to recirculate as the nut travels down the axis of the shaft. Both provide efficient and accurate linear positioning for motion control applications. Each has strengths and weaknesses that makes each type of technology more suitable for different types of applications.

**Ball Screws.**—Ball screws generally require lower-torque motors than similarly sized Acme screws due to their higher efficiency in converting energy into linear movement. This efficiency is generally above 90 percent compared to 40 percent for Acme screws with plastic nuts and 25 percent for acme screws with bronze-nuts. Ball screws can handle higher loading with high travel rates and lower backlash, though both technologies offer various anti-backlash nut assemblies. Ball screw life is more easily predicted using ball bearing load data. Compared to acme screws, ball screw assemblies exhibit a lower degradation in positional accuracy over time due to wear on the contact surfaces. Ball screws are more expensive and can be noisier than acme screws. Ball screws may back drive the shaft in vertical orientations.

Fig. 1a. Ball Screw Cross Section

Fig. 1b. Ball Screw Detail

**Acme Screws.**—Acme screws with plastic nuts generally have an initial lower cost and lower noise levels compared to ball screws. Bronze-nut acme screws offer the lowest leadscrew cost as well as the lowest leadscrew performance characteristics. Due to their low efficiency, bronze-nut acme screws may not back drive in some applications where a ball screw would. Loading and travel rates are lower than ball screws. Also, compared to ball screws, lubrication requirements are higher and predicting travel life of acme screws is more difficult due to higher variations in friction and heat build up.

Fig. 2a. Acme Leadscrew with Anti-backlash Nut.

Fig. 2b. Acme Screw Detail

**General Leadscrew Design Considerations.**—The following design criteria should be considered when selecting leadscrews.

*Load:* The load is the weight “as seen by the screw.” For vertical applications such as lifting or jacking the load equals the weight of the load being moved. For horizontal applications the “load seen” equals the weight of the load times the coefficient of friction of the supporting media. Another way to determine the load in an actual application is to attach a scale to the load and pull it. Base the load on the moving force required, not on the higher starting (breakaway) force.

*Tension and Compression Load:* For reduced screw thread sizes, design for tension loads whenever possible. Compression load designs must factor in column strength to prevent buckling.

*Back-drive:* When a ball screw or acme nut is forced to move linearly along the shaft by an applied force, or gravity in vertical orientation, it forces or back-drives the shaft making it rotate. With their higher efficiency and lower initial start up (breakway) friction value, ball screw assemblies in vertical orientations may back-drive their shafts.

*Driving Torque:* The driving torque ( $T_d$ ) is the amount of force required to rotate the screw and move a load.

$$T_d = \frac{P \times L}{2\pi e}$$

where  $T_d$  = driving torque (lb-in)

$P$  = load (lbs)

$L$  = lead of screw (in/revolution)

$e$  = ball bearing screw efficiency (approximately 0.90 for ball screws, 0.40 for acme screws with plastic nuts, and 0.25 for acme screws with bronze nuts.)

*Accuracy:* Several factors affect accuracy. One factor is the lead deviation in inches per foot. Typical values can range from 0.005 in/ft to 0.001 in/ft. Backlash may also be a consideration in applications that require precise positioning in both directions and in CNC applications. A final consideration is accuracy versus time degradation due to screw wear and ball bearing fatigue. This is especially important in systems that require precise positioning but do not have closed-loop feedback controls. Ball screws have an advantage in long term accuracy since the useful life of ball screws is determined by metal fatigue rather than the ordinary wear characteristics of a conventional screw. Due to rolling contact, very little dimensional change occurs over the life of a ball bearing screw, thus eliminating the need for frequent compensating adjustments.

*Lead:* The distance the nut travels with one rotation of the screw.

*Speed:* When rapid travel is required, design for screws with a high lead to reduce shaft speed to avoid rotational and vibrational side effects.

*Life:* The recommended operating loads for ball screw assemblies are based on a predicted life of one million inches of travel, providing the assembly is lubricated. However, it is possible to operate at greater loads if a reduced life is acceptable. The load should not exceed the maximum static load shown in manufacturer design tables.

*Backlash:* Backlash, end play, positional inaccuracy, or lost motion between the nut and the screw can be eliminated by utilizing a preloaded nut assembly. Backlash can also be reduced, at increased cost, in ball screws by changing the conformity ratio (ball track radius/ball diameter) as well as using ogival (gothic) ball tracks. Fig. 3 illustrates the contact points between a preloaded ball screw assembly and the shaft.

Fig. 3. Contact Points in a Preloaded Anti-Backlash Ball Screw Assembly

**End Supports:** End support type, free or fixed, and the number of end supports for a lead-screw shaft can have a significant impact on the speed and load capacity of the assembly.

**Environment:** Temperature extremes, dirty, dusty conditions, corrosive compounds, and metal chips can cause serious problems with lead-screw assemblies. For applications in such conditions the use of wipers, boots, or both should be considered. Stainless steel or plated assemblies should be considered for corrosive applications. Corrosive environments can also attack lubricants and thus indirectly damage the assemblies.

**Wipers:** Brush type wipers maximize ball screw performance by helping to spread lubricant over the length of the screw and preventing internal ball nut contamination from foreign materials. Bellows and telescopic wipers are recommended for severely "dirty" environments.

**Lubrication:** Ball screws must be lubricated and kept clean. Failure to lubricate can substantially reduce bearing life. Oil and grease can be used but grease is not recommended for low temperature or high speed applications.

**PV Value:** Speed and load limits for acme leadscrew assemblies using plastic nuts are generally limited by heat build-up. The factor which affects heat generation in an application is the product of the pressure (lbs/in<sup>2</sup>) on the nut, and the surface velocity at the thread major diameter. This product is called the PV value.

**CNC Considerations:** CNC machine tools require the elimination of backlash and the minimization of elastic deflection to achieve high system stiffness, response, and repeatability of positioning.

**Ball Screw Selection.**—Many types and styles of ball screws and ball screw assemblies are offered by manufacturers. Consult the vendor's specific data sheets for precise design criteria. The selection of the correct ball screw and nut for a particular application involves four factors, all of which are interrelated. These are: the equivalent load measured in pounds, the required life measured in linear inches of travel, travel speed measured in inches per minute, and the length between bearings measured in inches.

Fig. 4. Ball Screw Detail

**Design Overview:** To design a ball screw assembly many interrelated factors such as load, bearing length, life, and speed must be considered. Changing one parameter will influence others and generally an iterative approach to balancing these requirements is required. An example is the choice of a fine lead versus coarse lead. A fine line lead provides better positioning sensitivity and lower drive torque, but also requires a higher rotary speed to achieve the same linear rate of speed. A coarse lead results in lower rotary speed, but requires a higher drive torque that may require a larger motor and related drive components. **Table 1** identifies some of these design interrelationships.

**Table 1. Ball Screw Design Factor Interrelationships**

Increase In	Affects	How	Increase In	Affects	How
Screw Length	Critical speed	Decreases	End Mounting Rigidity	Critical speed	Increases
	Compression load	Decreases		Compression load	Increases
Screw Diameter	Critical speed	Increases	Load	System stiffness	Increases
	Inertia	Increases		Life	Decreases
	Compression load	Increases	Preload	Positioning accuracy	Increases
	Stiffness	Increases		System stiffness	Increases
	Spring Rate	Increases		Drag torque	Increases
Load capacity	Increases	Angular Velocity	Critical speed	Decreases	
Lead	Drive torque	Increases	Nut length	Load capacity	Increases
	Angular velocity	Decreases		Stiffness	Increases
	Load capacity	Increases	Ball diameter	Life	Increases
	Positioning accuracy	Decreases		Stiffness	Increases
	Ball diameter	Increases		Load capacity	Increases

**Screws, Power Transmission.**—The square form of thread has a somewhat higher efficiency than threads with sloping sides, although when the angle of the thread form is comparatively small, as in the case of an Acme thread, there is little increase in frictional losses. The Acme thread has superseded the square form on many classes of equipment requiring lead screws or other power transmitting screws, because the former has practical advantages in regard to cutting and also in compensating for wear between the screw and nut. Multiple thread screws are much more efficient than single-thread screws, as the efficiency is affected by the helix angle of the thread.

**Force Required to Turn Screw:** In determining the force which must be applied at the end of a given lever-arm in order to turn a screw (or nut surrounding it), there are two conditions to be considered:

1) When rotation is such that the load *resists* the movement of the screw, as in raising a

load with a screw jack,  $F = L \times \frac{l + 2r\pi\mu}{2r\pi - \mu l} \times \frac{r}{R}$ .

2) When rotation is such that the load *assists* the movement of the screw, as in lowering a

load,  $F = L \times \frac{2r\pi\mu - l}{2r\pi + \mu l} \times \frac{r}{R}$ .

In these formulas,  $F$  = force applied at end of lever-arm;  $L$  = load moved by screw;  $R$  = length of lever-arm;  $l$  = lead of screw thread;  $r$  = mean or pitch radius of screw;  $\mu$  = coefficient of friction. If lead  $l$  is large in proportion to the diameter so that the helix angle is large,  $F$  will have a negative value, indicating that the screw will turn due to the load alone. The efficiency between a screw and nut increases quite rapidly for helix angles up to 10 or 15 degrees (measured from a plane perpendicular to the screw axis). The efficiency remains nearly constant for angles between about 25 and 65 degrees, and the angle of maximum efficiency is between 40 and 50 degrees. A screw will not be self-locking if the efficiency exceeds 50 percent.

## ELECTRIC MOTORS

**Classes of NEMA Standards.**—National Electrical Manufacturers Association Standards (NEMA), available from NEMA at 1300 North 17th Street, Suite 900, Arlington, VA 22209, [www.nema.org](http://www.nema.org), are of two classes: 1) *NEMA Standard*, which relates to a product commercially standardized and subject to repetitive manufacture, which standard has been approved by at least 90 percent of the members of the Subdivision eligible to vote thereon; and 2) *Suggested Standard for Future Design*, which may not have been regularly applied to a commercial product, but which suggests a sound engineering approach to future development and has been approved by at least two-thirds of the members of the Subdivision eligible to vote thereon.

*Authorized Engineering Information* consists of explanatory data and other engineering information of an informative character not falling within the classification of NEMA Standard or Suggested Standard for Future Design.

**Mounting Dimensions and Frame Sizes for Electric Motors.**—Dimensions for foot-mounted electric motors as standardized in the United States by the National Electrical Manufacturers Association (NEMA) include the spacing of bolt holes in the feet of the motor, the distance from the bottom of the feet to the centerline of the motor shaft, the size of the conduit, the length and diameter of shaft, and other dimensions likely to be required by designers or manufacturers of motor-driven equipment. The Standard provides dimensions for face-mounted and flange-mounted motors by means of standard motor frame numbers.

Standard dimensions also are given where the motor is to be mounted upon a belt-tightening base or upon rails.

The NEMA standards also prescribe lettering for dimension drawings, mounting and terminal housing locations and dimensions, symbols and terminal connections, and provision for grounding of field wiring. In addition, the standards give recommended knock-out and clearance hole dimensions; tolerances on shaft extension diameters and keyseats; methods of measuring shaft run-out and eccentricity, also face runout of mounting surfaces; and tolerances of face-mounted and flanged-mounted motors.

**Design Letters of Polyphase Integral-Horsepower Motors.**—Designs A, B, C, and D motors are squirrel-cage motors designed to withstand full voltage starting and developing locked-rotor torque and breakdown torque, drawing locked-rotor current, and having a slip as specified below:

*Design A:* Locked-rotor torque as shown in [Table 2](#), breakdown torque as shown in [Table 3](#), locked-rotor current higher than the values shown in [Table 1](#), and a slip at rated load of less than 5 percent. Motors with 10 or more poles may have a slightly greater slip.

**Table 1. NEMA Standard Locked-Rotor Current of 3-Phase 60-Hertz  
Integral-Horsepower Squirrel-Cage Induction Motors Rated at 230 Volts**

Horse-power	Locked-rotor Current, Amps.	Design Letters	Horse-power	Locked-rotor Current, Amps.	Design Letters	Horse-power	Locked-rotor Current, Amps.	Design Letters
½	20	B, D	7½	127	B, C, D	50	725	B, C, D
¾	25	B, D	10	162	B, C, D	60	870	B, C, D
1	30	B, D	15	232	B, C, D	75	1085	B, C, D
1½	40	B, D	20	290	B, C, D	100	1450	B, C, D
2	50	B, D	25	365	B, C, D	125	1815	B, C, D
3	64	B, C, D	30	435	B, C, D	150	2170	B, C, D
5	92	B, C, D	40	580	B, C, D	200	2900	B, C

*Note:* The locked-rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage and frequency applied to the motor.

For motors designed for voltages other than 230 volts, the locked-rotor current is inversely proportional to the voltages. For motors larger than 200 hp, see NEMA Standard MG 1-12.34.

200	100	100	120	120	115	...	...					

<sup>a</sup> These values represent the upper limit of application for these motors.

*Note:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

The locked-rotor torque of Design D, 60- and 50-hertz 4-, 6-, and 8-pole single-speed, polyphase squirrel-cage motors rated 150 hp and smaller, with rated voltage and frequency applied is 275 percent of full-load torque, which represents the upper limit of application for these motors.

For motors larger than 200 hp, see NEMA Standard MG 1-12.37.

<sup>a</sup> Design A values are in excess of those shown.

These values represent the upper limit of the range of application for these motors. For above 200 hp, see NEMA Standard MG1-12.38.

*Design B:* Locked-rotor torque as shown in Table 2, breakdown torque as shown in Table 3, locked-rotor current not exceeding that in Table 1, and a slip at rated load of less than 5 percent. Motors with 10 or more poles may have a slightly greater slip.

*Design C:* Locked-rotor torque for special high-torque applications up to values shown in Table 2, breakdown torque up to values shown in Table 3, locked-rotor current not exceeding values shown in Table 1 and a slip at rated load of less than 5 percent.

*Design D:* Locked-rotor torque as indicated in Table 2, locked-rotor current not greater than that shown in Table 1 and a slip at rated load of 5 percent or more.

**Torque and Current Definitions.**—The definitions which follow have been adopted as standard by the National Electrical Manufacturers Association.

*Locked-Rotor or Static Torque:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

*Breakdown Torque:* The breakdown torque of a motor is the maximum torque which the motor will develop, with rated voltage applied at rated frequency, without an abrupt drop in speed (see Table 4).

*Full-Load Torque:* The full-load torque of a motor is the torque necessary to produce its rated horsepower at full load speed. In pounds at 1-foot radius, it is equal to the horsepower times 5252 divided by the full-load speed.

*Pull-Out Torque:* The pull-out torque of a synchronous motor is the maximum sustained torque which the motor will develop at synchronous speed with rated voltage applied at rated frequency and with normal excitation.

*Pull-In Torque:* The pull-in torque of a synchronous motor is the maximum constant torque under which the motor will pull its connected inertia load into synchronism at rated voltage and frequency, when its field excitation is applied.

*Pull-Up Torque:* The pull-up torque of an alternating current motor is the minimum torque developed by the motor during the period of acceleration from rest to the speed at which breakdown torque occurs. For motors which do not have a definite breakdown torque, the pull-up torque is the minimum torque developed up to rated speed.

*Locked Rotor Current:* The locked rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage (and rated frequency in the case of alternating-current motors) applied to the motor.

**Table 4. NEMA Standard Breakdown Torque of Polyphase Wound-Rotor Motors with Continuous Ratings — 60- and 50-Hertz**

Horsepower	Speed, rpm			Horsepower	Speed, rpm		
	1800	1200	900		1800	1200	900
	Percent of Full-load Torque				Percent of Full-load Torque		
1	...	...	250	7½	275	250	225
1½	...	...	250	10	275	250	225
2	275	275	250	15	250	225	225
3	275	275	250	20-200, incl.	225	225	225
5	275	275	250	...	...	...	...

These values represent the upper limit of the range of application for these motors.

**Standard Direction of Motor Rotation.**—The standard direction of rotation for all non-reversing direct-current motors, all alternating-current single-phase motors, all synchronous motors, and all universal motors, is counterclockwise when facing that end of the motor opposite the drive.

This rule does not apply to two- and three-phase induction motors, as in most applications the phase sequence of the power lines is rarely known.

**Motor Types According to Variability of Speed.**—Five types of motors classified according to variability of speed are:

*Constant-speed Motors:* In this type of motor the normal operating speed is constant or practically constant; for example, a synchronous motor, an induction motor with small slip, or a direct-current shunt-wound motor.

*Varying-speed Motor:* In this type of motor, the speed varies with the load, ordinarily decreasing when the load increases; such as a series-wound or repulsion motor.

*Adjustable-speed Motor:* In this type of motor, the speed can be varied gradually over a considerable range, but when once adjusted remains practically unaffected by the load; such as a direct-current shunt-wound motor with field resistance control designed for a considerable range of speed adjustment.

The base speed of an adjustable-speed motor is the lowest rated speed obtained at rated load and rated voltage at the temperature rise specified in the rating.

*Adjustable Varying-speed Motor:* This type of motor is one in which the speed can be adjusted gradually, but when once adjusted for a given load will vary in considerable degree with the change in load; such as a direct-current compound-wound motor adjusted by field control or a wound-rotor induction motor with rheostatic speed control.

*Multispeed Motor:* This type of motor is one which can be operated at any one of two or more definite speeds, each being practically independent of the load; such as a direct-current motor with two armature windings or an induction motor with windings capable of various pole groupings. In the case of multispeed permanent-split capacitor and shaded pole motors, the speeds are dependent upon the load.

**Pull-Up Torque.**—NEMA Standard pull up torques for single-speed, polyphase, squirrel-cage integral-horsepower motors, Designs A and B, with continuous ratings and with rated voltage and frequency applied are as follows: When the locked-rotor torque given in Table 2 is 110 percent or less, the pull-up torque is 90 percent of the locked-rotor torque; when the locked-rotor torque is greater than 110 percent but less than 145 percent, the pull-up torque is 100 percent of full-load torque; and when the locked-rotor torque is 145 percent or more, the pull-up torque is 70 percent of the locked-rotor torque.

For Design C motors, with rated voltage and frequency applied, the pull-up torque is not less than 70 percent of the locked-rotor torque as given in Table 2.

### Types and Characteristics of Electric Motors

**Types of Direct-Current Motors.**—Direct-current motors may be grouped into three general classes: series-wound; shunt-wound; and compound-wound.

In the *series-wound motor* the field windings, which are fixed in the stator frame, and the armature windings, which are placed around the rotor, are connected in series so that all current passing through the armature also passes through the field. In the *shunt-wound motor*, both armature and field are connected across the main power supply so that the armature and field currents are separate. In the *compound-wound motor*, both series and shunt field windings are provided and these may be connected so that the currents in both are flowing in the same direction, called *cumulative compounding*, or so that the currents in each are flowing in opposite directions, called *differential compounding*.

**Characteristics of Series-Wound Direct-Current Motors.**—In the series-wound motor, any increase in load results in more current passing through the armature and the field windings. As the field is strengthened by this increased current, the motor speed decreases. Conversely, as the load is decreased the field is weakened and the speed increases and at very light loads may become excessive. For this reason, series-wound direct-current motors are usually directly connected or geared to the load to prevent “runaway.” (A series-wound motor, designated as series-shunt wound, is sometimes provided with a light shunt field winding to prevent dangerously high speeds at light loads.) The increase in armature current with increasing load produces increased torque, so that the series-wound motor is

particularly suited to heavy starting duty and where severe overloads may be expected. Its speed may be adjusted by means of a variable resistance placed in series with the motor, but due to variation with load, the speed cannot be held at any constant value. This variation of speed with load becomes greater as the speed is reduced. Series-wound motors are used where the load is practically constant and can easily be controlled by hand. They are usually limited to traction and lifting service.

**Shunt-Wound Direct-Current Motors.**—In the shunt-wound motor, the strength of the field is not affected appreciably by change in the load, so that a fairly constant speed (about 10 to 12 percent drop from no load to full load speed) is obtainable. This type of motor may be used for the operation of machines requiring an approximately constant speed and imposing low starting torque and light overload on the motor.

The shunt-wound motor becomes an adjustable-speed motor by means of field control or by armature control. If a variable resistance is placed in the field circuit, the amount of current in the field windings and hence the speed of rotation can be controlled. As the speed increases, the torque decreases proportionately, resulting in nearly constant horsepower. A speed range of 6 to 1 is possible using field control, but 4 to 1 is more common. Speed regulation is somewhat greater than in the constant-speed shunt-wound motors, ranging from about 15 to 22 percent. If a variable resistance is placed in the armature circuit, the voltage applied to the armature can be reduced and hence the speed of rotation can be reduced over a range of about 2 to 1. With armature control, speed regulation becomes poorer as speed is decreased, and is about 100 percent for a 2 to 1 speed range. Since the current through the field remains unchanged, the torque remains constant.

*Machine Tool Applications:* The adjustable-speed shunt-wound motors are useful on larger machines of the boring mill, lathe, and planer type and are particularly adapted to spindle drives because constant horsepower characteristics permit heavy cuts at low speed and light or finishing cuts at high speed. They have long been used for planer drives because they can provide an adjustable low speed for the cutting stroke and a high speed for the return stroke. Their application has been limited, however, to plants in which direct-current power is available.

**Adjustable-Voltage Shunt-Wound Motor Drive.**—More extensive use of the shunt-wound motor has been made possible by a combination drive that includes a means of converting alternating current to direct current. This conversion may be effected by a self-contained unit consisting of a separately excited direct-current generator driven by a constant speed alternating-current motor connected to the regular alternating-current line, or by an electronic rectifier with suitable controls connected to the regular alternating-current supply lines. The latter has the advantage of causing no vibration when mounted directly on the machine tool, an important factor in certain types of grinders.

In this type of adjustable-speed, shunt-wound motor drive, speed control is effected by varying the voltage applied to the armature while supplying constant voltage to the field. In addition to providing for the adjustment of the voltage supplied by the conversion unit to the armature of the shunt-wound motor, the amount of current passing through the motor field may also be controlled. In fact, a single control may be provided to vary the motor speed from minimum to base speed (speed of the motor at full load with rated voltage on armature and field) by varying the voltage applied to the armature and from base speed to maximum speed by varying the current flowing through the field. When so controlled, the motor operates at constant torque up to base speed and at constant horsepower above base speed.

*Speed Range:* Speed ranges of at least 20 to 1 below base speed and 4 or 5 to 1 above base speed (a total range of 100 to 1, or more) are obtainable as compared with about 2 to 1 below normal speed and 3 or 4 to 1 above normal speed for the conventional type of control. Speed regulation may be as great as 25 percent at high speeds. Special electronic controls, when used with this type shunt motor drive, make possible maintenance of motor

speeds with as little variation as  $\frac{1}{2}$  to 1 percent of full load speed from full load to no load over a line voltage variation of  $\pm 10$  percent and over any normal variation in motor temperature and ambient temperature.

*Applications:* These direct-current, adjustable-voltage drives, as they are sometimes called, have been applied successfully to such machine tools as planers, milling machines, boring mills and lathes, as well as to other industrial machines where wide, stepless speed control, uniform speed under all operating conditions, constant torque acceleration and adaptability to automatic operation are required.

**Compound-Wound Motors.**—In the compound-wound motor, the speed variation due to load changes is much less than in the series-wound motor, but greater than in the shunt-wound motor (ranging up to 25 percent from full load to no load). It has a greater starting torque than the shunt-wound motor, is able to withstand heavier overloads, but has a narrower adjustable speed range. Standard motors of this type have a cumulative-compound winding, the differential-compound winding being limited to special applications. They are used where the starting load is very heavy or where the load changes suddenly and violently as with reciprocating pumps, printing presses and punch presses.

**Types of Polyphase Alternating-Current Motors.**—The most widely used polyphase motors are of the induction type. The “squirrel cage” induction motor consists of a wound stator which is connected to an external source of alternating-current power and a laminated steel core rotor with a number of heavy aluminum or copper conductors set into the core around its periphery and parallel to its axis. These conductors are connected together at each end of the rotor by a heavy ring, which provides closed paths for the currents induced in the rotor to circulate. The rotor bars form, in effect, a “squirrel cage” from which the motor takes its name.

*Wound-rotor Type of Induction Motor:* This type has, in addition to a squirrel cage, a series of coils set into the rotor which are connected through slip-rings to external variable resistors. By varying the resistance of the wound-rotor circuits, the amount of current flowing in these circuits and hence the speed of the motor can be controlled. Since the rotor of an induction motor is not connected to the power supply, the motor is said to operate by transfer action and is analogous to a transformer with a short-circuited secondary that is free to rotate. Induction motors are built with a wide range of speed and torque characteristics which are discussed under “Operating Characteristics of Squirrel-cage Induction Motors.”

*Synchronous Motor:* The other type of polyphase alternating-current motor used industrially is the *synchronous motor*. In contrast to the induction motor, the rotor of the synchronous motor is connected to a direct-current supply which provides a field that rotates in step with the alternating-current field in the stator. After having been brought up to synchronous speed, which is governed by the frequency of the power supply and the number of poles in the rotor, the synchronous motor operates at this constant speed throughout its entire load range.

**Operating Characteristics of Squirrel-Cage Induction Motors.**—In general, squirrel-cage induction motors are simple in design and construction and offer rugged service. They are essentially constant-speed motors, their speed changing very little with load and not being subject to adjustment. They are used for a wide range of industrial applications calling for integral horsepower ratings. According to the NEMA (National Electrical Manufacturers Association) Standards, there are four classes of squirrel-cage induction motors designated respectively as *A*, *B*, *C*, and *D*.

*Design A* motors are not commonly used since *Design B* has similar characteristics with the advantage of lower starting current.

*Design B* motors may be designated as a general purpose type suitable for the majority of polyphase alternating-current applications such as blowers, compressors, drill presses, grinders, hammer mills, lathes, planers, polishers, saws, screw machines, shakers,

stokers, etc. The starting torque at 1800 rpm is 250 to 275 percent of full load torque for 3 hp (2.24 kW) and below; for 5–75 hp (3.73–56 kW) ratings the starting torque ranges from 185 to 150 percent of full load torque. They have low starting current requirements, usually no more than 5 to 6 times full load current and can be started at full voltage. Their slip (difference between synchronous speed and actual speed at rated load) is relatively low.

*Design C* motors have high starting torque (up to 250 percent of full load torque) but low starting current. They can be started at full voltage. Slip at rated load is relatively low. They are used for compressors requiring a loaded start, heavy conveyors, reciprocating pumps and other applications requiring high starting torque.

*Design D* motors have high slip at rated load, that is, the motor speed drops off appreciably as the load increases, permitting use of the stored energy of a flywheel. They provide heavy starting torque, up to 275 percent of full load torque, are quiet in operation and have relatively low starting current. Applications are for impact, shock and other high peak loads or flywheel drives such as trains, elevators, hoists, punch and drawing presses, shears, etc.

*Design F* motors are no longer standard. They had low starting torque, about 125 percent of full-load torque, and low starting current. They were used to drive machines which required infrequent starting at no load or at very light load.

**Multiple-Speed Induction Motors.**—This type has a number of windings in the stator so arranged and connected that the number of effective poles and hence the speed can be changed. These motors are for the same types of starting conditions as the conventional squirrel-cage induction motors and are available in designs that provide constant horsepower at all rated speeds and in designs that provide constant torque at all rated speeds.

Typical speed combinations obtainable in these motors are 600, 900, 1200 and 1800 rpm; 450, 600, 900 and 1200 rpm; and 600, 720, 900 and 1200 rpm.

Where a gradual change in speed is called for, a wound rotor may be provided in addition to the multiple stator windings.

**Wound-Rotor Induction Motors.**—These motors are designed for applications where extremely low starting current with high starting torque are called for, such as in blowers, conveyors, compressors, fans and pumps. They may be employed for adjustable-varying speed service where the speed range does not extend below 50 percent of synchronous speed, as for steel plate-forming rolls, printing presses, cranes, blowers, stokers, lathes and milling machines of certain types. The speed regulation of a wound rotor induction motor ranges from 5 to 10 percent at maximum speed and from 18 to 30 percent at low speed. They are also employed for reversing service as in cranes, gates, hoists and elevators.

**High-Frequency Induction Motors.**—This type is used in conjunction with frequency changers when very high speeds are desired, as on grinders, drills, routers, portable tools or woodworking machinery. These motors have an advantage over the series-wound or universal type of high speed motor in that they operate at a relatively constant speed over the entire load range. A motor-generator set, a two-unit frequency converter or a single unit inductor frequency converter may be used to supply three-phase power at the frequency required. The single unit frequency converter may be obtained for delivering any one of a number of frequencies ranging from 360 to 2160 cycles and it is self-driven and self-excited from the general polyphase power supply.

**Synchronous Motors.**—These are widely used in electric timing devices; to drive machines that must operate in synchronism; and also to operate compressors, rolling mills, crushers which are started without load, paper mill screens, shredders, vacuum pumps and motor-generator sets. Synchronous motors have an inherently high power factor and are often employed to make corrections for the low power factor of other types of motors on the same system.

**Types of Single-Phase Alternating-Current Motors.**—Most of the single-phase alternating-current motors are basically induction motors distinguished by different arrangements for starting. (A single-phase induction motor with only a squirrel-cage rotor has no starting torque.) In the *capacitor-start* single-phase motor, an auxiliary winding in the stator is connected in series with a capacitor and a centrifugal switch. During the starting and accelerating period the motor operates as a two-phase induction motor. At about two-thirds full-load speed, the auxiliary circuit is disconnected by the switch and the motor then runs as a single-phase induction motor. In the *capacitor-start, capacitor-run* motor, the auxiliary circuit is arranged to provide high effective capacity for high starting torque and to remain connected to the line but with reduced capacity during the running period. In the *single-value capacitor* or *capacitor split-phase* motor, a relatively small continuously-rated capacitor is permanently connected in one of the two stator windings and the motor both starts and runs like a two-phase motor.

In the *repulsion-start* single-phase motor, a drum-wound rotor circuit is connected to a commutator with a pair of short-circuited brushes set so that the magnetic axis of the rotor winding is inclined to the magnetic axis of the stator winding. The current flowing in this rotor circuit reacts with the field to produce starting and accelerating torques. At about two-thirds full load speed the brushes are lifted, the commutator is short circuited and the motor runs as a single-phase squirrel-cage motor. The *repulsion* motor employs a repulsion winding on the rotor for both starting and running. The *repulsion-induction* motor has an outer winding on the rotor acting as a repulsion winding and an inner squirrel-cage winding. As the motor comes up to speed, the induced rotor current partially shifts from the repulsion winding to the squirrel-cage winding and the motor runs partly as an induction motor.

In the *split-phase* motor, an auxiliary winding in the stator is used for starting with either a resistance connected in series with the auxiliary winding (*resistance-start*) or a reactor in series with the main winding (*reactor-start*).

The *series-wound* single-phase motor has a rotor winding in series with the stator winding as in the series-wound direct-current motor. Since this motor may also be operated on direct current, it is called a *universal* motor.

**Characteristics of Single-Phase Alternating-Current Motors.**—Single-phase motors are used in sizes up to about  $7\frac{1}{2}$  horsepower (5.6 kW) for heavy starting duty chiefly in home and commercial appliances for which polyphase power is not available. The *capacitor-start* motor is available in normal starting torque designs for such applications as centrifugal pumps, fans, and blowers and in high-starting torque designs for reciprocating compressors, pumps, loaded conveyors, or belts. The *capacitor-start, capacitor-run* motor is exceptionally quiet in operation when loaded to at least 50 percent of capacity. It is available in low-torque designs for fans and centrifugal pumps and in high-torque designs for applications similar to those of the capacitor-start motor.

The *capacitor split-phase* motor requires the least maintenance of all single-phase motors, but has very low starting torque. Its high maximum torque makes it potentially useful in floor sanders or in grinders where momentary overloads due to excessive cutting pressure are experienced. It is also used for slow-speed direct connected fans.

The *repulsion-start, induction-run* motor has higher starting torque than the capacitor motors, although for the same current, the capacitor motors have equivalent pull-up and maximum torque. Electrical and mechanical noise and the extra maintenance sometimes required are disadvantages. These motors are used for compressors, conveyors and stokers starting under full load. The *repulsion-induction* motor has relatively high starting torque and low starting current. It also has a smooth speed-torque curve with no break and a greater ability to withstand long accelerating periods than capacitor type motors. It is particularly suitable for severe starting and accelerating duty and for high inertia loads such as laundry extractors. Brush noise is, however, continuous.

The *repulsion* motor has no limiting synchronous speed and the speed changes with the load. At certain loads, slight changes in load cause wide changes in speed. A brush shifting arrangement may be provided to adjust the speed which may have a range of 4 to 1 if full rated constant torque is applied but a decreasing range as the torque falls below this value. This type of motor may be reversed by shifting the brushes beyond the neutral point. These motors are suitable for machines requiring constant-torque and adjustable speed.

The *split-phase* and *universal* motors are limited to about  $\frac{1}{3}$  hp (0.25 kW) ratings and are used chiefly for small appliance and office machine applications.

**Motors with Built-in Speed Reducers.**—Electric motors having built-in speed-changing units are compact and the design of these motorized speed reducers tends to improve the appearance of the machines which they drive. There are several types of these speed reducers; they may be classified according to whether they are equipped with worm gearing, a regular gear train with parallel shafts, or planetary gearing.

The claims made for the worm gearing type of reduction unit are that the drive is quiet in operation and well adapted for use where the slow-speed shaft must be at right angles to the motor shaft and where a high speed ratio is essential.

For very low speeds, the double reduction worm gearing units are suitable. In these units two sets of worm gearing form the gear train, and both the slow-speed shaft and the armature shaft are parallel. The intermediate worm gear shaft can be built to extend from the housing, if required, so as to make two countershaft speeds available on the same unit.

In the parallel-shaft type of speed reducer, the slow-speed shaft is parallel with the armature shaft. The slow-speed shaft is rotated by a pinion on the armature shaft, this pinion meshing with a larger gear on the slow-speed shaft.

Geared motors having built-in speed-changing units are available with constant-mesh change gears for varying the speed ratio.

Planetary gearing permits a large speed reduction with few parts; hence, it is well adapted for geared-head motor units where economy and compactness are essential. The slow-speed shaft is in line with the armature shaft.

### Factors Governing Motor Selection

**Speed, Horsepower, Torque and Inertia Requirements.**—Where more than one speed or a range of speeds are called for, one of the following types of motors may be selected, depending upon other requirements: For direct-current, the standard shunt-wound motor with field control has a 2 to 1 range in some designs; the adjustable speed motor may have a range of from 3 to 1 up to 6 to 1; the shunt motor with adjustable voltage supply has a range up to 20 to 1 or more below base speed and 4 or 5 to 1 above base speed, making a total range of up to 100 to 1 or more. For polyphase alternating current, multi-speed squirrel-cage induction motors have 2, 3 or 4 fixed speeds; the wound-rotor motor has a 2 to 1 range. The two-speed wound-rotor motor has a 4 to 1 range. The brush-shifting shunt motor has a 4 to 1 range. The brush-shifting series motor has a 3 to 1 range; and the squirrel-cage motor with a variable-frequency supply has a very wide range. For single-phase alternating current, the brush-shifting repulsion motor has a  $2\frac{1}{2}$  to 1 range; the capacitor motor with tapped winding has a 2 to 1 range and the multi-speed capacitor motor has 2 or 3 fixed speeds. Speed regulation (variation in speed from no load to full load) is greatest with motors having series field windings and entirely absent with synchronous motors.

**Horsepower:** Where the load to be carried by the motor is not constant but follows a definite cycle, a horsepower-time curve enables the peak horsepower to be determined as well as the root-mean-square-average horsepower, which indicates the proper motor rating from a heating standpoint. Where the load is maintained at a constant value for a period of from 15 minutes to 2 hours depending on the size, the horsepower rating required will usually not be less than this constant value. When selecting the size of an induction motor, it should be kept in mind that this type of motor operates at maximum efficiency when it is

loaded to full capacity. Where operation is to be at several speeds, the horsepower requirement for each speed should be considered.

*Torque:* Starting torque requirements may vary from 10 percent of full load to 250 percent of full load torque depending upon the type of machine being driven. Starting torque may vary for a given machine because of frequency of start, temperature, type and amount of lubricant, etc., and such variables should be taken into account. The motor torque supplied to the machine must be well above that required by the driven machine at all points up to full speed. The greater the excess torque, the more rapid the acceleration. The approximate time required for acceleration from rest to full speed is given by the formula:

$$\text{Time} = \frac{N \times WR^2}{T_a \times 308} \text{ seconds}$$

where  $N$  = full load speed in rpm

$T_a$  = torque = average foot-pounds available for acceleration.

$WR^2$  = inertia of rotating part in pounds feet squared ( $W$  = weight and  $R$  = radius of gyration of rotating part).

308 = combined constant converting minutes into seconds, weight into mass and radius into circumference.

If the time required for acceleration is greater than 20 seconds, special motors or starters may be required to avoid overheating.

The running torque  $T_r$  is found by the formula:

$$T_r = \frac{5250 \times \text{HP}}{N} \text{ foot pounds}$$

where  $\text{HP}$  = horsepower being supplied to the driven machine

$N$  = running speed in rpm

5250 = combined constant converting horsepower to foot-pounds per minute and work per revolution into torque.

The peak horsepower determines the maximum torque required by the driven machine and the motor must have a maximum running torque in excess of this value.

*Inertia:* The inertia or flywheel effect of the rotating parts of a driven machine will, if large, appreciably affect the accelerating time and, hence, the amount of heating in the motor. If synchronous motors are used, the inertia ( $WR^2$ ) of both the motor rotor and the rotating parts of the machine must be known since the pull-in torque (torque required to bring the driven machine up to synchronous speed) varies approximately as the square root of the total inertia of motor and load.

**Space Limitations in Motor Selection.**—If the motor is to become an integral part of the machine which it drives and space is at a premium, a partial motor may be called for. A complete motor is one made up of a stator, a rotor, a shaft, and two end shields with bearings. A *partial motor* is without one or more of these elements. One common type is furnished without drive-end end shield and bearing and is directly connected to the end or side of the machine which it drives, such as the headstock of a lathe. A so-called *shaftless type of motor* is supplied without shaft, end shields or bearings and is intended for built-in application in such units as multiple drilling machines, precision grinders, deep well pumps, compressors and hoists where the rotor is actually made a part of the driven machine. Where a partial motor is used, however, proper ventilation, mounting, alignment and bearings must be arranged for by the designer of the machine to which it is applied.

Sometimes it is possible to use a motor having a smaller frame size and wound with Class B insulation, permitting it to be subjected to a higher temperature rise than the larger-frame Class A insulated motor having the same horsepower rating.

**Temperatures.**—The applicability of a given motor is limited not only by its load starting and carrying ability, but also by the temperature which it reaches under load. Motors are given temperature ratings which are based upon the type of insulation (Class A or Class B are the most common) used in their construction and their type of frame (open, semienclosed, or enclosed).

*Insulating Materials:* Class A materials are: cotton, silk, paper, and similar organic materials when either impregnated or immersed in a liquid dielectric; molded and laminated materials with cellulose filler, phenolic resins, and other resins of similar properties; films and sheets of cellulose acetate and other cellulose derivatives of similar properties; and varnishes (enamel) as applied to conductors.

Class B insulating materials are: materials or combinations of materials such as mica, glass fiber, asbestos, etc., with suitable bonding substances. Other materials shown capable of operation at Class B temperatures may be included.

*Ambient Temperature and Allowable Temperature Rise:* Normal ambient temperature is taken to be 40°C (104°F). For open general-purpose motors with Class A insulation, the normal temperature rise on which the performance guarantees are based is 40°C (104°F).

Motors with Class A insulation having protected, semiprotected, drip-proof, or splash-proof, or drip-proof protected enclosures have a 50°C (122°F) rise rating.

Motors with Class A insulation and having totally enclosed, fan-cooled, explosion-proof, waterproof, dust-tight, submersible, or dust-explosion-proof enclosures have a 55°C (131°F) rise rating.

Motors with Class B insulation are permissible for total temperatures up to 110°C (230°F) for open motors and 115°C (239°F) for enclosed motors.

**Motors Exposed to Injurious Conditions.**—Where motors are to be used in locations imposing unusual operating conditions, the manufacturer should be consulted, especially where any of the following conditions apply: exposure to chemical fumes; operation in damp places; operation at speeds in excess of specified overspeed; exposure to combustible or explosive dust; exposure to gritty or conducting dust; exposure to lint; exposure to steam; operation in poorly ventilated rooms; operation in pits, or where entirely enclosed in boxes; exposure to inflammable or explosive gases; exposure to temperatures below 10°C (50°F); exposure to oil vapor; exposure to salt air; exposure to abnormal shock or vibration from external sources; where the departure from rated voltage is excessive; and or where the alternating-current supply voltage is unbalanced.

Improved insulating materials and processes and greater mechanical protection against falling materials and liquids make it possible to use general-purpose motors in many locations where special-purpose motors were previously considered necessary. *Splash-proof motors* having well-protected ventilated openings and specially treated windings are used where they are to be subjected to falling and splashing water or are to be washed down as with a hose. Where climatic conditions are not severe, this type of motor is also successfully used in unprotected outdoor installations.

If the surrounding atmosphere carries abnormal quantities of metallic, abrasive, or non-explosive dust or acid or alkali fumes, a *totally enclosed fan-cooled motor* may be called for. In this type, the motor proper is completely enclosed but air is blown through an outer shell that completely or partially surrounds the inner case. If the dust in the atmosphere tends to pack or solidify and close the air passages of open splash-proof or totally enclosed fan-cooled motors, *totally enclosed (nonventilated) motors* are used. This type, which is limited to low horsepower ratings, is also used for outdoor service in mild or severe climates.

**Table 1. Characteristics and Applications of D.C. Motors, 1–300 Horsepower**

Type	Starting Duty	Maximum Momentary Running Torque	Speed Regulation	Speed Control <sup>a</sup>	Applications
Shunt-wound, constant-speed	Medium starting torque. Varies with voltage supplied to armature, and is limited by starting resistor to 125 to 200% full-load torque	125 to 200%. Limited by commutation	8 to 12%	Basic speed to 200% basic speed by field control	Drives where starting requirements are not severe. Use constant-speed or adjustable-speed, depending on speed required. Centrifugal pumps, fans, blowers, conveyors, elevators, wood- and metalworking machines
Shunt-wound, adjustable speed			10 to 20%, increases with weak fields	Basic speed to 60% basic speed (lower for some ratings) by field control	
Shunt-wound, adjustable voltage control			Up to 25%. Less than 5% obtainable with special rotating regulator	Basic speed to 2% basic speed and basic speed to 200% basic speed	
Compound wound, constant-speed	Heavy starting torque. Limited by starting resistor to 130 to 260% of full-load torque	130 to 260%. Limited by commutation	Standard compounding 25%. Depends on amount of series winding	Basic speed to 125% basic speed by field control	Drives requiring high starting torque and fairly constant speed. Pulsating loads. Shears, bending rolls, pumps, conveyors, crushers, etc.
Series-wound, varying-speed	Very heavy starting torque. Limited to 300 to 350% full-load torque	300 to 350%. Limited by commutation	Very high. Infinite no-load speed	From zero to maximum speed, depending on control and load	Drives where very high starting torque is required and speed can be regulated. Cranes, hoists, gates, bridges, car dumpers, etc.

<sup>a</sup> Minimum speed below basic speed by armature control limited by heating.

**Table 2. Characteristics and Applications of Polyphase AC Motors**

Polyphase Type	Ratings hp	Speed Regulation	Speed Control	Starting Torque	Breakdown Torque	Applications
General-purpose squirrel cage, normal stg current, normal stg torque. Design B	0.5 to 200	Less than 5%	None, except multispeed types, designed for two to four fixed speeds	100 to 250% of full-load	200 to 300% of full-load	Constant-speed service where starting torque is not excessive. Fans, blowers, rotary compressors, centrifugal pumps, woodworking machines, machine tools, line shafts
Full-voltage starting, high stg torque, normal stg current, squirrel-cage, Design C	3 to 150	Less than 5%	None except multispeed types, designed for two to four fixed speeds	200 to 250% of full-load	190 to 225% of full-load	Constant-speed service where fairly high starting torque is required at infrequent intervals with starting current of about 500% full-load. Reciprocating pumps and compressors, conveyors, crushers, pulverizers, agitators, etc.
Full-voltage starting, high stg torque, high-slip squirrel cage, Design D	0.5 to 150	Drops about 7 to 12% from no load to full load	None, except multispeed types, designed for two to four fixed speeds	275% of full-load depending on speed and rotor resistance	275% of full-load Will usually not stall until loaded to its maximum torque, which occurs at standstill	Constant-speed service and high-starting torque if starting not too frequent, and for taking high-peak loads with or without flywheels. Punch presses, die stamping, shears, bulldozers, bailers, hoists, cranes, elevators, etc.
Wound-rotor, external-resistance starting	0.5 to several thousand	With rotor rings short-circuited drops about 3% for large to 5% for small sizes	Speed can be reduced to 50% of normal by rotor resistance. Speed varies inversely as the load	Up to 300% depending on external resistance in rotor circuit and how distributed	200% when rotor slip rings are short circuited	Where high-starting torque with low-starting current or where limited speed control is required. Fans, centrifugal and plunger pumps, compressors, conveyors, hoists, cranes, ball mills, gate hoists, etc.
Synchronous	25 to several thousand	Constant	None, except special motors designed for two fixed speeds	40% for slow speed to 160% for medium speed 80% p-f designs. Special high-torque designs	Pull-out torque of unity-p-f motors 170%; 80%-p-f motors 225%. Special designs up to 300%	For constant-speed service, direct connection to slow-speed machines and where power-factor correction is required.

In addition to these special-purpose motors, there are two types of *explosion-proof motors* designed for hazardous locations. One type is for operation in hazardous dust locations (Class II, Group G of the National Electrical Code) and the other is for atmospheres containing explosive vapors and fumes classified as Class I, Group D (gasoline, naphtha, alcohols, acetone, lacquer-solvent vapors, natural gas).

### Electric Motor Maintenance

**Electric Motor Inspection Schedule.**—Frequency and thoroughness of inspection depend upon such factors as 1) importance of the motor in the production scheme; 2) percentage of days the motor operates; 3) nature of service; and 4) winding conditions.

The following schedules, recommended by the General Electric Company, and covering both AC and DC motors are based on average conditions in so far as duty and dirt are concerned.

**Weekly Inspection.**—1) *Surroundings.* Check to see if the windings are exposed to any dripping water, acid or alcoholic fumes; also, check for any unusual amount of dust, chips, or lint on or about the motor. See if any boards, covers, canvas, etc., have been misplaced that might interfere with the motor ventilation or jam moving parts.

2) *Lubrication of sleeve-bearing motors.* In sleeve-bearing motors check oil level, if a gage is used, and fill to the specified line. If the journal diameter is less than 2 inches, the motor should be stopped before checking the oil level. For special lubricating systems, such as wool-packed, forced lubrication, flood and disk lubrication, follow instruction book. Oil should be added to bearing housing only when motor is at rest. A check should be made to see if oil is creeping along the shaft toward windings where it may harm the insulation.

3) *Mechanical condition.* Note any unusual noise that may be caused by metal-to-metal contact or any odor as from scorching insulation varnish.

4) *Ball or roller bearings.* Feel ball- or roller-bearing housings for evidence of vibration, and listen for any unusual noise. Inspect for creepage of grease on inside of motor.

5) *Commutators and brushes.* Check brushes and commutator for sparking. If the motor is on cyclic duty it should be observed through several cycles. Note color and surface condition of the commutator. A stable copper oxide-carbon film (as distinguished from a pure copper surface) on the commutator is an essential requirement for good commutation. Such a film may vary in color all the way from copper to straw, chocolate to black. It should be clean and smooth and have a high polish. All brushes should be checked for wear and pigtail connections for looseness. The commutator surface may be cleaned by using a piece of dry canvas or other hard, nonlinting material that is wound around and securely fastened to a wooden stick, and held against the rotating commutator.

6) *Rotors and armatures.* The air gap on sleeve-bearing motors should be checked, especially if they have been recently overhauled. After installing new bearings, make sure that the average reading is within 10 percent, and reading should be less than 0.020 inch (0.51 mm). Check air passages through punchings and make sure they are free of foreign matter.

7) *Windings.* If necessary clean windings by suction or mild blowing. After making sure that the motor is dead, wipe off windings with dry cloth, note evidence of moisture, and see if any water has accumulated in the bottom of frame. Check if any oil or grease has worked its way up to the rotor or armature windings. Clean with carbon tetrachloride in a well-ventilated room.

8) *General.* This is a good time to check the belt, gears, flexible couplings, chain, and sprockets for excessive wear or improper location. The motor starting should be checked to make sure that it comes up to proper speed each time power is applied.

**Monthly or Bimonthly Inspection.**—1) *Windings.* Check shunt, series, and commutating field windings for tightness. Try to move field spools on the poles, as drying out may have caused some play. If this condition exists, a service shop should be consulted. Check motor cable connections for tightness.

2) *Brushes*. Check brushes in holders for fit and free play. Check the brush-spring pressure. Tighten brush studs in holders to take up slack from drying out of washers, making sure that studs are not displaced, particularly on DC motors. Replace brushes that are worn down almost to the brush rivet, examine brush faces for chipped toes or heels, and for heat cracks. Damaged brushes should be replaced immediately.

3) *Commutators*. Examine commutator surface for high bars and high mica, or evidence of scratches or roughness. See that the risers are clean and have not been damaged.

4) *Ball or roller bearings*. On hard-driven, 24-hour service ball- or roller-bearing motors, purge out old grease through drain hole and apply new grease. Check to make sure grease or oil is not leaking out of the bearing housing. If any leakage is present, correct the condition before continuing to operate.

5) *Sleeve bearings*. Check sleeve bearings for wear, including end-play bearing surfaces. Clean out oil wells if there is evidence of dirt or sludge. Flush with lighter oil before refilling.

6) *Enclosed gears*. For motors with enclosed gears, open drain plug and check oil flow for presence of metal scale, sand, or water. If condition of oil is bad, drain, flush, and refill as directed. Rock rotor to see if slack or backlash is increasing.

7) *Loads*. Check loads for changed conditions, bad adjustment, poor handling, or control.

8) *Couplings and other drive details*. Note if belt-tightening adjustment is all used up. Shorten belt if this condition exists. See if belt runs steadily and close to inside (motor edge) of pulley. Chain should be checked for evidence of wear and stretch. Clean inside of chain housing. Check chain-lubricating system. Note inclination of slanting base to make sure it does not cause oil rings to rub on housing.

**Annual or Biannual Inspection.**—1) *Windings*. Check insulation resistance by using either a megohmmeter or a voltmeter having a resistance of about 100 ohms per volt. Check insulation surfaces for dry cracks and other evidence of need for coatings of insulating material. Clean surfaces and ventilating passages thoroughly if inspection shows accumulation of dust. Check for mold or water standing in frame to determine if windings need to be dried out, varnished, and baked.

2) *Air gap and bearings*. Check air gap to make sure that average reading is within 10 percent, provided reading should be less than 0.020 inch (0.51 mm). All bearings, ball, roller, and sleeve should be thoroughly checked and defective ones replaced. Waste-packed and wick-oiled bearings should have waste or wicks renewed, if they have become glazed or filled with metal or dirt, making sure that new waste bears well against shaft.

3) *Rotors (squirrel-cage)*. Check squirrel-cage rotors for broken or loose bars and evidence of local heating. If fan blades are not cast in place, check for loose blades. Look for marks on rotor surface indicating foreign matter in air gap or a worn bearing.

4) *Rotors (wound)*. Clean wound rotors thoroughly around collector rings, washers, and connections. Tighten connections if necessary. If rings are rough, spotted, or eccentric, refer to service shop for refinishing. See that all top sticks or wedges are tight. If any are loose, refer to service shop.

5) *Armatures*. Clean all armature air passages thoroughly if any are obstructed. Look for oil or grease creeping along shaft, checking back to bearing. Check commutator for surface condition, high bars, high mica, or eccentricity. If necessary, remachine the commutator to secure a smooth fresh surface.

6) *Loads*. Read load on motor with instruments at no load, full load, or through an entire cycle, as a check on the mechanical condition of the driven machine.

## ADHESIVES AND SEALANTS

By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. The bond durability depends on the strength of the adhesive to the substrate (adhesion) and the strength within the adhesive (cohesion). Besides bonding a joint, an adhesive may serve as a seal against foreign matter. When an adhesive performs both bonding and sealing functions, it is usually referred to as an *adhesive sealant*. Joining materials with adhesives offers significant benefits compared with mechanical methods of uniting two materials.

Among these benefits are that an adhesive distributes a load over an area rather than concentrating it at a point, resulting in a more even distribution of stresses. The adhesive bonded joint is therefore more resistant to flexural and vibrational stresses than, for example, a bolted, riveted, or welded joint. Another benefit is that an adhesive forms a seal as well as a bond. This seal prevents the corrosion that may occur with dissimilar metals, such as aluminum and magnesium, or mechanically fastened joints, by providing a dielectric insulation between the substrates. An adhesive also joins irregularly shaped surfaces more easily than does a mechanical fastener. Other benefits include negligible weight addition and virtually no change to part dimensions or geometry.

Most adhesives are available in liquids, gels, pastes, and tape forms. The growing variety of adhesives available can make the selection of the proper adhesive or sealant a challenging experience. In addition to the technical requirements of the adhesive, time and costs are also important considerations. Proper choice of an adhesive is based on knowledge of the suitability of the adhesive or sealant for the particular substrates. Appropriate surface preparation, curing parameters, and matching the strength and durability characteristics of the adhesive to its intended use are essential. The performance of an adhesive-bonded joint depends on a wide range of these factors, many of them quite complex. Adhesive suppliers can usually offer essential expertise in the area of appropriate selection.

Adhesives can be classified as structural or nonstructural. In general, an adhesive can be considered structural when it is capable of supporting heavy loads; nonstructural when it cannot support such loads. Many adhesives and sealants, under various brand names, may be available for a particular bonding application. It is always advisable to check the adhesive manufacturers' information before making an adhesive sealant selection. Also, testing under end-use conditions is always suggested to help ensure bonded or sealed joints meet or exceed expected performance requirements.

Though not meant to be all-inclusive, the following information correlates the features of some successful adhesive compositions available in the marketplace.

### Bonding Adhesives

Reactive-type bonding adhesives are applied as liquids and react (cure) to solids under appropriate conditions. The cured adhesive is either a thermosetting or thermoplastic polymer. These adhesives are supplied as two-component no-mix, two-component mix, and one-component no-mix types, which are discussed in the following paragraphs.

### Two-Component No-Mix Adhesives

**Types of Adhesives.**—*Anaerobic (Urethane Methacrylate Ester) Structural Adhesives:* Anaerobic structural adhesives are mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between metal substrates. These adhesives can be used for large numbers of industrial purposes where high reliability of bond joints is required. Benefits include: no mixing is required (no pot-life or waste problems), flexible/durable bonds are made that withstand thermal cycling, have excellent resistance to solvents and severe environments, and rapid cure at room temperatures (eliminating

expensive ovens). The adhesives are easily dispensed with automatic equipment. An activator is usually required to be present on one surface to initiate the cure for these adhesives. Applications for these adhesives include bonding of metals, magnets (ferrites), glass, thermosetting plastics, ceramics, and stone.

*Acrylic Adhesives:* Acrylic adhesives are composed of a polyurethane polymer backbone with acrylate end groups. They can be formulated to cure through heat or the use of an activator applied to the substrate surface, but many industrial acrylic adhesives are cured by light. Light-cured adhesives are used in applications where the bond geometry allows light to reach the adhesive and the production rate is high enough to justify the capital expense of a light source. Benefits include: no mixing is required (no pot-life or waste problems); formulations cure (solidify) with activator, heat, or light; the adhesive will bond to a variety of substrates, including metal and most thermoplastics; and tough and durable bonds are produced with a typical resistance to the effects of temperatures up to 180°C. Typical applications include automobile body parts (steel stiffeners), assemblies subjected to paint-baking cycles, speaker magnets to pole plates, and bonding of motor magnets, sheet steel, and many other structural applications. Other applications include bonding glass, sheet metal, magnets (ferrite), thermosetting and thermoplastic plastics, wood, ceramics, and stone.

### Two-Component Mix Adhesives

**Types of Adhesives.**—*Epoxy Adhesives:* Two-component epoxy adhesives are well-established adhesives that offer many benefits in manufacturing. The reactive components of these adhesives are separated prior to use, so they usually have a good shelf life without refrigeration. Polymerization begins upon mixing, and a thermoset polymer is formed. Epoxy adhesives cure to form thermosetting polymers made up of a base side with the polymer resin and a second part containing the catalyst. The main benefit of these systems is that the depth of cure is unlimited. As a result, large volume can be filled for work such as potting, without the cure being limited by the need for access to an external influence such as moisture or light to activate the curing process.

For consistent adhesive performance, it is important that the mix ratio remain constant to eliminate variations in adhesive performance. Epoxies can be handled automatically, but the equipment involves initial and maintenance costs. Alternatively, adhesive components can be mixed by hand. However, this approach involves labor costs and the potential for human error. The major disadvantage of epoxies is that they tend to be very rigid and consequently have low peel strength. This lack of peel strength is less of a problem when bonding metal to metal than it is when bonding flexible substrates such as plastics.

Applications of epoxy adhesives include bonding, potting, and coating of metals, bonding of glass, rigid plastics, ceramics, wood, and stone.

*Polyurethane Adhesives:* Like epoxies, polyurethane adhesives are available as two-part systems or as one-component frozen premixes. They are also available as one-part moisture-cured systems. Polyurethane adhesives can provide a wide variety of physical properties. Their flexibility is greater than that of most epoxies. Coupled with the high cohesive strength, this flexibility provides a tough polymer able to achieve better peel strength and lower flexural modulus than most epoxy systems. This superior peel resistance allows use of polyurethanes in applications that require high flexibility. Polyurethanes bond very well to a variety of substrates, though a primer may be needed to prepare the substrate surface. These primers are moisture-reactive and require several hours to react sufficiently for the parts to be used. Such a time requirement may cause a production bottleneck if the bond-strength requirements are such that a primer is needed.

Applications for polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

### One-Component No-Mix Adhesives

**Types of Adhesives.**—*Light-Curable Adhesives:* Light-curing systems use a unique curing mechanism. The adhesives contain photoinitiators that absorb light energy and dissociate to form radicals. These radicals then initiate the polymerization of the polymers, oligomers, and monomers in the adhesive. The photoinitiator acts as a chemical solar cell, converting the light energy into chemical energy for the curing process. Typically, these systems are formulated for use with ultraviolet light sources. However, newer products have been formulated for use with visible light sources.

One of the biggest benefits that light-curing adhesives offer to the manufacturer is the elimination of the work time to work-in-progress trade-off, which is embodied in most adhesive systems. With light-curing systems, the user can take as much time as needed to position the part without fear of the adhesive curing. Upon exposure to the appropriate light source, the adhesive then can be fully cured in less than 1 minute, minimizing the costs associated with work in progress. Adhesives that utilize light as the curing mechanism are often one-part systems with good shelf life, which makes them even more attractive for manufacturing use.

Applications for light-curable adhesives include bonding of glass, and glass to metal, tacking of wires, surface coating, thin-film encapsulation, clear substrate bonding, and potting of components.

*Cyanoacrylate Adhesives (Instant Adhesives):* Cyanoacrylates or instant adhesives are often called Superglue™. Cyanoacrylates are one-part adhesives that cure rapidly, as a result of the presence of surface moisture, to form high-strength bonds, when confined between two substrates. Cyanoacrylates have excellent adhesion to many substrates, including most plastics and they achieve fixture strength in seconds and full strength within 24 hours. These qualities make cyanoacrylates suitable for use in automated production environments. They are available in viscosities ranging from water-thin liquids to thixotropic gels.

Because cyanoacrylates are a relatively mature adhesive family, a wide variety of specialty formulations is now available to help the user address difficult assembly problems. One of the best examples is the availability of polyolefin primers, which allow users to obtain high bond strengths on difficult-to-bond plastics such as polyethylene and polypropylene. One common drawback of cyanoacrylates is that they form a very rigid polymer matrix, resulting in very low peel strengths. To address this problem, formulations have been developed that are rubber-toughened. Although the rubber toughening improves the peel strength of the system to some extent, peel strength remains a weak point for this system, and, therefore, cyanoacrylates are poor candidates for joint designs that require high peel resistance. In manufacturing environments with low relative humidity, the cure of the cyanoacrylate can be significantly retarded.

This problem can be addressed in one of two ways. One approach is to use accelerators that deposit active species on the surface to initiate the cure of the product. The other approach is to use specialty cyanoacrylate formulations that have been engineered to be surface-insensitive. These formulations can cure rapidly even on dry or slightly acidic surfaces.

Applications for cyanoacrylate adhesives include bonding of thermoplastic and thermosetting plastics, rubber, metals, wood, and leather, also strain relief of wires.

*Hot-Melt Adhesives:* Hot-melt adhesives are widely used in assembly applications. In general, hot-melt adhesives permit fixturing speeds that are much faster than can be achieved with water- or solvent-based adhesives. Usually supplied in solid form, hot-melt adhesives liquify when exposed to elevated temperatures. After application, they cool quickly, solidifying and forming a bond between two mating substrates. Hot-melt adhesives have been used successfully for a wide variety of adherends and can greatly reduce both the need for clamping and the length of time for curing. Some drawbacks

with hot-melt adhesives are their tendency to string during dispensing and relatively low-temperature resistance.

Applications for hot-melt adhesives are bonding of fabrics, wood, paper, plastics, and cardboard.

**Rubber-Based Solvent Cements:** Rubber-based solvent cements are adhesives made by combining one or more rubbers or elastomers in a solvent. These solutions are further modified with additives to improve the tack or stickiness, the degree of peel strength, flexibility, and the viscosity or body. Rubber-based adhesives are used in a wide variety of applications such as contact adhesive for plastics laminates like counter tops, cabinets, desks, and tables. Solvent-based rubber cements have also been the mainstay of the shoe and leather industry for many years.

Applications for rubber-based solvent cements include bonding of plastics laminates, wood, paper, carpeting, fabrics, and leather.

**Moisture-Cured Polyurethane Adhesives:** Like heat-curing systems, moisture-cured polyurethanes have the advantage of a very simple curing process. These adhesives start to cure when moisture from the atmosphere diffuses into the adhesive and initiates the polymerization process. In general, these systems will cure when the relative humidity is above 25 percent, and the rate of cure will increase as the relative humidity increases.

The dependence of these systems on the permeation of moisture through the polymer is the source of their most significant process limitations. As a result of this dependence, depth of cure is limited to between 0.25 and 0.5 in. (6.35 and 12.7 mm). Typical cure times are in the range of 12 to 72 hours. The biggest use for these systems is for windshield bonding in automobile bodies.

Applications for moisture-cured polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

### Retaining Compounds

The term *retaining compounds* is used to describe adhesives used in circumferential assemblies joined by inserting one part into the other. In general, retaining compounds are anaerobic adhesives composed of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between cylindrical machine components. A typical example is a bearing held in an electric motor housing with a retaining compound. The first retaining compounds were launched in 1963, and the reaction among users of bearings was very strong because these retaining compounds enabled buyers of new bearings to salvage worn housings and minimize their scrap rate.

The use of retaining compounds has many benefits, including elimination of bulk needed for high friction forces, ability to produce more accurate assemblies and to augment or replace press fits, increased strength in heavy press fits, and reduction of machining costs. Use of these compounds also helps in dissipating heat through assembly, and eliminating distortion when installing drill bushings, fretting corrosion and backlash in keys and splines, and bearing seizure during operation.

The major advantages of retaining compounds for structural assemblies are that they require less severe machining tolerances and no securing of parts. Components are assembled quickly and cleanly, and they transmit high forces and torques, including dynamic forces. Retaining compounds also seal, insulate, and prevent micromovements so that neither fretting corrosion nor stress corrosion occurs. The adhesive joint can be taken apart easily after heating above 450°F (230°C) for a specified time.

Applications for retaining compounds include mounting of bearings in housings or on shafts, avoiding distortion of precision tooling and machines, mounting of rotors on shafts, inserting drill jig bushings, retaining cylinder linings, holding oil filter tubes in castings, retaining engine-core plugs, restoring accuracy to worn machine tools, and eliminating keys and set screws.

### Threadlocking

The term *threadlocker* is used to describe adhesives used in threaded assemblies for locking the threaded fasteners by filling the spaces between the nut and bolt threads with a hard, dense material that prevents loosening. In general, thread-lockers are anaerobic adhesives comprising mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components. A typical example is a mounting bolt on a motor or a pump. Threadlocker strengths range from very low strength (removable) to high strength (permanent).

It is important that the total length of the thread is coated and that there is no restriction to the curing of the threadlocker material. (Certain oils or cleaning systems can impede or even completely prevent the adhesive from curing by anaerobic reaction.) The liquid threadlocker may be applied by hand or with special dispensing devices. Proper coating (wetting) of a thread is dependent on the size of the thread, the viscosity of the adhesive, and the geometry of the parts. With blind-hole threads, it is essential that the adhesive be applied all the way to the bottom of the threaded hole. The quantity must be such that after assembly, the displaced adhesive fills the whole length of the thread.

Some threadlocking products cured by anaerobic reaction have a positive influence on the coefficient of friction in the thread. The values are comparable with those of oiled bolts. Prestress and installation torque therefore can be defined exactly. This property allows threadlocking products cured by anaerobic reaction to be integrated into automated production lines using existing assembly equipment. The use of thread-lockers has many benefits including ability to lock and seal all popular bolt and nut sizes with all industrial finishes, and to replace mechanical locking devices. The adhesive can seal against most industrial fluids and will lubricate threads so that the proper clamp load is obtained. The materials also provide vibration-resistant joints that require handtool dismantling for servicing, prevent rusting of threads, and cure (solidify) without cracking or shrinking.

The range of applications includes such uses as locking and sealing nuts on hydraulic pistons, screws on vacuum cleaner bell housings, track bolts on bulldozers, hydraulic-line fittings, screws on typewriters, oil-pressure switch assembly, screws on carburetors, rocker nuts, machinery driving keys, and on construction equipment.

### Sealants

The primary role of a sealant composition is the prevention of leakage from or access by dust, fluids, and other materials to assembly structures. Acceptable leak rates can range from a slight drip to bubbletight to molecular diffusion through the base materials. Equipment users in the industrial market want trouble-free operation, but it is not always practical to specify zero leak rates. Factors influencing acceptable leak rates are toxicity, product or environmental contamination, combustibility, economics, and personnel considerations. All types of fluid seals perform the same basic function: they seal the process fluid (gas, liquid, or vapor) and keep it where it belongs. A general term for these assembly approaches is gasketing. Many products are being manufactured that are capable of sealing a variety of substrates.

**Types of Sealants.**—*Anaerobic Formed-in-Place Gasketing Materials:* Mechanical assemblies that require the joining of metal-to-metal flange surfaces have long been designed with prefabricated, precut materials required to seal the imperfect surfaces of the assembly. Numerous gasket materials that have been used to seal these assemblies include paper, cork, asbestos, wood, metals, dressings, and even plastics. Fluid seals are divided into static and dynamic systems, depending on whether or not the parts move in relationship to each other. Flanges are classed as static systems, although they may be moved relative to each other by vibration, temperature, and/or pressure changes, shocks, and impacts.

The term *anaerobic formed-in-place gasketing* is used to describe sealants that are used in flanged assemblies to compensate for surface imperfections of metal-to-metal

components by filling the space between the substrates with a flexible, nonrunning material. In general, anaerobic formed-in-place gaskets are sealants made up of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between components. A typical example is sealing two halves of a split crankcase.

The use of anaerobic formed-in-place gaskets has many benefits, including the ability to seal all surface imperfections, allow true metal-to-metal contact, eliminate compression set and fastener loosening, and add structural strength to assemblies. These gaskets also help improve torque transmission between bolted flange joints, eliminate bolt retorquing needed with conventional gaskets, permit use of smaller fasteners and lighter flanges, and provide for easy disassembly and cleaning.

Applications in which formed-in-place gasketing can be used to produce leakproof joints include pipe flanges, split crankcases, pumps, compressors, power takeoff covers, and axle covers. These types of gaskets may also be used for repairing damaged conventional gaskets and for coating soft gaskets.

*Silicone Rubber Formed-in-Place Gasketing:* Another type of formed-in-place gasket uses room-temperature vulcanizing (RTV) silicone rubbers. These materials are one-component sealants that cure on exposure to atmospheric moisture. They have excellent properties for vehicle use such as flexibility, low volatility, good adhesion, and high resistance to most automotive fluids. The materials will also withstand temperatures up to 600°F (320°C) for intermittent operation.

RTV silicones are best suited for fairly thick section (gap) gasketing applications where flange flexing is greatest. In the form of a very thin film, for a rigid metal-to-metal seal, the cured elastomer may abrade and eventually fail under continual flange movement. The RTV silicone rubber does not unitize the assembly, and it requires relatively clean, oil-free surfaces for sufficient adhesion and leakproof seals.

Because of the silicone's basic polymeric structure, RTV silicone elastomers have several inherent characteristics that make them useful in a wide variety of applications. These properties include outstanding thermal stability at temperatures from 400 to 600°F (204 to 320°C), and good low-temperature flexibility at -85 to -165°F (-65 to -115°C). The material forms an instant seal, as is required of all liquid gaskets, and will fill large gaps up to 0.250 in. (6.35 mm) for stamped metal parts and flanges. The rubber also has good stability in ultraviolet light and excellent weathering resistance.

Applications for formed-in-place RTV silicones in the automotive field are valve, camshaft and rocker covers, manual transmission (gearbox) flanges, oil pans, sealing panels, rear axle housings, timing chain covers, and window plates. The materials are also used on oven doors and flues.

### Tapered Pipe-Thread Sealing

Thread sealants are used to prevent leakage of gases and liquids from pipe joints. All joints of this type are considered to be dynamic because of vibration, changing pressures, or changing temperatures.

Several types of sealants are used on pipe threads including noncuring pipe dopes, which are one of the oldest methods of sealing the spiral leak paths of threaded joints. In general, pipe dopes are pastes made from oils and various fillers. They lubricate joints and jam threads but provide no locking advantage. They also squeeze out under pressure, and have poor solvent resistance. Noncuring pipe dopes are not suitable for use on straight threads.

Another alternative is solvent-drying pipe dopes, which are an older method of sealing tapered threaded joints. These types of sealant offer the advantages of providing lubrication and orifice jamming and they also extrude less easily than noncuring pipe dopes. One disadvantage is that they shrink during cure as the solvents evaporate and fittings must be retorqued to minimize voids. These materials generally lock the threaded joint together by friction. A third type of sealer is the trapped elastomer supplied in the form of a thin

tape incorporating polytetrafluorethylene (PTFE). This tape gives a good initial seal and resists chemical attack, and is one of the only materials used for sealing systems that will seal against oxygen gas.

Some other advantages of PTFE are that it acts as a lubricant, allows for high torquing, and has a good resistance to various solvents. Some disadvantages are that it may not provide a true seal between the two threaded surfaces, and it lubricates in the off direction, so it may allow fittings to loosen. In dynamic joints, tape may allow creep, resulting in leakage over time. The lubrication effect may allow overtightening, which can add stress or lead to breakage. Tape also may be banned in some hydraulic systems due to shredding, which may cause clogging of key orifices.

**Anaerobic Pipe Sealants.**—The term *anaerobic pipe sealants* is used to describe anaerobic sealants used in tapered threaded assemblies for sealing and locking threaded joints. Sealing and locking are accomplished by filling the space between the threads with the sealant. In general, these pipe sealants are anaerobic adhesives consisting of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components to form an insoluble tough plastics. The strength of anaerobic pipe sealants is between that of elastomers and yielding metal.

Clamp loads need be only tight enough to prevent separation in use. Because they develop strength by curing after they are in place, these sealants are generally forgiving of tolerances, tool marks, and slight misalignment. These sealants are formulated for use on metal substrates. If the materials are used on plastics, an activator or primer should be used to prepare the surfaces.

Among the advantages of these anaerobic sealers are that they lubricate during assembly, they seal regardless of assembly torque, and they make seals that correspond with the burst rating of the pipe. They also provide controlled disassembly torque, do not cure outside the joint, and are easily dispensed on the production line. These sealants also have the lowest cost per sealed fitting. Among the disadvantages are that the materials are not suitable for oxygen service, for use with strong oxidizing agents, or for use at temperatures above 200°C (392°F). The sealants also are typically not suitable for diameters over M80 or 80 mm (approximately 3 inches).

The many influences faced by pipe joints during service should be known and understood at the design stage, when sealants are selected. Sealants must be chosen for reliability and long-term quality. Tapered pipe threads must remain leak-free under the severest vibration and chemical attack, also under heat and pressure surges.

Applications of aerobic sealants are found in industrial plant fluid power systems, the textile industry, chemical processing, utilities and power generation facilities, petroleum refining, and in marine, automotive, and industrial equipment. The materials are also used in the pulp and paper industries, in gas compression and distribution, and in waste-treatment facilities.

## O-RINGS

## Overview

An O-ring is a one-piece molded seal that distorts when squeezed between two parts to fill a gap. Most O-rings are toroidal (a round donut shape with a hole in the middle) and made from highly resilient materials, such as thermoplastic elastomers. Some O-rings are made from materials that permanently deform in use, such as PTFE (polytetrafluoroethylene).

To create the sealing geometry, an O-ring is contained in a cylindrical or planar groove cut into one part. An O-ring gland is composed of the groove in one part and a sealing surface in the other part. If the two parts fit together with no gap, the groove and gland depths are the same. From a sealing standpoint, it usually does not matter which part in the cylindrical or planar joint carries the gland or groove. Ease of manufacture and/or assembly normally drives that decision. When properly installed in a gland, an O-ring is slightly deformed, so that the naturally round cross section is squeezed diametrically out of round prior to application of pressure. This compression ensures that under static conditions, the O-ring is in forceful contact (or "interferes with") the sealing surfaces of both parts enclosing it. The resiliency of the material ensures adequate sealing force at zero applied pressure and allows some dimensional variation within the gland.

When pressure is applied, it tends to force the O-ring across the gland, causing the O-ring to further deform and increase the sealing force, as in Fig. 1(a). As additional pressure is applied, the O-ring deforms into a D shape and can flow into the clearance gap between the two parts, as in Fig. 1(b). When the applied pressure changes direction (sometimes referred to as *cycling*), the O-ring can be forced back and forth within the gland. In such cases, a stiffer or abrasion-resistant O-ring, backup rings, or a second O-ring seal (one for each direction) may be needed. (Other seal types also are available that are better suited to pressure-reversal applications.) In gaseous applications, the permeability of the O-ring material must be considered in estimating leakage rates and avoiding explosive decompression failure of the O-ring, particularly at high pressures.

Fig. 1. Effect of Fluid Pressure on the Cross Section of an O-Ring in a Gland

**O-Ring Standards and Designations.**—O-ring size is based on two parameters: inner diameter and cross-sectional diameter. However, to completely characterize an O-ring, both the size and the material must be specified. Manufacturers often use different designations to identify O-ring compounds.

Table 1 provides some prevailing standards for general-purpose inch and metric O-rings and gland designs. Note that previous O-ring metric standards BS 1806, DIN 3771, and JIS B 2401 have been superseded by the ISO standards shown in this table.

**Table 1. Commonly Referenced O-Ring Standards**

Application	Units	Standard	Title
O-ring dimensions and tolerances	inch	SAE AS568	Aerospace Size Standard for O-rings
	mm	ISO 3601-1	Fluid power systems – O-rings – Part 1: Inside diameters, cross-sections, tolerances and designation codes
General use piston or rod gland design, static and dynamic applications	inch	SAE AS4716	Gland Design, O-ring and Other Seals
	mm	ISO 3601-2	Fluid power systems – O-rings – Part 2: Housing dimensions for general applications
Static face seal (axial) gland design	inch	SAE AS6235	Face Seal Gland Design, Static, O-ring and Other Seals for Aerospace Hydraulic and Pneumatic Applications
	mm	ISO 3601-2	Fluid power systems – O-rings – Part 2: Housing dimensions for general applications
Backup rings	inch	SAE ( <i>various</i> )	( <i>Backup rings are contained in separate SAE standards based on material and style.</i> )
	mm	ISO 3601-4	Fluid power systems – O-rings – Part 4: Anti-extrusion rings (backup rings)

**Inch-System O-Rings:** The inch-basis SAE standard O-ring sizes are assigned three-digit size codes. A dash precedes the size code. The first digit refers to cross-sectional diameter, and the next two digits refer to inner diameter; however, the numbers that make up the size code are not derivative of the actual inch measurements. For example, for an SAE standard O-ring with designation -230-8307, the O-ring size code is -230, which specifies a cross-sectional diameter of 0.139 in. and inner diameter of 2.484 in. The complete designation number indicates that the O-ring is made from the vendor-specific material designated by material code 8307.

**Metric General-Purpose O-Rings:** According to ISO specifications, O-rings for general use are functionally equivalent to those found in SAE AS568 when used in the same glands. Size codes for these use the same three-digit numbers set by the SAE standard. But the ISO size code is completed by an added tolerance class designation (A or B). Tolerance class A O-rings, which are equivalent to those in the SAE (inch) standard, are suitable for aerospace or general applications requiring tight tolerances. Even in applications where tolerance needs are not as tight, class A O-rings are most often used. Tolerance class B O-rings, which are less tight and considered appropriate for general applications, are not as common in industry.

To give an ISO example of an SAE equivalent O-ring: for a part with nominal inside diameter of 63.09 mm and nominal cross-sectional diameter of 3.53 mm, the ISO size code is -230A, and the full designation is -230A-63.09x3.53-N. The final letter N is the grade. Grade indicates the inspection standards required per ISO 3601-3: Grade N = general purpose, S = special, and CS = critical service.

It is important to note that, as with SAE designations, ISO standard designations do not identify the material. A manufacturer-specific compound identifier must be appended or called out separately.

**Metric Aerospace O-Rings:** Another group of O-rings in the ISO standard is intended specifically for aerospace applications. These are designed for use in metric glands. This is advantageous when close fits are required or when working with metric bores and pistons. Codes for aerospace sizes differ from those for general applications; they are preceded by the letter A followed by a dash. The size code then begins with a cross section size identifier, designated from A to E; the next four digits give the inside diameter in tenths of a millimeter. There is only one tolerance class in this group, so a tolerance class identifier is not included, but the inspection standard per ISO 3601-3 is added to the end of the code. For example, a critical service aerospace O-ring with a 3.55 mm cross section and a 63 mm inside diameter has a size code of C0630 and the full designation is A-C0630-63.00x3.55-CS. In this case, the grade code is CS. This series of O-ring sizes are not covered here, but size codes and dimensional information can be found in ISO standards and supplier catalogs.

**O-Ring Size Selection.**—O-ring sizing involves determining the best inside and cross-sectional diameter for an application. Choice of inner diameter usually is determined by the basic needs of the assembly being sealed: the groove for the seal must fit in one of the assembled parts, leave enough material on the part to provide sufficient stiffness, and allow for installation. Deciding which part will bear the groove and choosing the O-ring is heavily influenced by cost and assembly considerations.

There are more variables involved in determining cross-sectional diameter that can substantially impact sealing effectiveness. Smaller cross section O-rings have the advantages of lighter weight, compact footprint, better resistance to explosive decompression, lower friction in dynamic sealing applications, and better physical performance for many materials. Disadvantages of smaller cross sections include higher likelihood of leaks due to surface defects in the gland, less stability in reciprocating applications, higher vulnerability to compression set, higher percentage swell (expansion due to fluid exposure or heat), and the need for tighter gland tolerances.

When working with an assembly containing thin or fragile parts, compression force of the O-ring also must be taken into account. Compression force depends on O-ring material properties, cross section, length (mean circumference), and amount of squeeze induced in the O-ring cross section by the gland.

SAE and ISO standards indicate appropriate sizes for various applications. A greater range of sizes are suitable for static applications than for dynamic applications. There also are differences in size ranges for internal pressure (pushing out from the O-ring's center) and external pressure (pushing inward from outside the O-ring) axial face seal applications. Fig. 2, Fig. 3, and the tables on the following pages show size ranges and relevant gland dimensions for SAE and ISO standard size codes.

<sup>a</sup> Positive values indicate no cramping.

Fig. 4. Extrusion Potential of O-Rings as a Function of Hardness and Clearance Gap

**Clearance Gap.**—When there is relative motion between two parts enclosing an O-ring, there must be a clearance gap between them (see Fig. 2 and Fig. 3). This broadly applies to piston and rod seals. Axial face seal applications also may have a clearance gap, but generally they do not.

For a piston gland (see Fig. 3), the radial clearance gap is the distance between the piston surface and the bore wall. For rod glands (again, see Fig. 3), the gap is the distance between the rod surface and the bore wall. The radial clearance gap on one side is at its maximum value when the piston or rod is side-loaded and touches the bore (zero clearance gap) on the other side. This gap often is expressed in terms of diametral clearance, which is twice the nominal radial clearance; diametral clearance is the same, regardless of piston or rod position.

If the radial clearance gap between the sealing surface and the gland edge is too large, or if the fluid pressure exceeds the deformation limits of the O-ring, it will extrude into the gap, reducing the effective life of the seal. This is especially problematic for soft silicone O-rings, where a 50 percent reduction in the standard clearance gap may be recommended. To prevent O-ring extrusion, reduce the clearance gap by modifying the gland dimensions, lower the system operating pressure, or install backup rings. A harder O-ring material may be used but could result in higher drag, increase the tendency of the seal to leak at low pressures, and necessitate additional dimensional changes.

Fig. 4 indicates effective diametral clearance values that may be used, depending on fluid pressure and O-ring hardness. If conditions of use fall to the right of the curve,

extrusion of the O-ring into the surrounding clearance gap is likely to occur, reducing the life of the O-ring. If conditions of use fall to the left of the curve, no extrusion should occur, in which case the O-ring can be expected to perform adequately. As the graph indicates, high-pressure applications require smaller clearances and harder O-rings for effective sealing.

As an example, in an O-ring application with a 0.004 in. (0.1 mm) diametral clearance and 2500 psi (17.24 MPa) pressure, extrusion will occur with a 70 Shore A durometer O-ring but not with an 80 Shore A durometer O-ring. Published gland dimensions normally apply to standard (70 Shore A) hardness O-rings and may need to be adjusted for use with harder materials.

**Backup Rings.**—Also referred to as *anti-extrusion rings*, backup rings are strongly recommended to prevent O-ring extrusion and nibbling in applications with pressures above 1500 psi (10.3 MPa), where pressure reversals are common, or where large clearance gaps are necessary. (*Nibbling* occurs when the O-ring extrudes into the clearance gap and then is pinched as the clearance gap opens and closes dynamically.) Backup rings are installed in the gland on one or both sides of the O-ring as shown in Fig. 5.

Backup rings may be made of leather, hard rubber, synthetic polymers such as phenolic or PTFE, various metals, or other hard materials. Two backup rings are required if pressure reversals will occur. (If space permits only one backup ring in an application with constant pressure direction, it should be placed so the O-ring is pushed into it when pressure is applied.)

Fig. 5. Preferred High-Pressure Configuration Including Backup Rings

**Groove Width and Slope.**—Groove widths are standardized to create a gland that approaches 85 percent filled when the O-ring is installed, assuming no swell, straight (perpendicular) walls, and no radii or edge breaks. If one or more backup rings are used, groove width must be increased as needed. If nonstandard gland dimensions are used in a customized application, gland fill must be evaluated to ensure groove width is sufficient. Groove widths for many O-ring sizes are shown in Table 2 and Table 3.

Perpendicular groove walls are best for preventing extrusion or nibbling, but sloped walls often facilitate machining and may be specified as a cost-saving measure. Groove walls slope outward up to 5 degrees from perpendicular generally are acceptable in low-pressure applications (less than 1500 psi or 10.34 MPa).

**O-Ring Stretch, Cramping, and Cross Section Reduction.**—*Stretch* occurs when the inner diameter of an installed and squeezed O-ring is smaller than that of the housing groove or rod. When an elastomeric O-ring is stretched, its cross-sectional area decreases. *Cramping*, also called *cramming*, occurs when the outer diameter of an installed and squeezed O-ring is larger than that of the housing groove or bore.

Interference caused by stretch or cramping provides some zero-pressure sealing force, stabilizes the O-ring, and works to hold it in place. Stretch and cramping allowance often is traded against the economic value of using standard stock and tooling sizes. Excess stretch or cramping can be successful; it can be found in the gland dimensional standards for some O-ring sizes. (Relevant stretch and cramping equations can be found for each gland type beginning on page 2682.)

**O-Ring Squeeze.**—The installed squeeze of an O-ring has a great effect on its sealing ability and effective life. Squeeze is the difference, often expressed as a percent, between the stretched O-ring cross-sectional diameter and the gland depth  $F$  (see Fig. 2). Any stretch applied to the O-ring by a radial gland will reduce the O-ring's cross-sectional diameter and affect squeeze. High squeeze values are used with very soft O-rings or with high pressures, while low squeeze values should be favored in dynamic applications where friction (heat and drag) is a concern. Sealing against vacuum also usually requires higher squeeze, with values between 10 and 30 percent not unusual.

Target squeeze will depend on O-ring size, material, and application parameters. For most elastomers and applications, the O-ring gland should ensure a minimum squeeze of 0.005 in. (0.13 mm) regardless of O-ring size to overcome the elastomers' tendency to permanently deform a very small amount. Standard general squeeze target ranges can be found in the sections specific to each gland type. O-rings with smaller cross sections tolerate higher squeeze better than larger cross section O-rings, but compression set or rupture can become a problem for most materials if squeeze is above 30 percent. (Relevant squeeze equations can be found for each gland type on page 2682.)

For inch-system static seals, many vendors recommend gland dimensions that adhere to the SAE AS5857 standard. This standard targets greater squeeze values than the general-use standards and applies to low-temperature, low-swell, and vacuum applications. It falls to the designer to decide if the greater squeeze values are necessary for a given application. Many O-ring suppliers have developed nonstandard glands; designers also may customize gland dimensions to optimize a particular application.

**Gland Fill.**—When installed, an O-ring compresses slightly and distorts into free space within the gland. Additional expansion or swelling also may occur due to contact of the O-ring with fluid or heat. The gland must be large enough to accommodate maximum expansion of the O-ring, to prevent it from extruding into the clearance gap or rupturing the assembly. In a dynamic application, any extruded O-ring material will quickly wear and fray, severely limiting seal life.

When designing a gland for a squeeze value that is higher than standard, gland fill must be carefully evaluated. Groove width can be increased to accommodate the squeezed volume of the O-ring, plus 15 percent to accommodate swell. This corresponds to an 85 percent gland fill target, assuming straight groove sides, no O-ring swell, and no internal or external radii. When significant swell is expected, further examination of gland fill must be undertaken. (Relevant gland fill equations can be found for each gland type below.)

**Axial Face Seal Glands.**—When an O-ring is compressed between two flat parts, this forms an axial face seal. This type of gland is always static, and it normally has no clearance gap between parts. A groove is cut into the face of one of the parts to house the O-ring, with gland fill considered when customizing gland dimensions. Groove diameter will depend on which direction the pressure or vacuum is coming from. If a face seal is expected to experience reversals in the direction of pressure, an O-ring is not the best solution; a flat gasket or other type of seal should be investigated.

**Internal Pressure Axial Face Seals:** If the pressure differential tends to expand the O-ring away from the center, this is considered internal pressure. When the gland is closed, the O-ring deforms as discussed below, with the outer diameter interfering (called *cramping* or *cramming*) in this case. Once squeezed, the O-ring will be in good contact with the outer wall of the gland, and the internal pressure should not cause O-ring movement. For SAE and ISO standard glands, the groove outer diameter maximum is often set equal to the O-ring nominal outer diameter; then the groove is adjusted to fulfill squeeze and gland fill targets. Using nominal dimensions, the SAE system allows up to 1 percent cramping, while the ISO system allows up to 5 percent cramping (reduces to 3 percent for inner diameters > 250 mm). Larger cramping values can work in some situations.

**External Pressure Axial Face Seals:** If the pressure differential tends to collapse the O-ring inward toward the center, this is considered external pressure. The inner diameter of the face groove should be specified to stretch the squeezed O-ring. SAE and ISO

standard glands set the inner diameter minimum as equal to the O-ring nominal inner diameter. The SAE system allows up to 5 percent stretch, while the ISO system allows up to 8 percent stretch of the squeezed O-ring inner diameter. Larger stretch values can work in some applications.

**Axial Face Gland Calculations:** When working with standard gland dimensions, the designer usually begins with a preferred cross section and inner diameter. Standards and catalogs can then be used to determine appropriate groove dimensions. These dimensions can be customized if desired, but the resulting O-ring stretch/cramping, squeeze, and gland fill must be evaluated to check for potential problems. Standard gland dimensions include some violations of standard recommended squeeze ranges. In the standards, target squeeze ranges are as follows:

SAE Sizes -0XX: 10–25%	SAE Sizes -1XX and -2XX: 10–20%	
SAE Sizes -3XX: 10–18%	SAE Sizes -4XX: 10–17%	
ISO Sizes -0XXA: 21–36%	ISO Sizes -1XXA: 19–30%	ISO Sizes -2XXA: 17–26%
ISO Sizes -3XXA: 15–23%	ISO Sizes -4XXA: 13–20%	

In axial face glands, most O-ring stretch/cramping occurs after it is squeezed and widens to interfere with (deform against) the groove wall. When an axial face gland is closed, the O-ring cross section is squeezed into an oval shape with length  $L$ . Assuming that the nominal mean diameter of the O-ring does not move, the squeezed O-ring inner diameter reduces and the outer diameter expands. This causes the O-ring to stretch and/or cramp in the gland, putting it in good contact with the groove walls and preventing movement of the O-ring. The following equations, which apply to Fig. 2, can be used to calculate stretch/cramping, squeeze, and gland fill for many elastomeric O-rings:

**Definition of variables:**

$ID$ = O-ring inner diameter	$W$ = O-ring cross section diameter
$AF$ = gland depth	$WR$ = reduced O-ring cross section in axial gland
$IDG$ = face groove inner diameter	$ODG$ = face groove outer diameter
$AG$ = groove width	$L$ = length of axially squeezed O-ring cross section
$ASID$ = axially squeezed O-ring inner diameter	$ASOD$ = axially squeezed O-ring outer diameter
$GVol$ = groove volume	$OVol$ = O-ring volume
$Fill\%$ = gland fill percent	$AStretch\%$ = inner diameter stretch (external pressure)
$Sq\%$ = axial O-ring squeeze percentage	$ACramp\%$ = outer diameter cramping (internal pressure)

**For Axial Glands:**

$WR_{min} = W_{min}$	$WR_{max} = W_{max}$
$L_{max} = \frac{\pi}{4AF_{min}}(W_{nom}^2 - AF_{min}^2) + AF_{min}$	$L_{min} = \frac{\pi}{4AF_{max}}(W_{nom}^2 - AF_{max}^2) + AF_{max}$
$ASID_{max} = ID_{nom} + W_{nom} - L_{min}$	$ASID_{min} = ID_{nom} + W_{nom} - L_{max}$
$ASOD_{max} = ID_{nom} + W_{nom} + L_{max}$	$ASOD_{min} = ID_{nom} + W_{nom} + L_{min}$
$ASretch\%_{max} = ((IDG_{max} - ASID_{min})/ASID_{min}) \times 100\%$	$ASretch\%_{min} = ((IDG_{min} - ASID_{max})/ASID_{max}) \times 100\%$
$ACramp\%_{max} = ((ODG_{min} - ASOD_{max})/ASOD_{max}) \times 100\%$	$ACramp\%_{min} = ((ODG_{max} - ASOD_{min})/ASOD_{min}) \times 100\%$
$AF_{max} = AF_{max}$ (given)	$AF_{min} = AF_{min}$ (given)
$Sq\%_{max} = ((WR_{max} - AF_{min})/W_{max}) \times 100\%$	$Sq\%_{min} = ((WR_{min} - AF_{max})/W_{min}) \times 100\%$
$OVol_{max} = \left(\frac{\pi^2}{4}\right) \times (ID_{max} + W_{max}) \times (W_{max}^2)$	$OVol_{min} = \left(\frac{\pi^2}{4}\right) \times (ID_{min} + W_{min}) \times (W_{min}^2)$
$Vol_{max} = \left(\frac{\pi}{4}\right) \times (ODG_{max}^2 - IDG_{min}^2) \times AF_{max}$	$GVol_{min} = \left(\frac{\pi}{4}\right) \times (ODG_{min}^2 - IDG_{max}^2) \times AF_{min}$
$Fill\%_{max} = (OVol_{max} / GVol_{min}) \times 100\%$	$Fill\%_{min} = (OVol_{min} / GVol_{max}) \times 100\%$

*Example:* Calculate stretch/cramping, squeeze, and gland fill for a -116 size O-ring (-116A in metric, shown in parentheses) in a standard axial face gland with external liquid pressure.

Given: Use gland standard SAE AS6235A-2015 (ISO 3601-2-2016):

$ID_{\max} = 0.746$	$ID_{\min} = 0.728$	$(ID_{\max} = 18.95)$	$(ID_{\min} = 18.49)$
$W_{\max} = 0.106$	$W_{\min} = 0.1$	$(W_{\max} = 2.71)$	$(W_{\min} = 2.53)$
$WR_{\min} = W_{\min} = 0.1$	$WR_{\max} = W_{\max} = 0.106$	$(WR_{\min} = W_{\min} = 2.53)$	$(WR_{\max} = W_{\max} = 2.71)$
$IDG_{\max} = 0.742$	$IDG_{\min} = 0.737$	$(IDG_{\max} = 18.9)$	$(IDG_{\min} = 18.84)$
$AF_{\max} = 0.09$	$AF_{\min} = 0.086$	$(AF_{\max} = 2.1)$	$(AF_{\min} = 2)$
$AG_{\min} = 0.141$	$AG_{\max} = 0.151$	$(AG_{\min} = 4)$	$(AG_{\max} = 4.2)$

Calculate:

$L_{\max} = 0.115$	$L_{\min} = 0.112$	$(L_{\max} = 3.125)$	$(L_{\min} = 3.018)$
$SID_{\max} = 0.728$	$SID_{\min} = 0.725$	$(SID_{\max} = 18.322)$	$(SID_{\min} = 18.215)$
$Stretch\%_{\max} = 2.4\%$	$Stretch\%_{\min} = 1.2\%$	$(Stretch\%_{\max} = 3.8\%)$	$(Stretch\%_{\min} = 2.9\%)$
$ODG_{\max} = 1.044$	$ODG_{\min} = 1.019$	$(ODG_{\max} = 27.3)$	$(ODG_{\min} = 26.85)$
$Sq\%_{\max} = 19\%$	$Sq\%_{\min} = 10\%$	$(Sq\%_{\max} = 26\%)$	$(Sq\%_{\min} = 17\%)$
$OVol_{\max} = 0.024$	$OVol_{\min} = 0.02$	$(OVol_{\max} = 392.5)$	$(OVol_{\min} = 331.98)$
$GVol_{\max} = 0.039$	$GVol_{\min} = 0.033$	$(GVol_{\max} = 643.31)$	$(GVol_{\min} = 571.15)$
$Fill\%_{\max} = 72\%$	$Fill\%_{\min} = 53\%$	$(Fill\%_{\max} = 69\%)$	$(Fill\%_{\min} = 52\%)$

Validate for the -116 SAE O-Ring:

$Stretch\%_{\max} = 2.4\%$	$Stretch\%_{\min} = 1.2\%$	Well within SAE limit of 5%.
$Sq\%_{\min} = 10\%$	$Sq\%_{\max} = 19\%$	Meets SAE recommendation of 10–20% for this cross section.
$Fill\%_{\max} = 72\%$	$Fill\%_{\min} = 53\%$	Within SAE target maximum of 85%.

Validate for the -116A ISO O-Ring:

$(Stretch\%_{\max} = 3.8\%)$	$(Stretch\%_{\min} = 2.9\%)$	Well within ISO limit of 8%.
$(Sq\%_{\min} = 17\%)$	$(Sq\%_{\max} = 26\%)$	ISO recommends 19–30% for this cross section. This slight lower limit violation invites caution in critical applications but is not uncommon.
$(Fill\%_{\max} = 69\%)$	$(Fill\%_{\min} = 52\%)$	Within ISO target maximum of 85%.

*PTFE O-Rings in Axial Face Seals:* Axial face seals can work with very stiff O-ring materials. Solid PTFE seals are often chosen because they are highly chemically inert and less costly than perfluorinated elastomer seals with similar chemical resistance. Glands for solid PTFE O-rings often target a squeeze of 10 to 20 percent for O-rings with cross-sectional diameters up to 0.210 in. (5.33 mm), and 10 to 15 percent for cross sections 0.210 to 0.275 in. (5.33 to 6.99 mm).

It is common practice to dimension the groove so that the groove's mean diameter (inner diameter plus one cross-sectional diameter) is equal to the O-ring's free-state mean diameter. Deliberate contact with the inner or outer groove walls also can be targeted as with elastomeric O-rings, but stretch and cramping should be zero or nearly zero. A groove with a full-radius floor is best to support the O-ring and control deformation. The groove width is normally 10 percent greater than the O-ring cross-sectional diameter. If a clearance gap is present, it must not exceed 0.005 in. (0.13 mm).

PTFE O-rings and their glands are extremely vulnerable to nicks, scratches, and particle contamination. These seals must be handled with care and installed in a clean environment.

If stretch is required, a PTFE O-ring can be heated up to 212 °F (100 °C) with boiling water or a dry heat source. If the gland is reopened after the O-ring is squeezed, the O-ring should be replaced, as PTFE will not rebound from compression and may not seal a second time.

**Axial Face Gland Dimensions:** Axial face seal grooves should have edge breaks or radii on the external edges to protect the O-ring from sharp edges during installation. Recommended edge breaks are 0.005–0.01 in. or 0.13–0.25 mm. Flatness must be tightly controlled for both mating parts, with 0.0004 in. per 4 in. (0.01 mm per 100 mm) a good target. Parallelism of the groove floor to the mating face also should be tightly controlled. A target parallelism of 0.0008 in. (0.02 mm) is normally sufficient. Ideally, groove walls should be vertical but may slope from vertical by up to 5 degrees to aid manufacturing. Table 2, Table 3, Table 4, and Table 5 contain a sampling of gland data for standard size ranges for axial face sealing. Many O-ring suppliers recommend axial gland dimensions according to the SAE AS5857 standard, which recommends greater squeeze and is suitable for low-temperature, low-swell, and vacuum applications.

Fig. 6. Dovetail and Half-Dovetail Grooves

**Dovetail Grooves.**—It is sometimes necessary to retain an O-ring in a static face groove more securely than by using the O-ring stretch alone. In these cases, if sticky O-ring grease is not a practical solution, a dovetail or half-dovetail groove (see Fig. 6) can be used. This is an expensive option, and it requires tight tolerances. Entry radii are critical for preventing installation damage and extrusion.

A half-dovetail groove is appropriate in cases where the applied pressure does not change direction. Be sure to orient a half-dovetail so that the pressure differential forces the O-ring against the vertical side of the groove. Full dovetail grooves can be used in applications with pressure reversals. The nominal mean diameter of these grooves should be the same as the nominal mean diameter of the O-ring (see Fig. 6 and Table 12).

Dovetail and half-dovetail grooves are not recommended for O-ring cross sections smaller than 0.139 in. (3.53 mm). These groove shapes also should not be used with rigid O-rings, because installation would cause permanent deformation. These glands can easily fail due to O-ring swell, and can cause problems in vacuum applications where the groove can release the trapped volume of air contained in its corner(s).

**Radial (Piston or Rod) Glands.**—Piston and rod seals can be static or dynamic, pneumatic or hydraulic. Different gland dimensions and O-ring size ranges may be required for different applications. Radial O-ring grooves for piston or rod seals should have edge breaks on the external edges to protect the O-ring during installation. Recommended edge breaks are 0.005–0.01 in. or 0.1–0.3 mm. Rod seals also will require a lead-in chamfer on the rod to facilitate assembly; piston seals will need an equivalent lead-in to the housing bore. Pneumatic radial seals are typically limited to pressures less than 150 psi (1 MPa), while hydraulic seals can perform at much higher pressures.

**Rod Glands:** Rod gland designs tend to begin with a known rod diameter. Rod glands contain the O-ring in a groove cut into the housing bore, and the groove diameter should be sized to cramp the O-ring outer diameter. The O-ring is often simultaneously stretched by the rod. Here the groove maximum outer diameter often is set equal to the nominal O-ring diameter as a starting point. Alternatively, using the minimum O-ring outside diameter and the

**Table 12. Dovetail and Half-Dovetail Groove Dimensions for Static Face Seals**  
(Zero Clearance Gap in Gland, 70 Shore A O-Rings)

Note: Sizes -0XX to -1XXA are not recommended for these grooves.

Note: Sizes -2XX to -2XXA should be used with caution in these grooves.

maximum housing diameter, target a maximum cramping of 1 percent of nominal O-ring dimensions at nominal squeeze in the SAE system or 5 percent in the ISO system for O-rings with an inner diameter less than 250 mm. Larger diameter metric O-rings are allowed only 3 percent cramping. Stretch on the rod is normally limited to 5 percent. It is sometimes acceptable to violate these limits, and standards commonly include such cases for smaller sizes.

**Piston Glands:** To design a piston gland, it is best to start with a known housing bore diameter. Piston glands have a groove cut into the outer diameter of a piston, where the O-ring is stretched slightly around the groove diameter and squeezed radially between the groove floor and housing bore. One exception to this is a pneumatic "floating" piston gland, discussed later. In most piston seal applications, limit maximum installed stretch of most elastomeric O-rings to 5 percent for long seal life. This can be exceeded for some small sizes, and standard gland dimensions include such exceptions.

**Radial Gland Calculations:** Designers usually begin a radial seal design with a preferred cross section and inner diameter selected to work with a given rod or bore. Standards and catalogs can then be used to determine appropriate gland dimensions. In the standards, target squeeze ranges are as follows:

SAE Sizes -0XX: 5-30%	SAE Sizes -1XX: 5-21%	SAE Sizes -2XX: 4-20%
SAE Sizes -3XX: 4-17%	SAE Sizes -4XX: 7-17%	
ISO Sizes -0XXA: 14-35% (static)	10-24% (pneumatic reciprocating)	13-27% (hydraulic reciprocating)
ISO Sizes -1XXA: 13-30% (static)	8-22% (pneumatic reciprocating)	12-24% (hydraulic reciprocating)
ISO Sizes -2XXA: 13-30% (static)	7-20% (pneumatic reciprocating)	11-22% (hydraulic reciprocating)
ISO Sizes -3XXA: 12-28% (static)	7-18% (pneumatic reciprocating)	11-20% (hydraulic reciprocating)
ISO Sizes -4XXA: 10-25% (static)	6-17% (pneumatic reciprocating)	9-19% (hydraulic reciprocating)

Radial gland depth used to calculate squeeze should take into account any clearance gap and groove eccentricity  $E$ . The radial clearance gap maximum and minimum are seen when the piston or rod is side-loaded and touching the wall of the bore. While SAE standards include these factors in squeeze range calculations and recommendations, ISO standards do not. Calculation by either method is valid, as long as it is compared with recommended ranges calculated the same way. (Calculated squeeze values given in tables here take clearance gap and eccentricity into account; as a result, some squeeze values shown may be outside ISO recommended ranges.)

Gland data for appropriate size ranges are given in Table 2, Table 3, and Table 6 to Table 11. These dimensions can be customized if desired, but the resulting O-ring stretch/cramping, squeeze, and gland fill must be evaluated to check for potential problems. Precise calculation methods for a radially stretched O-ring cross section are included in the

standards. As an approximation, Poisson's ratio ( $\mu$ ) with a value of 0.5 (for rubber) can be used as shown below. The following equations, which apply to Fig. 2 and Fig. 3, can be used to calculate stretch/cramping, squeeze, and gland fill for many elastomeric O-rings:

*Definition of variables:*

$ID$ = O-ring inner diameter	$W$ = O-ring cross section diameter
$G$ = groove width	$F$ = gland depth including clearance gap and groove eccentricity
$PISTON$ = outer diameter of the piston	$PG$ = diameter of a piston groove
$ROD$ = outer diameter of a rod	$BORE$ = inner diameter of the housing bore
$BG$ = diameter of a bore groove for a rod gland	$Stretch\%$ = percent O-ring stretch once installed in the groove
$Sq\%$ = O-ring squeeze percentage	$ACramp\%$ = outer diameter cramping
$GVol$ = groove volume	$OVol$ = O-ring volume
$Fill\%$ = gland fill percent	$WR$ = reduced cross section of a stretched O-ring
$\mu$ = Poisson's ratio = 0.5 (rubber)	$AR\%$ = approx. cross section reduction of stretched O-ring
$E$ = groove eccentricity	

Note: ISO standards omit the second two terms (clearance gap and eccentricity) in calculating  $F$ , affecting  $Squeeze\%$ .

**Piston Seal:**

$$Stretch\%_{min} = ((PG_{min} - ID_{max})/ID_{max}) \times 100\% \qquad Stretch\%_{max} = ((PG_{max} - ID_{min})/ID_{min}) \times 100\%$$

$$F_{max} = ((BORE_{max} - PG_{min})/2) + ((BORE_{max} - PISTON_{min})/2) + (E_{max}/2)$$

$$F_{min} = ((BORE_{min} - PG_{max})/2) - ((BORE_{min} - PISTON_{min})/2) - (E_{max}/2)$$

$$GVol_{max} = \left(\frac{\pi}{4}\right) \times (BORE_{max}^2 - PG_{min}^2) \times G_{max} \qquad GVol_{min} = \left(\frac{\pi}{4}\right) \times (BORE_{min}^2 - PG_{max}^2) \times G_{min}$$

**Rod Seal:**

$$Stretch\%_{min} = ((ROD_{min} - ID_{max})/ID_{max}) \times 100\% \qquad Stretch\%_{max} = ((ROD_{max} - ID_{min})/ID_{min}) \times 100\%$$

$$F_{max} = ((BG_{max} - ROD_{min})/2) + ((BORE_{max} - ROD_{min})/2) + (E_{max}/2)$$

$$F_{min} = ((BG_{min} - ROD_{max})/2) - ((BORE_{max} - ROD_{max})/2) - (E_{max}/2)$$

$$GVol_{max} = \left(\frac{\pi}{4}\right) \times (BG_{max}^2 - ROD_{min}^2) \times G_{max} \qquad GVol_{min} = \left(\frac{\pi}{4}\right) \times (BG_{min}^2 - ROD_{max}^2) \times G_{min}$$

**All Radial Seals:**

$$AR\%_{min} = (Stretch\%_{min} \times \mu) \qquad AR\%_{max} = (Stretch\%_{max} \times \mu)$$

$$WR_{max} = W_{max} - ((AR\%_{min}/100) \times W_{max}) \qquad WR_{min} = W_{min} - ((AR\%_{max}/100) \times W_{min})$$

$$Sq\%_{min} = ((WR_{min} - F_{max})/W_{min}) \times 100\% \qquad Sq\%_{max} = ((WR_{max} - F_{min})/W_{max}) \times 100\%$$

$$OVol_{max} = \left(\frac{\pi}{4}\right) \times (ID_{max} + W_{max}) \times (W_{max}^2) \qquad OVol_{min} = \left(\frac{\pi}{4}\right) \times (ID_{min} + W_{min}) \times (W_{min}^2)$$

$$Fill\%_{max} = (OVol_{max} / GVol_{min}) \times 100\% \qquad Fill\%_{min} = (OVol_{min} / GVol_{max}) \times 100\%$$

As an example, calculate stretch/cramping, squeeze, and gland fill for an SAE size -116 O-ring (-116A in ISO, shown in parentheses below) in a standard pneumatic reciprocating piston gland:

Given: Use gland standard SAE AS4716C-2017 (ISO 3601-2-2016):

$ID_{max} = 0.746$	$ID_{min} = 0.728$	$(ID_{max} = 18.95)$	$(ID_{min} = 18.49)$
$W_{max} = 0.106$	$W_{min} = 0.1$	$(W_{max} = 2.71)$	$(W_{min} = 2.53)$
$G_{min} = 0.141$	$G_{max} = 0.151$	$(G_{min} = 4)$	$(G_{max} = 4.2)$
$PG_{max} = 0.751$	$PG_{min} = 0.749$	$(PG_{max} = 19.17)$	$(PG_{min} = 19.137)$
$BORE_{max} = 0.927$	$BORE_{min} = 0.925$	$(BORE_{max} = 23.473)$	$(BORE_{min} = 23.44)$
$PISTON_{max} = 0.923$	$PISTON_{min} = 0.922$	$(PISTON_{max} = 23.42)$	$(PISTON_{min} = 23.399)$
$E_{max} = 0.002$		$(E_{max} = 0.025)$	

## Calculate:

$F_{\max} = 0.093$	$F_{\min} = 0.085$	$(F_{\max} = 2.218)$	$(F_{\min} = 2.102)$
$Stretch\%_{\max} = 3.2\%$	$Stretch\%_{\min} = 0.4\%$	$(Stretch\%_{\max} = 3.7\%)$	$(Stretch\%_{\min} = 1\%)$
$AR\%_{\max} = 1.6\%$	$AR\%_{\min} = 0.2\%$	$(AR\%_{\max} = 1.8\%)$	$(AR\%_{\min} = 0.5\%)$
$WR_{\max} = 0.106$	$WR_{\min} = 0.098$	$(WR_{\max} = 2.697)$	$(WR_{\min} = 2.483)$
$Sq\%_{\min} = 6\%$	$Sq\%_{\max} = 20\%$	$(Sq\%_{\min} = 11\%)$	$(Sq\%_{\max} = 22\%)$
$GVol_{\max} = 0.035$	$GVol_{\min} = 0.032$	$(GVol_{\max} = 587.69)$	$(GVol_{\min} = 543.02)$
$Fill\%_{\max} = 73\%$	$Fill\%_{\min} = 58\%$	$(Fill\%_{\max} = 72.3\%)$	$(Fill\%_{\min} = 56.5\%)$

## Validate for the -116 SAE O-Ring:

$Stretch\%_{\max} = 3.2\%$	$Stretch\%_{\min} = 0.4\%$	Well within SAE limit of 5%.
$Sq\%_{\min} = 6\%$	$Sq\%_{\max} = 20\%$	Meets SAE recommendation of 5–21% for this cross section.
$Fill\%_{\max} = 73\%$	$Fill\%_{\min} = 58\%$	Within SAE target maximum of 85%.

## Validate for the -116A ISO O-Ring:

$(Stretch\%_{\max} = 3.7\%)$	$(Stretch\%_{\min} = 1\%)$	Well within ISO limit of 5%.
$(Sq\%_{\min} = 11\%)$	$(Sq\%_{\max} = 22\%)$	Meets ISO recommendation of 8–22% for this cross section.
$(Fill\%_{\max} = 72.3\%)$	$(Fill\%_{\min} = 56.5\%)$	Within ISO target maximum of 85%.

**Floating Piston Glands:** In pneumatic reciprocating applications, where friction (manifesting as drag and/or heat) is a critical consideration, a “floating” piston gland design can be beneficial because it applies zero stretch to the O-ring. The gland is located on the piston and is overly deep to avoid contact with the O-ring and allow some radial flotation. Groove width is reduced by about 20 percent to help prevent axial movement in the absence of stretch. All compression of the O-ring happens at the outer diameter, where it interferes slightly (called “cramping”) with the housing bore. The amount of recommended cramping increases with O-ring cross section. Some recommended cramping values for floating piston glands are as follows:

Here, floating piston gland cramping = O-ring nominal outside diameter – housing bore diameter minimum

Sizes -006 to -012:	Cramping = 0.033–0.040 in. (0.8–1.0 mm)
Sizes -104 to -116:	Cramping = 0.036–0.060 in. (0.9–1.5 mm)
Sizes -201 to -222:	Cramping = 0.059–0.080 in. (1.5–2.0 mm)
Sizes -309 to -349:	Cramping = 0.082–0.122 in. (2.1–3.1 mm)
Sizes -425 to -460:	Cramping = 0.138–0.173 in. (3.5–4.4 mm)

Floating piston glands are suitable for low-pressure hydraulics below 200 psi (1.38 MPa) that allow for some leakage. Pneumatic piston glands also can be designed to float, but floating pneumatic rod glands have drag problems due to rod-induced stretch and therefore are not recommended. Each time the direction of pressure changes and the O-ring moves from one side of the groove to the other, fluid or gas can travel under and around the seal until the O-ring is again in contact with a groove wall. Lubrication is needed for pneumatic applications.

**Rotary Motion Radial Seals:** Lip seals and other engineered seals generally work best in rotary applications, but O-rings made of wear-resistant, hard material may be used with caution. Rotary O-ring applications are configured with the groove in the housing bore to prevent centrifugal expansion of the O-ring. The shaft should rotate inside the O-ring, and squeeze must be kept very low. Groove diameter normally is sized 5 percent smaller than the O-ring outer diameter to prevent rotation of the O-ring and cramp it against the shaft. The shaft must be supported with bearings, with the O-ring simply acting as a seal. This application requires reliable lubrication and heat management.

**O-Ring Lubrication.**—Dynamic seals typically rely on system fluid to lubricate the seal as it rubs against the facing part. Installation instructions for O-rings in dynamic applications often suggest coating the O-ring in either the process fluid if applicable, or an acceptable seal lubricant. Lubrication issues can arise when sealing a dry, volatile, or crystallizing fluid. In pneumatic applications, lubrication is provided either by using lubricated air or with periodic lubrication of the seals. Reciprocating seals maintain lubrication film thickness best at high piston velocities.

**Gland Surface Quality.**—All gland surfaces should be free of burrs, nicks, and scratches; the chosen machining method should not leave tool marks that cut across the gland. To seal properly, the gland and O-ring surfaces must be clean of debris. Surface quality and cleanliness matter most with small cross section O-rings and/or stiff materials. In a static seal, an O-ring made from softer material can be used to compensate for a rough gland. It should be noted that the two systems of measurement recommend nonequivalent maximum surface roughness average (Ra) for various cases, as follows:

Face seals, sealing surfaces:	SAE: 16 $\mu\text{in.}$	ISO: 1.6 $\mu\text{m}$
Face seals, contact wall of groove:	SAE: 32 $\mu\text{in.}$	ISO: 1.6 $\mu\text{m}$
Face seals, non-contact wall of groove:	SAE: 63 $\mu\text{in.}$	ISO: 1.6 $\mu\text{m}$
Piston and rod seals, sealing surfaces:	SAE: Liquids: 32 $\mu\text{in.}$ (Gases: 16 $\mu\text{in.}$ )	ISO: Dynamic: 0.4 $\mu\text{m}$ (Static: 1.6 $\mu\text{m}$ )
Piston and rod seals, groove walls:	SAE: Dynamic: 32 $\mu\text{in.}$ (Static: 63 $\mu\text{in.}$ )	ISO: 1.6 $\mu\text{m}$

Surface finishes of less than 5  $\mu\text{in.}$  (0.13  $\mu\text{m}$ ) Ra are too smooth to ensure long seal life because they wipe too cleanly, causing the O-ring to wear against the housing in the absence of a lubricating film. The best quality surfaces are honed, burnished, or hard chromium-plated. Soft and stringy metals, such as aluminum, brass, bronze, Monel, or free machining stainless steel, should not be used in contact with moving seals.

**O-Ring Installation.**—During installation, O-rings must not traverse across sharp edges or external threads. All edges encountered by the O-ring must have chamfers or radii. In radial glands, a generous lead-in chamfer of 15 to 20 degrees with a rounded edge is necessary to prevent damage, although an installation mandrel still may be needed in some cases. Never twist or roll an O-ring, and pay special attention during installation of O-rings with a large ratio of inner diameter to cross-sectional diameter. Avoid stretching the inner diameter of an elastomeric O-ring more than 50 percent, and certainly not more than 100 percent during installation. Rigid O-rings normally should not be stretched, though some materials may allow gentle expansion through applied heat for installation purposes.

The preferred bore materials are steel and cast iron, and pistons should be softer than the bore to avoid scratching them. The bore sections should be thick enough to resist expansion and contraction under pressure so that the radial clearance gap remains constant, reducing the chance of damage to the O-ring by extrusion and nibbling. Some compatibility problems may occur when O-rings are used with plastics parts because certain compounding ingredients may attack the plastics, causing crazing of the plastics surface.

**O-Rings Used as Drive Belts.**—O-rings are frequently used as driving belts in round bottom or V-grooves with light tension for low-power drive elements. Special compounds are available with high resistance to stress relaxation and fatigue for these applications. Best service is obtained in drive belt applications when the initial belt tension is between 80 and 200 psi and the initial installed stretch is between 8 and 25 percent of the circumferential length. Most of the compounds used for drive belts operate best between 10 and 15 percent stretch, although polyurethane has good service life when stretched as much as 20 to 25 percent.

**Table 13. Typical O-Ring Compounds**

Nitrile	General-purpose compound for use with most petroleum oils, greases, gasoline, alcohols and glycols, LP gases, propane and butane fuels. Also for food service to resist vegetable and animal fats. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}\text{F}$ ( $-40$ to $121^{\circ}\text{C}$ ). Excellent compression set, tear and abrasion resistance, but poor resistance to ozone, sunlight and weather. Higher-temperature nitrile compounds with similar properties are also available.
Hydrogenated Nitrile	Similar to general-purpose nitrile compounds with improved high-temperature performance, resistance to aging, and petroleum product compatibility.
Polychloroprene (Neoprene)	General-purpose compound with low compression set and good resistance to elevated temperatures. Good resistance to sunlight, ozone, and weathering, and fair oil resistance. Frequently used for refrigerator gases such as Freon. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}\text{F}$ ( $-40$ to $121^{\circ}\text{C}$ ).
Ethylene Propylene	General-purpose compound with excellent resistance to polar fluids such as water, steam, ketones, and phosphate esters, and brake fluids, but not resistant to petroleum oils and solvents. Excellent resistance to ozone and flexing. Recommended for belt-drive applications. Continuous duty service in temperatures up to $250^{\circ}\text{F}$ ( $121^{\circ}\text{C}$ ).
Silicone	Widest temperature range ( $-150^{\circ}$ to $500^{\circ}\text{F}$ or $-101$ to $260^{\circ}\text{C}$ ) and best low-temperature flexibility of all elastomeric compounds. Not recommended for dynamic applications, due to low strength, or for use with most petroleum oils. Shrinkage characteristics similar to organic rubber, allowing existing molds to be used.
Polyurethane	Toughest of the elastomers used for O-rings, characterized by high tensile strength, excellent abrasion resistance, and tear strength. Compression set and heat resistance are inferior to nitrile. Suitable for hydraulic applications that anticipate abrasive contaminants and shock loads. Temperature service range of $-65^{\circ}$ to $212^{\circ}\text{F}$ ( $-54$ to $100^{\circ}\text{C}$ ).
Fluorosilicone	Wide temperature range ( $-80^{\circ}$ to $450^{\circ}\text{F}$ or $-62$ to $232^{\circ}\text{C}$ ) for continuous duty and excellent resistance to petroleum oils and fuels. Recommended for static applications only, due to limited strength and low abrasion resistance.
Polyacrylate	Heat resistance better than nitrile compounds, but inferior low temperature, compression set, and water resistance. Often used in power steering and transmission applications due to excellent resistance to oil, automatic transmission fluids, oxidation, and flex cracking. Temperature service range of $-20^{\circ}$ to $300^{\circ}\text{F}$ ( $-29$ to $149^{\circ}\text{C}$ ).
Fluorocarbon (Viton)	General-purpose compound suitable for applications requiring resistance to aromatic or halogenated solvents or to high temperatures ( $-20^{\circ}$ to $500^{\circ}\text{F}$ or $-29$ to $260^{\circ}\text{C}$ with limited service to $600^{\circ}\text{F}$ or $316^{\circ}\text{C}$ ). Outstanding resistance to blended aromatic fuels, straight aromatics, and halogenated hydrocarbons and other petroleum products. Good resistance to strong acids (temperature range in acids $-20^{\circ}$ to $250^{\circ}\text{F}$ or $-29$ to $121^{\circ}\text{C}$ ), but not effective for use with very hot water, steam, and brake fluids.

**O-Ring Materials.**—Thousands of O-ring compounds have been formulated for specific applications. Some of the most common types of compounds and their typical applications are given in [Table 13](#). The Shore A durometer is the standard instrument used for measuring the hardness of elastomeric compounds. The softest O-rings are 50 and 60 Shore A and stretch more easily, exhibit lower breakout friction, seal better on rough surfaces, and need less clamping pressure than harder rings. For a given squeeze, the higher the durometer hardness of a ring, the greater the associated friction because a greater compressive force is exerted by hard rings than soft rings.

The most widely used rings are medium-hard O-rings with 70 Shore A hardness, which have the best wear resistance and frictional properties for running seals. Applications that involve oscillating or rotary motion frequently use 80 Shore A materials. Rings with a hardness above 85 Shore A often leak more because of less effective wiping action. These harder rings have a greater resistance to extrusion, but for small sizes may break easily during installation. O-ring hardness varies inversely with temperature, but when used for continuous service at high temperatures, the hardness may eventually increase after an initial softening of the compound.

O-ring compounds have thermal coefficients of expansion in the range of 7 to 20 times that of metal components, so shrinkage or expansion with temperature change can pose problems of leakage past the seal at low temperatures and excessive pressures at high temperatures when a ring is installed in a tight-fitting groove. Likewise, when an O-ring is immersed in a fluid, the compound usually absorbs some of the fluid and consequently increases in volume. Manufacturer's data give volumetric increase data for compounds completely immersed in various fluids. For confined rings (those with only a portion of the ring exposed to fluid), the size increase may be considerably lower than for rings completely immersed in fluid. Certain fluids can also cause ring shrinkage during "idle" periods, i.e., when the seal has a chance to dry out. If this shrinkage is more than 3 to 4 percent, the seal may leak.

Excessive swelling due to fluid contact and high temperatures softens all compounds approximately 20 to 30 Shore A points from room temperature values and designs should anticipate the expected operating conditions. At low temperatures, swelling may be beneficial because fluid absorption may make the seal more flexible. However, the combination of low temperature and low pressure makes a seal particularly difficult to maintain. A soft compound should be used to provide a resilient seal at low temperatures. Below  $-65^{\circ}\text{F}$ , only compounds formulated with silicone are useful; other compounds are simply too stiff, especially for use with air and other gases.

Compression set is another material property and a very important sealing factor. It is a measure of the shape memory of the material, that is, the ability to regain shape after being deformed. Compression set is a ratio, expressed as a percentage, of the unrecovered to original thickness of an O-ring compressed for a specified period of time between two heated plates and then released. O-rings with excessive compressive set will fail to maintain a good seal because, over time, the ring will be unable to exert the necessary compressive force (squeeze) on the enclosing walls. Swelling of the ring due to fluid contact tends to increase the squeeze and may partially compensate for the loss due to compression set. Generally, compression set varies by compound and ring cross-sectional diameter, and increases with the operating temperature.

## ROLLED STEEL, WIRE, SHEET METAL, WIRE ROPE

## Rolled Steel Sections

**Lengths of Angles Bent to Circular Shape.**—To calculate the length of an angle-iron used either inside or outside of a tank or smokestack, the following table of constants may be used: Assume, for example, that a stand-pipe, 20 feet inside diameter, is provided with a 3 by 3 by  $\frac{3}{8}$  inch angle-iron on the inside at the top. The circumference of a circle 20 feet in diameter is 754 inches. From the table of constants, find the constant for a 3 by 3 by  $\frac{3}{8}$  inch angle-iron, which is 4.319. The length of the angle then is  $754 - 4.319 = 749.681$  inches. Should the angle be on the outside, add the constant instead of subtracting it; thus,  $754 + 4.319 = 758.319$  inches.

Size of Angle	Const.	Size of Angle	Const.	Size of Angle	Const.
$\frac{1}{4} \times 2 \times 2$	2.879	$\frac{5}{16} \times 3 \times 3$	4.123	$\frac{1}{2} \times 5 \times 5$	6.804
$\frac{5}{16} \times 2 \times 2$	3.076	$\frac{3}{8} \times 3 \times 3$	4.319	$\frac{3}{8} \times 6 \times 6$	7.461
$\frac{3}{8} \times 2 \times 2$	3.272	$\frac{1}{2} \times 3 \times 3$	4.711	$\frac{1}{2} \times 6 \times 6$	7.854
$\frac{1}{4} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.403	$\frac{3}{8} \times 3\frac{1}{2} \times 3\frac{1}{2}$	4.843	$\frac{3}{4} \times 6 \times 6$	8.639
$\frac{5}{16} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.600	$\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$	5.235	$\frac{1}{2} \times 8 \times 8$	9.949
$\frac{3}{8} \times 2\frac{1}{2} \times 2\frac{1}{2}$	3.796	$\frac{3}{8} \times 4 \times 4$	5.366	$\frac{3}{4} \times 8 \times 8$	10.734
$\frac{1}{2} \times 2\frac{1}{2} \times 2\frac{1}{2}$	4.188	$\frac{1}{2} \times 4 \times 4$	5.758	$1 \times 8 \times 8$	11.520
$\frac{1}{4} \times 3 \times 3$	3.926	$\frac{3}{8} \times 5 \times 5$	6.414	...	...

**Standard Designations of Rolled Steel Shapes.**—Through a joint effort, the American Iron and Steel Institute (AISI) and the American Institute of Steel Construction (AISC) have changed most of the designations for their hot-rolled structural steel shapes. The present designations, standard for steel producing and fabricating industries, should be used when designing, detailing, and ordering steel. The accompanying Table 1 compares the present designations with the previous descriptions.

Table 1. Hot-Rolled Structural Steel Shape Designations (AISI and AISC)

Present Designation	Type of Shape	Previous Designation
W 24 × 76	W shape	24 WF 76
W 14 × 26	W shape	14 B 26
S 24 × 100	S shape	24 I 100
M 8 × 18.5	M shape	8 M 18.5
M 10 × 9	M shape	10 IR 9.0
M 8 × 34.3	M shape	8 × 8 M 34.3
C 12 × 20.7	American Standard Channel	12 I 20.7
MC 12 × 45	Miscellaneous Channel	12 × 4 I 45.0
MC 12 × 10.6	Miscellaneous Channel	12 IR 10.6
HP 14 × 73	HP shape	14 BP 73
L 6 × 6 × 3/4	Equal Leg Angle	∠ 6 × 6 × 3/4
L 6 × 4 × 3/8	Unequal Leg Angle	∠ 6 × 4 × 3/8
WT 12 × 38	Structural Tee cut from W shape	ST 12 WF 38
WT 7 × 13	Structural Tee cut from W shape	ST 7 B 13
St 12 × 50	Structural Tee cut from S shape	ST 12 I 50
MT 4 × 9.25	Structural Tee cut from M shape	ST 4 M 9.25
MT 5 × 4.5	Structural Tee cut from M shape	ST 5 JR 4.5
MT 4 × 17.15	Structural Tee cut from M shape	ST 4 M 17.15
PL 1/2 × 18	Plate	PL 18 × 1/2
Bar 1	Square Bar	Bar 1
Bar 1 1/4 Ø	Round Bar	Bar 1 1/4 Ø
Bar 2 1/2 × 1/2	Flat Bar	Bar 2 1/2 × 1/2
Pipe 4 Std.	Pipe	Pipe 4 Std.
Pipe 4 X-Strong	Pipe	Pipe 4 X-Strong
Pipe 4 XX-Strong	Pipe	Pipe 4 XX-Strong
TS 4 × 4 × .375	Structural Tubing: Square	Tube 4 × 4 × .375
TS 5 × 3 × .375	Structural Tubing: Rectangular	Tube 5 × 3 × .375
TS 3 OD × .250	Structural Tubing: Circular	Tube 3 OD × .250

Table 2a. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:

**W 18 × 64**

indicates a wide-flange section having a nominal depth of 18 inches, and a nominal weight per foot of 64 pounds. Actual geometry for each section can be obtained from the values below.

Designation	Area, A inch <sup>2</sup>	Depth, d inch	Flange		Web Thick- ness, t <sub>w</sub> inch	Axis X-X			Axis Y-Y		
			Width, b <sub>f</sub> inch	Thick- ness, t <sub>f</sub> inch		I inch <sup>4</sup>	S inch <sup>3</sup>	r inch	I inch <sup>4</sup>	S inch <sup>3</sup>	r inch
W 27 × 178	52.3	27.81	14.085	1.190	0.725	6990	502	11.6	555	78.8	3.26

<sup>a</sup> Consult the AISC Manual, noted above, for W steel shapes having nominal depths greater than 27 inches.

Symbols: I = moment of inertia; S = section modulus; r = radius of gyration.

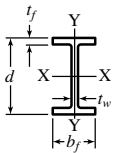

Data taken from the "Manual of Steel Construction," 8th Edition, 1980, with permission of the American Institute of Steel Construction.

Table 2b. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot. Thus:

**W 16 × 78**

indicates a wide-flange section having a nominal depth of 16 inches, and a nominal weight per foot of 78 pounds. Actual geometry for each section can be obtained from the values below.

Table 2d. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:

**W 8 × 67**

indicates a wide-flange section having a nominal depth of 8 inches, and a nominal weight per foot of 67 pounds. Actual geometry for each section can be obtained from the values below.

Designation	Area, A inch <sup>2</sup>	Depth, d inch	Flange		Web Thick- ness, t <sub>w</sub> inch	Axis X-X			Axis Y-Y

Table 6. Steel Angles with Unequal Legs

These angles are commonly designated by section symbol, width of each leg, and thickness, thus:

$$L7 \times 4 \times \frac{1}{2}$$

indicates a 7 × 4-inch angle of ½-inch thickness.

Structural sections are available in 6061-T6 aluminum alloy. Data supplied by The Aluminum Association.

### Wire and Sheet Metal Gages

The thicknesses of sheet metals and the diameters of wires conform to various gaging systems. These gage sizes are indicated by numbers, and the following tables give the decimal equivalents of the different gage numbers. Much confusion has resulted from the use of gage numbers, and in ordering materials it is preferable to give the exact dimensions in decimal fractions of an inch. While the dimensions thus specified should conform to the gage ordinarily used for a given class of material, any error in the specification due, for example, to the use of a table having "rounded off" or approximate equivalents, will be apparent to the manufacturer at the time the order is placed. Furthermore, the decimal method of indicating wire diameters and sheet metal thicknesses has the advantage of being self-explanatory, whereas arbitrary gage numbers are not. The decimal system of indicating gage sizes is now being used quite generally, and gage numbers are gradually being discarded. Unfortunately, there is considerable variation in the use of different gages. For example, a gage ordinarily used for copper, brass and other nonferrous materials, may at times be used for steel, and vice versa. The gages specified in the following are the ones ordinarily employed for the materials mentioned, but there are some minor exceptions and variations in the different industries.

**Wire Gages.**—The wire gage system used by practically all of the steel producers in the United States is known by the name Steel Wire Gage or, to distinguish it from the Standard Wire Gage (S.W.G.) used in Great Britain, it is called the United States Steel Wire Gage. It is the same as the Washburn and Moen, American Steel and Wire Company, and Roebling wire gages. The name has the official sanction of the Bureau of Standards at Washington but is not legally effective. The only wire gage which has been recognized in Acts of Congress is the Birmingham Gage (also known as Stub's Iron Wire). The Birmingham Gage is, however, nearly obsolete in both the United States and Great Britain, where it originated. Copper and aluminum wires are specified in decimal fractions. They were formerly universally specified in the United States by the American or Brown & Sharpe Wire Gage. Music spring steel wire, one of the highest quality wires of several types used for mechanical springs, is specified by the piano or music wire gage.

In Great Britain one wire gage has been legalized. This is called the Standard Wire Gage (S.W.G.), formerly called Imperial Wire Gage.

**Gages for Rods.**—Steel wire rod sizes are designated by fractional or decimal parts of an inch and by the gage numbers of the United States Steel Wire Gage. Copper and aluminum rods are specified by decimal fractions and fractions. Drill rod may be specified in decimal fractions but in the carbon and alloy tool steel grades may also be specified in the Stub's Steel Wire Gage and in the high-speed steel drill rod grade may be specified by the Morse Twist Drill Gage (Manufacturers' Standard Gage for Twist Drills). For gage numbers with corresponding decimal equivalents see the tables of American Standard Straight Shank Twist Drills, for example, page 933, and Table 5a on page 2710.

**Gages for Wall Thicknesses of Tubing.**—At one time the Birmingham or Stub's Iron Wire Gage was used to specify the wall thickness of the following classes of tubing: seamless brass, seamless copper, seamless steel, and aluminum. The Brown & Sharpe Wire Gage was used for brazed brass and brazed copper tubing. Wall thicknesses are now specified by decimal parts of an inch but the wall thickness of steel pressure tubes and steel mechanical tubing may be specified by the Birmingham or Stub's Iron Wire Gage. In Great Britain the Standard Wire Gage (S.W.G.) is used to specify the wall thickness of some kinds of steel tubes.

Table 1. Wire Gages in Approximate Decimals of an Inch

No. of Wire Gage	American Wire or Brown & Sharpe Gage	Steel Wire Gage (US) <sup>a</sup>	British Standard Wire Gage (Imperial Wire Gage)	Music or Piano Wire Gage	Birmingham or Stub's Iron Wire Gage	Stub's Steel Wire Gage	No. of Wire Gage	Stub's Steel Wire Gage

<sup>a</sup> Also known as Washburn and Moen, American Steel and Wire Co. and Roebling wire gages. A greater selection of sizes is available and is specified by what are known as split gage numbers. They can be recognized by  $\frac{1}{2}$  fractions which follow the gage number; i.e.,  $4\frac{1}{2}$ . The decimal equivalents of split gage numbers are in the Steel Products Manual entitled: *Wire and Rods, Carbon Steel* published by the American Iron and Steel Institute, Washington, DC.

<sup>a</sup> Gauge is Birmingham Wire Gauge (same as Stub's Iron Wire Gauge)

**Strength and Stiffness of Perforated Metals.**—It is common practice to use perforated metals in equipment enclosures to provide cooling by the flow of air or fluids. If the perforated material is to serve also as a structural member, then calculations of stiffness and strength must be made that take into account the effect of the perforations on the strength of the panels.

The accompanying table provides equivalent or effective values of the yield strength  $S^*$ ; modulus of elasticity  $E^*$ ; and Poisson's ratio  $\nu^*$  of perforated metals in terms of the values for solid material. The  $S^*/S$  and  $E^*/E$  ratios, given in the accompanying table for the standard round hole staggered pattern, can be used to determine the safety margins or deflections for perforated metal use as compared to the unperforated metal for any geometry or loading condition.

Perforated material has different strengths depending on the direction of loading; therefore, values of  $S^*/S$  in the table are given for the width (strongest) and length (weakest) directions. Also, the effective elastic constants are for plane stress conditions and apply to the in-plane loading of thin perforated sheets; the bending stiffness is greater. However, since most loading conditions involve a combination of bending and stretching, it is more convenient to use the same effective elastic constants for these combined loading conditions. The plane stress effective elastic constants given in the table can be conservatively used for all loading conditions.

Value in parentheses specifies holes per square inch instead of center distance.  $S^*/S$  = ratio of yield strength of perforated to unperforated material;  $E^*/E$  = ratio of modulus of elasticity of perforated to unperforated material;  $\nu^*$  = Poisson's ratio for given percentage of open area.

IPA is Industrial Perforators Association.

**Sheet Metal Gages.**—Thicknesses of steel sheets given in **Table 2** are based upon a weight of 41.82 pounds per square foot per inch of thickness, which is known as the Manufacturers' Standard Gage for Sheet Steel. This gage differs from the older United States Standard Gage for iron and steel sheets and plates, established by Congress in 1893, based upon a weight of 40 pounds per square foot per inch of thickness which is the weight of wrought-iron plate.

<sup>a</sup> Manufacturers' Standard Gage for Sheet Steel

<sup>b</sup> B.G. is the Birmingham Gage for sheets and hoops.

*The United States Standard Gage* (not shown above) for iron and steel sheets and plates was established by Congress in 1893 and was primarily a *weight* gage rather than a thickness gage. The equivalent thicknesses were derived from the weight of wrought iron. The weight per cubic foot was taken at 480 pounds, thus making the weight of a plate 12 inches square and 1 inch thick, 40 pounds. In converting weight to equivalent thickness, gage tables formerly published contained thicknesses equivalent to the basic weights just mentioned. For example, a No. 3 US gage represents a wrought-iron plate having a weight of 10 pounds per square foot; hence, if the weight per square foot per inch thick is 40 pounds, the plate thickness for a No. 3 gage =  $10 \div 40 = 0.25$  inch, which was the original thickness equivalent for this gage number. Because this and the other thickness equivalents were derived from the weight of wrought iron, they are not correct for steel.

Zinc sheets are usually ordered by specifying decimal thickness although a zinc gage exists and is shown in [Table 2](#).

Most sheet metal products in Great Britain are specified by the British Standard Wire Gage (Imperial Wire Gage). Black iron and steel sheet and hooping, and galvanized flat and corrugated steel sheet, however, are specified by the Birmingham Gage (B.G.), which was legalized in 1914, and are also shown in [Table 2](#). This Birmingham Gage should not be confused with the Birmingham or Stub's Iron Wire Gage mentioned previously.

Thicknesses of aluminum, copper, and copper-base alloys were formerly designated by the American or Brown & Sharpe Wire Gage but now are specified in decimals or fractions of an inch. American National Standard B32.1-1952 (Withdrawn) entitled Preferred Thicknesses for Uncoated Thin Flat Metals (see accompanying [Table 3](#)) gives thicknesses that are based on the 20- and 40-series of preferred numbers in American National Standard Preferred Numbers — ANSI Z17.1 (see Handbook page [687](#)) and are applicable to uncoated, thin, flat metals and alloys. Each number of the 20-series is approximately 12 percent greater than the next smaller one, and each number of the 40-series is approximately 6 percent greater than the next smaller one.

...	0.106	0.045	0.045	...	0.019	0.004	0.004

The American National Standard ANSI/ASME B32.1-1952 (Withdrawn) lists preferred thicknesses that are based on the 20- and 40-series of preferred numbers and states that those based on the 40-series should provide adequate coverage. However, where intermediate thicknesses are required, the Standard recommends that thicknesses be based on the 80-series of preferred numbers (see Handbook page [687](#)).

Thicknesses for copper and copper-base alloy flat products below  $\frac{1}{4}$  inch thick are specified by the 20-series of American National Standard Preferred Numbers given in ANSI/ASME B32.1. Although the table in ANSI/ASME B32.1 gives only the 20- and 40-series of numbers, it states that when intermediate thicknesses are required they should be selected from thicknesses based on the 80-series of numbers (see Handbook page [687](#)).

**Metric Sizes for Flat Metal Products.**—American National Standard B32.100-2016 establishes a preferred series of metric thicknesses, widths, and lengths for flat metal products of rectangular cross section; the thickness and width values are also applicable to base metals that may be coated in later operations. The standard also establishes a preferred series of metric sizes for round and hexagonal metal products.

The First Choice of sizes of this standard are derived from Renard's R5 series of preferred numbers (see *American National Standard for Preferred Numbers* on page 687, also ANSI/ASME B4.2 or ISO 497) in which each preferred number is approximately 60 percent larger than the preceding number in the series. The Second Choice series are derived from the R10 series in which each number is approximately 25 percent larger than the preceding, and Third Choice sizes are generally from the R20 series in which each number is approximately 12.5 percent larger than the preceding number.

Table 4a gives preferred metric diameters from 1 to 500 millimeters for round metal products; Table 4b lists the preferred thicknesses; Table 4c lists the preferred widths. Wherever possible, sizes should be selected from the First Choice series shown in the tables. Second and Third Choice series are also shown. For preferred metric diameters less than 1 millimeter, preferred across flat metric sizes of square and hexagon metal products, preferred across flat metric sizes of rectangular metal products, and preferred metric lengths of metal products, reference should be made to the B32.100-2016 Standard.

**Wire Drawing History.**—Wire drawing is the process used for producing wire by drawing a wire or rod of larger diameter through a plate or die provided with a hole which reduces the size to the desired dimension. Previous to wire drawing, wire was made by hammering or beating metal into thin sheets or plates, which were cut into continuous strips. These strips were then afterwards rounded by hammering. There is evidence that wire was produced by a simple hammering process as early as 2000 B.C., and perhaps earlier. The history of the art does not clearly indicate when simple hammering was superseded by the method of drawing through a die, but records are available to show that wire drawing on a commercial scale was practiced in France in 1270, in Germany in 1350, and in England in 1466. The first wire-drawing mill in America was built in 1775, in Norwich, Conn., by Nathaniel Niles, who was granted a loan of \$1500 by the court for this purpose.

**Shaped Wire.**—Shaped wire is any wire not round in section; it may be square, rectangular, hexagonal, triangular, half-round, oval, etc. Some sections of shaped wire may be either rolled or drawn. Shaped wire is a specialty, subject to agreement between purchaser and manufacturer as to size, finish, temper, and weight of coils and packages.

### Strength and Properties of Wire Rope

**Wire Rope Construction.**—Essentially, a wire rope is made up of a number of strands laid helically about a metallic or non-metallic core. Each strand consists of a number of wires also laid helically about a metallic or non-metallic center. Various types of wire rope have been developed to meet a wide range of uses and operating conditions. These types are distinguished by the kind of core; the number of strands; the number, sizes, and arrangement of the wires in each strand; and the way in which the wires and strands are wound or laid about each other. The following descriptive material is based largely on information supplied by the Bethlehem Steel Co.

**Rope Wire Materials:** Materials used in the manufacture of rope wire are, in order of increasing strength: iron, phosphor bronze, traction steel, plow steel, improved plow steel, and bridge rope steel. Iron wire rope is largely used for low-strength applications such as elevator ropes not used for hoisting, and for stationary guy ropes.

Phosphor bronze wire rope is used occasionally for elevator governor-cable rope and for certain marine applications as life lines, clearing lines, wheel ropes and rigging.

Traction steel wire rope is used primarily as hoist rope for passenger and freight elevators of the traction drive type, an application for which it was specifically designed.

Ropes made of galvanized wire or wire coated with zinc by the electro-deposition process are used in certain applications where additional protection against rusting is required. As will be noted from the tables of wire-rope sizes and strengths, the breaking strength of galvanized wire rope is 10 percent less than that of ungalvanized (bright) wire rope. Bethanized (zinc-coated) wire rope can be furnished to bright wire rope strength when so specified.

Galvanized carbon steel, tinned carbon steel, and stainless steel are used for small cords and strands ranging in diameter from  $\frac{1}{64}$  to  $\frac{3}{8}$  inch and larger.

Marline clad wire rope has each strand wrapped with a layer of tarred marline. The cladding provides hand protection for workers and wear protection for the rope.

**Rope Cores:** Wire-rope cores are made of fiber, cotton, asbestos, polyvinyl plastic, a small wire rope (independent wire-rope core), a multiple-wire strand (wire-strand core) or a cold-drawn wire-wound spring.

**Fiber** (manila or sisal) is the type of core most widely used when loads are not too great. It supports the strands in their relative positions and acts as a cushion to prevent nicking of the wires lying next to the core.

**Cotton** is used for small ropes such as sash cord and aircraft cord.

**Asbestos cores** can be furnished for certain special operations where the rope is used in oven operations.

**Polyvinyl plastics cores** are offered for use where exposure to moisture, acids, or caustics is excessive.

**Wire-strand core** often referred to as WSC, consists of a multiple-wire strand that may be the same as one of the strands of the rope. It is smoother and more solid than the independent wire rope core and provides a better support for the rope strands.

The **independent wire rope core**, often referred to as IWRC, is a small  $6 \times 7$  wire rope with a wire-strand core and is used to provide greater resistance to crushing and distortion of the wire rope. For certain applications it has the advantage over a wire-strand core in that it stretches at a rate closer to that of the rope itself.

Wire ropes with wire-strand cores are, in general, less flexible than wire ropes with independent wire-rope or non-metallic cores.

Ropes with metallic cores are rated  $7\frac{1}{2}$  percent stronger than those with non-metallic cores.

*Wire-Rope Lay:* The lay of a wire rope is the direction of the helical path in which the strands are laid and, similarly, the lay of a strand is the direction of the helical path in which the wires are laid. If the wires in the strand or the strands in the rope form a helix similar to the threads of a right-hand screw, i.e., they wind around to the right, the lay is called right hand and, conversely, if they wind around to the left, the lay is called left hand. In the *regular lay*, the wires in the strands are laid in the opposite direction to the lay of the strands in the rope. In right-regular lay, the strands are laid to the right and the wires to the left. In left-regular lay, the strands are laid to the left, the wires to the right. In *Lang lay*, the wires and strands are laid in the same direction, i.e., in right Lang lay, both the wires and strands are laid to the right and in left Lang they are laid to the left.

Alternate lay ropes having alternate right and left laid strands are used to resist distortion and prevent clamp slippage, but because other advantages are missing, have limited use.

The regular lay wire rope is most widely used and right regular lay rope is customarily furnished. Regular lay rope has less tendency to spin or untwist when placed under load and is generally selected where long ropes are employed and the loads handled are frequently removed. Lang lay ropes have greater flexibility than regular lay ropes and are more resistant to abrasion and fatigue.

In preformed wire ropes the wires and strands are preshaped into a helical form so that when laid to form the rope they tend to remain in place. In a non-preformed rope, broken wires tend to "wicker out" or protrude from the rope and strands that are not seized tend to spring apart. Preforming also tends to remove locked-in stresses, lengthen service life, and make the rope easier to handle and to spool.

*Strand Construction:* Various arrangements of wire are used in the construction of wire rope strands. In the simplest arrangement six wires are grouped around a central wire thus making seven wires, all of the same size. Other types of construction known as "filler-wire," Warrington, Seale, etc. make use of wires of different sizes. Their respective patterns of arrangement are shown diagrammatically in the table of wire weights and strengths.

**Specifying Wire Rope.**—In specifying wire rope the following information will be required: length, diameter, number of strands, number of wires in each strand, type of rope construction, grade of steel used in rope, whether preformed or not preformed, type of center, and type of lay. The manufacturer should be consulted in selecting the best type of wire rope for a new application.

**Properties of Wire Rope.**—Important properties of wire rope are strength, wear resistance, flexibility, and resistance to crushing and distortion.

*Strength:* The strength of wire rope depends upon its size, kind of material of which the wires are made and their number, the type of core, and whether the wire is galvanized or not. Strengths of various types and sizes of wire ropes are given in the accompanying tables together with appropriate factors to apply for ropes with steel cores and for galvanized wire ropes.

*Wear Resistance:* When wire rope must pass back and forth over surfaces that subject it to unusual wear or abrasion, it must be specially constructed to give satisfactory service.

Such construction may make use of 1) relatively large outer wires; 2) Lang lay in which wires in each strand are laid in the same direction as the strand; and 3) flattened strands.

The object in each type is to provide a greater outside surface area to take the wear or abrasion. From the standpoint of material, improved plow steel has not only the highest tensile strength but also the greatest resistance to abrasion in regularly stocked wire rope.

**Flexibility:** Wire rope that undergoes repeated and severe bending, such as in passing around small sheaves and drums, must have a high degree of flexibility to prevent premature breakage and failure due to fatigue. Greater flexibility in wire rope is obtained by 1) using small wires in larger numbers; 2) using Lang lay; and 3) preforming, that is, the wires and strands of the rope are shaped during manufacture to fit the position they will assume in the finished rope.

**Resistance to Crushing and Distortion:** Where wire rope is to be subjected to transverse loads that may crush or distort it, care should be taken to select a type of construction that will stand up under such treatment.

Wire rope designed for such conditions may have 1) large outer wires to spread the load per wire over a greater area; and 2) an independent wire core or a high-carbon cold-drawn wound spring core.

**Standard Classes of Wire Rope.**—Wire rope is commonly designated by two figures, the first indicating the number of strands and the second, the number of wires per strand, as:  $6 \times 7$ , a six-strand rope having seven wires per strand, or  $8 \times 19$ , an eight-strand rope having 19 wires per strand. When such numbers are used as designations of standard wire rope classes, the second figure in the designation may be purely nominal in that the number of wires per strand for various ropes in the class may be slightly less or slightly more than the nominal as will be seen from the following brief descriptions. (For ropes with a wire strand core, a second group of two numbers may be used to indicate the construction of the wire core, as  $1 \times 21$ ,  $1 \times 43$ , and so on.)

**$6 \times 7$  Class (Standard Coarse Laid Rope):** Wire ropes in this class are for use where resistance to wear, as in dragging over the ground or across rollers, is an important requirement. Heavy hauling, rope transmissions, and well drilling are common applications. These wire ropes are furnished in right regular lay and occasionally in Lang lay. The cores may be of fiber, independent wire rope, or wire strand. Since this class is a relatively stiff type of construction, these ropes should be used with large sheaves and drums. Because of the small number of wires, a larger factor of safety may be called for.

Fig. 1c.  
 $6 \times 7$  with  $1 \times 19$  WSC

Fig. 1d.  
 $6 \times 7$  with IWRC

As shown in Fig. 1a through Fig. 1d, this class includes a  $6 \times 7$  construction with fiber core; a  $6 \times 7$  construction with  $1 \times 7$  wire strand core (sometimes called  $7 \times 7$ ); a  $6 \times 7$  construction with  $1 \times 19$  wire strand core; and a  $6 \times 7$  construction with independent wire rope core. Table 1 provides strength and weight data for this class.

Two special types of wire rope in this class are: aircraft cord, a  $6 \times 6$  or  $7 \times 7$  Bethanized wire rope of high tensile strength and sash cord, a  $6 \times 7$  iron rope used for a variety of purposes where strength is not an important factor.

**6 × 19 Class (Standard Hoisting Rope):** This rope is the most popular and widely used class. Ropes in this class are furnished in regular or Lang lay and may be obtained preformed or not preformed. Cores may be of fiber, independent wire rope, or wire strand. As can be seen from Table 2 and Fig. 2a through Fig. 2h, there are four common types: 6 × 25 filler wire construction with fiber core (not illustrated), independent wire core, or wire strand core (1 × 25 or 1 × 43); 6 × 19 Warrington construction with fiber core; 6 × 21 filler wire construction with fiber core; and 6 × 19, 6 × 21, and 6 × 17 Seale construction with fiber core.

**6 × 37 Class (Extra Flexible Hoisting Rope):** For a given size of rope, the component wires are of smaller diameter than those in the two classes previously described and hence have less resistance to abrasion. Ropes in this class are furnished in regular and Lang lay with fiber core or independent wire rope core, preformed or not preformed.

independent wire core, a special large shovel rope usually furnished in Lang lay; and 6 × 46 filler wire construction with fiber core or independent wire rope core, a special large shovel and dredge rope.

*8 × 19 Class (Special Flexible Hoisting Rope):* This rope is stable and smooth-running, and is especially suitable, because of its flexibility, for high speed operation with reverse bends. Ropes in this class are available in regular lay with fiber core.

As shown in Table 4 and Fig. 4a through Fig. 4d, there are four common types: 8 × 25 filler wire construction, the most flexible but the least wear resistant rope of the four types; Warrington type in 8 × 19 construction, less flexible than the 8 × 25; 8 × 21 filler wire construction, less flexible than the Warrington; and Seale type in 8 × 19 construction, which has the greatest wear resistance of the four types but is also the least flexible.

Also in this class, but not shown in Table 4, are elevator ropes made of traction steel and iron.

**18 × 7 Non-rotating Wire Rope:** This rope is specially designed for use where a minimum of rotating or spinning is called for, especially in the lifting or lowering of free loads with a single-part line. It has an inner layer composed of 6 strands of 7 wires each laid in left Lang lay over a fiber core and an outer layer of 12 strands of 7 wires each laid in right regular lay. The combination of opposing lays tends to prevent rotation when the rope is stretched. However, to avoid any tendency to rotate or spin, loads should be kept to at least one-eighth and preferably one-tenth of the breaking strength of the rope. Weights and strengths are shown in Table 5.

**Flattened Strand Wire Rope:** The wires forming the strands of this type of rope are wound around triangular centers so that a flattened outer surface is provided with a greater area than in the regular round rope to withstand severe conditions of abrasion. The triangular shape of the strands also provides superior resistance to crushing. Flattened strand wire

rope is usually furnished in Lang lay and may be obtained with fiber core or independent wire rope core. The three types shown in Table 6 and Fig. 6a through Fig. 6c are flexible and are designed for hoisting work.

**Flat Wire Rope:** This type of wire rope is made up of a number of four-strand rope units placed side by side and stitched together with soft steel sewing wire. These four-strand units are alternately right and left lay to resist warping, curling, or rotating in service. Weights and strengths are shown in Table 7.

**Simplified Practice Recommendations.**—Because the total number of wire rope types is large, manufacturers and users have agreed upon and adopted a US Simplified Practice Recommendation to provide a simplified listing of those kinds and sizes of wire rope which are most commonly used and stocked. These, then, are the types and sizes which are most generally available. Other types and sizes for special or limited uses also may be found in individual manufacturer's catalogs.

**Sizes and Strengths of Wire Rope.**—The data shown in Table 1 through Table 7 have been taken from US Simplified Practice Recommendation 198-50 but do not include those wire ropes shown in that Simplified Practice Recommendation which are intended primarily for marine use.

**Wire Rope Diameter:** The diameter of a wire rope is the diameter of the circle that will just enclose it, hence when measuring the diameter with calipers, care must be taken to obtain the largest outside dimension, taken across the opposite strands, rather than the smallest dimension across opposite "valleys" or "flats." It is standard practice for the nominal diameter to be the minimum with all tolerances taken on the plus side. Limits

for diameter as well as for minimum breaking strength and maximum pitch are given in Federal Specification for Wire Rope, RR-R—571a.

*Wire Rope Strengths:* The strength figures shown in the accompanying tables have been obtained by a mathematical derivation based on actual breakage tests of wire rope and represent from 80 to 95 percent of the total strengths of the individual wires, depending upon the type of rope construction.

**Table 7. Weights and Strengths of Standard Flat Wire Rope, Not Preformed**

**Safe Working Loads and Factors of Safety.**—The maximum load for which a wire rope is to be used should take into account such associated factors as friction, load caused by bending around each sheave, acceleration and deceleration, and, if a long length of rope is to be used for hoisting, the weight of the rope at its maximum extension. The condition of the rope — whether new or old, worn or corroded — and type of attachments should also be considered.

Factors of safety for standing rope usually range from 3 to 4; for operating rope, from 5 to 12. Where there is the element of hazard to life or property, higher values are used.

## SHAFT ALIGNMENT

## Introduction

Shaft alignment is the positioning of the rotational centers of two or more shafts so that the shafts are co-linear when the machines are operating. The purpose of shaft alignment is to increase the operating life span of rotating machinery and to achieve high motor efficiency. It is not easy to detect misalignment when machines are running, but secondary effects of misalignment can be observed, such as excessive radial and axial vibration; high temperature in casings, bearings, or lubricant; loose, broken or missing coupling bolts or foundation bolts; cracks in shafts; and excessive amounts of lubricant leakage.

There are no universally accepted specifications for shaft alignment, however, there are defined limits for shaft-to-shaft alignment of coupled machines. The limits are defined in terms of two measures of misalignment, *angularity* and *offset*.

**Angular Misalignment.**—Angular misalignment is the difference in the slope of one shaft, as compared to slope of the other shaft. The units are expressed as rise/run. Rise is measured in mils (1 mil = 0.001 inch), and the run (distance along shaft) is measured in inches. The process of correcting this type of alignment problem is sometimes called *gap* or *face alignment*.

Fig. 1. Shafts in Angular Misaligned Position

**Offset Misalignment.**—Offset misalignment is the distance between the shaft centers of rotation measured at the plane of power transmission or coupling center. The units of measurement are mils.

Fig. 2. Shafts in Offset Misaligned Position

There are four alignment parameters to be measured and corrected; vertical angularity, vertical offset, horizontal angularity, and horizontal offset. Values in Table 1 may be used as a general guide for acceptable limits of misalignment. Proper shaft alignment is especially critical when shafts are running at high speeds, thus the allowable limits of misalignment decrease as shaft speeds increase.

Table 1. Misalignment Tolerance Guide

RPM	Offset Misalignment (Mils)		Angular Misalignment (mils/inch)	
	Excellent	Acceptable	Excellent	Acceptable
600	±2.00	±4.00	0.80	1.25
900	±1.50	±3.00	0.70	1.00
1200	±1.25	±2.00	0.50	0.80
1800	±1.0	±1.50	0.30	0.50
3600	±0.50	±0.75	0.20	0.30
≥4000	±0.50	±0.75	0.10	0.25

When the shafts of two machines require alignment, the process generally calls for one of the machines to be permanently mounted and the other one to be movable. The fixed unit is usually the driven machinery, such as the pump in a pump-motor pair. The second machine (usually the motor) is moved into approximate alignment (by eye and straight edge, for example) in preparation for measurements that will determine the magnitude and direction of moves required to put it in final alignment with the fixed machine. It is the movable machine whose shaft will be aligned with the shaft of the fixed machinery. The position of the movable machine is adjusted vertically by adding and/or removing shims from under its feet, and horizontally by making small lateral moves as required until satisfactory final alignment is obtained.

### Shaft Alignment with Dial Indicators

The material that follows describes the process of shaft alignment when dial indicators are used to measure the alignment data.

**Instruments and Methods.**—Numbers of instruments are available for making shaft measurements and calculating moves, but the most important requirement for any shaft alignment system is repeatability of the readings. Dial indicators and lasers are two choice measuring systems.

*Dial indicators* provide accurate and reliable measurement of shaft alignment. They are the most useful because they can be used to measure bearing alignment, shaft runout, and soft foot directly. Measurement accuracy down to 0.001 inch (1 mil) or 0.025 mm may be achieved if care is taken in mounting and reading the indicators correctly, and controlling or accounting for such variables as indicator sag, axial endplay in the shaft, and vibration from outside sources. The data obtained from properly installed dial indicators are converted by equations described later in this section into the vertical and horizontal movements required to bring the movable unit into alignment with the fixed unit.

*Laser measurement systems* are another popular choice for shaft alignment work, although the cost of such systems is much greater than dial indicators. Accuracy of 0.0001 inch (0.0025 mm) or greater is possible, and setup and operation is generally faster and simpler than with dial indicators. Many laser systems can perform some or all of the calculations required to obtain the horizontal and vertical moves. Lasers may not be safe for use in explosive environments.

**Runout Check.**—A runout test of either or both couplings is important only if there is a runout problem. Seldom will the runout of a pump or motor coupling be enough to detect with the eye alone. Standard practice is to position a rim and face indicator setup on the uncoupled couplings (one at a time) and roll said couplings through several 360° turns while monitoring the indicators. The indicator bracket should be firmly attached to a static object close to the pump or motor coupling being checked. Usually a magnetic base designed to hold indicators is used for this purpose if the two couplings involved are more than five or six inches apart. For an ordinary pump and motor, however, it is frequently convenient to mount the indicator jig to the motor to check the runout on the pump and then vice-versa for the motor.

Fig. 3 shows a profile view on the left and a motor- or pump-eye view (right) of a typical runout check setup involving the use of indicators attached to a magnetic base. Assume the rim indicator to have been adjusted to zero, the coupling being checked is rotated several full turns. Repeated turns deliver repeated readings of a maximum minus of  $-0.XXX$  inch at one extreme, and a maximum plus of  $0.XXX$  inch at the other extreme. Assuming there is no paint or rust, etc. involved, at least three possibilities exist.

- 1) the coupling was bored off-center
- 2) the shaft is bent
- 3) a combination of the above two conditions

Fig. 3. Indicators Set Up for a Runout Check

In field applications, mount the face dial as near as possible to the rim indicator. The face indicator is drawn at the 6 o'clock position in both views for clarity.

Concerning **Item 3**) in the previous list, it is possible (however unlikely) for a coupling that was bored off center and would have shown up as coupling runout with a rim indicator test except that a slight bend in the shaft has canceled out what would normally have been evident due to the off-center bored coupling. This odd situation can cause vibration even when a standard test proves there is no misalignment. Coupling runout can also be caused by too large a coupling bore, with the slack being taken up by set screws.

*Interpreting the Indicators:* The actual amount of runout registered by the rim indicator is *half of the difference between the plus and minus reading extremes.*

*Example:* A rim indicator is mounted as shown in **Fig. 3** and set on zero. Then, several full turns of the shaft reveals a maximum minus of  $-0.006$  inch and a maximum plus of  $+0.012$  inch on the indicator. The total variation is  $0.018$  inch and half of  $0.018$  is  $0.009$ . Thus, the result of **Items 1), 2), or 3)** is  $0.009$  inch of eccentricity, or  $0.018$  inch TIR (total indicator reading) of coupling runout. *Note:* Much less coupling runout than is described above is usually expected.

If the face indicator shows zero at all points around a coupling while the rim indicator moves between  $+0.XXX$  inch and  $-0.XXX$  inch, it is probable that the coupling was bored off-center. If the rim indicator shows practically zero movement while the face indicator moves between  $-0.XXX$  inch and  $+0.XXX$  inch, the cause could be **Item 2)** or **3)** above, or the coupling was bored essentially centered, but at an angle other than perpendicular to the face of the coupling, as is shown in **Fig. 4**.

Fig. 4. Coupling Bore Centered but Not Perpendicular to Coupling Face  
Face Indicator Shown, Rim Indicator Not Shown

In **Fig. 4**, both the indicators shown will alternate from plus to minus and back again as the coupling being checked is rotated. Even if the shaft centerline goes through the center of the coupling, it will do so at an angle other than perpendicular to the face of the coupling. The result is serious coupling runout on the face indicator and less serious runout on the rim indicator.

Face runout can easily show up when there is none. If a machine has sleeve bearings and if the shaft is not axially restrained by a thrust bearing during the runout test, severe face runout will likely be indicated when little, if any, exists.

*Note:* Unacceptable runout of either or both couplings should be of little concern in the alignment process. The extended centerlines of the two shafts can be aligned even when

there is serious coupling runout. A runout check is mainly to have recorded information if excessive vibration occurs.

**Soft Legs.**—One of the most often overlooked precautions relevant to motor alignment is the firming up of the soft legs. For the motor in Fig. 5, one leg (D) is  $\frac{1}{2}$  inch short. In alignment jargon, the short leg is said to be *soft*. It is also clear that if a  $\frac{1}{2}$  inch shim were placed under the short leg, all four motor feet would firmly support the motor. On the other hand, if the motor were tightened down without the use of proper shims, its support would be very spongy and would produce non-repeatable indicator readings.

Fig. 5. Profile (a) and Overhead (b) Views of Motor with Soft Foot

On an ordinary electric motor any of the four motor feet may be either raised or lowered via the placement or removal of shims, as applicable, to render the motor equally supported by all four feet. Geometry may allow a certain freedom of choice, so it is practical to be very selective about which motor foot or feet will receive additional shims during the firming up of the motor.

When a soft leg involves only a few thousandths of an inch, it is much less obvious than in Fig. 5. By using what is known to some mechanics as the rock-a-bye method, it is possible to detect a slight amount of instability in the motor supports. With the bolts inserted, but only partly threaded in, alternately apply heel-of-the-hands pressure on or above two motor feet at a diagonal. If no rock-a-bye is evident when heel-of-the-hands pressure is alternately applied above feet A and D, switch to B and C. If rock-a-bye is found, remove applicable shims if possible or add shims under one or both of the unstable feet.

For the  $\frac{1}{2}$  inch (12.7 mm) gap shown in Fig. 5, downward heel-of-the-hands pressure at points A and D would yield more movement than the indicators could handle. On more subtle soft feet, it takes an experienced feel to detect only a few mils of rock-a-bye at a motor foot. When feel becomes too little to be certain, it is time to apply indicators.

On units where 0.010 inch (0.254 mm) or more of movement is evident, a tapered wedge gauge can be inserted under the motor foot as the motor is gently rocked. When the motor will no longer rock, the approximate thickness of the wedge gauge under the motor foot will be the amount of shim material to insert under that foot. If a single foot requires more shim thickness than is desirable, put half the thickness under the soft foot and the other half under the opposite diagonal foot; then, a second slight amount of shim placed under one of the two feet should remove any unwanted slack. During the rock-a-bye test, trial and error shimming will eliminate any obvious soft feet in a few tries. The careful step-by-step elimination of unwanted slack in the support feet of a motor or other movable unit should result in a very stable movable unit.

On larger motors, leverage proportional to resistance should be used, involving anything from a small pry-bar to hydraulics. When the rock-a-bye method gets so involved, it is advisable to have dial indicators mounted at the applicable motor feet and/or at the motor coupling, with the indicator button on top of the pump coupling or comparable static object, to register any movement.

A heavy duty version of the rock-a-bye method is to have all the hold-down bolts tight and then loosen them one at a time while monitoring the indicators.

Fig. 6. Rim Indicator Mounted to Test for Soft Feet

Fig. 6 shows a profile view (left) and overhead view (right) of the motor previously shown. In this figure, the indicator illustrated is mounted exactly as the rim indicator will later be mounted for checking alignment, and any soft leg activity will register the same as in the line-up process. Once a motor gets a clean bill of health from this soft foot check, it is safe to proceed with the normal procedures of motor alignment. Mount the indicators in the most convenient manner that will apply to the problem at hand and select the proper formula as discussed in the material that follows. Be sure all the bolts are tight before making the first (vertical) indicator reading.

**Other Mounting Issues:** Any combination of the mounting conditions illustrated in Fig. 7 will produce soft motor feet, even if the motor feet are machined properly. The motor, base, or shims will need alterations to circumvent the illustrated problems. Depending on the magnitude of the angle in a problem of this sort, wedge-shaped shims or machine work on the motor or the base may be required.

Sometimes on relatively unimportant equipment, it is permissible to simply fold shims in various thicknesses to take up the slack. This method should not be used as common practice; but as an emergency measure, it is very effective.

Fig. 7. Mounting Conditions That Produce Soft Motor Feet.

**Mounting Dial Indicators, Perpendicular versus Otherwise.**—When indicators are mounted to get a rim reading on a coupling, the indicator stem should be set to aim straight through the center of the shaft, and at a perpendicular to the axis of the shaft. This center shot at a perpendicular does not have to be absolutely perfect, but it should be close enough so that a closer than casual visual inspection can find no flaw. This is close enough for practical purposes.

Fig. 8. Indicator Stem Orientation, Correct at A and B, Incorrect at C and D

In Fig. 8 observe the rim indicator settings at positions A, B, C, and D. Indicators at positions A and B are set correctly, indicators at C and D are not. A slight tilt in the mounting of the indicators will make too little difference to matter, but any tilt over a few degrees should be avoided.

Just as important, the face indicator should be set perpendicular to the coupling face with the centerline of the indicator stem parallel to the axis of the fixed unit coupling shaft.

Fig. 9a shows a setup with rim and face indicators set at odd angles that will cause incorrect readings. Note the difference between the arrangement of Fig. 9a, and the correct one shown in Fig. 9b.

Fig. 9a. Incorrect Positioning of Dial Indicators Fig. 9b. Correct Positioning of Dial Indicators

**Preparations.**—Before starting an alignment process several important factors need to be considered, among them the following. Is temperature rise in the coupled machinery a consideration? What is the indicator sag of the dial indicators in use? Is coupling runout a consideration? Are there improperly supported or “soft feet” in the movable machine? Are the motor feet, jack bolts, and shims clean? Can the movable unit be moved laterally far enough to permit alignment, or is movement restricted by bolts (“bolt bound”) or nearby obstructions? Is the driving unit powered off and locked out?

**Thermal Effects:** Metals increase in length as temperature increases, and decrease in length as temperature decreases. Rotating equipment at rest slowly attains the temperature of the surrounding environment, the *ambient* or room temperature. In service, machinery such as electric motors and fuel-burning engines generate heat and increase in temperature during operation; other machinery such as pumps may warm or cool during operation.

If initial alignment adjustments are made when machines are at *ambient* or room temperature, thermal movement will occur in various parts of the machines as they reach operating temperature. The various dimensions will not increase or decrease uniformly. In a motor-pump combination, for example, the motor shaft height above the base may increase while the pump shaft height may decrease.

The amount of thermal expansion can be estimated by the formula  $\Delta e = \alpha H \Delta T$ :

where  $\Delta e$  = change in height of shaft

$H$  = vertical height or distance between shaft centerline and shims

$\alpha$  = expansion coefficient of material in  $\mu\text{in}/\text{in}\text{-}^\circ\text{F}$  (for stainless steel 7.4, mild steel 6.3, cast iron 5.9, bronze 10, and aluminum 12.6). *Note:*  $1 \mu\text{in}/\text{in}\text{-}^\circ\text{F} = 1.8 \mu\text{m}/\text{m}\text{-}^\circ\text{C}$

$\Delta T$  = the difference between operating temperature and ambient (initial measurement) temperature

**Example 1(a):** A pump is to be installed and aligned with a motor. The cast iron pump delivers fresh water at  $34^\circ\text{F}$  and is at present at  $75^\circ\text{F}$ . The pump shaft centerline is 12 inches above the baseline of the pump. The carbon steel motor is also at  $75^\circ\text{F}$  and is expected to rise to  $140^\circ\text{F}$  when in operation. The motor shaft centerline is 12 inches above the base of the motor. At operating temperature, compare the expected thermal growth of the pump and motor shaft centerlines.

For the pump, the change in shaft height:

$$\Delta e = \alpha H \Delta T = 0.000059 \times 12 \times (34 - 75) = -0.002903 \text{ inch}$$

For the motor, the change in shaft height is:

$$\Delta e = \alpha H \Delta T = 0.0000063 \times 12 \times (140 - 75) = 0.004914 \text{ inch}$$

These calculations indicate that the pump and motor shafts, if they were in alignment at ambient temperature, would be misaligned at operating temperature by approximately 0.0078 inch difference in elevation.

**Indicator Bracket Sag:** Indicator sag, indicator bracket sag, or jig sag are all terms commonly used to describe the effect on indicator readings of the weight of the dial indicator(s) in combination with the length, weight, and orientation of the indicator bracket. Dial indicators are designed to be used in the vertical position and indicator bracket sag is especially significant in measurements that are made when the dial indicator is inverted in the vertical plane. Consider a rim indicator and bracket mounted on a shaft with the indicator zeroed at the 12 o'clock position; when the shaft and fixture are rotated to put the dial indicator in the 6 o'clock position, the reading will indicate a non-zero negative value, which is the indicator fixture sag factor.

Indicator bracket sag is dependent on the mounting arrangement of the indicators, and is difficult to measure accurately on equipment that is being aligned because the effect of shaft misalignment will combine with the indicator bracket sag to produce incorrect results.

To measure indicator fixture sag, set up the indicator and mounting components on the machinery to be aligned exactly as if doing alignment, and tighten everything down. Then, remove the bracket and indicator from the machine and remount in exactly the same manner on a rigid fixture, such as a piece of pipe supported by V-blocks. Zero the indicator at the 12 o'clock (reference) position, then without changing the setup carefully rotate the fixture and read the indicator at the 6 o'clock (reading) position. At the reading position, the indicator displays the total indicator reading (TIR) and this value is the *total sag factor*. The actual sag in the indicator bracket is equal to one half of the total indicator reading.

When the indicator bracket sag has been determined, it can be accounted for in measurements taken during the alignment procedure. One procedure is to add the indicator bracket sag factor to the indicator value when the indicator is "zeroed" at the reference position, so that the sag factor is accounted for throughout subsequent calculations. For example, if an indicator is zeroed at the 12 o'clock position and reads 0.006 inch at the 6 o'clock position, set the indicator to positive 0.006 at the 12 o'clock reference position to account for the sag factor in further measurements. If the reference position used for checking indicator sag is the 6 o'clock position (indicator zeroed at 6 o'clock position), the positive reading found at the 12 o'clock position is the sag factor that must be subtracted from indicator value when the indicator is zeroed at the 6 o'clock (reference) position.

**Alignment Procedures for Machinery.**—The *face and rim method* and the *reverse dial indicator method* are the techniques most commonly used for aligning machinery shafts. The usual shaft alignment procedure is to establish one machine as fixed, and the other as the movable machine. The driven machinery is usually the fixed unit. The shaft of the movable unit is positioned, as required, to align with the shaft of the fixed unit. Most aligning specialists recommend vertical alignment first, and then horizontal alignment. It is important to verify in advance that the movable unit has sufficient horizontal clearance and freedom of movement to obtain the required horizontal position before starting on the vertical alignment.

**Vertical Moves:** Vertical adjustments are accomplished by adding or removing shims from under the machine feet. Use as few shims as possible. Too many shims under a foot may cause it to act like a soft foot by creating a spring effect; usually a maximum of four shims are allowed. Shims should be measured by micrometer before placing. If possible, apply a single shim that is the total thickness required under the foot. Insert the shims all the way until the shim slot bottoms out on the bolt, then pull the shim back about a quarter inch before tightening the bolts. If alignment is not possible with four shims, then use fewer,

amounting to the required thickness. Tighten bolts to their prescribed torque each time after placing shims to avoid any movement when working on the other side of the machine.

Never loosen all hold-down bolts at the same time. A maximum of two bolts are allowed to be loosened at a time. Loosening all hold-down bolts will lose the entire alignment. Loosen the bolts from either the left or right side of the machine. Then, raise that side just enough to make the shim change. Raising the machine too high can bend the foot. Once the machine is lifted, remove all shims and add or subtract the number of shims required to make the necessary vertical move. Be very cautious at this point not to get confused among a lot of loose shims.

**Horizontal Moves:** It is preferable to utilize a base plate with jackbolts for horizontal moves. If jack bolts are not available, a small hydraulic jack, pipe clamps, or pony clamps can be used. The most accurate method for measuring the horizontal move is to place dial indicators around the machine at convenient locations, such as at machine feet. The indicators can be located anywhere convenient as long as the dimensions used in the alignment calculations reflect the actual position at which measurements are made. When the indicators are mounted, adjust the dials to zero, and move the unit the distance and direction indicated by the calculations. Once the horizontal move has been completed, a final set of readings should be taken to verify both vertical and horizontal alignment.

**Safety:** Shaft alignment should not be performed when machines are running. Before shaft alignment, all sources of power to the machine should be off and verified. Energy sources must be locked out by electrical controls; steam valves, gas main valve, and fuel oil valve must be shut down before shaft alignment.

**Rim and Face Alignment Procedure.**—Fig. 10 and Fig. 11 show dial indicator arrangements for rim and face alignment that are typical of those used in the remainder of this section. Fig. 10 illustrates a chain indicator jig, but it could be of any type. The arrangement in Fig. 11 represents an equivalent setup. In each figure, two dial indicators are shown, one for the rim reading and the other for the face reading. Darkened squares, triangles or circles are simply to indicate attachment points.

Fig. 10.

Fig. 11.

Starting on page 2731, a number of different indicator arrangements are illustrated in Fig. 1a through Fig. 16a. Each arrangement is associated with a specific equation and a chart that facilitates understanding the dial and face readings and the corresponding tasks of determining where shims need to be added or removed and what horizontal moves are required. To use this system, the mechanic needs to set up the rim and face indicators in the most convenient manner, then turn to the figure of the matching indicator arrangement and use the formulas provided.

**Example Aligning a Motor with a Pump by the Rim and Face Method:** A 10-horsepower (7.5 kW) electric motor needs to be precision aligned to a specific pump. Both the pump and motor are to be mounted on a base that when finished will look similar to Fig. 12. Not shown are the intake and discharge piping, electrical fixtures, and other incidentals including shims under the motor feet.

The shims are omitted to visually explain why the motor will usually have a little less distance from the motor shaft centerline to the base than the pump has. This set up is desirable because with the motor shaft a little lower than the pump shaft, the motor can be shimmed up until both shafts share a common elevation. If the motor shaft is higher than the pump shaft, it can be very difficult to alter the position of the pump because of the rigidly connected piping.

Fig. 12. Pump and Motor are to be Aligned

The motor in Fig. 12 is in its approximate finished position about 8 inches (203.2 mm) from the pump. The spool piece shown in Fig. 12 is to be bolted between the motor and pump couplings after alignment is complete. The spool piece (not shown in Fig. 13) is 8 inches long and there is an  $8\frac{1}{8}$  inch (206.4 mm) space between pump and motor couplings.

Fig. 13 shows a viable mounting of dial indicators in the process of procuring readings from the zero setting at 12 o'clock (broken lines) to the 6 o'clock position (solid lines). Some calibrated eyeballing, a scale measure and some straight edging are used to align the motor initially to the pump.

Fig. 13. Alignment Setup for Pump and Motor

There are many ways to mount and adjust dial indicators to measure the remaining misalignment between the two units. Several are correct and only a few are optimum. The mounting of the pair of dial indicators between the motor and pump shown in Fig. 13 is as good as any and commonly used. Many other arrangements are shown starting on page 2731.

Although there seem to be four dial indicators in Fig. 13, there are only two. The two indicators with broken lines are drawn at the initial 12 o'clock position where they are zeroed with about half the indicator stems exposed, (both indicator pointers are shown at 12 o'clock). Then the motor and pump shafts are both turned 180° to the 6 o'clock position (those indicators are drawn with solid lines, and the pointers are shown set to the 3 o'clock and 9 o'clock positions in Fig. 13). In real life alignments, the pointers might be aimed anywhere on the dial face, but the dial face will rotate 360°, so the zero can be manually adjusted to align with the pointer no matter which direction the needle points.

*Solution for Vertical Alignment:* Once a motor has been aligned with straight edges and such, it is probably close enough to use dial indicators. The dials most often used have a stem range of just over 0.200 inch (roughly  $\frac{1}{32}$  inch). These dial indicators (usually two) are positioned with the buttons of the indicators against the rim and face of the pump coupling respectively, as shown in Fig. 13. The seasoned millwright/mechanic will adjust the indicator jig/bracket in such manner that the stem on each of the indicators has freedom to travel inward or outward about 0.100 inch. This adjustment is made at the 12 o'clock position, shown by broken lines in Fig. 13.

A good arrangement is for the rim indicator in Fig. 13 to register a minus  $r$  reading at the 6 o'clock position and the face indicator to register a plus  $f$  reading (see bottom right of Fig. 1b on page 2732). Readings on both indicators show that the motor needs to be raised, involving the simple task of determining how much shim material to add under each foot. For the indicator arrangement in Fig. 13, the required shim thickness can be determined by using the equations below.

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{A} \quad \text{and} \quad R = \frac{\pm r}{-2} + \frac{\pm f \times C}{A}$$

where  $F$  =  $\pm$ change in shim thickness needed under the front feet

$R$  =  $\pm$ change in shim thickness needed under the rear feet

$r$  = plus or minus rim indicator reading

$f$  = plus or minus face indicator reading

$A$  = diameter of face indicator path on coupling

$B$  = distance from rim indicator path to front feet

$C$  = distance from rim indicator path to rear feet

The equations use the gathered data to calculate the correct shim placement. With either equation, a positive solution indicates that shims equal to the calculated value are added, and a negative solution indicates that shims equal to the calculated value are removed.

The rim and face indicator setup depicted in Fig. 13 is one of the sixteen arrangements described in the material that follows. Each of these formats has its own similar but unique formula; just plug the variables into the formulas that matches the current indicator format and calculate the shims required.

*Solution for Horizontal Alignment:* Fig. 14 shows a top view of the motor in Fig. 13, with indicators in the reading positions for horizontal alignment. The rim and face indicators are zeroed at the position  $180^\circ$  opposed to that shown in Fig. 14.

The directions corresponding to horizontal movement of the motor in Fig. 14 are indicated by east and west arrows. Magnetic-mount dial indicators (not shown) may be set up to monitor the horizontal movements. The dimensions  $B$  and  $C$  represent the distances from the rim indicator path to the locations of the monitoring indicators or jackbolts.

If jackbolts (or monitor indicators) are positioned on the west side as indicated in Fig. 14, the  $B$  and  $C$  dimensions are used in the equations. If jackbolts (or monitor indicators) are positioned at a different location on the east side (for example, jackbolts shown by dashed lines in Fig. 14), the east-side set of dimensions,  $B'$  and  $C'$ , are used in the equations.

The equations are the same as previously used in the vertical alignment procedure. Per the indicator arrangement in Fig. 14, a positive solution demands a move eastward, and a negative solution requires a westward move.

$F$  =  $\pm$ east-west movement needed at the front monitoring location

$R$  =  $\pm$ east-west movement needed at the rear monitoring location

$r$  = plus or minus rim indicator reading

$f$  = plus or minus face indicator reading

$A$  = diameter of face indicator path

$B$  = distance from rim indicator path to front monitoring location

$C$  = distance from rim indicator path to rear monitoring location

Fig. 14. Top View of Motor from Fig. 13

*Side to Side Adjustment Using Jackbolts:* Avoid using jackbolts that are longer than necessary. Make sure internal and external threads are clean and lubricated enough to be functional. Then, if heavy resistance is encountered when adjusting jackbolts, it indicates a mechanically-bound condition, not a rusty jackbolt thread. Before advancing jackbolts on one side of the movable unit, back off the jackbolts on the opposite side about  $1\frac{1}{2}$  turns to provide enough space to make the movement without creating a mechanical bind.

Jackbolts should not be left in a “bind” against the movable unit to assist in keeping the movable unit in alignment. After alignment is complete, the jackbolts should be removed and stored for future use. This action will prevent jackbolt corrosion, and leave the jackbolt nuts vacant to receive a tap and lubrication, prior to being used again.

On movable units outfitted with jackbolts, one complete ( $360^\circ$ ) turn of a jackbolt will advance the thread an amount equal to the pitch of the screw thread. For inch-threaded screws, pitch equals 1 divided by the number of threads per inch ( $1 \div TPI$ ). The axial travel per head flat is the pitch divided by the number of flats on the bolt head.

*Example:* A jackbolt has a  $\frac{1}{2}$ -13 thread. Find the axial travel per revolution and per flat for square-head and hex-head bolts. The thread has 13 threads per inch.

$$\text{advance per revolution (full turn) of bolt} = \frac{1}{TPI} = \frac{1}{13} = 0.0769 \text{ inch}$$

$$\text{advance per flat (1/4 turn) of square-head bolt} = \frac{1}{TPI \times 4} = \frac{1}{(13 \times 4)} = 0.0192 \text{ inch}$$

$$\text{advance per flat (1/6 turn) of hex-head bolt} = \frac{1}{TPI \times 6} = \frac{1}{(13 \times 6)} = 0.0128 \text{ inch}$$

*Example:* A motor needs to be moved 0.064 inch east at the front jackbolt and 0.091 inch east at the rear. The square-head jackbolts are  $\frac{5}{8}$ -11. How many turns of the front and rear jackbolts are need to bring the unit into approximate alignment?

$$\text{one full turn of jackbolt} = \frac{1}{11} = 0.0909 \text{ inch}$$

$$\text{full turns at front jackbolt} = \frac{0.064}{0.0909} = 0.7040 \approx \frac{3}{4} \text{ turn or 3 flats}$$

$$\text{full turns at rear jackbolt} = \frac{0.091}{0.0909} = 1.0011 \text{ turn} \approx 1 \text{ turn or 4 flats}$$

### Practical Rim and Face Dial Indicator Arrangements for Shaft Alignment

This phase of millwright/machinist work is usually referred to as motor-to-pump alignment. The true objective is to correctly align the axis of one shaft to the axis of another by any of a rather wide range of dial indicator mountings, depending on a myriad of varying situations. These motor to pump scenarios can be duplicated on almost any shaft that is axially in close proximity to another shaft that has to share a common axis. Addressed here is standard rim and face pump alignment.

There are sixteen indicator arrangements to select from in this rim and face section. Units are aligned as closely as possible with a straight edge before using the dial indicators. At the first indicator reading, a neat sketch of the scenario is made, along with a carefully measured dimensioning schedule such as that shown in Fig. 1a. Based on indicator readings, select the applicable block from the second illustration, Fig. 1b, that matches the current plus or minus ( $\pm$ ) indicator reading. The dashed lines in Fig. 1b represent the centerline of the movable unit shim shaft. The two heavy round dots on the dashed lines (to the right of the couplings) represent points directly above or below the movable unit shim locations, and indicate that the movable unit must be raised or lowered at that location. The diagrams will help clarify the results of the shim calculations made using the appropriate formulas. Be certain to use minus signs any time they are called for in the formulas.

*Note:* In all the rim and face formats that follow, the axial location of the rim indicator always dictates the beginning point of the dimensions that are used in the various formulas. Also, the dial indicator arrangements in Fig. 1a through Fig. 16a are shown in the reading position, after having been zeroed at the position  $180^\circ$  opposite that shown and then rotated into the position shown.

**1st Arrangement.**—Fig. 1a illustrates the most universally accepted method of mounting dial indicators for shaft alignment, and it is also the same arrangement that was used in the preceding example, illustrated by Fig. 13 and Fig. 14.

When a reading of the rim and face indicators has been made, find the diagram in Fig. 1b that corresponds to the signs (positive or negative) of the readings obtained (positive rim value and negative face value, for example). The appropriate diagram will provide a visual clue to the meaning of the indicator readings, and indicate the direction that the motor feet must be moved to obtain alignment of the movable shaft with the fixed shaft.

Finally, use the equations adjacent to Fig. 1a to calculate the exact thickness of shims that need to be added or removed at each foot.

Fig. 1a. Dial Indicator Arrangement 1

In the rim and face format in Fig. 1a,  $r$  and  $f$  represent the values of the rim and face indicators in their reading positions. The  $F$  and  $R$  below the motor are the front and rear feet, corresponding to the  $F$  and  $R$  values in the formulas that represent the needed plus or minus ( $\pm$ ) shim packs. The formulas adjacent to Fig. 1a, are used to calculate the necessary addition or subtraction of shims required on the front or rear feet.

Fig. 1b. Interpreting Dial Indicator Readings for Indicator Arrangement 1

Indicators are shown in the reading position. Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

**Example 1(a), Vertical Alignment:** Calculate the necessary shims for a pump and motor alignment where dimensions are  $A = 4$  inches,  $B = 6.5$  inches, and  $C = 18$  inches. The two indicator dials read  $r = \text{minus } (-)0.014$  inch and  $f = \text{plus } (+)0.021$  inch respectively.

**Solution:** The lower left block in Fig. 1b corresponds to a negative rim reading and a positive face reading. The figure indicates that both the front and rear feet will require shims, and that the rear feet will require more shims than the front feet. Shims on front and rear feet will be as follows:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\
 &= \frac{-0.014}{-2} + \frac{0.021 \times 6.5}{4} & &= \frac{-0.014}{-2} + \frac{0.021 \times 18}{4} \\
 &= 0.007 + 0.034125 & &= 0.007 + 0.0945 \\
 &= 0.041 \text{ inch} & &= 0.102 \text{ inch}
 \end{aligned}$$

The calculations indicate that 0.041 inch of shims is required under both front feet, and 0.102 inch of shims is required under both rear feet.

**Example 1(b), Horizontal Alignment:** Fig. 1a shows the indicators in the reading position for horizontal alignment, if the figure is thought of as a view looking down at the motor from the top. Assuming the same data obtained in the previous example, the two indicator dials read  $r = \text{minus } (-)0.014$  inch and  $f = \text{plus } (+)0.021$  inch respectively. Calculate the necessary horizontal movement required to align the motor to the pump.

**Solution:** The equations adjacent to Fig. 1a apply, as in the previous example. The dimensions  $B$  and  $C$  in Fig. 1a are the respective distances from the rim indicator path on the coupling to the locations at the front and rear of the motor, not necessarily the feet, where the horizontal adjustments will be made. These locations could be the front and rear jackbolts, or they could be magnetic base monitoring indicators placed conveniently near the front and rear feet, as discussed previously with respect to Fig. 14.

The diagram in the lower left corner of Fig. 1b indicates the direction of the move when the figure is viewed as if looking at the motor from the top. If  $B$  and  $C$  are 6.5 and 18 inches, respectively, then the equations indicate that the front and rear of the motor must be moved in the same direction, +0.041 inch and +0.102 inch respectively, to attain alignment.

**2nd Arrangement.**—Rim and face indicators are placed as shown in Fig. 2a. This arrangement is commonly used when the space between couplings is limited.

Fig. 2a. Dial Indicator Arrangement 2

Fig. 2b. Interpreting Dial Indicator Readings for Indicator Arrangement 2

Indicators are shown in the reading position. Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. The generic graph gives a picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.75$  inches,  $B = 7.75$  inches, and  $C = 17.25$  inches. The two indicator dials read  $r = \text{plus (+)} 0.004$  inch and  $f = \text{minus (-)} 0.022$  inch respectively.

*Solution:* The lower right block in Fig. 2b corresponds to a positive rim reading and a negative face. The diagram indicates that shims will be required under both the front and rear feet. Calculations confirm this, as follows:

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{-A}$$

$$= \frac{0.004}{-2} + \frac{-0.022 \times 7.75}{-4.75}$$

$$= -0.002 + 0.036$$

$$= 0.034 \text{ inch}$$

$$R = \frac{\pm r}{-2} + \frac{\pm f \times C}{-A}$$

$$= \frac{0.004}{-2} + \frac{-0.022 \times 17.25}{-4.75}$$

$$= -0.002 + 0.07989$$

$$= 0.078 \text{ inch}$$

**3rd Arrangement.**—Place rim and face indicators as shown in Fig. 3a.

Fig. 3a. Dial Indicator Arrangement 3

Fig. 3b. Interpreting Dial Indicator Readings for Indicator Arrangement 3

Solid lines represent the desired location for the dashed (movable) unit. The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.25$  inches,  $B = 8.875$  inches, and  $C = 28.75$  inches. The two indicators read  $r = \text{plus (+)}0.042$  inch and  $f = \text{minus (-)}0.036$  inch respectively.

*Solution:* Only the lower left block in Fig. 3b corresponds to a negative face reading and a positive rim reading. The diagram indicates that shims will be required under both front and rear feet. The required shim thickness for front and rear feet is calculated as follows:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} \\ &= \frac{0.042}{2} + \frac{-0.036 \times 8.875}{-4.25} \\ &= 0.021 + 0.075 \\ &= 0.096 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{0.042}{2} + \frac{-0.036 \times 28.75}{-4.25} \\ &= 0.021 + 0.244 \\ &= 0.265 \text{ inch} \end{aligned}$$

**4th Arrangement.**—Place rim and face indicators as shown in Fig. 4a.

Fig. 4a. Dial Indicator Arrangement 4

Fig. 4b. Interpreting Dial Indicator Readings for Indicator Arrangement 4

Solid lines represent the desired location for the dashed (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 3.5$  inches,  $B = 8.25$  inches, and  $C = 19.25$  inches. The two indicators read  $r = \text{minus} (-)0.011$  inch and  $f = \text{minus} (-)0.019$  inch respectively.

*Solution:* According to the top left block in Fig. 4b, the negative rim and negative face values indicate that the motor needs to have shims removed from beneath both the front and rear feet. The calculations that follow confirm that 0.05 inch needs to be removed from beneath the front feet, and 0.11 inch from below the rear feet. This adjusting may be difficult if the motor is sitting on its base without shims.

$$\begin{aligned}
 F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\
 &= \frac{-0.011}{2} + \frac{-0.019 \times 8.25}{3.5} \\
 &= -0.0055 + (-0.04479) \\
 &= -0.050 \text{ inch}
 \end{aligned}$$

$$\begin{aligned}
 R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\
 &= \frac{-0.011}{2} + \frac{-0.019 \times 19.25}{3.5} \\
 &= -0.0055 + (-0.1045) \\
 &= -0.110 \text{ inch}
 \end{aligned}$$

**5th Arrangement.**—Place rim and face indicators as shown in Fig. 5a. In the figure, notice that the origin of the dimensions  $B$  and  $C$  is the line of the rim indicator.

Fig. 5a. Dial Indicator Arrangement 5

Fig. 5b. Interpreting Dial Indicator Readings for Indicator Arrangement 5

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.0$  inches,  $B = 5.50$  inches, and  $C = 17$  inches. The two indicator dials read  $r = \text{plus } (+) 0.042$  inch and  $f = \text{minus } (-) 0.036$  inch respectively.

*Solution:* The top right block in Fig. 5b corresponds to the positive rim value and a negative face value of the indicators, and indicates that both ends of the motor need to be moved down. This requirement is confirmed by the negative shim numbers that provide the exact distance as follows:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} \\ &= \frac{0.042}{-2} + \frac{-0.036 \times 5.50}{4.0} \\ &= -0.021 + (-0.0495) \\ &= -0.0705 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\ &= \frac{0.042}{-2} + \frac{-0.036 \times 17.0}{4.0} \\ &= -0.021 + (-0.153) \\ &= -0.174 \text{ inch} \end{aligned}$$

**6th Arrangement.**—Place rim and face indicators as shown in Fig. 6a.

Fig. 6a. Dial Indicator Arrangement 6

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{-A}$$

$$R = \frac{\pm r}{-2} + \frac{\pm f \times C}{-A}$$

Fig. 6b. Interpreting Dial Indicator Readings for Indicator Arrangement 6

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.75$  inches,  $B = 6.25$  inches, and  $C = 31.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.024$  inch and  $f = \text{plus } (+) 0.005$  inch respectively.

*Solution:* The top left block in Fig. 6b describes the situation of negative rim and positive face values. The generic graph suggests that both the front and rear feet need some shims to be removed, but the calculations below require that some positive movement of the front feet is required. If in doubt, follow the numbers; the graphs are not drawn to scale. The formulas call for 0.005 inch added under the front feet and the rear feet to be lowered by 0.021 inch:

$$F = \frac{\pm r}{-2} + \frac{\pm f \times B}{-A}$$

$$= \frac{-0.024}{-2} + \frac{0.005 \times 6.25}{-4.75}$$

$$= 0.012 - 0.006578$$

$$= 0.005 \text{ inch}$$

$$R = \frac{\pm r}{-2} + \frac{\pm f \times C}{-A}$$

$$= \frac{-0.024}{-2} + \frac{0.005 \times 31.75}{-4.75}$$

$$= 0.012 + (-0.03342)$$

$$= -0.021 \text{ inch}$$

**7th Arrangement.**—Place rim and face indicators as shown in Fig. 7a.

Fig. 7a. Dial Indicator Arrangement 7

Fig. 7b. Interpreting Dial Indicator Readings for Indicator Arrangement 7

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 12.375$  inches,  $B = 14.875$  inches, and  $C = 47.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.002$  inch and  $f = \text{plus } (+) 0.001$  inch respectively.

*Solution:* This motor is almost in alignment. The upper right block of Fig. 7b corresponds to the negative rim and positive face condition. The graph suggests both the front and rear motor feet be lowered, depending on the magnitude of the variables. The formula solution dictates exactly how much the movable unit needs to be lowered at both front and rear shim points. Shims on front and rear feet will be as follows:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.002}{2} + \frac{0.001 \times 14.875}{-12.375} \\ &= -0.001 + (-0.001) \\ &= -0.002 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.002}{2} + \frac{0.001 \times 47.75}{-12.375} \\ &= -0.001 + (-0.003858) \\ &= -0.005 \text{ inch} \end{aligned}$$

**8th Arrangement.**—Place rim and face indicators as shown in Fig. 8a.

Fig. 8a. Dial Indicator Arrangement 8

Fig. 8b. Interpreting Dial Indicator Readings for Indicator Arrangement 8

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 12.375$  inches,  $B = 14.875$  inches, and  $C = 47.75$  inches. The two indicator dials:  $r = \text{minus } (-) 0.042$  inch and  $f = \text{minus } (-) 0.002$  inch respectively.

*Solution:* In Fig. 8b, the top right block conforms to negative rim and negative face values. The graph suggests both the front and rear motor feet be lowered. The formula dictates exactly how much the movable unit is to be lowered at both front and rear shim points. Shims removed on front and rear feet will be as follows:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\ &= \frac{-0.042}{2} + \frac{-0.002 \times 14.875}{12.375} \\ &= -0.021 + (-0.002) \\ &= -0.023 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\ &= \frac{-0.042}{2} + \frac{-0.002 \times 47.75}{12.375} \\ &= -0.021 + (-0.0077) \\ &= -0.029 \text{ inch} \end{aligned}$$

**9th Arrangement.**—Place rim and face indicators as shown in Fig. 9a. The driven unit here could be any of several devices including the “catch” drum for a centrifugal clutch.

Fig. 9a. Dial Indicator Arrangement 9

Fig. 9b. Interpreting Dial Indicator Readings for Indicator Arrangement 9

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 10.375$  inches,  $B = 22.0$  inches, and  $C = 48.0$  inches. The two indicator dials read  $r = 0.00$  inch and  $f = \text{plus (+)} 0.017$  inch respectively.

*Solution:* In Fig. 9b, the center block of the bottom row represents zero rim and positive face values. The graph suggests both the front and rear motor feet be moved up by adding shims, depending on the magnitude of the variables. The formula solution below dictates that the front feet be moved up 0.036 inch and the rear feet be moved up 0.079 inch:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} & R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\
 &= \frac{0.00}{-2} + \frac{0.017 \times 22}{10.375} & &= \frac{0.00}{-2} + \frac{0.017 \times 48}{10.375} \\
 &= -0.00 + 0.036 & &= -0.00 + 0.079 \\
 &= 0.036 \text{ inch} & &= 0.079 \text{ inch}
 \end{aligned}$$

**10th Arrangement.**—Fig. 10a illustrates an arrangement used for taking two separate readings with one dial indicator.

Fig. 10a. Dial Indicator Arrangement 10

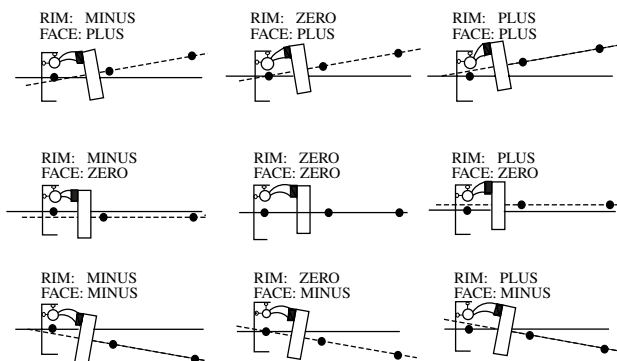

Fig. 10b. Interpreting Dial Indicator Readings for Indicator Arrangement 10

Solid lines represent the desired location for the dashed (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 5.50$  inches,  $B = 14.0$  inches, and  $C = 35.0$  inches. The indicator readings are  $r = \text{plus (+)} 0.030$  inch and  $f = \text{plus (+)} 0.022$  inch, respectively.

*Solution:* In Fig. 10b locate the block illustrating the positive rim and positive face condition. The graph suggests both the front and rear motor feet be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned}
 F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} \\
 &= \frac{0.030}{-2} + \frac{0.022 \times 14}{-5.5} \\
 &= -0.015 + (-0.056) \\
 &= -0.071 \text{ inch}
 \end{aligned}$$

$$\begin{aligned}
 R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\
 &= \frac{0.030}{-2} + \frac{0.022 \times 35}{-5.5} \\
 &= -0.015 + (-0.140) \\
 &= -0.155 \text{ inch}
 \end{aligned}$$

**11th Arrangement.**—Place rim and face indicators as shown in Fig. 11a.

Fig. 11a. Dial Indicator Arrangement 11

Fig. 11b. Interpreting Dial Indicator Readings for Indicator Arrangement 11

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the necessary shims for a pump and motor alignment where dimensions are  $A = 6.50$  inches,  $B = 16.625$  inches, and  $C = 42.0$  inches. The two indicator dials read  $r = 0.000$  inch and  $f = \text{minus } (-) 0.026$  inch respectively.

*Solution:* The center block in the last row of Fig. 11b describes the zero rim and negative face value condition. The motor is too low because of angularity (face reading), but the elevation is correct at the axial position of the rim indicator reading. The graph suggests both the front and rear motor feet be moved up. The formula solution dictates exactly how much the movable unit is raised at both front and rear shim points:

$$\begin{aligned}
 F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} & R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\
 &= \frac{0.00}{2} + \frac{-0.026 \times 16.625}{-6.50} & &= \frac{0.00}{2} + \frac{-0.026 \times 42}{-6.50} \\
 &= 0.00 + 0.0665 & &= 0.00 + 0.168 \\
 &= 0.0665 \text{ inch} & &= 0.168 \text{ inch}
 \end{aligned}$$

**12th Arrangement.**—The set up in Fig. 12a could be one indicator with two stems, or one indicator taking separate face and rim readings at the same location.

Fig. 12a. Dial Indicator Arrangement 12

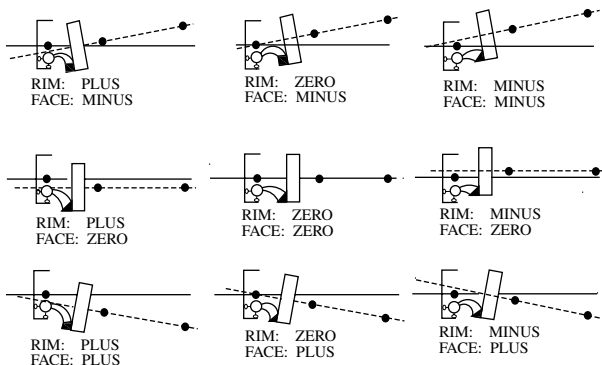

Fig. 12b. Interpreting Dial Indicator Readings for Indicator Arrangement 12

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 23.0$  inches,  $B = 41.0$  inches, and  $C = 96.0$  inches. The two indicator readings are  $r = \text{plus } (+)0.004$  inch and  $f = \text{minus } (-)0.003$  inch, respectively.

*Solution:* For practical purposes, this unit is already within tolerance by most standards. However, the block in the upper left corner of Fig. 12b illustrates the positive rim and negative face condition. The graph suggests both the front and rear motor feet be lowered. Removal of 0.003 inch of shim at the front and 0.011 inch at the rear feet will reduce misalignment to less than a mil on the next reading.

$$\begin{aligned}
 F &= \frac{\pm r}{2} + \frac{\pm f \times B}{A} \\
 &= \frac{0.004}{2} + \frac{-0.003 \times 41}{23.0} \\
 &= 0.002 + (-0.005) \\
 &= -0.003 \text{ inch}
 \end{aligned}
 \qquad
 \begin{aligned}
 R &= \frac{\pm r}{2} + \frac{\pm f \times C}{A} \\
 &= \frac{0.004}{2} + \frac{-0.003 \times 96}{23.0} \\
 &= 0.002 + (-0.013) \\
 &= -0.011 \text{ inch}
 \end{aligned}$$

**13th Arrangement.**—In Fig. 13a, the indicator jig is mounted on the static unit and two separate readings are taken from surfaces of the inside of a centrifugal clutch drum on the movable unit.

Fig. 13a. Dial Indicator Arrangement 13

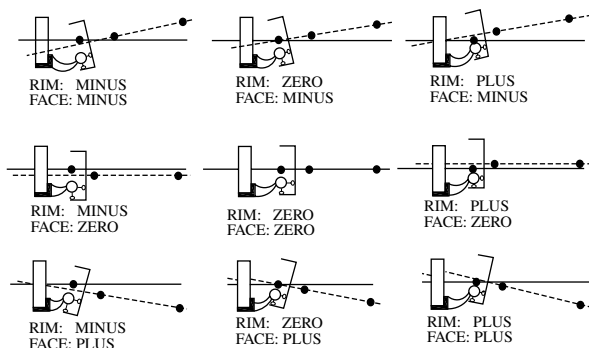

Fig. 13b. Interpreting Dial Indicator Readings for Indicator Arrangement 13

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 23.0$  inches,  $B = 20.0$  inches, and  $C = 75.0$  inches. The indicator readings are  $r = \text{plus } (+) 0.004$  inch and  $f = \text{minus } (-) 0.003$  inch, respectively.

*Solution:* The positive rim and negative face condition is illustrated in the top right block of Fig. 13b. The graph suggests that both the front and rear motor feet needs to be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{A} \\ &= \frac{0.004}{-2} + \frac{-0.003 \times 20}{23.0} \\ &= -0.002 + (-0.0026) \\ &= -0.005 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{A} \\ &= \frac{0.004}{-2} + \frac{-0.003 \times 75}{23.0} \\ &= -0.002 + (-0.00978) \\ &= -0.012 \text{ inch} \end{aligned}$$

**14th Arrangement.**—Place rim and face indicators as shown in Fig. 14a.

Fig. 14a. Dial Indicator Arrangement 14

Fig. 14b. Interpreting Dial Indicator Readings for Indicator Arrangement 14

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.625$  inches,  $B = 10.75$  inches, and  $C = 32.5$  inches. The two indicator dials read  $r = \text{minus } (-) 0.014$  inch and  $f = \text{plus } (+) 0.036$  inch respectively.

*Solution:* In Fig. 14b, the negative rim and positive face condition is shown in the top left block. The graph suggests that both the front and rear motor feet should be lowered, depending on the magnitude of the variables. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{-2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.014}{-2} + \frac{0.036 \times 10.75}{-4.625} \\ &= 0.007 + (-0.0837) \\ &= -0.077 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{-2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.014}{-2} + \frac{0.036 \times 32.5}{-4.625} \\ &= 0.007 + (-0.25297) \\ &= -0.246 \text{ inch} \end{aligned}$$

**15th Arrangement.**—Place rim and face indicators as shown in Fig. 15a.

Fig. 15a. Dial Indicator Arrangement 15

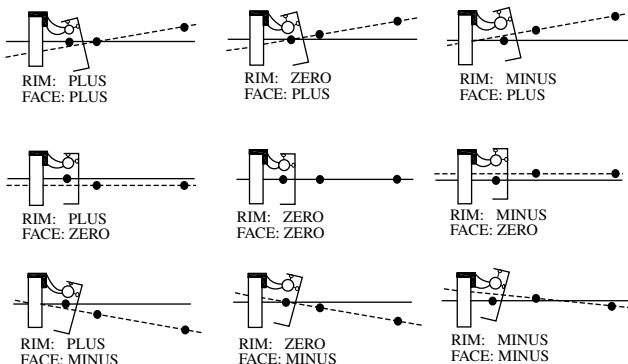

Fig. 15b. Interpreting Dial Indicator Readings for Indicator Arrangement 15

Solid lines represent the desired location for the dashed lines (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the generic graph gives a mental picture of what the formulas should yield.

**Example:** Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 6.0$  inches,  $B = 38.0$  inches, and  $C = 84.0$  inches. The two indicator dials reads  $r = \text{minus } (-) 0.002$  inch and  $f = \text{plus } (+) 0.003$  inch respectively.

**Solution:** The negative rim and positive face condition is found in the top right corner of Fig. 15b. The graph suggests that both the front and rear motor feet need to be lowered. The formula solution dictates exactly how much the movable unit is to be lowered at both front and rear shim points:

$$\begin{aligned} F &= \frac{\pm r}{2} + \frac{\pm f \times B}{-A} \\ &= \frac{-0.002}{2} + \frac{0.003 \times 38.0}{-6.0} \\ &= -0.001 + (-0.019) \\ &= -0.020 \text{ inch} \end{aligned}$$

$$\begin{aligned} R &= \frac{\pm r}{2} + \frac{\pm f \times C}{-A} \\ &= \frac{-0.002}{2} + \frac{0.003 \times 84.0}{-6.0} \\ &= -0.001 + (-0.042) \\ &= -0.043 \text{ inch} \end{aligned}$$

**16th Arrangement.**—Place rim and face indicators as shown in Fig. 16a.

Fig. 16a. Dial Indicator Arrangement 16

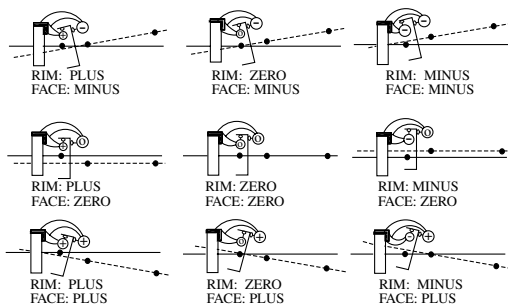

Fig. 16b. Interpreting Dial Indicator Readings for Indicator Arrangement 16

Solid lines represent the desired location for the dashed line (movable unit). The plus, minus, and zero readings on the indicators are represented by one of these nine scenarios. Depending on the magnitude of the variables, the graph gives a mental picture of what the formulas should yield.

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 16.0$  inches,  $B = 26.0$  inches, and  $C = 54.0$  inches. The two indicator dials read  $r = \text{minus } (-)0.002$  inch and  $f = \text{minus } (-)0.006$  inch respectively.

*Solution:* The rim and face numbers indicate that the whole movable machine is one mil high (from the rim indicator,  $\frac{1}{2} = 0.002 \times \frac{1}{2} = 0.001$ ), and the angularity from the face indicator say that for every 16 inches of axial length from the rim indicator there is an upward incline toward the rear of 0.006 inch. In Fig. 16b, locate the block with negative rim and negative face values. The graph suggests both the front and rear motor feet be lowered. The formula solution dictates that the movable unit is to be lowered at both front and rear shim points:

$$F = \frac{\pm r}{2} + \frac{\pm f \times B}{A}$$

$$= \frac{-0.002}{2} + \frac{-0.006 \times 26}{16}$$

$$= -0.001 + (-0.00975)$$

$$= -0.011 \text{ inch}$$

$$R = \frac{\pm r}{2} + \frac{\pm f \times C}{A}$$

$$= \frac{-0.002}{2} + \frac{-0.006 \times 54.0}{16}$$

$$= -0.001 + (-0.02025)$$

$$= -0.021 \text{ inch}$$

**Rim and Face Method Extended to Motors with Extra Feet.**—Fig. 17 illustrates an alignment problem that is complicated by the fact that the motor has ten feet. The indicator

arrangement used matches the arrangement illustrated in Fig. 14a. In this problem the solution is obtained by using the same equations as were used to obtain the solution of Fig. 14a, adapted slightly to deal with the additional feet.

Shim calculations for motor to pump alignment when the motor has more than four feet are performed in the same manner as the examples previously used. However, care must be used in determining the dimensions used in the equations. As in all the previous examples, the horizontal dimensions are measured from the location of the rim indicator. Distances to motor feet to the right of the rim indicator are assigned positive values, and distances measured to feet that are to the left of the rim indicator are assigned negative values in the formulas. The revised equations for this arrangement are shown beside Fig. 17. In the equations,  $S_F$  is the shim requirement at foot F,  $S_{F1}$  is the shim requirement at foot F1, etc.

Fig. 17. Shaft Alignment When More than Four Feet are Involved  
Dimensions are measured from the path of the rim indicator. Dimensions to locations left of the rim indicator enter the equations as minus (-) values, and dimension to the right of the rim indicator enter the equations as positive (+) quantities.

$$S_F = \frac{\pm r}{-2} + \frac{\pm f \times (-F)}{-A}$$

$$S_{F1} = \frac{\pm r}{-2} + \frac{\pm f \times (-F1)}{-A}$$

$$S_{F2} = \frac{\pm r}{-2} + \frac{\pm f \times F2}{-A}$$

$$S_{F3} = \frac{\pm r}{-2} + \frac{\pm f \times F3}{-A}$$

$$S_R = \frac{\pm r}{-2} + \frac{\pm f \times R}{-A}$$

*Example:* Calculate the shims necessary for a pump and motor alignment where dimensions are  $A = 4.5$  inches,  $F = 22.0$  inches,  $F1 = 10.0$  inches,  $F2 = 8.0$  inches,  $F3 = 24.0$  inches, and  $R = 46.0$  inches. The two indicator dials read  $r =$  minus  $(-)$ 0.054 inch and  $f =$  plus  $(+)$ 0.032 inch, respectively.

*Solution, Vertical Alignment:*

$$S_F = \frac{\pm r}{-2} + \frac{\pm f \times (-F)}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times (-22)}{-4.5} = 0.027 + 0.156 = 0.183 \text{ inch}$$

$$S_{F1} = \frac{\pm r}{-2} + \frac{\pm f \times (-F1)}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times (-10)}{-4.5} = 0.027 + 0.071 = 0.098 \text{ inch}$$

$$S_{F2} = \frac{\pm r}{-2} + \frac{\pm f \times F2}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 8}{-4.5} = 0.027 + (-0.156) = -0.030 \text{ inch}$$

$$S_{F3} = \frac{\pm r}{-2} + \frac{\pm f \times F3}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 24}{-4.5} = 0.027 + (-0.171) = -0.144 \text{ inch}$$

$$S_R = \frac{\pm r}{-2} + \frac{\pm f \times R}{-A} = \frac{-0.054}{-2} + \frac{0.032 \times 46}{-4.5} = 0.027 + (-0.327) = -0.300 \text{ inch}$$

The calculations show that more shims are required under the two pairs of front feet,  $F$  and  $F1$ , and need to be reduced for the other three pairs of rear feet. The top left figure in Fig. 14b (negative rim and positive face indicator readings) confirms that the numerical solution appears reasonable.

*Solution, Horizontal Alignment:* The horizontal alignment solution follows the same procedure as the vertical solution above, and will use the same equations if the indicator set up shown in Fig. 17 is used.

The dimensions  $F$ ,  $F1$ ,  $F2$ ,  $F3$ , and  $R$  are the distances from the rim indicator path to the respective locations where the move occurs, whether it be the location of the hold-down bolts, or another location where a monitoring dial indicator is mounted. See *Solution for Horizontal Alignment* on page 2729 for additional information on this subject.

## FLUID POWER

## Introduction

A fluid is a substance which deforms continuously when subjected to a shear stress. Fluid power systems convert mechanical or potential energy into fluid energy, and usually perform work with the fluid energy. The fluid used can be either a liquid or a gas. When liquids are used, it is a hydraulic system, and when a gas is used it is a pneumatic system.

**Properties of Liquids and Gases.**—One of the main differences between liquids and gases has to do with compressibility. Compressibility is a measure of the relative volume change of a substance with a change in pressure. Liquids are only slightly compressible, and are usually considered to be incompressible for the purposes of fluid power calculations. Gases, on the other hand, are very compressible under normal conditions.

Specific weight is the weight of a fluid per unit of volume. Mass density of a fluid is the mass contained within a unit of volume. When a fluid is pressurized, its density and specific weight increase, and when a fluid is heated, its density and specific weight decrease. Liquids are affected very little by these factors, while gases are very much affected. Specific gravity is the ratio between specific weight or density at actual versus standard conditions. Specific gravity changes with specific weight or density. Standard conditions are taken to be 4°C for water, and 0°C for air. Other fluids may have different standard conditions. Standard symbols and equations for these properties are shown below. [Table 1](#), [Table 2](#) and [Table 3](#) contain the properties of some common fluids.

## Fluid Property Symbols and Equations

Specific weight: lbf/ft <sup>3</sup> , N/m <sup>3</sup>	$\gamma = \rho g = \frac{w}{V}$
Density	$\rho = \frac{m}{V}$
slugs/ft <sup>3</sup> , kg/m <sup>3</sup>	$\rho$
lbfm/ft <sup>3</sup>	$\rho_{\text{lbfm}} = \rho g_c$
Gravitational Constant: lbfm-ft/lbf-s <sup>2</sup>	$g_c = 32.2$
Specific Gravity: dimensionless	$SG = \frac{\gamma}{\gamma_c} = \frac{\rho}{\rho_c}$
The control specific weight $\gamma_c$ for liquids is water, and for gases is air.	

The density of dry air at 32 degrees F and atmospheric pressure (29.92 inches of mercury or 14.70 pounds per square inch) is 0.08073 pound per cubic foot.

The density of air at any other temperature or pressure is

$$\rho = \frac{1.325 \times B}{T}$$

in which  $\rho$  = density in pounds per cubic foot;  $B$  = height of barometric pressure in inches of mercury;  $T$  = absolute temperature in degrees Rankine. (When using pounds as a unit care must be exercised to differentiate between pounds mass and pounds force. See *Acceleration of Gravity g Used in Mechanics Formulas* on page 157.)

The absolute zero from which all temperatures must be counted when dealing with the weight and volume of gases is assumed to be -459.7 degrees F. Hence, to obtain the absolute temperature  $T$  used in the preceding formula, add the value 459.7 to the temperature observed on a regular Fahrenheit thermometer.

In obtaining the value of  $B$ , 1 inch of mercury at 32 degrees F may be taken as equal to a pressure of 0.491 pound per square inch.

Table 1. Density of Air at Different Pressures and Temperatures

Temp. of Air, °F	Gage Pressure, Pounds															
	0	5	10	20	30	40	50	60	80	100	120	150	200	250	300	
	Density in Pounds per Cubic Foot

**Table 3. Properties of Common Fluids at Atmospheric Pressure**

Fluid	Temperature		Density		Specific Weight		Specific Gravity
	°F	°C	slug/ft <sup>3</sup>	kg/m <sup>3</sup>	lbf/ft <sup>3</sup>	N/m <sup>3</sup>	
Air	68	20	$2.33 \times 10^{-3}$	1.205	0.075	11.8	1
Nitrogen	68	20	$2.26 \times 10^{-3}$	1.165	...	...	0.9669
Water	68	20	1.936	998.2	62.4	$9.81 \times 10^3$	1
Seawater	68	20	1.987	1024	63.9	$10.03 \times 10^3$	1.025

**Pressure.**—Pressure,  $p$ , is defined as the average force per unit area,  $A$ , exerted by a fluid.

$$p = \frac{F}{A}$$

The pressure at a point in a static fluid is the same in all directions, and the same at all points in that fluid. The pressure exerted by a fluid on a solid surface is always perpendicular to that surface. Pressure measured relative to atmospheric pressure is called gauge pressure.

Pressure measured relative to a perfect vacuum is called absolute pressure. The relationship between absolute pressure and gauge pressure is given in the following equation:

$$P_a = P_g + P_{atm}$$

where  $P_a = 14.696$  psi (US); and,  $P_a = 101.325$  kPa (SI).

The change in pressure in a non-moving liquid due to a change in elevation is dependent on the specific weight of the fluid and can be calculated using the following equations. Elevation is always taken to be positive in the upward direction relative to the reference plane. The pressure caused by elevation is independent of the shape and size of the container and its free surface.

$$p = \gamma h \text{ where } \gamma \text{ is specific weight (lbf/ft}^3 \text{ or N/m}^3\text{), } h \text{ is elevation (ft or m), and } p \text{ is pressure (lbf/ft}^2 \text{ or N/m}^2\text{)}$$

$$p = \frac{\gamma h}{144} \text{ where } \gamma \text{ is specific weight (lbf/ft}^3\text{), } h \text{ is elevation (ft), and } p \text{ is pressure (psi)}$$

For ideal gases, the relationship between pressure, temperature, and specific volume can be found in the following equations. Specific volume is the volume occupied by a unit mass of a fluid.

$$PV = 1545.3nT \quad \text{For fps units}$$

$$PV = 8314nT \quad \text{For SI units}$$

in which  $P$  = absolute pressure in pounds per square foot or Pa ( $\text{N/m}^2$ )

$V$  = volume in cubic feet or cubic meter

$T$  = absolute temperature in degrees R or degrees K

$n$  = number of pound moles or kg moles. A mole is the mass of substance, in appropriate units, divided by its molecular weight. The equations above are general forms that apply to any gas that behaves the ideal gas law.

**Viscosity.**—Viscosity is a liquid property that indicates its resistance to flow. It is a measure of a fluid's resistance to a shearing force. High viscosity fluids require a greater force to shear at a given rate than low viscosity fluids. This is the most important property of fluids when designing and analyzing fluid power systems. An ideal fluid has zero viscosity, and gases have nearly zero viscosity. For most fluids, viscosity varies significantly with temperature. It is relatively unaffected by changes in pressure, unless they are extreme. Newtonian fluids are those whose viscosity is independent of velocity gradient.

Viscosity index is the change in viscosity relative to change in temperature. Absolute, or dynamic, viscosity relates shearing stress in a fluid to the velocity gradient. Kinematic viscosity is the ratio of a fluid's absolute viscosity to its mass density. Absolute viscosity is often measured in centipoise (cP), and kinematic viscosity in centistokes (cSt).

Equations and conversion factors for absolute and kinematic viscosity are given below. The absolute and kinematic viscosity of various fluids can be found in [Table 4](#).

$$\text{Absolute viscosity: } \mu = \frac{F dy}{A dv} \text{ lbf-s/ft}^2 \text{ or N-s/m}^2 \text{ (Pa-s)}$$

Units may be expressed in centipoise, cP

$$\text{cP} = 2.09 \times 10^{-5} \text{ lbf-s/ft}^2$$

$$\text{cP} = 1 \times 10^{-3} \text{ Pa-s}$$

$$\text{Kinematic viscosity: } \nu = \frac{\mu}{\rho} \text{ ft}^2/\text{s or m}^2/\text{s}$$

Units may be expressed in centistokes, cSt

$$\text{cSt} = 1.07 \times 10^{-5} \text{ ft}^2/\text{s}$$

$$\text{cSt} = 1 \times 10^{-6} \text{ m}^2/\text{s}$$

**Table 4. Viscosity of Common Fluids at Atmospheric Pressure**

Fluid	Absolute Viscosity			Kinematic Viscosity		
	lbf-s/ft <sup>2</sup>	Pa-s	cP	ft <sup>2</sup> /s	m <sup>2</sup> /s	cSt
Air	$3.75 \times 10^{-7}$	$1.80 \times 10^{-5}$	0.018	$1.64 \times 10^{-4}$	$1.52 \times 10^{-5}$	15.24
Nitrogen	$3.75 \times 10^{-7}$	$1.80 \times 10^{-5}$	0.018	$1.64 \times 10^{-4}$	$1.52 \times 10^{-5}$	15.24
Water	$2.09 \times 10^{-5}$	$1.00 \times 10^{-3}$	1	$1.07 \times 10^{-5}$	$1.00 \times 10^{-6}$	1
Seawater	$2.26 \times 10^{-5}$	$1.08 \times 10^{-3}$	1.08	$1.13 \times 10^{-5}$	$1.05 \times 10^{-6}$	1.15
Mercury	$3.34 \times 10^{-5}$	$1.60 \times 10^{-3}$	1.6	$1.27 \times 10^{-6}$	$1.18 \times 10^{-7}$	0.118

Properties based on temperature 68°F or 20°C.

### Fluid Circuits

Fluid circuits contain compressed and flowing fluid, either liquid or gas, and convey it to perform work. They usually employ a valve to stop and/or control the direction of flow.

**Standard Fluid Circuit Components.**—Fluid circuits typically include fluid preparation components, valves, actuators, and connecting lines. Pneumatic circuits also normally include provisions for gas to be exhausted to the atmosphere, through a silencer, to a reclassifying filter, or to an exhaust manifold where it can be ducted elsewhere. Quick exhausting of gas is essential for fast pneumatic circuit response. Hydraulic circuits are generally closed, that is, recirculating fluid rather than discharging it.

**Fluid Circuit Types.**—There are two main fluid circuit types, which are classified in terms of how the valve functions.

*Open and Closed Center Circuits:* Open center circuits permit nearly unrestricted flow through the valve and back to the source when the valve is de-energized. Closed center circuits block flow through the valve when the valve is de-energized. This type of circuit is recommended when you have multiple circuits on a single supply.

*Flow Control Circuits:* To control the speed of an actuator in a pneumatic circuit, use flow controls. Flow controls always generate some heat in hydraulic circuits, so with hydraulics they should be avoided where possible and other methods used. There are three types of flow control circuits: meter-in, meter-out, and bleed-off (or bypass). Pneumatic and some hydraulic systems use meter-in and meter-out circuits, while many hydraulic circuits use bleed-off types.

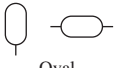

Meter-in circuits have a flow control valve before an actuator. Meter-in control can be used for actuator speed control. For hydraulic systems, a regulated bypass circuit is recommended rather than a restrictive flow control to reduce generated heat.

Meter-out circuits are best for pneumatic actuator speed control, and are required for applications with large negative loads on actuators. For example when lowering a heavy weight, a meter-out circuit is best. Flow control is placed after the actuator to restrict flow coming out. Because the positive side of the actuator sees full system pressure and flow, the mechanical system is very stable under loading. Care must be taken to avoid overloading actuators when using meter-out circuits.

**Fluid Component Symbols and Circuit Diagrams.**—Fluid power circuits are documented through the use of circuit diagrams or schematics. The components in a circuit are represented symbolically and connected with lines representing pipe or tubing. The symbols are used to identify and represent the function of the components. Symbols for fluid power components have been standardized by ANSI Y32.10 and ISO 1219. Some common symbols can be found in Table 5.

Directional control valve symbols show the valve's positions, methods of actuation, flow paths, and ports. The valve positions are represented by boxes. The methods of left and right valve actuation are represented by symbols on each end of the valve symbol. The flow path for each position is shown within its respective position box. Ports are marked on the position box that corresponds to the de-energized state of the valve.

**Table 5. Selected ANSI Fluid Component Symbols**

Solid Line Main Line Conductor, Physical Outline, or Shaft	Dashed Line Pilot Line for Control	Dotted Line Exhaust or Drain Line	Center Line Enclosure Outline
			
Circle Device, Connector, or Component	Triangle Indicates Flow Direction <sup>2</sup> : (See footnote <sup>3</sup> )	Square Reservoir (Closed, Open)	Oval Accumulator or Receiver

**Table 5. (Continued) Selected ANSI Fluid Component Symbols**

 Diamond Fluid Conditioner (Filter, Strainer)	 Arrow Through Symbol at 45° Indicates Component Can Be Adjusted	 Pump, Fixed Capacity (One direction of flow)	 Pump, Variable Capacity (Two directions of flow)
 Single Acting Air Cylinder	 Single Acting Spring Return Air Cylinder	 Double Acting Air Cylinder	 Double Acting Rotary Actuator
 Pressure Regulator, Adjustable and Relieving	 Pressure Gauge	 Temperature Gauge	 Cooler
 Check Valve	 Shut-off Valve	 Flow Control Valve, Adjustable	 Pressure Control Valve
 Pressure Relief Valve	 Directional Valve Two Port, Two Position (2/2) Two Way, Normally Open	 Directional Valve Three Port, Two Position (3/2) Two Way, Normally Closed	 Directional Valve Five Port, Two Position (5/2) Four Way, Normally Open
 Directional Valve Five Port, Three Position (5/3) Four Way, Normally Closed	 Directional Valve Two Position, Three Way, Normally Open, With Manual Actuation and Spring Return	 Directional Valve Two Position, Three Way, Normally Open, With Single Solenoid and Spring Return	 Directional Valve Two Position, Three Way, Normally Open, With Double Solenoids and Manual Overrides

<sup>a</sup> A pneumatic direction symbol is shown as an outline; a hydraulic symbol is filled.

**Fluid Circuit Analysis Considerations.**—When designing or analyzing a fluid circuit, one must consider fluid type, flow rate, velocity, pressure, and temperature. Fluid type and temperature will determine how it behaves as it is manipulated. Excessive velocities can lead to noise, vibration, and stresses. Pressure and flow rate will determine what size and type of pipe, tube, and components can be used. Also important to consider is the structural integrity of the system, including the weight of components, connections, and fluid. Every component in a fluid circuit, with the exceptions of pumps and compressors, will cause energy to be lost from the fluid. Friction, gravity, directional change, and restriction are all causes of lost energy. A careful analysis of energy added and lost from a fluid circuit must be completed as part of the design process.

**Safety Notes.**—When designing fluid circuits, safety should be of paramount importance. The logic of all circuits should be checked for proper performance during startup, shutdown, pressure loss, emergency stops, and other foreseeable events. Before selecting any control element, it is important to first know the safety category for the function being controlled by the fluid circuit. The manufacturer can assist in selecting components with the proper safety functions and ratings. It is important to note that any compressed gas other than air is an asphyxiation hazard. Air quality monitoring devices should be used when the volume of available gas has the potential to create an unsafe environment in the event of a leak. Some fluids can be incompatible with materials used in the circuit. Check material compatibility of seals, tubing, and other components. Check the temperature ratings of any components against the expected temperature of the fluid application.

### Pressure and Flow

Fluids are often delivered at a much higher pressure than needed. This pressure can be measured through a variety of means and brought down to a set level using a pressure regulator. When delivery pressure fluctuates, the installation of a regulator set at a lower pressure can stabilize pressure downstream for the fluid power components in the circuit.

**Pressure Generation.**—Pressure is raised in fluids in a variety of ways, the most common being pumps, compressors, and diffusers. Diffusers are sometimes contained within pumps, and are commonly part of HVAC systems.

**Compressors, Fans, Blowers, and Pumps:** Liquids have their pressures increased by pumps, while gases have their pressures increased by compressors, fans, and blowers. Compressors and some types of fans and blowers are similar to pumps, but the compression of gases is subject to the laws of thermodynamics. More information about gas compressors, fans, and blowers can be found in the section *Pneumatics* starting on page 2810.

**Diffusers:** Diffusers use a gradual enlargement of a pipe to convert velocity energy into pressure. Diffusers are used both to raise pressure and to decrease velocity of a fluid. They are used in pipelines to reduce the energy loss when the pipe goes through an enlargement. More on the energy loss of sudden versus gradual enlargement can be found later in this text. The pressure increase generated by a diffuser can be calculated using the following equation:

$$\Delta p = p_o - p_i = \gamma \left[ \frac{(v_i^2 - v_o^2)}{2g} - h_l \right]$$

where  $p_o$  and  $v_o$  are pressure and velocity at the outlet,  $p_i$  and  $v_i$  are pressure and velocity at the inlet, and  $h_l$  is the energy loss through the diffuser.

**Pressure Measurement.**—Pressure is measured in the United States in terms of pounds per square inch (psi). Where pressures are quite low, inches of water gauge (inH<sub>2</sub>O, or in.w.g.) is used. In SI units, pressure is measured in pascals (Pa), kilopascals (kPa), and Megapascals (MPa). Other units of pressure are bars and mmH<sub>2</sub>O. Pressure is usually expressed relative to atmospheric pressure (gauge pressure), as opposed to absolute pressure. Negative gauge pressure is a vacuum. Some common pressure unit conversions are given in the following table.

#### Pressure Conversions

US	SI
1 inH <sub>2</sub> O = 0.036 psi	1 mmH <sub>2</sub> O = 9.81 Pa
1 psi = 6895 Pa	1 Pa = 0.000145 Psi
1 psi = 144 psf	1 Pa = 1 N/m <sup>2</sup>
1 atm = 14.7 psi	1 bar = 100,000 Pa
1 atm = 1.01 bar	1 bar = 0.99 atm
1 inHg = 0.49 psi	1 mmHg = 133 Pa

**Manometers:** Manometers are devices which expose a static column of relatively dense fluid (mercury and oils are commonly used) to a differential pressure. These are used for liquid pressure measurement. In many cases, one end is exposed to a pressurized fluid while the other is left open to atmospheric pressure. The change in elevation of the column of fluid can be used to calculate the pressure of the fluid being measured by using the relationship between pressure and elevation.

Commercial manometers are calibrated and can be purchased in a variety of ranges. Piezometer tubes are types of manometers used for relatively low pressures. They consist of a vertical glass tube inserted into the wall of a pipe or pressure vessel. Its end is open to

atmosphere or some known pressure reservoir. The height of the liquid in the tube is read against a calibrated scale and is related to pressure in the pipe or vessel.

**Barometers:** Barometers are used to measure atmospheric pressure. They operate on the same principle as manometers, where the change in height of a column of gauge fluid (commonly mercury) is used to calculate a change in pressure. Commercial barometers are calibrated and generally measure in the range between 25.5 and 32.5 inches (650–825 mm) of mercury. Corresponding pressures in pound per square inch and pound per square foot are given in [Table 6](#).

**Table 6. Relation Between Barometric Pressure, and Pressures in Pounds per Square Inch and Square Foot**

Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>	Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>	Barometer, Inches	Pressure in Psi <sup>a</sup>	Pressure in Psf <sup>a</sup>
28.00	13.75	1980	29.25	14.36	2068	30.50	14.98	2156
28.25	13.87	1997	29.50	14.48	2086	30.75	15.10	2174
28.50	13.99	2015	29.75	14.61	2103	31.00	15.22	2192
28.75	14.12	2033	30.00	14.73	2121	31.25	15.34	2210
29.00	14.24	2050	30.25	14.85	2139	...	...	...

<sup>a</sup> Psi is pound per square inch; Psf is pound per square foot

**Pressure Gauges:** The most common method of measuring pressure in a fluid power circuit is by using a pressure gauge. There are gauges for liquids and gauges for gases. There are a variety of methods of construction of pressure gauges, including elastic diaphragm, dead weight, magnetic, and Bourdon tube gauges. Commercial gauges are normally calibrated to read zero at standard atmospheric pressure and temperature. Pressure gauges are available in a variety of ranges and units.

Some are capable of reading vacuum, or negative gauge pressure. Liquid filled gauges provide more stable readouts when vibration or pulsation is present in the system. The use of a snubber is recommended when fluid pressure pulsates.

**Pressure Transducers:** These are used when the display needs to be decoupled from the measurement device. Transducers convert pressures to electrical signals which can be transmitted to remote displays. Pressure transducers can be linear differential transformers, piezoelectric, quartz resonators, or solid state devices.

**Pressure Regulation.**—Fluids are often delivered at pressures higher than needed. Pressure regulators are used where pressure needs to be lowered and controlled. There are regulators for liquids and others for gases. A pressure regulator is a device generally comprised of three elements; a pressure reducing or restrictive element, a sensing element, and a force generator (usually a spring). In operation, the force generator opens the valve. Pressure introduced into the inlet port then flows through the valve and applies pressure to the sensing device (usually a diaphragm or piston). The pressure acts on the sensing element to produce a force which opposes the opening force and closes the valve. Regulators may be manually or electronically adjusted, and may include a pressure gauge or sensor.

In some cases, pressure may fluctuate due to variable supply and/or demand. This may be undesirable where work is being performed. A pressure reservoir with a regulator after it is a desirable source for most fluid circuits because the combination can buffer pressure variations and supply multiple circuits.

When choosing a pressure regulator, there are many factors to consider. The allowable ranges of inlet and outlet pressures must be known when sizing a regulator. The maximum flow rate and any porting requirements are also factors. It is also important to consider the chemical properties of the fluid before determining the best materials for your application. There are a wide range of materials available to suit all applications. A non-relieving

regulator is preferred for use with hazardous, explosive, or expensive gases since a relieving regulator will vent excess pressure to atmosphere.

The temperature range that the regulator will see is also a factor. Extreme operating temperatures may affect flow capacity and/or the spring rate.

**Flow Measurement.**—There are many ways to measure the flow of liquid or gas. Measurement can be in terms of velocity, volume flow rate, or mass flow rate. When selecting a flow meter, one must consider the viscosity and chemical compatibility of the fluid being measured, the desired output units, the range of flow values being measured, the desired accuracy, and the maximum pressure encountered by the unit. The ratio of the maximum to the minimum flow rate a meter can measure within the expected accuracy is called “turndown.”

When designing a pipe system, it is often beneficial to run a bypass system of pipes with valves to allow service of a flow meter without interrupting system flow. Flow meters should be placed in straight sections of pipe for best measurement results. The length of straight pipe before and after each meter will depend on its type, the pipe diameter, and the type of nearest fitting or bend.

*Pitot Tubes:* Some pitot tubes are available to measure liquids and others are made for gases. These devices measure fluid flow velocity directly as a function of the height of a stationary column of fluid pushed out of the flow stream into a narrow tube. Most of the fluid flows past the device, but a small amount is captured in the static tube. Pitot tubes can be permanently installed in a pipe or duct, or used as a portable device for insertion as needed. The location of the capture tip of the pitot tube is critical, since flow velocity in a pipe varies across its cross section. Pitot-static tubes have ports perpendicular to the fluid flow direction to measure the static pressure of the fluid. Velocity is then calculated using the following equation:

$$v = \sqrt{\frac{2(p_t - p_s)}{\rho}}$$

where  $v$  is fluid velocity at the collection point;  $p_s$  is static pressure; and  $p_t$  is the stagnation pressure measured as a function of displacement of the fluid in the tube.

*Cup Anemometer:* Air velocity is often measured with one of these devices. They consist of several cups arranged about a shaft that is free to spin. As air flows perpendicularly to the cups, the device rotates at a speed dependent on the air flow velocity.

*Hot Wire Anemometer:* These devices employ a thin wire inserted into a gas stream. The wire is heated by current passing through it, and the gas flowing by tends to dissipate this heat. Some hot wire anemometers apply a fixed current, and thus the change in resistance of the wire (related to temperature change) is related to flow velocity. Others vary the current to maintain a fixed temperature, and thus the current required is related to flow velocity. Hot wire anemometers tend to break when used with liquids, so hot film probes are used in liquid applications.

*Venturi Meters:* These flow-through meters measure the pressure drop across a restriction and relate that to volume flow rate. The restriction is called a “throat” and has a gradual contraction followed by a gradual expansion. Venturi meters are more expensive than orifice meters, but cause less pressure loss in the system. Overall pressure loss is generally 5 to 20 percent of the measured differential pressure. Many venturi meters are available for measuring liquids, and others are meant for gases. They are suitable for contaminated fluids and slurries. The lengths of straight pipe required upstream and downstream of a Venturi meter for accurate flow measurement are given in ISO 5167-1. Flow rate  $Q$  through a venturi is calculated using the following equation:

$$Q = C \left( \sqrt{\frac{2\Delta p}{\rho}} \right) \frac{A_1}{\sqrt{\left(\frac{A_1}{A_2}\right)^2 - 1}}$$

where  $\Delta p$  is the measured differential pressure,  $A_1$  is the area at the upstream pressure tap, and  $A_2$  is the area at the throat. Coefficient  $C$  is generally 1 for ideal fluids, and 0.90 to 0.98 for viscous fluids.

*Orifice Plates and Meters:* These are the most widely used method of flow measurement in industry. Similar to venturi meters, these flow-through devices measure pressure drop across a restriction. The restriction is generally a hole in a plate placed across the flow path. This causes sudden contraction and expansion. The placement of the pressure measurement point is critical and dependent on the shape of the orifice. These meters generally create a larger energy loss than venturi meters due to the turbulence created by sudden changes in diameter, but are very cost-effective. The relevant standard covering orifice plates is ISO 5167. Flow through an orifice meter can be calculated using the following equation.

$$Q = C_f A_o \sqrt{\frac{2\Delta p}{\rho}}$$

where  $A_o$  is the area of the orifice. The coefficient  $C_f$  is generally between 0.6 and 0.9, and depends on the Reynolds number as well as pipe and orifice diameter. Tabulations of coefficient  $C_f$  can be found in various reference sources.

*Flow Nozzle Meters:* Similar to venturi and orifice meters, these flow-through devices measure pressure drop caused by flow restriction. Flow nozzles have a smooth elliptical inlet leading to a throat section with a sharp outlet. The geometry of these nozzles has been highly standardized by ASME and ISO. The nozzle tends to have a well-rounded intake, and therefore creates a much lower energy loss than an orifice meter. This higher efficiency means greater flow capacity when compared to most other differential meters of the same size. Energy loss does tend to be higher than with venturi tubes. Nozzle meters are available in standard and long radius configurations, with different discharge coefficients. Flow is calculated similarly to orifice and venturi meters, using Bernoulli's equation and the appropriate coefficient.

*Variable Area Flow Meters:* These devices are extremely common in industry, and are available for measuring liquids or gases. There are tube and vane types. Tube meters have a weighted float that is suspended in the flowing fluid. The clearance space between the float and the tube forms an annular passage or orifice. Since the tube is tapered, the area of this orifice is larger when the float is near the top than it is when the float is near the bottom. Volumetric flow is measured based on the height the float is carried to. As a result, these meters must be installed vertically. Vane type meters use a vane to obstruct a bend in the pipe. It is normally closed, and fluid flow swings it open. Both tube and vane meters are for use with clean fluids at moderate pressures. Some types allow the float or vane to be viewed against a calibrated scale. In those cases, the fluid must be clear enough to see the float. Other types of variable area flow meters are suitable for high pressures and opaque fluids, and use sensors to detect the position of the float or vane and display the result remotely. Due to the restriction caused by the float or vane in the fluid stream, some energy is lost by fluid flowing through these meters.

*Elbow Meters:* These meters are simply a bend in a pipe through which the fluid flows. These meters are sometimes the only choice where space constraints do not allow the other types of meters. Pressure differential is measured between a point on the outside radius and a point on the inside radius. Because the fluid is moving faster along the outside radius, it will be generate higher pressure.

**Turbine Flow Meters:** These meters allow fluid flowing through to turn a turbine rotor. The speed at which the rotor turns is indicative of the fluid velocity. The speed of the rotor is mechanically or electronically monitored. Because the turbine obstructs the fluid stream to some extent, some energy is lost due to restriction. These meters can be used for liquids or gases. Care must be taken when using these meters in a fluid that is non-lubricating, since the bearings that support the rotor may prematurely wear. Turbine flowmeters are less accurate at low flow rates due to drag, and should be operated above 5 percent of rated flow. Use in dirty fluids should generally be avoided to reduce the possibility of wear and damage. Two-phase flow and abrupt transitions from gas to liquid should be avoided because this can damage the mechanism.

**Vortex Shedding Flow Meters:** These are flow-through meters used for both liquids and gases. Placement of a blunt obstruction, called a *bluff body*, in the fluid stream causes vortices to be shed at a frequency dependent on the flow velocity. The shedding frequency is independent of fluid properties such as density, viscosity, conductivity, etc., however the flow must be turbulent for vortex shedding to occur. Sensors electronically monitor the shedding vortices. The obstruction need not be very large, and varies between manufacturers. Therefore, the energy lost by the fluid varies greatly from device to device. The advantage of this type of meter is that it is suitable for a wide range of fluids and gases. However, if a fluid includes substances likely to stick to or coat the bluff body, the meter's characteristics will change and accuracy will be compromised. The minimum measured flow rate should be at least twice the minimum rate detectable by the meter. The maximum flow capacity of the meter should be at least five times the anticipated maximum flow rate. The energy loss through a vortex meter is about half that of an orifice plate. The installed cost of vortex meters is competitive with that of orifice meters in sizes under six inches.

**Magnetic Flow Meters:** For use with conducting fluids only, magnetic flow meters use electrodes to detect the voltage generated in a fluid as it moves between two electromagnetic coils. The voltage generated is dependent on fluid velocity. Since there is nothing obstructing flow, these flow-through meters cause less energy loss than obstructing types. Another advantage of these meters is their suitability for a wide variety of fluids because their function is not affected by temperature, viscosity, or specific gravity.

**Ultrasonic Flow Meters:** These flow-through devices are attached to the outside of a pipe or tube, and therefore do not restrict flow or cause energy loss in the fluid. There are meters for gases and for fluids. Ultrasonic signals are transmitted through the pipe and fluid. The time it takes the signal to reach the receiver depends on the flow rate of the fluid. Some ultrasonic flow meters measure across the pipe, while others measure axially. A special type of ultrasonic flow meter, called a "Doppler" meter, is used for fluids with particulate content which may obstruct traversing ultrasonic signals. These meters measure the time it takes for signals to be reflected back from the fluid.

**Positive Displacement Flow Meters:** These are not flow-through devices, but instead allow fluid to fill a volumetrically calibrated chamber before the fluid is released. These meters can utilize a wide variety of mechanisms to capture and release volumes of fluid, one of the most common being diaphragm types typical to home gas meters. Other designs incorporate gears, pistons, and nutating disks (wobble plates). These meters are most often used for liquids, but can be used for gases as well.

**Coriolis Mass Flow Meters:** These flow-through devices measure mass flow rate directly, as opposed to measuring volume flow rate or velocity. By routing fluid through looping geometry, Coriolis force is generated and measured with sensors. Measurement results depend on the vibration of the tubes, so changes in tube rigidity due to temperature and pressure changes will affect calibration of the meter. These factors can be compensated for, but pitting, cracking, coating, erosion, or corrosion of the tubes cannot. Some energy is lost as the looping geometry causes changes in direction and velocity. These devices can be outfitted to monitor density of the fluid.

**Thermal Mass Flow Meters:** These devices are used almost exclusively for gas flow applications. Resistance temperature detectors (RTD) exhibit a linear change in resistance with respect to temperature. To measure mass flow rate, two RTD probes are used. One probe measures the fluid temperature, while the second probe is maintained at a higher temperature. As fluid flows by the heated probe, it dissipates the heat. The energy required to maintain the heated probe temperature is proportional to mass flow rate of the fluid. Some fluid energy is lost due to the obstruction of the probes in the fluid stream.

**Flow Control.**—Flow control is accomplished with manual or automatic valves, for both liquids and gases. Monitoring and control are often combined into a single device, in which flow is measured and the results are used to control a proportional valve to regulate flow. There are many types of flow controllers available, including manual needle valves and fully automated flow controllers. When density and viscosity is known and constant, and temperature is known, mass flow control can be performed. Mass flow controllers are usually used with gases, but some are available for liquids. Commercial flow control devices range in accuracy and flow capacity, and often contain proprietary control software and flow measurement technology.

**Coefficient of Velocity,  $C_v$ .**— $C_v$  is defined as the flow rate in US gallons per minute (gpm) of water at 60°F with a pressure drop across the device of 1 psi. This is directly applicable to hydraulic components, but  $C_v$  is also applied to pneumatic devices as an indication of their flow capacity. This value is normally used when matching valves to actuators, or sizing other fluid power devices.

Flow capacity of valves in a circuit must be equal to or greater than flow required by the devices they supply. For actuators, higher  $C_v$  values can also indicate faster movement capability.

$C_v$  is typically used in the United States and calculated using English units. The SI system has its own flow coefficient,  $K_v$ , which is calculated using metric units. These two values are not equivalent.  $K_v$  is defined as the flow rate in cubic meters per hour ( $m^3/h$ ) of water at a temperature of 16°C, with a pressure drop across the valve of 1 bar.

$C_v$  is commonly used by manufacturers for both English and metric products, and is normally provided in catalogs. The equations used to calculate  $C_v$  and  $K_v$  are listed below. The equations for liquids are simpler than those for gases, because gases are compressible.

$$\text{Conversion: } C_v = 1.157K_v \quad K_v = 0.864C_v$$

#### $C_v$ and $K_v$ Equations for Liquids

for Non-choked Turbulent Flow when  $\Delta p < F_L^2(p_i - F_F P_v)$

$$C_v = Q \sqrt{\frac{SG}{\Delta p}} \quad K_v = Q \sqrt{\frac{SG}{\Delta p}}$$

for Choked Turbulent Flow when  $\Delta p \geq F_L^2(p_i - F_F P_v)$

$$C_v = \frac{Q}{F_L} \sqrt{\frac{SG}{p_i - F_F P_v}} \quad K_v = \frac{Q}{F_L} \sqrt{\frac{SG}{p_i - F_F P_v}}$$

for Laminar or Transitional Flow

$$C_v = \frac{Q}{F_R} \sqrt{\frac{SG}{\Delta p}} \quad K_v = \frac{Q}{F_R} \sqrt{\frac{SG}{\Delta p}}$$

**$C_v$  and  $K_v$  Equations for Gases**for Non-choked Turbulent Flow when  $x < F_\gamma x_T$ 

$$C_v = \frac{Q}{1360 p_i \gamma \sqrt{\frac{SG p_i T_i Z}{\Delta p}}} \quad K_v = \frac{Q}{482 p_i \gamma \sqrt{\frac{SG p_i T_i Z}{\Delta p}}}$$

for Choked Turbulent Flow when  $x \geq F_\gamma x_T$ 

$$C_v = \frac{Q}{907 p_i \sqrt{\frac{SG p_i T_i Z}{F_\gamma \Delta p}}} \quad K_v = \frac{Q}{321.5 p_i \sqrt{\frac{SG p_i T_i Z}{F_\gamma \Delta p}}}$$

for Laminar or Transitional Flow

$$C_v = \frac{Q}{N_1 F_R \sqrt{\frac{M T_i}{\Delta p (p_i + p_o)}}} \quad K_v = \frac{Q}{N_2 F_R \sqrt{\frac{M T_i}{\Delta p (p_i + p_o)}}}$$

$$N_1 = 1730 \text{ for } T_s = 0^\circ\text{C}$$

$$N_1 = 1840 \text{ for } T_s = 15^\circ\text{C}$$

$$N_2 = 4920 \text{ for } T_s = 0^\circ\text{C}$$

$$N_2 = 5200 \text{ for } T_s = 15^\circ\text{C}$$

The following definitions apply to equations for  $C_v$  and  $K_v$  given above: $Q$  = flow in gpm for liquids, and flow in SCFM for gasses

SG = specific gravity

 $\Delta p = p_i - p_o$  is the pressure differential between upstream and downstream,  $p_i$  is inlet absolute pressure (psia or bar), and  $p_o$  is outlet absolute pressure (psia or bar) $F_F$  = liquid critical pressure ratio factor (ranges between 0.68 to 0.96) $F_L$  = liquid pressure recovery factor.  $F_L$  depends on valve geometry and ranges between 0.6 for ball valves and 0.9 for globe valves $P_v$  = absolute vapor pressure of the liquid at inlet temperature $x = \frac{\Delta p}{p_i}$  is the ratio of the pressure differential to the inlet absolute pressure $F_\gamma$  = specific heat ratio factor.  $F_\gamma = 1$  for air, otherwise  $F_\gamma = \frac{\gamma}{1.4}$  $x_T$  = choked flow pressure differential ratio factor, experimentally determined, that varies from 0.3 to 0.9 depending on valve geometry $Y$  = expansion factor for gases.  $Y = 1 - \frac{x}{3 F_\gamma x_T}$  for normal flow, and ranges from  $Y = 1$  to  $Y = 0.667$  at choked flow $Z$  = compressibility factor (assume  $Z = 1$  for ideal gasses) $F_R$  = Reynolds number factor that depends on valve characteristics, and is limited to  $F_R \leq 1$  $M$  = molecular mass of fluid in kg/kg-mol or lb/lb-mol $T_i$  = absolute inlet temperature for the gas, °C $T_s$  = absolute reference temperature for the gas, °C

For additional information on flow equations see International Electrotechnical Commission standard IEC 60534.

### Pipe, Tubing, and Fittings

Design of pipe systems must be undertaken with great care. Safety, performance, reliability, and cost are all significantly affected by selection of appropriate pipe sizes, materials, and connection methods. For many applications, the design must comply with codes and standards. Organizations such as ISO, ASTM, NSF, NFPA, AWWA, AFSA, and IAPMO should be consulted when working with pipe. Tubing systems are also covered by standards in cases of sanitary, food, medical, and high pressure applications.

**Metal Pipe.**—Metal pipe is ideal for applications where structural strength is needed. Metal pipe is also resistant to high temperatures and is non-combustible. Extremely low temperatures should be avoided. Metal pipe systems may need proper grounding to prevent shocks and accelerated corrosion. A wide range of materials is available.

*Materials:* Steel is the most commonly used metal pipe material for general use. Steel pipe is highly resistant to shock and vibration from water hammer or external sources. To carry a given pressure, steel pipe can be made with a thinner wall than pipes made from other materials, and as a result the pipe will have a larger flow capacity. Carbon steel pipes are susceptible to corrosion and oxidation, so additional allowance should be made when calculating flow capacity. Galvanized steel can inhibit atmospheric corrosion to some extent, but the coating can break down when exposed to constant moisture. Stainless steel pipes cost more, but are resistant to corrosion and oxidation. Stainless steel is also compatible with a wide variety of chemicals.

Ductile iron pipe is commonly used for water and sewer applications. It combines the physical strength of mild steel with the long life of gray cast iron. It has superseded cast iron pipe in the water handling industry. In addition to the benefits of long life, corrosion resistance, high structural strength, and tight joints, ductile iron is also readily machinable. Although somewhat corrosion resistant when in contact with water, these pipes are often internally lined or coated to inhibit corrosion further.

Copper pipe is commonly used in household and industrial supply lines for both liquids and gases. It costs more than steel pipe, but is much easier to join. It is extremely thermally conductive, which makes it a top choice for heat exchangers and other thermal applications. Copper resists corrosion, is unaffected by UV radiation, and inhibits the growth of bacteria. It will corrode in the presence of high or low pH liquids.

Connecting pipes and fittings of different metals is not recommended because galvanic corrosion to occur. Protective coatings should be employed where necessary to prevent contamination or failure of the joint.

*Schedules and Classes:* Schedule number designations for steel pipe, previously called “Iron Pipe Sizes (IPS)” are an indicator of wall thickness. Schedules range from 10 to 160, with higher numbers designating thicker walls. Schedules 40 and 80 are the most commonly used. From the IPS system, designations like STD, XS or XHY (extra heavy or strong), and XXS or XXHY (double extra strong or heavy) are still used. For a given pipe size, all schedules have the same outside diameter.

Higher schedule pipes of the same diameter have smaller flow areas. The nominal pipe size (NPS) is given, along with the schedule or IPS designation to indicate the full dimensional characteristics of the pipe.

Ductile iron pipe ranges in size from 3 to 64 inches and in pressure classes from 150 psi to 350 psi, although custom sizes and pressure ratings can be obtained.

Copper pipe is classified as copper tube. Information on copper tube can be found in the section *Metal Tube* starting on page 2771. Copper pipe is suitable for water and steam service at pressures up to 250 psi (1750 kPa) and temperatures up to 406°F (208°C).

*Sizes:* Nominal sizes for commercial steel pipe are generally given in inches. Actual diameter of the pipe can be different from the nominal designation, so refer to [Table 7](#) for actual dimensions of common pipe sizes up to 6 inches in diameter. This is the Nominal

Pipe Size (NPS) system. ISO has designated metric equivalent pipes for customary US pipe sizes. As with US pipe, metric pipe dimensions often differ from the nominal size designations.

Sizes of ductile iron pipe follow the Ductile Iron Pipe Sizes (DIPS) standard. These sizes and dimensions can be found in [Table 8](#). Flanged pipes are normally furnished with a maximum length of 19" - 6". The minimum length varies with pipe size. The minimum class thickness for ductile iron flanged pipe to be threaded is Special Thickness Class 53 for sizes up through 54 and pressure class 350 for 60 and 64 sizes. Greater pipe wall thicknesses are available.

**Pressure Ratings:** When working with ductile iron pipe applications, the designer should choose the appropriate class of pipe to carry the anticipated working pressure.

When working with other types of metal pipe, wall thickness must be selected or calculated based on working pressure. ANSI/ASME Standard B31.1-1998: "Power Piping" details a method of calculating the minimum wall thickness for pipes. The maximum working pressure for a pipe is often provided by the manufacturer, and can be calculated using US standard units in the following equation:

$$P_{\max} = \frac{2S(0.875t - A)}{D - 2Y(0.875t - A)}$$

where  $S$  is the allowable tensile stress in psi,  $t$  is the wall thickness in inches,  $D$  is the outer diameter in inches,  $A$  is an allowance for corrosion and threading, and  $Y$  is a temperature factor given in [Table 9](#). A factor of safety should be used when selecting allowable stress.

Allowance  $A$  is added to compensate for corrosion, erosion, threads, and bends, which thin the walls of the pipe. Allowance  $A = 0.05$  for threaded steel up to 3/8" OD and for unthreaded steel up to 1/2 OD.  $A = 0.065$  for unthreaded steel larger than 3/8" OD. For threaded steel larger than 3/8" OD,  $A$  is equal to the thread depth.

Wall thickness based on pressure requirement can be calculated using the following equation and [Table 9](#). This is for straight pipe, and wall thickness tolerances should be taken into account.

$$t = \frac{pD_o}{2(S + pY)} + A$$

where  $D_o$  is the outside diameter of the pipe,  $p$  is internal pressure,  $Y$  is the temperature coefficient given in [Table 9](#),  $A$  is the allowance discussed above, and  $S$  is the maximum allowable stress in the material.  $S$  should be modified to account for welds and joints according to the standards, and a factor of safety should be used.

The temperature at which material properties are given must be considered. Many hydraulic systems run at a temperature of approximately 100°F (38°C). A factor of safety of 3 to 4 should be used when calculating pressure ratings. If the tube is carrying liquid, the pressure rating must be derated to account for the pressure spikes that occur during valve closures. Derating for pressure spikes (water hammer) is often 20 percent. Derating to account for fittings is usually also done, with 25 percent additional reduction a typical value.

**Connections:** There are many types of connections for metal pipe, the most common of which are threaded, flanged, welded, and soldered.

Threaded connections on pipes normally use tapered threads per the standard for either American National Pipe Thread (NPT) or British Standard Pipe Thread (BSP). Metric pipe uses ISO standard pipe threads. These threads are detailed in [PIPE AND HOSE THREADS](#) starting on page 2089. Sealing is accomplished through thread interlocking and the use of a sealing compound or PTFE tape. The compound or tape lubricates the threads and ensures that spiral leak paths through the threads are blocked. Tape must be used in just the right amount to be effective. Too much tape can cause the joint to fail. Tape should not be used on bull plugs on heat exchangers. Tape is available in several

thicknesses. Thicker tape should be used on higher pressure or larger size installations. Always follow the manufacturer's recommendations when using liquid thread compounds, and always verify chemical compatibility with the process fluid.

Threaded connections are specified by the nominal pipe size and the type of thread (NPT, BSP or other).

Threaded pipe connections require the rotation of one of the pipes in the joint. When this is not practical, a threaded union may be used. Unions are comprised of two halves that form a flange connection.

Flanged connections are commonly used on large piping systems. For process and utilities, the two most common flange standards are ANSI B16.5 and BS 1560. Wellhead flanges are specified by API 6A. Flanges of different standards are not normally joined. There are three commonly used types of flange facings: Ring Type Joint (RTJ), Raised

$$^a \text{ If } D_o + t < 6, \text{ calculate } Y = \frac{D_i}{D_i + D_o}.$$

Face (RF), and Flat Face (FF). RTJ facings use ring type metal gaskets and are for the most severe duties, such as with high pressure gas piping. Raised face flanges have a nonmetallic gasket that fits within the bolts of the flange.

The face has a series of grooves into which the gasket flows upon compression. A flat face flange also uses a series of grooves, but the nonmetallic gasket fits over the entire face of the flange. Flat face flanges are used for the lowest pressure duties. The way in which the flange is attached to the pipe determines the flange type. Weld-Neck (WN) flanges are butt-welded to the pipe, and are used on high pressure and hazardous applications. Socket Weld (SW) flanges are fillet welded onto the pipe and are also suitable for high pressures, but are limited to pipe sizes of 1½ inch or less. Slip-On Weld (SO) flanges are used for low pressure, low hazard applications. The pipe is welded both to the hub and the bore of the flange. This weld configuration makes it impractical to radiographically inspect the welds. Composite lap joint flanges are used to save material expense on alloy pipe systems, where a backing flange of an inexpensive material is added to a hub welded to the pipe. Swivel ring flanges, like composite lap joint flanges, use a hub welded to the

pipe. A swivel ring fits over the hub for the purpose of bolting the joint together. The swivel ring flange facilitates flange alignment. There are a number of compact flange designs that include tapered sections or proprietary designs. Always comply with the manufacturer's specifications when using this type of flange connection.

Flanges are specified using the nominal pipe size, type and facing, pressure class, material, schedule, and applicable standard. Since surface condition is critical to flange sealing, all surfaces must be carefully inspected before use, and all scratches, rust, and burrs removed. Gasket selection must be done with consideration of temperature, internal pressure, cycling conditions, vibration, material compatibility, erosive/corrosive potential of the media, and potential to leach substances into the fluid. Gaskets may be ring-type, spiral wound, or sheet. They must be inspected carefully before use for damage, and should never be trimmed or re-used. Bolts must be of the proper material and grade for the joint, and tightened gradually according to standard procedure. Lubricant of the proper type should be used if recommended, and a torque wrench should be employed upon final tightening to ensure proper compression.

Welded and soldered pipe connections should be made according to applicable standards and safety precautions. Steel pipe is often welded, while copper pipe is typically joined by soldering. In soldered pipe joints, capillary fittings are used.

*Expansion with Temperature:* Metal pipe expands and contracts with temperature by an amount dependent on both temperature change and material. This must be considered when designing pipe systems where temperature will change between installation and operation, or when the fluids pumped will be above or below installation temperature. Use the factors in the following table to calculate length increase or decrease for each pipe run.

**Linear Expansion and Contraction Factors per 100 Feet of Pipe**

Temperature Change, °F	Pipe Material				
	Steel	Copper	PVC	FRP	PP & PVDF
0	0	0	0	0	0
20	0.15	0.25	0.62	0.26	2.00
40	0.30	0.45	1.30	0.52	4.00
60	0.46	0.65	2.20	0.78	6.00
80	0.61	0.87	2.80	1.05	8.00
100	0.77	1.10	3.50	1.31	10.00
120	0.92	1.35	4.25	1.57	12.00
140	1.08	1.57	4.80	1.83	14.00
160	1.24	1.77	5.50	2.09	16.00
180	1.40	2.00	6.30	2.35	18.00
200	1.57	2.25	7.12	2.62	20.00

Multiply length of pipe by the table factor and divide by 100 for the increase or decrease in length.

**Plastic Pipe.**—Plastic pipe is lighter and less expensive than metal pipe, and can be more chemically inert. It is generally non-conductive and thermally insulative. Due to its smooth inner surfaces, it can offer better flow characteristics than metal pipe. However, plastic pipe can be affected by ultraviolet radiation and extreme temperatures. The most common plastic pipe is suitable for nonflammable liquids up to 150 psi (1000 kPa) and temperatures up to 140°F (60°C). Plastic pipe expands with temperature much more than metal pipe.

*Materials:* Many types of plastics are available as plastic pipe. Polyvinyl chloride (PVC), acrylonitrile butadiene styrene (ABS), and polyethylene (PE) are the most common in the United States. Crosslinked polyethylene (PEX) is common in Europe and gaining popularity in the United States.

PVC and chlorinated PVC (CPVC) are related, but CPVC can withstand a wider range of temperatures. PVC is limited to 140°F while CPVC can be used up to 190°F. PVC has inherently superior fire retarding properties due to its chlorine content. The ignition temperature of PVC is as high as 455°C. PVC and CPVC are highly resistant to oxidation and are very durable. PVC is resistant to acids, bases, and most inorganic chemicals. PVC swells or dissolves in aromatic hydrocarbons, ketones, and cyclic ethers. These plastics crack when frozen, and CPVC requires more mechanical support than PVC.

ABS pipes are used mainly in applications where rigidity and impact strength are needed. ABS can be tailored to a wide range of needs by altering its chemical composition. It is suitable for water transport and has good resistance to a wide range of diluted inorganic acids, organic acids, salts, animal fats and oils. ABS is not resistant to organic solvents, alcohol, gasoline, acetic acid or vegetable oils. ABS is resistant to temperatures up to 70°C, but its pressure capacity must be derated with elevated temperature. ABS is non-toxic and is used for food and beverage applications.

PE pipes can be joined through heat fusion, and are common in municipal water applications. They are extremely slippery when wet. PE Water Service lines are typically  $\frac{1}{2}$  to 3 nominal diameter pipe or tubing in accordance with AWWA C901, ASTM D2239, ASTM D3035, or ASTM D2737. PE water distribution lines are typically 4 to 12 nominal diameter pipe in accordance with AWWA C906, ASTM D3035, or ASTM F714. Install PE pressure pipe in accordance with ASTM D2774. PE pipe may be cold bent. The allowable bend ratio is determined by the pipe diameter ( $D$ ) and the Standard Dimension Ratio ( $SDR$ ) in accordance with Table 10.

**Table 10. Cold Bend Radius, Polyethylene Pipe**

Standard Dimension Ratio, $SDR$	Minimum Bend Radius to Centerline of Pipe
7 through 9	$20 \times$ Pipe Outside Diameter
11 through 13.5	$25 \times$ Pipe Outside Diameter
17 through 21	$27 \times$ Pipe Outside Diameter
Fitting in Bend	$100 \times$ Pipe Outside Diameter

PEX is gaining popularity for residential water service because it is flexible, does not corrode, is easy to work and connect, and is resistant to scale and chlorine. It is made from crosslinked HDPE and subject to ASTM F876. It can be bent according to table, as well as used with compression tube fittings. Standard PEX does admit some oxygen, so an added oxygen barrier may be needed in some applications. PEX can be used at temperatures from below freezing to almost boiling.

**Table 11. Bend Radius, PEX Pipe or Tube**

PEX Size, inch	Outside Diameter, inch	Minimum Bend Radius, inch
$\frac{3}{8}$	0.500	4
$\frac{1}{2}$	0.625	5
$\frac{5}{8}$	0.750	6
$\frac{3}{4}$	0.875	7
1	1.125	9

*Schedules:* Schedule number designations for plastic pipe are an indicator of wall thickness. Schedules 40 and 80 are the most commonly used, and 120 is also widely available. For a given nominal pipe size, all schedules have the same outside diameter. Therefore, higher schedule pipes of the same diameter have smaller flow areas. The nominal pipe size

(NPS) is given, along with the schedule or IPS designation to indicate the full dimensional characteristics of the pipe.

*Sizes:* Plastic pipe size designations are often tied to the outside diameter, as they are for steel pipe according to the NPS system. PVC has its own ASTM pipe sizing standard, while CPVC is available in either ASTM standard sizing or CPVC-CTS (Copper Tube Standard). Dimensions for schedule 40, 80, and 120 PVC pipe are given in Table 12. Alternative sizing methods are the Standard Inside Dimension Ratio (SIDR) method and the Standard Dimension Ratio (SDR) method. The SDR method uses OD and wall thickness, and SIDR uses ID and wall thickness. The SIDR method is useful when designing flow-critical applications. The SDR method is useful when pressure rating is of primary concern. PEX is most commonly sized as tube, which is covered in the section *Plastic Tube* starting on page 2773.

**Table 12. PVC Pipe Dimensions, Schedule 40, 80, and 120, Sizes Up To 12"**

PVC Pipe Size, inch	Outside Diameter, inch	Inside Diameter, inch		
		SCH 40	SCH 80	SCH 120
1/8	0.405	0.249	0.195	...

10	10.75	9.976	9.493	...
12	12.75	11.889	11.294	...

*Pressure Ratings:* Pressure rating of plastic pipe is highly dependent on material, as well as wall thickness. Most commercially available plastic pipe will be rated by the manufacturer. PEX pressure ratings are 160 psi at 74°F and 100 psi at 180°F.

Pressure ratings for polyethylene pipes depend on the material formulation. Pressure ratings of standard sizes of PVC pipe are given in Table 13. Pressure ratings must be derated with elevated temperature. Derating factors for PVC pipe are given in Table 14. Further derating must be done to account for water hammer, and this is often 20 percent.

*Connections:* Some plastic pipe is threaded for use with threaded fittings. Threading normally follows the NPT standard. If the pipe is not threaded, a variety of other connection methods may be used. PVC pipe is usually bonded into socket fittings using solvent cement. PE pipe can be joined using heat fusion and electrofusion. In some cases, tube fittings may be used to connect plastic pipe.

*Expansion with Temperature:* Plastic pipe expands and contracts with temperature by an amount dependent on both temperature change and material. This must be considered

**Table 13. Pressure Ratings of Schedule 40, 80, 120 PVC Pipe Up To 12" at 73.4°F**

when designing pipe systems where temperature will change between installation and operation, or when the fluids pumped will be above or below installation temperature. Plastics expand much more than metals, so this may become a factor in selecting one over the other. Use the factors in Table 15 to calculate length increase or decrease for each pipe run. To use the tabulated factors, use the equation  $\Delta L = \alpha L_0 \Delta T$  where  $L_0$  is the length at the installation temperature, and  $\Delta T$  is the difference between the installation temperature and the temperature in question.

**Table 15. Coefficient of Linear Expansion ( $\alpha$ ) for Common Pipe Materials**

Material	Coefficient of Linear Expansion	
	$10^{-6}$ in/in °F	$10^{-6}$ m/m °C
Carbon Steel	6.5	11.7
Copper	9.3	16.8
Stainless Steel	9.9	17.8
ABS	35	63
HDPE	67	120
PE	83	150
CPVC	44	79

**Pipe Fittings.**—Pipe fittings are used to connect pipes together either permanently or non-permanently. Pipe systems should be designed to minimize the number of fittings because they cause pressure loss, require pressure derating, and are a potential source of leaks.

**Materials:** Pipe fittings are available in a variety of materials, and should be selected for compatibility with the pipe material and the substance being transported. Dissimilar metals should be avoided to prevent galvanic corrosion. Plastic fittings are also available for use with plastic pipe.

**Types:** Pipe fittings may be threaded, slip, or interference type connections. Interference connections, like compression or stab fittings, are used with plastic pipe and with metal and plastic tubing. PEX pipe is typically connected using either a copper crimp ring or expansion fittings with outer expansion rings. In the crimping method, a copper crimp ring is put over the pipe near the end, a copper fitting is inserted into the pipe end, and a crimping tool is used to crimp the ring over the pipe and fitting. In the expansion fitting method, an expansion tool is used to open the diameter of the pipe, into which an expansion fitting is inserted. The pipe shrinks over the fitting as it cools, and then a plastic expansion ring is pressed over the pipe and fitting. Compression fittings can be used as an alternative; that method is discussed in the section *Tube Fittings* on page 2776.

The most common types of pipe fittings are illustrated in Table 16. These examples are by no means exhaustive of the types and shapes available.

**Table 16. Common Pipe Fittings**

**Pressure Considerations:** Pipe fittings have pressure ratings that must be considered during the selection process. Low pressure pipe fittings are generally rated to 150 psi. Medium pressure fittings are commonly found rated to 300 psi. High pressure fittings are rated as high as 3,000 psi, and extreme pressure fittings can be found rated to 6,000 psi or even higher. Pressure rating depends on schedule, size, material, and connection type.

**Metal Tube.**—Metal tube is generally smaller and thinner than metal pipe. The same considerations in terms of material properties, mechanical stresses, and environmental factors apply to both tube and pipe.

**Material:** Steel tubing is usually made from carbon steel (plain or galvanized) or stainless steels (304 or 316). It is used in a variety of applications to carry liquids or gases. Stainless steel is known for its corrosion resistance when exposed to a variety of materials.

Copper tubing is typically offered as either soft annealed or hard drawn. Annealed tubing is easy to bend, while drawn tubing is stiff. Drawn tubing has a higher pressure rating than annealed. Flare fittings may be installed on annealed temper tube, but not on drawn temper; both types can be soldered or brazed. Copper tube types and applications are given in [Table 17](#).

**Table 17. Copper Tubing Types and Applications**

**Sizes:** Steel tubing is highly standardized, with designations of outside diameter and wall thickness. Imperial and metric sizes are available. A selection of Imperial sizes and pressure ratings of stainless steel tubing is given in [Table 18](#).

The system of Copper Tube Sizes (CTS) depends on type. Types K, L, M, DVW (Drain Waste Vent), and OXY/MED all have an outside diameter  $1/8$ " larger than the nominal size designation. Type ACR (Air Conditioning & Refrigeration) tubing outside diameter is equal to the nominal size designation. Dimensions of copper tube are found in [Table 19](#).

**Pressure Ratings:** Pressure ratings for stainless steel tubes were given in [Table 18](#). Allowable maximum pressure for metal tubes can be calculated as it was for metal pipes.

**Table 18. Stainless Steel Tube Specifications, Selected Sizes**

Tube OD (in.)	Wall Thickness (in.)	Working Pressure (psig)
1/16	0.014	8100
	0.020	12000

	0.134	3400
2	0.134	2500
	0.188	3600

Alternatively, the maximum working pressure of metal tubing can be calculated using the Barlow formula for thin-walled cylinders as given in the following equation. This formula is typically used for steel tubing connected with flare fittings.

$$P_{\max} = \frac{2St}{D}$$

where  $S$  is the ultimate tensile strength,  $t$  is wall thickness, and  $D$  is outer diameter. A factor of safety between 1.5 and 10 should be applied.

If the tube is carrying liquid, the pressure rating must be derated to account for the pressure spikes that occur during valve closures. The amount of reduction of working pressure is called the "water hammer factor" and is typically 20 percent. The types of fittings being used must be carefully considered when working with elevated pressures, and further derating of the system may be required. For pressure ratings of copper tube, consult the "Copper Tube Handbook," available from the Copper Development Association, Inc.

**Plastic Tube.**—Plastic tube is often selected for its flexibility, clarity, or non-conductivity. When selecting from the wide variety of available tubing materials, one must consider the operating temperature range in the application, the media being transported, the environment in which the tubing will be located, the pressures involved, whether there will be vacuum, whether there are any standards or certifications needed, whether standard tubing tolerances will be acceptable, and whether the tubing must be transparent. Temperature must be considered not only for extremes, but also for slight variations from 73°F (22°C) because most plastic tubing expands and softens even with slight changes in temperature.

**Table 19. Copper Tube and Pipe Dimensions**

Nominal Size	Actual Outer Diameter, inch	Type

**Materials:** Some of the more popular tubing materials are polyvinyl chloride (PVC), low density polyethylene (LDPE), high density polyethylene (HDPE), polypropylene (PP), nylon (PA 6, 6/6, 11, 12), silicone, polyurethane, fluoropolymers (PTFE, FEP, PFA, PVDF, ETFE), and polyetheretherketone (PEEK). PEX tube is also common in Europe for water applications.

PVC can be rigid or flexible, and can be transparent. Exposure to water can cause clouding of clear PVC over time. Flexibility will depend on the amount of plasticizer present, so a variety of durometers are available. Flexible PVC is rated for fairly low pressures, unless reinforced with braiding.

LDPE is low cost, light weight, relatively transparent, and flexible. It is suitable for air, water, and some chemicals. Caution should be used when barbed fittings are employed

because LDPE has poor environmental crack resistance, which can be accentuated when solvents are present.

HDPE is similar to LDPE in terms of material compatibility. It is fairly opaque, and is more dense and rigid than LDPE.

Polypropylene has high impact resistance combined with good stiffness and excellent chemical resistance. PP is often mixed with polyethylene or rubber to improve its impact and low temperature properties. PP is more heat resistant than PE, with an operating range up to 60°C.

Nylons can be used at elevated temperatures. They cost more than PE and PP, but exhibit superior abrasion resistance and stiffness. Types 11 and 12 are more flexible than type 6, and have better chemical resistance to acids and bases.

Silicone tubing is suitable for elevated temperatures and can be sterilized using heat. It is extremely soft and flexible, and is non-toxic. There are different ways to cure silicone tubing, so material properties may vary.

Polyurethane tubing is flexible and can be relatively transparent. This type of tubing has good abrasion resistance and tensile strength. It is flexible at low temperatures and holds its properties over time. There are two types of polyurethane: esters and ethers. Esters have good chemical and oil resistance. Ethers have good water compatibility and are suitable for outdoor applications. Both can be made FDA compliant.

Fluoropolymers are chemically inert and often chosen for harsh applications or high purity applications. They are also suitable for high temperatures in the 300–500 °F (148–260 °C) range. Rigidity varies with composition, but they are generally stiff but bendable. FEP is flexible and transparent.

PEEK is fairly rigid but bendable, has excellent mechanical stability and chemical compatibility, and can be used to 100 °C. It is often used where stainless steel tubing has material compatibility issues.

PEX tubing is of the same material and properties as PEX piping, discussed in the section *Plastic Pipe* starting on page 2767. It comes in a variety of colors, or a natural hazy clear state.

There are many more materials than those listed. In addition, there are many brand-name and proprietary formulations.

*Sizes:* Most plastic tubing is sized according to OD, ID, and wall thickness. A wide variety of sizes are available for each material. PEX tubing is sized according to the Copper Tube Size standard for outer diameter. Standard PEX dimensions are given in Table 20.

**Table 20. Standard PEX Dimensions**

Nominal PEX Size inch	Outside Diameter inch	Inside Diameter inch	Wall Thickness, inch
$\frac{3}{8}$	0.500	0.350	0.070
$\frac{1}{2}$	0.625	0.475	0.070
$\frac{5}{8}$	0.750	0.574	0.083
$\frac{3}{4}$	0.875	0.677	0.097
1	1.125	0.863	0.125

All dimensions are in inches.

*Pressure Ratings:* Care must be taken when using plastic tubing because pressure ratings are generally much lower than with metal tubing. In addition, if vacuum is to be used in the system, the tubing must be vacuum rated to ensure that it does not collapse.

Pressure rating will depend on material, diameter, and wall thickness. Consult the manufacturer's pressure rating when specifying plastic tubing.

**Tube Fittings.**—Tube fittings are used to connect tubing to tubing, or tubing to pipes or other objects. Tube fittings are generally non-permanent connections, although they may permanently deform the end of the tube.

*Materials:* Fitting materials should be chosen for compatibility with the tubing and the fluid being transported. Combining dissimilar metals should be avoided to prevent galvanic corrosion. Metal fittings and plastic fittings are widely available. Some plastic fittings have metal ferrules, and some metal fittings can have elastomeric seals. It is critical to check material compatibility with all components of a fitting. Plastic fittings are used with plastic tubing that is softer than the fitting material. Steel fittings are used with steel or plastic tubing. Brass fittings are used with copper, aluminum, and plastic tubing.

*Types:* There are many types of tube fittings, including proprietary and name-brand fittings. The most common general types are barbed, compression, flare, and push-in.

*Barbed fittings* are used with soft plastic tubing which can expand enough to fit over the barb end but have elastic memory enough to seal over the barb or barbs. A clamp should be employed to hold the tube on if pressures are moderate. Pressure in the system should not exceed 150 psi when using barbed connections. To specify a barbed fitting connection, one must know the tube inner diameter, process pressure, material compatibility, and whether the tubing is suitable for use with barbed fittings.

*Compression fittings* are used on metal tubing and stiff plastic tubing. Metal and plastic compression fittings are available. They are suitable for high pressures when constructed out of high strength material and combined with a high pressure rated tube. There are numerous designs available, but all include at least one ferrule, a nut, and a fitting body. When the nut is tightened, the ferrule swages the tube to form a pressure tight seal. The tube does not need to rotate during tightening. Compression fittings can be re-used if care is taken not to damage the ferrule or tube end. To specify a compression fitting, one must know the tube outer diameter, wall thickness, process pressure, and material compatibility requirements. To ensure proper sealing, the tube should be clean and cut square without burrs. The tube material must always be softer than the fitting material. Plastic compression fittings are used with softer plastic tubing, and stainless compression fittings are generally used with stainless tubing. Brass fittings can be used with firmer plastic, aluminum, and copper tubing. Carbon steel compression fittings are used with carbon steel tubing.

*Flare fittings* are typically used with metal tubing which is forced over a flared seat and secured with a nut to create a leak-tight seal. They are similar to compression fittings but have a sleeve instead of a ferrule. A flaring tool is used on the end of the tubing to create the proper flare for the fitting being used. These fittings are suitable for high pressures, even greater than with compression fittings. The most common flare fitting standards in use today are the 45° SAE fitting, and the 37° JIC fitting. The 37° style generally has a higher pressure rating for a given size tubing. The 45° style is generally used for low pressure refrigeration applications, while the 37° style is used for high pressure hydraulic applications. SAE and JIC fittings are incompatible due to the different flare angles. Flare fittings can be reused if care is taken not to damage the flared end of the tubing. Stainless steel fittings are used with flareable seamless stainless tubing. Brass fittings are used with flareable seamless copper. Carbon steel fittings are used with flareable welded and seamless carbon steel tubing. Aluminum fittings are used with seamless aluminum tubing.

*Push-in fittings* are popular for pneumatic connections, but are also made for liquid applications. These fittings have an internal gripping ring and usually an o-ring. The tube must be cut square and be burr-free. A leak-free seal is created when the end of the tube is pushed into the fitting. To release the tubing, the end of the fitting must be compressed axially to release the gripping mechanism. These fittings normally have elastomeric, plastic, and stainless steel components, regardless of the body material, so material compatibility can become an issue. These fittings can be selected to accept plastic or metal tubing, and pressure ratings vary. Pressure capability of push-in fittings is generally less than compression fittings but greater than or equivalent to barbed fittings.

Many other fittings and couplings are available. Couplings attach to the ends of two tubes and have a leak-free means of connecting the halves of the coupling together. Couplings are available with and without shut-off valves to prevent spillage when disconnected.

### Flow and Energy Loss in Pipe, Tube, and Fittings

Fluids experience energy loss due to friction when flowing through pipes and fittings. The energy lost is dependent on the length and diameter of the pipe/tube, the surface conditions, and the number and shape of any bends or restrictions.

**Flow Rates.**—The principal of continuity for constant flow dictates that the volumetric flow rate (or mass flow rate) remains the same along a pipe, even if the pipe expands, contracts, or is restricted. This means that velocity changes with flow area. One can calculate the velocity before or after a change in flow area if the velocity on the other side of the change is known.

$$Q_i = A_i v_i = Q_o = A_o v_o$$

where  $A$  is the cross sectional flow area,  $Q$  is volumetric flow rate, and  $v$  is velocity.

The behavior of a fluid, and its energy losses through pipe and fittings, is dependent upon whether it follows a laminar, transitional, or turbulent flow regime. To determine what flow regime is present, the dimensionless Reynolds number is calculated with the following equations. If the Reynolds number is less than 2000, the flow is laminar. If the Reynolds number is greater than 4000, flow is turbulent. Between those values lies the transitional flow regime. Note that the Reynolds number is dependent on fluid viscosity.

$$R_e = \frac{\rho v D}{\mu}$$

where  $D$  is the flow diameter,  $\rho$  is the density,  $v$  is the mean velocity,  $\mu$  is the absolute viscosity of the fluid.

$$R_e = \frac{v D}{\nu} = \frac{Q D}{A \nu}$$

where  $Q$  is the volumetric flow rate,  $A$  is the cross sectional area of flow, and  $\nu$  is the kinematic viscosity.

For general liquid piping applications, the US Army Corps of Engineers manual "Liquid Process Piping" recommends a flow velocity of  $7 \pm 3$  ft/s ( $2.1 \pm 0.9$  m/s) with a maximum velocity of 7 ft/s at discharge points including pump suction lines and drains.

All formulas for calculating the mean velocity of flow through a pipe or tube are approximate. The following is a formula for low viscosity liquids that will yield results within 5 to 10 percent of actual if applied to carefully laid pipe in fair condition:

$$v = C \sqrt{\frac{hd}{L + 54d}}$$

where  $C$  is taken from Table 21,  $h$  is total head in feet,  $d$  is the inside diameter of a round pipe in feet, and  $L$  is the total length of the pipe in feet. Length, where pressure drop due to bends and fittings is a factor, is equivalent length. See *Energy Loss in Fittings and Valves* on page 2783, and *Energy Loss in Fittings and Valves* on page 2783 for more on this topic.

For air, the following velocity equation can be used to estimate flow:

$$v = \sqrt{\frac{25,000 dp}{L}} \quad p = \frac{Lv^2}{25,000 d}$$

where  $v$  = velocity of air in feet per second

$p$  = loss of pressure due to flow through the pipes in ounces per square inch

$d$  = inside diameter of pipe in inches

$L$  = length of pipe in feet

**Table 21. Values of Coefficient C**

Dia. of Pipe		C	Dia. of Pipe		C	Dia. of Pipe		C
Feet	Inches		Feet	Inches		Feet	Inches	
0.1	1.2	23	0.8	9.6	46	3.5	42	64
0.2	2.4	30	0.9	10.8	47	4.0	48	66
0.3	3.6	34	1.0	12.0	48	5.0	60	68
0.4	4.8	37	1.5	18.0	53	6.0	72	70
0.5	6.0	39	2.0	24.0	57	7.0	84	72
0.6	7.2	42	2.5	30.0	60	8.0	96	74
0.7	8.4	44	3.0	36.0	62	10.0	120	77

The quantity of air discharged in cubic feet per second is the product of the velocity as obtained from the preceding formula and the area of the pipe in square feet. The horsepower required to drive air through a pipe equals the volume of air in cubic feet per second multiplied by the pressure in pounds per square foot, and this product divided by 550.

**Volume of Air Transmitted Through Pipes, in CFM**

Velocity of Air in Feet per Second	Actual Inside Diameter of Pipe, Inches									
	1	2	3	4	6	8	10	12	16	24

**Flow of Compressed Air in Pipes.**—When there is a comparatively small difference of pressure at the two ends of a pipe, the volume of flow in cubic feet per minute is found by the formula:

$$V = 58 \sqrt{\frac{pd^5}{WL}}$$

where  $V$  = volume of air in cubic feet per minute

$p$  = difference in pressure at the two ends of the pipe in pounds per square inch

$d$  = inside diameter of pipe in inches

$W$  = weight in pounds of one cubic foot of entering air

$L$  = length of pipe in feet

**Flow in Branched (Parallel) Pipes.**—Pipe systems commonly have parallel sections to allow some fluid to bypass a component. The principle of continuity dictates that in a steady flow situation, total flow into a branched system is equal to total flow exiting the branched system. The following are the governing equations for branching pipe systems.

$$Q_i = A_1 v_1 + A_2 v_2$$

where  $Q_i$  is the total flow rate entering the branching system.  $A_1$  and  $v_1$  are the cross sectional area and flow velocity of the first branch, and subscript 2 refers to the second branch.

Head loss is equal in all branches and equal to the total head loss across the network:

$$h_L = h_{L1} = h_{L2}$$

**Energy Loss in Pipes.**—As fluid moves through straight pipe and tube, some energy is lost to friction. The relationship between pressures and velocities at two ends of a pipe is governed by Bernoulli's equation:

$$\frac{p_1}{\gamma_1} + \frac{v_1^2}{2g} + z_1 = \frac{p_2}{\gamma_2} + \frac{v_2^2}{2g} + z_2$$

where  $p$  is pressure,  $v$  is velocity,  $z$  is elevation, and  $g$  is acceleration due to gravity.

For inviscid, incompressible liquid flow moving through a pipe, Bernoulli's equation simplifies because the specific weight of the fluid is assumed to be the same at both points of interest.

*Darcy-Weisbach Equation and the Moody Diagram:* This equation can be used to calculate friction loss in Newtonian liquids for all flow regimes. It requires the use of a friction factor, which is dimensionless and can be determined using the equation for laminar flow, the Colebrook equation for turbulent flow, or graphically through the use of the Moody diagram (Fig. 1). The Darcy-Weisbach equation is:

$$h_L = \frac{fLv^2}{2gD}$$

where  $h_L$  is head loss in units of length,  $L$  is pipe length,  $v$  is average fluid velocity,  $D$  is inside diameter of the pipe, and  $f$  is the friction factor.

The friction factor for laminar flow is  $f = \frac{64}{Re}$ . The Colebrook equation for turbulent flow is  $\frac{1}{\sqrt{f}} = -2 \log_{10} \left( \frac{\epsilon}{3.7D} + \frac{2.51}{Re \sqrt{f}} \right)$  where  $\epsilon$  is the pipe roughness, and  $D$  is the inside

diameter. This applies when the pipe is completely full of fluid. Calculators are available online for this factor, or it can be solved numerically.

Moody's diagram was generated experimentally. A chart of surface roughness of common pipe and tube materials can be found in Table 22 for use with the turbulent flow equation and Moody diagram.

**Table 22. Surface Roughness of Common Pipe and Tube**

Material	Surface Roughness		Material	Surface Roughness	
	ft × 10 <sup>-6</sup>	m × 10 <sup>-6</sup>		ft × 10 <sup>-6</sup>	m × 10 <sup>-6</sup>
Glass	0.0003	0.0001	Ductile Iron (Coated)	400	120
Plastic	0.0003–0.0023	0.0001–0.0007	Concrete (Smooth)	400	120
Drawn Metal Tubing	5	2	Galvanized Iron	500	150
Carbon Steel	150	46	Ductile Iron (Uncoated)	800	240
Wrought Iron	150	46	Cast Iron	850	260

**Hazen-Williams Equation for Water Flow:** For the special case of 60°F water in pipes between 2 inch and 6 feet in diameter, at velocities less than 10 ft/s, the Hazen-Williams formula or nomograph (Fig. 2) can be used. The coefficient values of common pipes can be found in Table 23. The nomograph is read by aligning a straightedge with the known values and reading the unknowns at the intersection points. The Hazen-Williams formula for US units is:

$$v = 1.32 C_h R^{0.63} \left( \frac{h_f}{L} \right)^{0.54}$$

where  $v$  is average velocity (ft/s),  $R$  is hydraulic radius (ft),  $L$  is length of pipe (ft),  $h_f$  is head loss (ft), and  $C_h$  is the Hazen-Williams coefficient (see Table 23). The Hazen-Williams formula for SI units, with  $R$ ,  $h$ , and  $L$  in meters, and  $v$  in m/s is:

$$v = 0.85 C_h R^{0.63} \left( \frac{h_f}{L} \right)^{0.54}$$

A solution of the Hazen-Williams equations may be found by use of the nomograph in Fig. 2, based on the Hazen-Williams formula and using  $C_h = 100$ . For larger or smaller values of  $C_h$ , the discharge or velocity obtained from the nomograph is multiplied by the ratio of the given value of  $C_h$  to 100. If the discharge or velocity is given, it should be multiplied by the ratio of 100 to the known value of  $C_h$  before the nomograph is used.

*Example:* By using Fig. 2, determine the discharge, in cubic feet per second (cfs), from a 12-inch pipe for which  $C_h = 120$  when the loss of head is 5 feet per 1000 feet.

*Solution:* The discharge corresponding to the given diameter and loss of head for a value of  $C_h = 100$  is found first. A straightedge passing through 12 on the diameter line and 5 on the loss-of-head line will intersect the discharge line at 2.5 cfs. Therefore, the discharge is  $2.5 \times 120 = 3.0$  cfs.

Fig. 2. Nomograph for Hazen-Williams equations in which  $C_h = 100$ .

**Table 23. Hazen-Williams Coefficient, Selected Values**

Pipe Type	$C_h$	Pipe Type	$C_h$
Corrugated Metal	60	Copper	130–140
ABS Plastic	130	Drawn metal	130–140
Aluminum	130–150	Ductile iron pipe	140
Brass	130–140	Ductile iron, cement lined	120
Cast iron	100	Fiberglass	150

bituminous lined	140	PVC, CPVC	150
cement lined	140	Steel new unlined	140–150
sea-coated	120		
Concrete	100–140		
lined, steel forms	140		
lined, wooden forms	120		

**Energy Loss for Gas Flow:** Bernoulli's equation can be applied to examine pressure loss for gas flow through pipes. Gas flowing through pipes can be considered incompressible and treated like a liquid if the pressure ratio is small enough. Pressure ratio is calculated using the following equation. Engineering judgment should be used when applying this equation. In different industries, different values are used to make the decision how to treat gas flow.

$$PR\% = 100 \left( \frac{P_1 - P_2}{P_1} \right)$$

where  $p$  is pressure at the point of interest and  $PR\%$  is the pressure ratio.

Pressure drop for gas flow in pipes can be calculated most easily if certain assumptions are made. One can assume flow is isothermal, the gas is perfect, the pipe is straight and horizontal, the friction factor is constant, and flow is steady. This simplifies the pressure drop equation to the following form:

$$p_i^2 - p_o^2 = Z_m RT \left( \frac{m}{A} \right)^2 \left( f \frac{L}{D} \right)$$

where  $p_i$  and  $p_o$  are the inlet and outlet pressures,  $Z_m$  is the mean compressibility factor,  $R$  is the gas constant,  $T$  is temperature,  $A$  is pipe cross sectional area,  $f$  is the friction factor,  $L$  is pipe length,  $D$  is inner diameter, and  $m$  is mass flow rate.

Alternative methods of calculation include the Weymouth and Panhandle formula, and the Renouard equation for natural gas flow.

**Energy Loss in Pipe and Tube Bends.**—The energy lost by fluid in a pipe bend is caused by both friction and momentum changes as the direction of flow changes. This loss depends on the bend angle, the curvature ratio (bend mean radius divided by pipe diameter,  $R/D$ ), the roughness of the pipe, and the angle of bend. To compute the energy lost by liquids in bends, use the following equations and Table 24.

$$h_l = K_b \frac{V^2}{2g} \quad K_b = f \frac{L_e}{D}$$

where the head loss,  $h_l$ , is expressed in units of length;  $V$  is the average velocity in the pipe; and  $K_b$  is the bend loss coefficient;  $f$  is the friction factor given in the Moody diagram, (Fig. 1); and  $L_e/D$  is given in Table 24.  $K_b$  increases with relative roughness (or screwed connections) and bend angle, but decreases with the curvature ratio.

**Table 24. Bend Equivalent Length Ratio,  $L_e/D$** 

Bend Type	Bend Angle	$R/D$	$L_e/D$	Bend Type	Bend Angle	$R/D$	$L_e/D$	
Radius Bend	90°	1	20	Miter Bend	30°	...	8	
		2	12		45°	...	15	
		3	12		60°	...	25	
		4	14		90°	...	60	
		6	17		Close Return Bend		180°	...
		8	24					
		10	30					
		12	34					
		16	42					

$R/D$  is the bend mean radius divided by pipe diameter

The loss of head due to a bend in the pipe is most frequently given as the equivalent length of straight pipe, which would cause the same loss in head as the bend. Experiments show that a right-angle bend should have a radius of about three times the diameter of the pipe. Assuming this curvature, then, if  $d$  is the diameter of the pipe in inches, and  $L$  is the length of straight pipe in feet that causes the same loss of head as the bend in the pipe, the following formula gives the equivalent length of straight pipe that should be added to simulate a right-angle bend:

$$L = 4d \div 3$$

**Energy Loss in Fittings and Valves.**—There are two standard ways to calculate the energy lost in fittings and valves: the resistance coefficient method, and the equivalent length method. The method chosen will depend on what information is provided with the fitting to be analyzed.

*Resistance Coefficient Method:* Resistance coefficients are commonly reported by the manufacturers of liquid fittings and valves. The following equations and Table 25 (or manufacturer's data) can be used to calculate friction loss in terms of resistance coefficient. There are methods that use up to 3 different resistance coefficients to improve the accuracy of the calculation.

$$h_f = K_F \left( \frac{v^2}{2g} \right) \quad K_F = f \frac{L_e}{D}$$

where  $v$  is average velocity,  $h_f$  is head loss in units of length,  $K_F$  is the resistance coefficient for the fitting or valve,  $f$  is the friction factor given in the Moody diagram, Fig. 1, and  $L_e/D$  is the equivalent length ratio given in Table 25.

**Table 25. Equivalent Length Ratio ( $L_e/D$ ) for Liquid Fittings and Valves**

Fitting or Valve Type	$L_e/D$	Fitting or Valve Type	$L_e/D$
Elbow	30	Swing Check Valve	100
Street Elbow	50	Ball Check Valve	150
Long Radius Elbow	20	Foot Valve (hinged)	75
45° Elbow	16	Ball Valve	3
Close Return Bend	50	Gate Valve	8
Tee (Flow thru Run)	20	Gate Valve, 1/2 Closed	160
Tee (Flow thru Branch)	60	Butterfly Valve (< 8")	45
		Globe Valve	340

Valves fully open unless otherwise specified.

**Equivalent Length Method:** Pressure loss can be calculated for systems based on the equivalent length of straight pipe representing all pipe, fittings, and valves in the circuit. Equivalent lengths of some common fittings and valves for liquids can be found in Table 26.

**Table 26. Equivalent Length in Feet of Selected Pipe Fittings and Valves for Liquid**

Nominal Pipe Size (in.)	Elbows					Standard Tee		
	90° Std.	45° Std.	90° Long Radius	90° Street	45° Street	Square Corner	Flow thru Run	Flow thru Branch
¼	0.9	0.5	0.6	1.5	0.8	1.7	0.6	1.8
½	1.6	0.8	1.0	2.6	1.3	3.0	1.0	4.0
¾	2.1	1.1	1.4	3.4	1.8	3.9	1.4	5.1
1	2.6	1.4	1.7	4.4	2.3	5.0	1.7	6.0

12	29.8	15.9	24.7	49.7	25.9	56.7	24.7	59.7

Energy loss, in terms of pressure, for gas flow through fittings is often found using tabulated values of pressure drops for fittings of different sizes. The equivalent length method can also be used, with pressure loss calculated in terms of the total equivalent length of all pipe and fittings. Table 27 includes some equivalent lengths of selected pneumatic fittings and valves.

**Table 27. Selected Pneumatic Fittings and Valves, Equivalent Lengths**

Pipe Size, inch	Elbow	Long Radius Elbow	Close Return Bend	Gate Valve	Globe Valve
½	0.84	0.41	1.30	0.31	2.50
¾	1.20	0.57	1.80	0.44	3.50
1	1.60	0.77	2.30	0.57	4.70
1½	2.60	1.30	3.90	0.98	7.80
2	3.60	1.70	5.30	1.30	10.60
3	5.70	3.00	8.50	2.10	17.10
4	7.90	3.90	11.80	3.00	23.70

**Entrance, Exit, Enlargement, and Contraction Losses for Subsonic Flow.**—Any change in diameter of a pipe will cause energy losses in the fluid.

**Sudden Enlargement:** Sudden enlargement of a pipe or tube causes minor losses due to turbulence. The friction loss, in terms of head, due to sudden enlargement can be approximated using the following equations:

$$h_l = \frac{(v_i - v_o)^2}{2g} = K \left( \frac{v_i^2}{2g} \right)$$

$$K = \left[ 1 - \left( \frac{A_i}{A_o} \right) \right]^2$$

where head loss  $h_l$  is measured in units of length;  $v_i$  is velocity entering the enlargement;  $v_o$  is velocity leaving the enlargement;  $K$  is the loss coefficient for sudden enlargement;  $A_i$  and  $A_o$  are the areas before and after the enlargement. The equation for  $K$  is only valid if velocity at the inlet is less than 4 ft/sec (1.2 m/s). For faster flow rates, a graph of experimentally determined  $K$  values must be used.

**Gradual Enlargement:** Gradual enlargement causes less energy loss than sudden enlargement because it causes less turbulence. Diffusers are gradual enlargement devices. Velocity decreases while pressure increases. Gradual enlargements generally have a conical section that joins two different pipe diameters. The divergence angle is the included angle in the cone. The following two equations give approximations of head loss in a gradual enlargement.  $K_L$  is the Gibson loss coefficient (see Fig. 3).  $K_D$  is the resistance coefficient (see Fig. 4). Both depend on the ratio of areas and the angle of divergence. The formulas to calculate this loss ignore the effects of friction inside the conical section. If the enlargement is very gradual, the effects of friction can become significant. Therefore, an included angle of  $6^\circ$  or more is recommended in the conical section to mitigate the effects of friction. For area ratios up to 6:1 with angles of divergence of  $40^\circ$  or more, head loss may be less with a sudden expansion than with a gradual one. These two effects are clearest on the graph of  $K_L$  (Fig. 3).

$$h_l = K_D \frac{v_i^2}{2g} \quad h_l = K_L \frac{(v_i^2 - v_o^2)}{2g}$$

Fig. 3. Head Loss Coefficient  $K_L$ , Conical Diffuser

**Sudden Contraction:** Sudden contraction causes energy loss due to turbulence. This head loss can be calculated by using the following equation and Fig. 5. Because loss varies with the square of velocity, small changes in flow can greatly affect energy loss.

$$h_l = K_C \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity at the outlet and  $K_C$  is the loss coefficient.  $D_i/D_o$  is the ratio of the inlet diameter to the outlet diameter.

Fig. 4. Head Loss Coefficient  $K_D$ , Conical Diffuser

Fig. 5. Head Loss Coefficient  $K_C$ , Sudden Contraction

**Gradual Contraction:** Gradual contraction, like gradual enlargement, reduces losses by reducing turbulence. Like with gradual enlargement, if the angle is shallow enough, friction losses become significant. Included angles greater than  $15^\circ$  avoid this effect. Good performance can be achieved with included angles as high as  $60^\circ$ . To approximate head loss due to gradual contraction, use the following equation and Fig. 6.

$$h_l = K_G \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity at the outlet and  $K_G$  is the loss coefficient.  $D_i/D_o$  is the ratio of the inlet diameter to the outlet diameter. By rounding the exposed edge of the contraction, one can reduce the head loss even further.

Fig. 6. Head Loss Coefficient  $K_G$ , Conical Gradual Contraction

**Exit Loss:** Discharge into a static volume of fluid causes minor losses as the fluid loses its kinetic energy as its velocity drops to zero. This is called exit loss, and is calculated in terms of head using the following equation:

$$h_l = \frac{v_l^2}{2g}$$

where  $v_l$  is the velocity in the pipe before entering the reservoir.

**Entrance Loss:** Entrance into a pipe from a static volume of fluid causes energy loss due to contraction turbulence. This is called entrance loss, and it is reduced by breaking the corners of the inlet with chamfers, or preferably, radii. Entrance head loss is calculated using the following equation and Table 28.

$$h_l = K_E \frac{v_o^2}{2g}$$

where  $v_o$  is the velocity in the pipe exiting the reservoir, and  $K_E$  is the resistance coefficient for entrance.

Table 28. Entrance Head Loss Coefficient,  $K_E$

Condition	$K_E$	Condition	$K_E$
Rounded Inlet, $R/D_o$ :		Square-edged Inlet	0.5
0.02	0.28	Chamfered Inlet	0.25
0.04	0.24	Inward Projecting Pipe	1
0.06	0.15		
0.1	0.09		
>0.15	0.04		

### Fluid Power Valves

There are many types of pneumatic and hydraulic valves. Valves can be normally open or normally closed. Normally open valves allow flow when the valve is not energized. Normally closed valves block flow when not energized. Valves may be actuated manually or automatically. Automatic valves typically change state using solenoids, often assisted by energy from either internal or external pilot pressure. An external pilot supply should be used to control valve when the supply pressure to the valve is insufficient to shift the valve or when the medium being controlled by the valve would damage the shifting

mechanism. Automatic valves can be equipped with manual overrides which permit the operator to actuate the valve manually.

**Valve Types.**—There are many valve types commercially available. The most common types are check valves, foot valves, ball valves, gate valves, globe valves, butterfly valves, relief valves, and directional control valves.

*Check Valves and Foot Valves:* Check valves are constructed to allow flow in one direction and stop flow in the other direction. This type of valve is essential in pipe and tube systems where backflow could cause damage or flooding. The two most common types of check valves are ball type and swing type. Ball check valves create a higher energy loss due to restriction around the ball. Check valves have a “minimum cracking pressure” that is the pressure required to open the valve and allow flow. This may be expressed as a minimum pressure or a minimum flow velocity, depending on the application.

Foot valves are commonly used on the intake lines of pumps that draw fluid from an open reservoir. They are comprised of a check valve outfitted with a low-loss strainer to keep out debris. The strainer should be cleaned regularly to prevent suction line restriction.

*Restriction Valves:* There are several types of valves that are used to reduce flow or to stop flow entirely. Ball valves contain a sphere with a hole through it inside the valve body. When the sphere is turned, the through-hole can be aligned to allow full flow or to obstruct flow partially or completely. These valves are fully actuated with one quarter turn, and are typically used for on/off control rather than throttling. Gate valves have a blade or gate that is cranked into or out of the flow path to allow full flow, partial flow, or no flow. Globe valves are true throttling valves, and can be used even in high flow applications. Due to their design, they cause a significantly higher pressure drop than other types of valves, even when fully open. Butterfly valves consist of a disk that can be turned to fully or partially block flow. When fully open, the disk is still in the flow path, but is turned to present its edge to the flow.

*Relief Valves:* Pressure relief valves are used to protect the fluid circuit and its components from dangerously high pressures. A pressure relief valve opens to relieve pressure at a predetermined set point. These valves can be selected such that they close again when the system pressure has returned to a safe level. Since pressure relief valves are safety devices, their design and use is covered by various codes. The information and calculations required to properly size pressure relief valves is quite extensive and beyond the scope of this text. Most major pressure relief valve manufacturers also offer sizing software. In liquid pumping systems, the relief valve should discharge to the suction reservoir in a way that prevents gases from entering the suction line to the pump.

*Directional Control:* Directional control valves are used to change the direction of flow. They can also be used to stop and start flow. Directional control valves are functionally described in terms of the number of ports, the number of positions (usually 2 or 3), the number of paths (passing and non-passing) the fluid can take through the valve, and the valve's de-energized state. The number of paths the fluid can take through the valve is said to be the number of “ways.” Three way valves have one output and four way valves have two outputs. Generally, three way valves operate single acting linear actuators and four way valves operate double acting linear actuators. Some of the most commonly used directional control valves are:

- Two port, two position (2/2) two way valves have one inlet and one outlet port. They perform a basic on/off function.
- Three port, two position (3/2) two way valves have one inlet, one outlet, and one exhaust port. These valves switch flow between inlet and exhaust, and are commonly used to pressurize and exhaust a single actuator supply line.
- Five port, two position (5/2) four way valves are typically used to control pressure and exhaust to two output lines. This is ideal for controlling double acting cylinders. 5/2 valves are also available with four ports. Five ported valves have separate exhaust

ports for each supply port. Flow controls can be installed on each exhaust port and thus the speed of an actuator can be controlled in each direction.

- Five port, three position (5/3) four way valves also can control pressure and exhaust to two output lines. These valves often have the center position normally closed when the valve is de-energized. This valve is also excellent for control of double acting cylinders. The closed position makes it possible to 'jog' actuators.

Directional control valves can be either manually controlled or automatically controlled. Manual control valves are outfitted with buttons, levers, or knobs. Automatic control valves are electrically operated solenoids. Solenoid valves are most commonly actuated using spools or poppets. These valves can be single or double acting. Single acting valves normally have spring returns. Double acting valves use fluid pressure on either side of the valve to actuate back and forth.

Automatic control valves can be either direct acting or pilot operated. Direct acting solenoid valves open and close the valve. They are used in systems with low flow capacities or low pressure differentials across the valve. The sealing surface that opens and closes the main valve orifice is connected to the solenoid plunger. Direct acting valves can operate with a zero pressure differential, or up to the maximum rated pressure differential (MOPD) regardless of fluid pressure. Pressure drop across the valve is not required to hold the valve open.

Pilot operated valves use system fluid pressure to open and close the valve. In a normally closed valve, the sealing surface is opened when the pilot is energized. When a normally open valve is energized, fluid pressure builds up behind the sealing surface, forcing it to close the valve. Pneumatic solenoid valves are generally pilot operated. When vacuum or air with insufficient pressure is the medium, separate pilot lines must be provided with sufficient positive pressure to actuate the valve.

**Energy Loss in Valves.**—Energy is lost in all valves due to restriction, friction, and changes in direction of flow. The type of valve and its specific geometry will determine the amount of energy lost. Manufacturers will generally provide equivalent length of straight pipe values or resistance coefficients for their valves. Equivalent length is added to the pipe circuit when calculating pressure drop through the system. Resistance coefficient  $K$  is used in previous equations for friction loss. Some values for equivalent lengths are given in [Table 26](#) and [Table 27](#).

**Valve Selection and Sizing.**—Valves should be selected by first considering their function and selecting a type. Compatibility with the fluid must be carefully evaluated, since most valves include seals and mechanical components of different materials. The temperature and pressure range of the system should be taken into account. The cleanliness of the fluid matters when selecting valves with small or sensitive internal components. A fluid filter (with its own pressure drop) may be required. Pressure drop across the valve should be examined at the operating flow rate to determine if it meets the valve's minimum pressure differential requirement in the case of pilot operated valves.

Valves are usually sized based on Coefficient of Velocity ( $C_v$ ). These values are normally listed in manufacturer's catalogs.  $C_v$  and its calculation is covered in [Coefficient of Velocity,  \$C\_v\$](#)  on page 2760. Using  $C_v$  to size valves is industry standard practice, but be aware that it is only an approximation. Energy loss in the circuit due to pipe and tubing runs, fittings, and other components will cause deviation of system performance from ideal. Valve switching response time can also be a factor to consider when selecting a valve. To select the proper size valve for an actuator to perform a specific task, first calculate the  $C_v$  of the actuator, and then select a valve that has a corresponding or greater  $C_v$ .

### Fluid Power Actuators

**Linear Actuators.**—When a gas, typically air, is used in a linear actuator, it is called a gas cylinder or air cylinder. When a liquid is used, it is typically called a hydraulic ram or cylinder. These are essentially the same in form and function. Linear actuators can be either single or double acting.

*Single Acting Cylinders:* Single acting actuators with spring return use a spring to push the actuator to its free state when fluid pressure is removed. The free state of a single acting cylinder is usually fully retracted. A fluid pressure differential is used to extend the cylinder. Single acting cylinders use half the fluid of double acting cylinders. Single acting cylinders can be actuated with three way valves.

*Double Acting Cylinders:* These cylinders require pressure differentials on both the extend and retract strokes. When pressure equalizes across the cylinder, the state of the actuator becomes indeterminate. Double acting cylinders are most commonly actuated using four way valves. Double acting cylinders use twice the fluid of single acting cylinders, which matters most in pneumatic applications where that air is exhausted and lost.

*Selection of Linear Actuators:* Linear actuators are available with a variety of options. In addition to single and double acting versions, some cylinders are available with a magnet embedded in the piston to enable position sensing. For applications with side loading, a double rod cylinder or external bearing may be needed. When a cylinder is guiding a load that should not rotate, anti-rotation options such as a non-round rod or integral guide rods are commonly used. For heavy loads or high speeds, internal or external end cushions are usually offered to soften the impacts and allow the cylinder to withstand higher kinetic energy movements.

*Force Exerted by Linear Actuators:* The force exerted by a linear actuator is calculated using the following equation:

$$F = \eta pA$$

where  $\eta_{\text{hydraulic}} = 0.9$  and  $\eta_{\text{pneumatic}} = 1$ , and  $A$  is the effective area of the cylinder. Effective area on the retract stroke is the piston area minus the rod area.

It is good practice to oversize the load-carrying capacity of an actuator by 25 percent to ensure smooth operation and account for losses in the system. For high speed operation, oversizing by 50 percent is not uncommon. For a spring return cylinder, the force on the retraction stroke will be equal to the spring force rather than a function of air pressure. For applications where rapid retraction speed is critical, double acting cylinders may be the best choice.

*Speed of Linear Actuators:* The speed achieved by an unloaded linear actuator depends on the effective area of the cylinder and the flow rate of the fluid. Actuation velocity can be calculated for an unloaded cylinder using the following equation:

$$v = \frac{231Q}{A}$$

where  $v$  is velocity in inches per minute,  $Q$  is flow rate in gallons per minute, and  $A$  is piston active area in square inches. Active area is reduced by the area of the rod when a rod is present on the acting side of the cylinder.

Most manufacturers provide graphs of actuator speed versus loading for their products. Fluid supply can be characterized by Coefficient of Velocity ( $C_v$ ) factor. Valves and circuits with a higher  $C_v$  will be capable of moving an actuator faster because they can provide more air flow.

If the  $C_v$  of a valve and other system components is known, it can be used to determine the time required to extend or retract a cylinder. It is common to oversize the speed of an actuator by 25 percent in critical applications to account for losses.

**Kinetic Energy and Linear Actuators:** Kinetic energy is generated when a load is moved. When a moving load is stopped, the kinetic energy is absorbed by the mechanism that stops it. Actuators can have either internal or external stops. External stops can generally withstand greater impacts than internal stops. Manufacturers normally publish the kinetic energy limits of their actuators.

**Safe Loading of Linear Actuators:** Rod failure and piston wear is of concern when linear actuators are used in compression or are subjected to side loading. Side loading can be a result of external forces, eccentrically mounted loads, or mounting and operating a cylinder at some angle rather than vertical. It is critical to align connections to a cylinder such that side loading due to misalignment or eccentric loading is minimized. Compliant connections are often used to eliminate overconstraint and resultant loading. When rod bending or buckling is a risk, the use of external bearings or double rod cylinders can help reduce the risk. For horizontal cylinder installations, center trunnion mounting can help reduce the side loading on the cylinder. Another way to reduce premature failure due to side loading is to limit the extension stroke of a cylinder so that it cannot fully extend.

The potential for buckling must be evaluated for any cylinder in compression. To increase the buckling strength of a cylinder, increase the piston rod diameter. Critical buckling load is calculated as shown in the following equation.

Equivalent length is used to calculate critical buckling load rather than actual rod length. The equivalent length is dependent on the end conditions of the cylinder. The length  $L$  used to calculate equivalent length is assumed to be the distance at maximum extension between the exposed end of the piston rod and the nearest point of fixation.

$$F_{cr} = \frac{\pi^2 EI}{L_e^2} \quad I = \frac{\pi r^2}{4}$$

where  $F_{cr}$  is the critical buckling load,  $E$  is the modulus of elasticity for the rod material, and  $L_e$  is given in Table 29.

**Table 29. Equivalent Length, Linear Actuator**

Actuator and Load Fixations	Equivalent Length $L_e$
Actuator Rigidly Mounted, Load Free	$2L$
Actuator and Load Pin Connected	$L$
Actuator Rigidly Mounted, Load Pinned	$0.7L$
Actuator and Load Rigidly Mounted	$0.5L$

**Intensifiers and Hydraulic Presses.**—Intensifiers use the energy in a relatively large volume (work cylinder) of moderate pressure fluid to displace a smaller piston (ram). The two pistons are usually mechanically linked, so their stroke is the same. Intensifiers will hold a fixed pressure without additional input energy. The intensifier ratio, output pressure, and stroke are found using the following equations.

$$R_I = \frac{p_o}{p_i} \quad p_o = \frac{p_i A_i}{A_o} \quad S_1 = \frac{V_w + V_C}{A_r} + l$$

$$V_C = 0.1 V_{oil} \frac{p_r}{1000} \quad S_2 = \frac{V_o + V_C}{A_r} + X + l$$

where  $R_I$  = the intensifier ratio

$p_o$  and  $p_i$  = output and input pressures

$A_o$  and  $A_i$  = the two different piston areas

$S_1$  = the stroke of a single pressure intensifier

$V_w$  = the volume of the work cylinder

$V_C = 0.1 V_{oil} \frac{P_r}{1000}$  is the compressibility allowance, where  $p_r$  is the pressure in the high pressure circuit, and  $V_{oil}$  is the total volume of oil in the high pressure circuit

$l$  = any pretravel of the work cylinder required

$A_r$  = the area of the ram

$S_2$  = the stroke of a dual pressure intensifier

$V_o$  = the oil volume required to move the work cylinder through the high pressure portion of the stroke

$X$  = the stroke required to close the high pressure seal on the intensifier (often assumed to be 2 inches)

Intensifiers can be either pneumatically driven or fully hydraulic. Fully hydraulic intensifiers are more efficient than air driven ones. They operate on the same principle, with liquid used on both sides of the actuator. Commercial hydraulic intensifiers are generally powered by electric motors or diesel engines. Hydraulic intensifiers can be either single or dual pressure. A single pressure intensifier is used when the work cylinder requires a high pressure for the entire stroke. A dual pressure intensifier is recommended if the high pressure is required only during the last portion of the work cylinder stroke. For best economy, select the smallest driving cylinder bore size for a given intensifier ratio. Minimize pressure losses by keeping lines short and by sizing lines and fittings as large as practical. Size the lines so that fluid velocity does not exceed 7 ft/sec. Self-bleeding boosters be used wherever possible to ensure that air does not build up in the system and cause "spongy" operation.

Hydraulic presses, like intensifiers, use two pistons of different diameters. They operate on a shared fluid volume. When a force is applied to the small cylinder to create pressure, that pressure is reflected in the large cylinder. When the large cylinder is exposed to high pressure, it can exert a lot more force than was applied to the small cylinder. The mechanical advantage of the press is the ratio of output to input force. Hydraulic presses are subject to the following equations:

$$p_1 = p_2 = \frac{F_1}{A_1} = \frac{F_2}{A_2} \quad F_1 s_1 = F_2 s_2 \quad R = \frac{F_1}{F_2} = \frac{A_1}{A_2} = \frac{s_1}{s_2}$$

where  $F$  is force,  $p$  is pressure, and  $A$  is area,  $s$  is stroke, and  $R$  is the gear ratio of the press. Note that the stroke of the smaller diameter cylinder will be greater than that of the larger diameter cylinder.

**Rotary Actuators.**—These actuators use fluid pressure to induce rotary motion, and tend to be double acting. Rotary actuators can have either internal or external stops. External stops can generally withstand greater impacts than internal stops. Stops on rotary actuators are often adjustable. Rotary actuators can be hydraulic, pneumatic, or a combination of both.

*Types:* Rotary actuators come in two main types: vane and rack and pinion. Vane type actuators offer the smallest package and zero backlash, but are usually capable of only up to 270° of rotation. They employ a rotary vane mechanism to turn the actuator under fluid pressure. Rack and pinion actuators use one or more linear actuators to move racks back and forth, thereby turning a pinion shaft. They can be outfitted to have multiple stopping positions, and are capable of 360° rotation. Many packaging options are available for both vane and rack and pinion types, with many mounting and output shaft options.

*Sizing Rotary Actuators:* When sizing rotary actuators, one must know the accuracy and actuation time required, the required angle of rotation, any resisting torque, and the moment of inertia of any mass loading about the center of rotation. Torque values for both directions of rotation as a function of input pressure are normally provided by

manufacturers. Manufacturers sometimes publish the  $C_v$  of their actuators, or it can be calculated using the rotary swept volume. Kinetic energy is of particular concern with rotary actuators. Manufacturers normally publish the kinetic energy limits of their actuators. Although cushions are normally provided as part of rotary actuators, it is recommended to use proportional valves to decelerate rotating loads where loading is significant. Kinetic energy is calculated using the following equation:

$$KE = \frac{1}{2}I\omega^2$$

where  $\omega$  is the angular velocity (peak) in radians/sec, and  $I$  is the mass moment of inertia of the load carried on the rotary actuator shaft.

**Shock Absorbers and Hydraulic Dampers.**—These devices are special types of linear actuators that are used to control applied loads. Pneumatic and hydraulic types are commercially available. All have frequency limitations that should be examined when sizing them for an application.

*Pneumatic Shock Absorbers and Gas Springs:* Pneumatic shock absorbers and gas springs use the compressibility of gas (usually nitrogen) to resist an applied force. Shock absorbers are used to decelerate an applied load over a distance, and are generally quite small. Gas springs are used mostly to counterbalance loads and often have very long strokes. Some gas springs have intermediate holding positions.

Shock absorbers are normally used when no return assistance is required and no restriction of velocity is required. There are some available with an orifice in the piston that provides velocity control. Shock absorbers often have a spring to provide a return function and assist in decelerating loads. They also usually have a mechanical stop, such as an adjustable nut, to prevent overcompression.

Shock absorbers are sized according to impact speed, stroke, and energy absorbing capacity. The energy absorbed will be the sum of the kinetic energy of the moving load and any external thrust provided by a driving mechanism. Vertical applications will also need to resist the weight of the applied load. Kinetic and thrust energies are calculated using the following equations:

$$E_{total} = KE + E_t$$

$$KE = \frac{1}{2}mv^2 = \text{Kinetic energy of a linear impact, where } m \text{ is mass and } v \text{ is velocity.}$$

$$E_t = Fs = \text{Thrust energy of a linear impact, where } F \text{ is applied force and } s \text{ is the shock absorber stroke.}$$

$$KE = \frac{1}{2}I\omega^2 = \text{Kinetic energy of a rotary impact, where } I \text{ is moment of inertia and } \omega \text{ is angular velocity.}$$

$$E_t = \frac{TR}{R} = \text{Thrust energy of a rotary impact, where } T \text{ is applied torque and } R \text{ is radius from the moment center and impact point.}$$

$$KE = mgh = \text{Kinetic energy of a falling weight impact, where } m \text{ is mass and } h \text{ is height.}$$

$$E_t = mgs = \text{Thrust energy of a falling weight impact.}$$

Gas springs are used when return assistance or load support (counterbalance) is required throughout the range of motion. If the gas spring is the quick return type, the force increases as the piston moves. If an orifice is present in the piston through which the gas can escape, they can limit velocity and provide a more constant force over the full stroke.

Gas springs can be either push or pull (tension or traction) type, depending on where the gas chamber is relative to the piston rod. Gas springs usually have a reservoir of oil near the rod outlet of the cylinder that is used to lubricate the rod seal. They are designed to be stored and installed with the rod pointing down, at an angle of 60° or less from vertical to ensure that the seal is lubricated. The oil also serves to dampen the end of stroke. When they cannot be installed rod down, special gas springs with provisions for lubrication are required. Due to their long, narrow form factor, side loading should be avoided.

Sizing gas springs is done with consideration of the required stroke, compressed length, diameter, compressed force, and extended force. Extended force is normally given at a point short of full extension because they should never be fully extended in operation to minimize the chances of buckling. Hysteresis is the difference between the actual and rated output force of a spring caused by friction. *K* factor, or progression, is the spring rate of a gas spring, and is calculated based on the following equation:

$$K = \frac{F_2}{F_1} \text{ where } F_2 \text{ is force at the compressed position, and } F_1 \text{ is the uncompressed force.}$$

Progression occurs because as the rod enters the chamber during compression, it reduces the available volume for the gas to occupy. This causes a pressure increase.

*Hydraulic Dampers (Hydraulic Shock Absorbers):* These devices are used to safely control the speed of applied loads. Dampers consist of a piston in a pressure tube containing a hydraulic fluid. When force is applied to the piston rod to move the piston, the damping fluid must pass through orifices in the piston. As a result, the damping force is dependent on the piston speed. As the fluid is forced through the orifices, kinetic energy is converted into thermal energy. Using valving on the orifices, it is possible to regulate the damping forces in each direction independently. Hydraulic dampers are usually self-contained, sealed units. They can be single or double acting. In some designs, the damping speed is adjustable over a range by turning the rod while fully extended. Hydraulic dampers are sized according to diameter, stroke length, and required damping characteristics. When extreme speeds and forces are required, cavitation/foaming of the oil can introduce gas bubbles into the chamber and cause a drop in damping capacity.

### Hydraulics

**Hydraulic Fluids.**—Hydraulic systems use liquids as their medium. Water is a common hydraulic medium in general cases. When actuators are involved, petroleum based oils are the most common type of hydraulic fluid, but silicones, synthetics, and water based fluids are also common. Hydraulic fluids can be broken down in these major categories: hydraulic fluids based on mineral oils and related hydrocarbons (ISO 11158), environmentally acceptable hydraulic fluids (ISO 15380), fire-resistant, water-free hydraulic fluids (ISO 12922), and fire-resistant, water-containing hydraulic fluids (ISO 12922).

When selecting a hydraulic fluid, one must consider viscosity, viscosity index, lubricity, compressibility, flammability, foaming resistance, resistance to rust/oxidation, resistance to bacterial growth, pour point, flash point, chemical compatibility with system seals/components, cleanliness, cost, and environmental impact. The manufacturer of the hydraulic components should be consulted as well.

Viscosity at the required temperatures is the most important selection factor. Many petroleum products are graded according to the ISO Viscosity Classification System, approved by the international standards organization (ISO). Each ISO viscosity grade number corresponds to the mid-point of a viscosity range expressed in centistokes (cSt) at 40°C. A chart of viscosity related to the various systems of grading fluids is given in Fig. 7.

**Fluid Conditioning and Stabilization.**—To provide useful work, fluid must have energy added in the form of pressure. Pumps are usually used to pressurize fluid, unless gravity can perform the needed energy. Strainers and filters are needed to keep contaminants out

Viscosities can be related horizontally

Fig. 7. Hydraulic Fluid Viscosity Chart

The viscosity/temperature relationships are based on 95 VI oils and are usable only for mono grade engine oils, gear oils and other 95 VI oils. Crankcase oils and gear oils are based on 100°C viscosity. The “W” grades are classified mono grade engine oils, gear oils and other 95 VI oils. ISO oils and AGMA grades are based on 40°C viscosity.

of sensitive components, and accumulators are used to stabilize the fluid pressure and act as reservoirs. In some cases, cooling must be provided, either passively or actively.

**Strainers and Filters:** Despite being closed systems, hydraulic circuits can become contaminated with particles due to component wear and incoming fluid contaminants. Filters are generally installed after a pump. Installation in the suction line, while more protective, would cause pressure loss in the suction line and jeopardize pump efficiency. An additional coarse strainer that creates very little pressure drop is often placed in the suction line to protect the pump. The pressure drop induced by a commercial filter is normally provided by the manufacturer.

Hydraulic filters must be capable of handling the pressures and temperatures encountered in the system.

Chemical compatibility of the filter membrane, body, and seals must also be considered. The filter must be rated for the maximum system flow rate and must be able to handle the viscosity of fluid used in the system. The allowable particle size that can pass through the filter will determine the membrane type. Hydraulic filters are available as in-line, in-tank, and other configurations. Regular maintenance will be required, so filters must be chosen and installed to facilitate membrane replacement.

*Liquid Pulsation (Water Hammer):* Valves and reciprocating pumps are often the culprits when water hammer occurs. Water hammer is a pressure spike in a fluid circuit caused by a sudden stoppage of flow. A valve closing can cause a shock wave in the liquid, resulting in noise. Reciprocating pumps cause acceleration and deceleration of the fluid that result in pressure variations. Hydraulic water hammer can be severe enough to burst pipes. Pulsation dampeners are recommended when water hammer is likely. An equation for the pressure rise that can occur due to water hammer follows:

$$\Delta p = \frac{Q}{20d^2} \sqrt{SGb}$$

where  $p$  is pressure in psi,  $Q$  is flow rate in GPM,  $SG$  is specific gravity,  $b$  is bulk modulus in psi, and  $d$  is pipe inside diameter, in inches, upstream of the point of interest.

Accumulators and pulsation dampeners are used to store pressurized hydraulic fluid, which contains potential energy. This fluid and its energy can then be released to smooth out intermittent system cycles, dampen pulsations, absorb shocks, and compensate for leaks in the system.

*Accumulators:* Pressurization against an accumulation of fluid can be accomplished through weight loading, spring loading, or compressed gas loading. Hydro-pneumatic, or gas loaded, accumulators are the most common. The three most common of this class are piston, bladder, and diaphragm accumulators. In these, a piston, bladder, or diaphragm separates the fluid from the compressed gas.

When a hydro-pneumatic accumulator has a closed volume of gas, the change in volume of hydraulic fluid is equal to the change in volume of the gas. The equation for polytropic processes can then be used to calculate accumulator volume or pressure, depending on which values are known. The polytropic exponent,  $n$ , depends on the type of process. For slow gas expansion and compression processes which occur almost isothermally, the polytropic exponent can be assumed to be  $n = 1$ . For rapid processes, the adiabatic exponent can be taken as  $n = 1.4$  for Nitrogen and air. For pressures above 3000 psi the real gas behavior deviates considerably from the ideal one, which reduces the effective fluid volume. In such cases the adiabatic exponent used is greater than 1.4.

The equation for polytropic processes is:

$$p_0 V_0^n = p_1 V_1^n = p_2 V_2^n = \text{Constant}$$

where  $p_0$  is the gas precharge pressure,  $p_1$  is the minimum working pressure, and  $p_2$  is the maximum working pressure.  $V_0$ ,  $V_1$ , and  $V_2$  are the gas volumes in each of the states.

For low pressure applications of less than 150 psi, absolute gas pressures must always be used in the equation for required gas volume. These equations are assuming ideal gas behavior. Correction factors must be used to take into account real gas behavior. Those correction factors can range from 1 to 2 depending on the pressures involved.

$$V_0 = \frac{\Delta V}{\left(\frac{p_0}{p_1}\right)^{\frac{1}{n}} - \left(\frac{p_0}{p_2}\right)^{\frac{1}{n}}}$$

where  $V_0$  is the precharge volume of gas, and  $\Delta V = V_1 - V_2$

Precharge pressure for energy storage is generally about 90 percent of system minimum working pressure. For shock absorption, precharge is usually 60 to 90 percent of median working pressure; for pulsation dampening, precharge is usually 60 to 80 percent of median working pressure. A small amount of fluid should remain inside the accumulator at minimum working pressure to prevent the mechanical components from rubbing or impacting. Therefore the precharge pressure should be slightly lower than the minimum working system pressure.

**Pulsation Dampeners & Snubbers:** Pulsating flow can wreak havoc with hydraulic devices in a circuit. A pulsation dampener is a type of accumulator that absorbs these pressure variations and stabilizes the downstream flow velocity. They absorb only the portion of fluid accelerated above the mean flow rate, store the excess fluid momentarily, and then discharge it during the portion of the cycle where flow rate drops below mean. These devices are less effective at higher frequencies. For best results, dampeners are placed as close as possible to a pump or source of pulsation. Snubbers are generally placed before gauges. Suction stabilizing dampeners are placed soon after the supply reservoir to protect a pump from acceleration head variations.

The diaphragm and bladder types of pulsation dampener are extremely common. The diaphragm or bladder is pressurized on one side with a gas (nitrogen is common) to about 70 to 80 percent of system peak pressure. A pulsation dampener can be as simple as a section of elastic tubing in a circuit that can expand and contract as pressure builds and subsides. Sometimes pulsations can be dampened by placing a restriction in the line to limit fluid flow. This method is less preferred because dangerous levels of pressure may occur behind the restriction.

Gauge snubbers vary in their method of dampening. Less expensive ones often restrict flow using a porous disc, while more expensive snubbers use a piston mechanism to dampen pulsations.

The most common application for a pulsation dampener involves a reciprocating piston pump system. Since the dampener must absorb and store the volume of fluid above the mean discharge volume of the pump, this excess fluid volume is the sizing criterion. A simplex pump (one piston) displaces a volume of fluid above mean equal to about 60 percent of total displacement. A duplex pump (two pistons) displaces a fluid volume above mean equal to about 30 percent of total displacement. A triplex pump displaces a fluid volume above mean equal to about 4 percent of total displacement. Piston displacement is calculated by multiplying face area by stroke. The following equation is used to calculate the volume of gas required for the pulsation dampener.

$$V_g = \frac{V_p}{p_g X C_p}$$

where  $V_g$  is the volume of gas required,  $V_p$  is the piston displacement volume,  $p_g$  is the gas precharge percent (as a decimal),  $X$  is the level of dampening desired (as a decimal), and  $C_p$  is the pump constant. The level of dampening is the residual peak to peak pulsations, such that lower values correspond to more dampening.

The precharge percentage of system pressure is typically 70 to 80 percent, as mentioned earlier, so as a decimal this would be expressed as 0.7 to 0.8. The level of dampening desired is expressed as the percentage of residual peak to peak pulsations. So, for 5 percent residual pulsations, this would be expressed in decimal form as 0.05. Conservative values for the pump constant are 1.5 (Simplex), 2 (Duplex), and 7 (Triplex).

Snubbers, on the other hand, are sized primarily based on the pressure range they are going to experience in operation. The pressure spikes must be quantified when selecting a snubber.

**Head.**—The energy added to a liquid by a pump or by gravity is often quantified in terms of head. Head has units of length, usually feet or meters. Pressure can be calculated from head, and vice-versa, through use of the following equations:

$$p = 0.434 \times h \times SG \text{ where } h \text{ is head in feet, } p \text{ is pressure in psi}$$

$$p = 0.0981 \times h \times SG \text{ Where } h \text{ is head in meters, } p \text{ is pressure in bar}$$

$$h = 2.31p \times SG \text{ where } h \text{ is head in feet, } p \text{ is pressure in psi}$$

$$h = 10.197p \div SG \text{ where } h \text{ is head in meters, } p \text{ is pressure in bar}$$

For water at 70°F (20°C), head and pressure equivalents can be found in Table 30 and Table 31.

**Table 30. Pressure in Pounds per Square Inch for Different Heads of Water**

Bernoulli's equation is commonly used in the design of hydraulic systems. In terms of head, it takes the following form. This equation assumes steady flow, so additional terms are used in cases of pulsating flow as with reciprocating pumps.

$$h_1 = h_2 + h_L \quad \text{or} \quad z_1 + \frac{v_1^2}{2g} + \frac{p_1}{\gamma} = z_2 + \frac{v_2^2}{2g} + \frac{p_2}{\gamma} + h_L$$

where  $h_L$  is minor loss of head due to viscous and turbulent shear stresses and other factors. The terms of this equation are explored further in this section.

**Elevation Head:** This is the vertical distance between the point of concern and the free surface of the fluid. This head is considered positive if the free surface is above the point of concern, and negative if the point of concern is above the free surface. No equation is required. When applied to a suction line, when the pump is above the fluid free surface (negative head) this is often referred to as "suction lift." Elevation head is often represented by the letter  $z$  or as  $h_z$ .

**Pressure Head:** The equivalent head imparted by the pressure applied to the fluid at its free surface. This is calculated using the following equation:

$$h_p = \frac{p}{\gamma} \quad \text{where } p \text{ is applied absolute pressure and } \gamma \text{ is specific weight.}$$

**Static Head:** This term is used to include static effects like elevation and pressure head, while excluding dynamic effects like friction and velocity head.

**Dynamic or Velocity Head:** The head imparted by the specific kinetic energy of the fluid. This value is proportional to the square of the fluid's velocity. Velocity head is calculated using the following equation:

$$h_v = \frac{v^2}{2g}$$

**Acceleration Head:** This head is critical when evaluating the suction side of reciprocating positive displacement pumps and other pumps with pulsating flow. It is also important to consider during startup of a kinetic pump. Acceleration head is subtracted from the *NPSHA*, which is covered in the section *NPSHR and NPSHA* starting on page 2804.

Acceleration head is the head required to accelerate the fluid in the line. It must be considered when evaluating cavitation risk at the inlet and peak loads on the pump components at discharge. It is calculated using the following equation and Table 32.

$$h_a = \frac{LVNC}{gk}$$

where  $h_a$  is acceleration head in feet,  $L$  is the length of the suction line in feet,  $V$  is the average liquid velocity in the suction line (ft/sec),  $N$  is the speed of the pump in RPM,  $g$  is the gravitational constant, and  $C$  and  $k$  are given in Table 32.

**Table 32. Acceleration Head Constants**

Pump Type	Constant C	Fluid Type	Constant k
Single Acting Simplex	0.4	Non-Compressible (degassed)	1.4
Single Acting Duplex	0.2	Most Liquids	1.5
Double Acting Duplex	0.115	Compressible	2.5
Triplex	0.066		
Quintuplex	0.04		
Septuplex	0.028		

**Friction Head:** The head required to overcome friction effects in the line due to surface roughness and restrictions. Restrictions can include fittings, valves, and other devices. Velocity of the fluid is directly proportional to friction head. Friction head is calculated as the sum of all energy losses incurred in the pipe system and fittings. These equations were given in section *Energy Loss in Pipes* on page 2779, and following pages.

**Vapor Pressure Head:** This head term ( $h_{vp}$ ) is used on the suction line to evaluate the potential for cavitation. It is the head equal to the vapor pressure of the liquid being used, and is calculated using the equation for pressure head. The vapor pressure is equal to the saturation pressure at a given temperature. The vapor pressure head of water at 68°F (20°C) is 0.84 ft (2.338 kPa). When the pressure of a liquid drops below its vapor pressure, it boils.

**Discharge from Tanks.**—To calculate the velocity of discharge of liquid from a tank the following equations can be used:

For a non-pressurized tank,

$$v_o = C_v \sqrt{2gh}$$

where  $v_o$  is velocity through the discharge orifice,  $h$  is the height of the free surface of liquid in the tank above the orifice, and  $C_v$  is coefficient of velocity for the discharge orifice (see Table 33).

For a tank at gauge pressure  $p$ ,

$$v_o = C_v \sqrt{2g \left[ \left( \frac{p}{\gamma} \right) + h \right]}$$

The time required to drain a tank can be calculated using the following equation if the tank has a constant cross-sectional area and is not replenished. Strategies to reduce turbulence as a fluid exiting a tank into a mouthpiece or discharge tube include employing a re-entrant mouthpiece that protrudes into the tank, or using a convergent-divergent mouthpiece.

$$t = \frac{2A_t(\sqrt{z_1} - \sqrt{z_2})}{C_d A_o \sqrt{2g}}$$

where  $t$  is time in seconds,  $A_t$  is the cross-sectional area of the tank,  $A_o$  is the cross-sectional area of the discharge orifice,  $z_1$  and  $z_2$  are the initial and final liquid heights in the tank, and  $C_d$  is the coefficient of discharge for the type of orifice used (see Table 33).

**Table 33. Discharge and Velocity Coefficients**

Orifice Type	$C_d$	$C_v$
Sharp Edged	0.62	0.98
Round Edged	0.98	0.98
Short Tube (Fluids separates from walls)	0.61	0.61
Sharp Tube (No fluid separation)	0.82	0.82
Sharp Tube with Rounded Entrance	0.97	0.98
Re-entrant Tube, $L < 0.5d$	0.54	0.99
Re-entrant Tube, $2 \leq L \leq 3$	0.72	0.72
Smooth, Well-Tapered Nozzle	0.98	0.99

**Pumps.**—Pumps are used to move fluid. More generally, pumps add pressure energy to fluid through a variety of means. Pumps fall into two general classifications: positive displacement pumps and kinetic (dynamic) pumps. Some pumps are meant to be submerged completely in the fluid being pumped, while others are not.

*Positive Displacement Pumps:* Positive displacement pumps move a fixed amount of fluid during each discharge stroke or revolution. Flow rate is directly related to the speed of the moving parts of the pump, and for many of these pumps flow pulsates as the cavity or cavities discharge and refill. These pumps are suitable for low to moderate flow rates, for moving highly viscous fluids, and generating very high pressures. Because of the high pressure capability of these pumps, they tend to be sturdily built and the use of a pressure relief valve is recommended in fluid circuits employing these pumps. Positive displacement pumps can be further broken down into reciprocating and rotary types. The most common types of reciprocating pumps are: bladder, diaphragm, peristaltic, and piston or plunger pumps. Commonly encountered rotary types are: gear, lobe, vane, screw, and progressive cavity pumps. Metering pumps are positive displacement pumps that have a precisely controlled discharge volume. This volume is normally adjustable through stroke adjustment.

Bladder pumps deliver pulsing flow, usually by inflating and deflating a bladder arranged axially along a pumping chamber. Diaphragm pumps deliver pulsing flow from a single cavity, but can be arranged in multiples to provide smoother flow. Peristaltic pumps deliver pulsing flow, and have the advantage of completely containing the fluid within a section of tubing that runs through the pump mechanism. The pump uses a series of rollers to progressively pinch the tube and move the fluid ahead of the pinch point.

Piston pumps and plunger pumps deliver pulsing flow. Axial piston pumps are designed with multiple pistons arranged axially to the motor. A tilted swashplate turns and actuates the pistons in sequence. More pistons in the pump produce smoother flow. Radial piston pumps have pistons arranged radially around a central cam that actuates them in sequence. Reciprocating piston and plunger pumps used for fluid transfer are typically either single acting or double acting, which means the piston delivers fluid on one or both directions of movement. These are driven with a crank arrangement or other reciprocating mechanism. A simplex pump has one cylinder, and a duplex pump has two cylinders. Arrangements with more cylinders are possible.

Gear pumps deliver pulsing flow at high pressures and fairly high flow capacities. They rely on close clearances to capture the fluid. This means that the fluid being moved must be free of particulate matter. These pumps perform best with viscous fluids. Lobe pumps deliver pulsing flow. They are similar to gear pumps, but the lobes in mesh do not contact one another. These pumps are often used to move fluid with large particulate inclusions. The lobes are often non-metallic, and are suitable for handling delicate items in a fluid stream. Vane pumps deliver pulsing flow at moderately high pressures. They are comprised of a rotating set of vanes that capture and release fluid inside a round housing.

Screw pumps deliver smooth flow at moderately high pressures. They are commonly found in single, double, and triple screw configurations. Single screw pumps are sometimes called progressing-cavity pumps. Direct acting pumps are driven by a fluid with a differential pressure, and generally use a piston. They can use air, steam, or a liquid as the driver. These pumps are suitable for high pressure, low flow applications. They have the disadvantage of consuming high volumes of drive fluid.

*Kinetic Pumps:* Kinetic pumps generate momentum in a fluid, which is then transformed into pressure. These pumps do not have a fixed discharge volume, and therefore do not impart a pulsation to the fluid being moved. The most common type of kinetic pump is the centrifugal pump. Other types of kinetic pumps include air lifts, hydraulic rams, turbine pumps, and jet pumps

Centrifugal pumps use a one or more spinning impellers to accelerate a fluid radially from the inlet. The fluid is then slowed by a spiral volute, converting the velocity energy into pressure energy. Centrifugal pumps can be radial, axial, and mixed flow types. The pump specific speed determines which would be the best type for a given application. Some centrifugal pumps are configured to handle fluids with solids. In those cases, a grinder can be integrated into the pump. Centrifugal pumps are used mainly in high flow applications with moderate heads. Multistage versions are suitable for high head applications. The size of a centrifugal pump is designated by the discharge port size, inlet port size, impeller diameter, and number of stages. Therefore, a 1 x 2 x 5 pump would be a single stage pump with a 1 inch discharge, a 2 inch inlet, and a 5 inch impeller. If the pump case is supported at the centerline of the shaft, it is said to be "centerline mounted". This mounting configuration is ideal for high temperature applications because shaft alignment with the driver is maintained as the case expands due to heat. Foot mounted pumps are supported under the case, and frame mounted pumps are supported under the bearing housing.

Air lift pumps use a stream of air bubbles injected into the submerged base of a pipe to entrain the fluid. The fluid rises with the air bubbles. These pumps are used when only light suction is needed.

Hydraulic ram pumps operate cyclically to deliver pulsing flow. A hydraulic ram is typically comprised of a spring or weight loaded normally open valve, and a check valve. Flowing water with kinetic energy creates pressure against the normally open valve until it closes. This elevated pressure sends fluid through the check valve to a higher elevation. The check valve then prevents the fluid from reversing. Once pressure is relieved, the normally open valve opens once more and the cycle begins again.

Turbine pumps are comprised of a series of progressive impellers. Each stage, or impeller, increases the energy of the fluid. Jet pumps are commonly used in home water well

systems. These pumps are comprised of a centrifugal pump located above, with a jet assembly down in the well. The centrifugal pump pressurizes the water, which is then passed through a nozzle. The jet created by the nozzle entrains additional water and lifts it up toward the pump inlet. In the suction line there is also a diffuser, which slows the water and converts velocity to pressure energy.

*The Effect of Viscosity on Pumps:* Viscosity affects positive displacement pumps, resulting in higher friction head values for a given flow rate. When centrifugal pumps handle fluids more viscous than water, the pumping efficiency decreases and the flow for a given head also decreases. Centrifugal pump performance is typically rated at values achieved when pumping cool water. For computing centrifugal pump performance, some correction factors for viscous fluids can be found in Fig. 8. To use the chart, enter at capacity, go straight up to the head curve, over horizontally to the viscosity curve, and then straight up to the correction factor curve. The correction factors are applied according to the following equations:

$Q_v = C_Q Q_{water}$  where  $Q_v$  is the corrected viscous capacity,  $C_Q$  is the capacity correction factor, and  $Q_{water}$  is the flow rate achieved while pumping cool water.

$h_v = C_h h_{water}$  where  $h_v$  is the corrected viscous head,  $C_h$  is the head correction factor, and  $h_{water}$  is the head achieved while pumping cool water.

$\eta_v = C_\eta \eta_{water}$  where  $\eta_v$  is the corrected viscous efficiency,  $C_\eta$  is the efficiency correction factor, and  $\eta_{water}$  is the efficiency achieved while pumping cool water.

$P_v = \frac{P_{water}}{C_\eta}$  where  $P_v$  is the corrected viscous pumping power, and  $P_{water}$  is the power achieved while pumping cool water.

*Pump Capacity:* Flow rate through a pump is known as capacity. For positive displacement pumps, flow rate is simply related to cavity volume and cycle rate. For centrifugal pumps, a change in impeller diameter or speed results in a capacity change according to the affinity laws discussed later in *Affinity and Similarity* on page 2808.

Centrifugal pumps are intended to be used at or near rated capacity. When operated below this capacity, the pump experiences higher axial thrust loads, elevated temperatures, and there is a potential for gases to become trapped in the pump case. Another effect, called *recirculation*, can also occur in which flow reversals occur at the inlet or discharge tips of the impeller. This can result in pressure pulsations which can damage the pump. In cases where demand is likely to fall below pump capacity, a parallel pump arrangement can be considered, or a bypass installed in the discharge line of the pump to allow the pump to operate at higher flow than demanded.

*Total Suction Head:* This is the sum of all the heads imparted on the fluid in the suction line supplying a pump. It includes static and dynamic heads, unless otherwise specified. The general equation for total suction head is:  $h_{t(s)} = h_z + h_p + h_v - h_f$  where  $h_z$  is static head,  $h_p$  is pressure head,  $h_v$  is velocity head, and  $h_f$  is friction head. All are taken with respect to the suction line. Acceleration head can also be subtracted when dealing with reciprocating pumps.

*Total Discharge Head:* This is the sum of all the heads imparted on the fluid in the discharge line exiting a pump. The general equation for total discharge head is:  $h_{t(d)} = h_z + h_p + h_v + h_f$ . Here the terms are taken with respect to the discharge line. Acceleration head can also be added for reciprocating pumps.

Fig. 8. Centrifugal Pump Viscosity Correction Factors

SSU are Saybolt Universal Seconds. ASTM D2161 covers conversion of kinematic viscosity to SSU at a given temperature. BEP is *Best Efficiency Point*.

**System Head or Total Dynamic Head (TDH):** This is equal to the difference between total discharge head and total suction head:  $h_t = h_{t(d)} - h_{t(s)}$

For centrifugal pumps, a change in impeller diameter or speed results in a change in head according to the affinity laws discussed in *Affinity and Similarity* on page 2808.

Using the following equation, head can be calculated from impeller and fluid speeds for radial and mixed-flow pumps where the incoming fluid velocity is nearly zero.

$$h_t = \frac{\eta_i v_i v_f}{g}$$

where  $\eta_i$  is impeller efficiency (typically 0.85–0.95),  $v$  is tangential impeller velocity at a given radius, and  $v_f$  is the tangential velocity of the fluid.

*NPSHR and NPSHA: Net Positive Suction Head Required* is the minimum fluid energy required at the pump inlet for normal operation. *NPSHR* is measured when the pump total head is reduced by 3 percent due to cavitation. *NPSHR* depends on flow rate as well as the characteristics of the pump and suction line. This value is normally provided by pump manufacturers for one or more flow rates. To some extent, *NPSHR* depends on the characteristics of the valves used on the pump inlet and discharge ports. If *NPSHR* for one flow rate is known, it can be calculated for another flow rate using the equation:

$$\frac{NPSHR_2}{NPSHR_1} = \left(\frac{Q_2}{Q_1}\right)^2$$

*Net Positive Suction Head Available* is the actual fluid energy at the pump inlet, which can be calculated for the suction line as the difference between total suction head and the vapor pressure head using the following equation. For reciprocating pumps, acceleration head ( $h_a$ ) must be accounted for as well.

$$NPSHA = h_z + h_p + h_v - h_f - h_{vp} - h_a$$

where all terms are taken with respect to the suction line.

*Cavitation:* Cavitation occurs when the pressure of the fluid in the inlet of a pump drops below its vapor pressure for a given temperature. A fluid whose pressure drops below its vapor pressure boils, or vaporizes, degrading pumping performance. The symptoms of cavitation include noise, vibration, and pitting of pump surfaces. In extreme cases, structural damage can occur. If  $NPSHA < NPSHR$ , the fluid will cavitate excessively and the pump will not run as expected. An additional margin is recommended, with recommendations ranging from 10 to 200 percent depending on application. If the liquid has been exposed to gas other than its own vapor, additional margin of *NPSHR* over *NPSHA* is needed to prevent cavitation. If *NPSHR* is not yet known, the designer must aim for a *NPSHA* as high as reasonably possible, and certainly above zero.

Cavitation can be caused by a variety of conditions, including: high pump speeds, high fluid temperatures, low suction head, and fluids with high vapor pressures. When working at high altitudes, the effect of altitude on vapor pressure must be taken into account when calculating suction head. If *NPSHA* is zero or negative, the suction head is by definition below the fluid's vapor pressure. To increase *NPSHA* and prevent cavitation, the inlet pressure can be increased through a variety of methods: pressurizing the fluid source or using a booster pump, raising the fluid source, reducing the flow rate, cooling the fluid, shortening and/or widening the suction line, and reducing suction line losses due to friction or turns. Additional strategies include adding a suction line stabilizer (pulsation dampener) to the suction line, or adding a section of highly flexible hose to the suction line to allow some dampening.

*Hydraulic (Pump) Power:* Hydraulic power, or pump power, is a function of mass flow rate and total dynamic head (added head). This is the energy imparted to the fluid per unit time by the pump. Typical units for power are horsepower or kilowatts. The equations for hydraulic power are given below. These equations assume the density of water is 62.4 lbm/ft<sup>3</sup> (1000 kg/m<sup>3</sup>).

**Hydraulic Kilowatt**

In the equations that follow,  $Q$  is in l/s;  $m$  is in kg/s; and  $\dot{V}$  is in m<sup>3</sup>/s.

$$KW = 9.81 \frac{h_t Q (\text{SG})}{1000} = 9.81 \frac{h_t \dot{m}}{1000} = 9.81 h_t \dot{V} (\text{SG}) \text{ where } h_t \text{ is in meters}$$

$$KW = \frac{\Delta p Q}{1000} = \frac{\Delta p \dot{m}}{1000 (\text{SG})} = \Delta p \dot{V} \text{ where } \Delta p \text{ is in kPa}$$

$$KW = \frac{WQ (\text{SG})}{1000} = \frac{W \dot{m}}{1000} = W \dot{V} (\text{SG}) \text{ where } W \text{ is in J/kg}$$

**Hydraulic Horsepower**

In the equations that follow,  $Q$  is in gal/min;  $m$  is in lbm/s; and  $\dot{V}$  is in ft<sup>3</sup>/s.

$$HP = \frac{h_t Q (\text{SG})}{3956} = \frac{h_t \dot{m} g}{550 g_c} = \frac{h_t \dot{V} (\text{SG})}{8.814} \text{ where } h_t \text{ is in feet}$$

$$HP = \frac{\Delta p Q}{1714} = \frac{\Delta p \dot{m} g}{238.3 (\text{SG}) g_c} = \frac{\Delta p \dot{V}}{3.819} \text{ where } \Delta p \text{ is in psi}$$

$$HP = \frac{\Delta p Q}{246800} = \frac{\Delta p \dot{m} g}{34320 (\text{SG}) g_c} = \frac{\Delta p \dot{V}}{550} \text{ where } \Delta p \text{ is in psf}$$

$$HP = \frac{WQ (\text{SG})}{3956} = \frac{W \dot{m}}{550} = \frac{W \dot{V} (\text{SG})}{8.814} \text{ where } W \text{ is in ft-lbf/lbm}$$

For centrifugal pumps, a change in impeller diameter or speed results in a change in power according to the affinity laws discussed in *Affinity and Similarity* on page 2808. Required power for centrifugal pumps is directly proportional to the specific gravity of the liquid being pumped. It is influenced also by viscosity.

**Pump Efficiency:** Pump efficiency is the ratio of the actual power delivered by the pump driver (usually a motor) and the power the pump ideally delivers to the fluid. Losses occur in the system due to friction between the fluid and the pump, as well as friction and/or slip within the pump mechanism. Since hydraulic power is a function of mass flow rate, efficiencies of pumps are often given in terms of flow rate, speed, or specific speed. Drive power to a pump is often called "brake horsepower" (bhp). Pump efficiency is defined by the following equation:

$$\eta_p = \frac{P_{\text{hydraulic}}}{P_{\text{brake}}}$$

where  $P_{\text{hydraulic}}$  is the power delivered to the fluid, and  $P_{\text{brake}}$  is the drive power to the pump.

For positive displacement pumps, volumetric efficiency is often used to measure performance. This is the ratio of volumetric flow rate input to displacement per unit time delivered by the pump. Torsional efficiency is also commonly used for positive displacement pumps. This is the ratio of actual to ideal torque required to drive the pump. Overall efficiency of a positive displacement pump is the ratio of actual energy delivered, to the input power to the pump.

Volumetric efficiency is calculated using the following equation:

$$\eta_V = 1 - \left( \Delta p \beta \frac{C}{D} \right) + L_V$$

where  $\beta$  is the compressibility factor of the fluid,  $C/D$  is the pumping chamber clearance to displacement ratio, and  $L_V$  is the fluid loss to slippage back through the pump valves before they can seal.  $\Delta p = p_d - p_s$  where  $p_d$  is pressure at discharge and  $p_s$  is pressure at suction.

Centrifugal pumps are intended for use near their best efficiency. When operated below peak efficiency, a phenomenon called "recirculation" can occur, which causes flow reversal at the inlet or discharge tips of the impeller. This can be very detrimental to performance and damaging to the pump.

*Specific Speed:* Centrifugal pumps are characterized in terms of specific speed. Specific speed is the speed of an ideal pump needed to raise a unit of volume through a unit of head in a unit of time. It assumes the ideal pump is geometrically similar to the pump being evaluated. Specific speed is used to determine the geometry (type of impeller) needed for a given set of input and output requirements. It is calculated using the following equations where  $n$  is rotation in RPM:

$$\eta_s = \frac{n\sqrt{Q}}{h_t^{0.75}} \text{ where } Q \text{ is in gal/min, and } h_t \text{ is total dynamic head in feet.}$$

$$\eta_s = \frac{n\sqrt{V}}{h_t^{0.75}} \text{ where } V \text{ is in m}^3/\text{sec, and } h_t \text{ is in meters.}$$

Low specific speeds produce the largest heads. In US units, specific speeds range from approximately 500 to 1500 RPM for radial vane pumps, 1500–4000 for Francis vane, 4000–9000 for mixed flow impeller designs, and above 9000 for axial flow impellers. When specific speed is low for a given style, efficiency suffers, and a multi-stage pump should be used. Once specific speed has been calculated from a given head, drive speed, and flow rate, the appropriate type of impeller can be selected. In addition, pump efficiency, *NPSHR*, maximum speed, and suction lift can be determined using specific speed. It is good practice to select a centrifugal pump that has the highest specific speed, since that will yield the smallest pump.

*Critical Speed:* Critical speed is related to static deflection of the shaft in the horizontal position. When operated within about 20 percent of critical speed, the pump will vibrate excessively and damage can occur. The wet critical speed must be well above the operating speed of the pump in order to ensure smooth running. Centrifugal pumps have a "dry" critical speed and a "wet" critical speed. Wet critical speed is normally higher (smaller deflections experienced) than dry critical speed. As the pump shaft support components (bearings or bushings) wear, the wet critical speed drops. When a pump is operated away from its best efficiency, higher deflections are likely, causing critical speed to drop. Dry critical speed can be determined using the following equations:

$$n_c = \frac{187.7}{\sqrt{y}}$$

where  $y$  is shaft deflection in inches, and  $n_c$  is critical speed in RPM. Shaft deflection is typically limited to 0.006 inches in commercial pumps. This leads to a critical speed value of 2423 RPM.

$$n_c = \frac{946}{\sqrt{y}}$$

where  $y$  is shaft deflection in mm. A maximum shaft deflection of 0.15mm leads to a critical speed of 2442 RPM.

**Pump Shaft Loading:** Piston pumps carry the entire piston compression force on their drive rod. The axial load on the rod is easily calculated as force = pressure/area. Buckling of the load bearing members and/or piston rod may also need consideration. Many pumps are rated based on the maximum discharge plunger load that can be carried when the suction pressure is zero. If the piston is massive, or pump speeds high, the force to accelerate the piston must be taken into account.

For radially driven pumps, the torque on the motor shaft driving a pump depends upon the type of pump being driven. Pumps which produce pulsating flow must accelerate the fluid during each cycle, and therefore experience variable shaft torque. Centrifugal pumps experience a steady torque on the shaft, which can be calculated either from brake power and speed or from the change in momentum of the fluid being pumped. Torque can be calculated using the following equations:

$$T = \frac{63025 P}{n}$$

where  $T$  is torque in in-lbf,  $P$  is brake horsepower, and  $n$  is rotation in RPM.

$$T = \frac{9549 P}{n}$$

where  $T$  is torque in N-m,  $P$  is brake power in kW, and  $n$  is rotation in RPM.

$$T = \frac{\dot{m}}{g_c} (v_{t(d)} r - v_{t(i)} r_i)$$

where  $T$  is torque,  $\dot{m}$  is mass flow rate,  $v_{t(d)}$  and  $v_{t(i)}$  are tangential velocity at the discharge and inlet,  $r$  is the radius of the impeller, and  $r_i$  is the radius at the inlet. When the inlet is central to the impeller, the tangential velocity at the inlet is zero.

If a pump is driven using a belt or chain, overhung loads on both the motor and the pump shafts should be calculated. Additional bearing support or larger shafts may be required.

In centrifugal pumps and some rotary positive displacement pumps, axial thrust is generated that must be accommodated by the pump drive shaft. In some multi-stage centrifugal pumps, mounting the impellers in opposing directions can balance the thrust load and reduce axial load transferred to the drive shaft. In other cases, a hydraulic balancing device is used. This type of device is piped to the suction line or reservoir and exerts an opposing force to the thrust generated by the impellers.

For axially driven reciprocating pumps, the axial loading on the drive shaft must be considered, as well as radial loading, moment loading, and torque. Axial and radial/moment loading on the motor shaft can be calculated using simple trigonometric relationships. Torque required to axially drive the motor will depend on how the pump is being driven. In some cases, a lead screw or equivalent mechanism is used and the lead screw equation for torque is applicable.

**Pump Curves:** Pump performance can be shown graphically by plotting various performance parameters as a function of flow rate. These graphs are usually supplied by pump manufacturers and usually include efficiency, power requirement, dynamic head, and *NPSHR*. These values are given as a function of the pump alone, and normally are measured in a way that minimizes the influence of suction/discharge line effects. Pump curves are also normally generated using water as the fluid. Since hydraulic power is a function of the fluid's specific gravity, care must be taken when planning to pump a fluid with a different specific gravity. In those cases, the pump's power rating should be multiplied by the specific gravity of the planned fluid.

The performance of a centrifugal pump is generally based on capacity (gal/min or m<sup>3</sup>/h), added fluid head (ft or m), input power (bhp or kW), efficiency (%), and speed (rpm). It is common to plot centrifugal pump curves for a range of impeller diameters together for a fixed speed. This allows selection of the diameter when looking at operating points.

**System Head Curves:** System performance curves display the influence of suction and discharge line configurations. On a system head curve, head requirements of the system are plotted versus capacity. The curve represents a total static head plus friction losses. When system head is variable, as with changing reservoir levels or when there is switching between lines through valving, multiple system head curves will be represented on the graph.

**Operating Point:** The operating point is the intersection of the pump curve and the system curve on a graph that sets head against flow rate. From this graph, the flow rate and head of the pump/system combination can be easily determined. An example of the operating point on a graph can be seen in Fig. 9. A pump/system combination will have multiple viable operating points if there are multiple pump curves given for different speeds and/or geometries. The designer should choose the operating point with the highest pump efficiency. Another case where multiple operating points are seen is in systems where the system head varies and multiple system head curves are present. The designer should ensure that the pump can meet the system requirements at all operating points. When dealing with centrifugal pumps, the pump curve chosen for the operating point will in turn determine the speed and/or impeller. It is good practice to select a centrifugal pump with the largest impeller diameter that will meet the application needs while operating at or near its maximum rated speed.

Fig. 9. Operating Point of a Pump

The operating point of a pump in a system can be changed by throttling the discharge line. The suction line should never be throttled because it could lead to cavitation. When a pump is throttled, the operating point moves along the pump curve as the flow rate is reduced. Operating point can also be changed through the use of a variable speed drive. Changing the viscosity of the fluid being pumped also moves the operating point in the direction of less flow for a given head.

**Combining Pumps in Series or Parallel:** When one pump discharges into the suction line of another pump, this is a series system. Pumps in series are capable of producing higher discharge heads than single pumps. A slight increase in flow rate will also be seen when pumps are combined in series. To generate a pump curve for pumps in series, the head of each pump is added at each flow rate to create a new curve. This curve is then graphed together with the system curve to find a new operating point. Multistage pumps contain multiple impellers in one pump body to achieve a similar effect as a series of pumps.

A system of pumps in parallel experiences an increase primarily in flow capacity, with only a slight increase in head. Parallel pump systems have the advantage of increased reliability, and the ability to efficiently adjust to variations in demand. When demand varies, flow rate moves away from the operating point, resulting in decreased efficiency.

When two or more parallel pumps are used, they can be engaged and disengaged to keep the system flow rate near demand.

**Affinity and Similarity:** Comparing centrifugal pumps can be done if one assumes the efficiencies of the two pumps are the same. This becomes less true as the difference in

size between pumps grows. Note that as the specific speed increases, the accuracy of the affinity equations decreases. To estimate the efficiency of a very different size pump, the following equation can be used.

$$\left(\frac{D_L}{D_S}\right)^n = \frac{1 - \eta_S}{1 - \eta_L}$$

where subscript  $L$  denotes the larger pump, and  $S$  denotes the smaller pump.  $D$  is impeller diameter and  $n$  is speed.

The affinity equations (assuming equal efficiencies) which allow comparison between pumps are as follows:

- When the impeller diameter is constant while the speed changes:

$$\frac{n_2}{n_1} = \frac{Q_2}{Q_1} \quad \left(\frac{n_2}{n_1}\right)^2 = \frac{h_2}{h_1} = \left(\frac{Q_2}{Q_1}\right)^2 \quad \left(\frac{n_2}{n_1}\right)^3 = \frac{P_2}{P_1} = \left(\frac{Q_2}{Q_1}\right)^3$$

- When the speed is constant and the impeller size changes:

$$\frac{D_2}{D_1} = \frac{Q_2}{Q_1} \quad \left(\frac{D_2}{D_1}\right)^2 = \frac{h_2}{h_1} \quad \left(\frac{D_2}{D_1}\right)^3 = \frac{P_2}{P_1}$$

- When flow is assumed to be turbulent and the percentage of wide open flow is assumed to be the same, similarity can be used as follows:

$$\frac{Q_2}{Q_1} = \frac{n_2(D_2)^3}{n_1(D_1)^3} \quad \frac{h_2}{h_1} = \left(\frac{n_2}{n_1}\right)^2 \left(\frac{D_2}{D_1}\right)^2 \quad \frac{P_2}{P_1} = \frac{\rho_2(n_2)^3(D_2)^5}{\rho_1(n_1)^3(D_1)^5}$$

**Startup Conditions:** Priming is necessary for all types of pumps to begin operation. During priming, the inlet chamber is flooded with fluid, and gas is purged from the pump mechanism. Submersible pumps are generally self-priming, as are some types of non-submersible pumps.

The torque requirements of centrifugal pumps at startup are greatly different from running torque requirements. Full-load torque is required for starting against full discharge pressure. To reduce the startup torque required, the designer can pipe the discharge back to the suction line, and close it off from any head inherent in the running discharge line. This equalizes discharge and suction pressure and eliminates the load on the pump during startup. Using valves, this loop can be closed off and the pump discharge connected to the discharge pipe system once the pump gets up to running speed.

**Piping Considerations:** To ensure peak performance of hydraulic systems, some points to consider are:

- Make piping runs as short and direct as possible.
- Design for minimum fluid velocities and accelerations.
- Use long radius bends rather than elbows to redirect piping where possible.
- Design pipe systems to preclude the collection of vapor bubbles, except where venting is provided.
- Include pulsation dampeners and suction stabilizers where acceleration head is high or the fluid needs degassing. A suction stabilizer is a device placed on the suction line of a pump that both absorbs pulsations and separates free gases from the liquid being pumped.
- Always ensure that  $NPSHA \gg NPSHR$ .
- Include strainers only when absolutely necessary, and ensure regular maintenance is conducted.
- Provide a relief valve that is adequately sized.
- Pipe a bypass line around the pump with valves so that the pump may be started with low load. This must be done slowly to avoid shock to the system.
- In systems with high static discharge heads, install a check valve at the pump discharge to prevent static pressure from loading the pump during startup.

### Pneumatics

Pneumatic systems use compressed and flowing gas, usually air, to perform work. Many pneumatic components, such as valves, actuators, and compressors share similarities with components used with liquids. In many cases, pneumatic components and calculations should be evaluated and limited as much as possible when designing a pneumatic circuit. Silencers are essential to limit noise produced by exhausting air.

**Gas Consumption Calculation and Measurement.**—It is common practice to exhaust air used in pneumatic circuits to atmosphere through silencers, or to an exhaust manifold and/or filter. Since that air is lost, and compression of air costs money, air consumption should be evaluated and limited as much as possible when designing a pneumatic circuit. Silencers are essential to limit noise produced by exhausting air.

In US units, the volumetric flow rate of gases is normally expressed in cubic feet per minute (cfm). Velocity in US units is normally expressed in feet per minute. SI units for gas volumetric flow are cubic meters per second and meters per second for velocity. Liters per second is used for volumetric flows in low ranges.

*Gas Consumption:* Compressors and devices using compressed air are often rated in terms of free air delivery (f.a.d.), which is the quantity of air used per unit time assuming the air is at standard atmospheric pressure and temperature. These values are 14.7 psia (0.101 MPa) and 60°F (15°C). When conditions differ from standard, the following equation can be used:

$$Q_a = \frac{Q_s p_s T_a}{(p_{atm} + p_a) T_s}$$

where  $Q_a$  is actual volumetric flow rate,  $Q_s$  is flow rate at standard conditions,  $p_s$  is standard absolute atmospheric pressure,  $p_{atm}$  is actual absolute atmospheric pressure,  $p_a$  is actual gauge pressure,  $T_a$  and  $T_s$  are actual and standard absolute temperature (°R or K).

This equation is often used in another form to calculate the flow of free air required to supply a given compressed air flow. When the free air is at standard temperature, this takes the form of the following equation:

$$Q_s = \frac{Q_a (p_{atm} + p_a)}{p_s}$$

where  $Q_s$  is the free air flow at standard temperature,  $Q_a$  is the compressed air flow,  $p_a$  is actual gage pressure, and  $p_s$  is the absolute standard pressure. The ratio of absolute pressure to absolute standard pressure is known as the *compression ratio*. In US units, the free flow is normally given in units of SCFM and compressed air flow is in units of CFM.

**Fans and Blowers.**—Fans and blowers add energy to air. When static pressure is very low, fans are typically used. Blowers are appropriate when static pressure is higher.

*Types of Fans and Blowers:* Axial propeller fans have a number of blades arranged around a spinning shaft. They move air axially through themselves with very low pressure and velocity increase. Axial fans are normally used to move large quantities of air against static pressures below 0.4 psig (3kPa). A diffuser can be added after a fan to increase static pressure output. Axial propeller fans are the least expensive of the fan types, but are not as efficient as centrifugal fans. Vane-axial blowers are similar to propeller fans, but have highly optimized casing geometry that creates much higher pressures than propeller fans.

Centrifugal fans and blowers use a rotating impeller to accelerate air radially outward from a central intake. Significant velocity energy is added, which is then converted to pressure energy when the air is slowed using a volute. The inlet and volute geometry is usually organized so that air enters and exits the centrifugal device axially. Scroll casings are arranged such that the air exiting the device is radial. Centrifugal fans are appropriate up to a static pressure of approximately 2 psi (15 kPa). Forward-curved centrifugal fans

(squirrel cage fans) are the most common type, but with an efficiency of approximately 75 percent they are the least efficient of all the centrifugal designs. Backward-curved centrifugal fans are less likely to overload than forward-curved fans, and their increased efficiency over forward-curved centrifugals makes up for their increased cost. Radial blade fans are commonly found in industrial cooling applications where a large volume of air is required at moderate pressure. Centrifugal blowers look more like centrifugal pumps than fans. The impeller is typically gear-driven. The two most common types of centrifugal blowers are pressure blowers and volume blowers. Pressure blowers are designed to draw or push air at high pressures, rated in static pressure water gauge (SPWG). Volume blowers are designed to draw or push larger volumes of air, rated in cubic feet of air per minute (CFM), at lower static pressures than pressure blowers.

Cross-flow fans and blowers have air enter and exit the impeller tangentially. The pressure produced by these impellers is low. Mixed-flow fans and blowers use impellers that impart both axial and radial momentum to a gas. These impellers can be housed in either axial or scroll-type casings to output either axial or radial flow. Positive displacement blowers are essentially positive displacement pumps used for moving air. Positive displacement pumps are described earlier in this text.

*Fan and Blower Calculations:* When selecting a fan or blower, one must consider the cleanliness and type of gas being moved, the pressure differential or velocity needed, the volumetric flow rate required, the energy loss in the ductwork or system, the noise produced, and the cost.

Fan capacity is a measure of the maximum volumetric flow rate of the fan or blower. Total pressure of a fan or blower is the difference between the inlet and outlet pressures, and it is also the sum of static pressure and velocity pressure. Static and velocity pressures are often measured in inches of water (in. w.g.). Fan static, velocity, and total pressures at standard conditions can be calculated using the following equations:

$$p_s(\text{in. w. g.}) = \frac{P_{\text{psi g}}}{0.0361}$$

$$p_v(\text{in. w. g.}) = \left( \frac{v_{\text{fpm}}}{4005} \right)^2$$

$$p_t = p_s + p_v = \frac{p}{\gamma} + \frac{\rho v^2}{2}$$

where  $p_s$  is static pressure, and the specific weight of water is assumed to be 0.0361 lbf/in<sup>3</sup>;  $p_v$  is velocity pressure;  $v_{\text{fpm}}$  is velocity in fpm; and  $p_t$  is total pressure.

When a fan is connected to ductwork, the pressure drop through the duct and fittings should be taken into account using the following equations, by using the Moody diagram given in Fig. 1, or by using friction loss graphs like those published by ASHRAE. The Darcy-Weisbach equation (see *Darcy-Weisbach Equation and the Moody Diagram* on page 2779) should be used for “non-standard” duct type such as flex duct.

$$p_{f(\text{in. w. g.})} = \frac{(3.9 \times 10^{-9}) v_{\text{fpm}}^{2.43} L_{ft}}{Q_{CFM}^{0.61}}$$

where  $p_f$  is friction pressure of air moving through ducts. This assumes clean, galvanized, circular ducts with a specific roughness of 0.0005 ft.

$$p_{f(\text{in. w. g.})} = K \left( \frac{v_{\text{fpm}}}{4005} \right)^2$$

where  $p_f$  is friction pressure of air moving through fittings. The loss coefficient  $K$  can be found in Table 34.

**Table 34. Loss Coefficients, Air Duct Fittings**

Compressibility factor is the ratio of total pressure that would be developed with an incompressible fluid to the total pressure developed with a compressible gas. When fan total pressure is less than 12 in.w.g., the compressibility factor can be assumed to be equal to 1 (incompressible flow). Power output is the product of capacity, total pressure, and compressibility factor. Total efficiency is the ratio of power output to power input. Static efficiency is the product of total efficiency and the ratio of static pressure to total pressure. These values can be calculated using the following equations. Fan efficiency grades have been established to classify fan performance.

$$P_o = K_p Q P_t$$

where  $P_o$  is output power imparted to the gas,  $K_p$  is compressibility factor, and  $P_t$  is fan total pressure.

$$\eta_t = \frac{P_o}{P_B}$$

where  $P_B$  is power supplied to the driver.

$$\eta_t = \frac{Q_{CFM} P_t (\text{in. w.g.})}{6356 P_B} \quad \eta_s = \frac{Q_{CFM} P_s (\text{in. w.g.})}{6356 P_B}$$

The fan laws of similarity and affinity rely on the fact that two geometrically similar impellers of different sizes are homologous. These laws can be used to compare similar fans, and are expressed in the following equations. It is essential to make sure that the fans under consideration have the same efficiency. When one fan is compared at different speeds:

$$\frac{Q_2}{Q_1} = \frac{n_2}{n_1} \quad \frac{p_2}{p_1} = \left(\frac{n_2}{n_1}\right)^2 \quad \frac{P_{o2}}{P_{o1}} = \frac{P_{B2}}{P_{B1}} = \left(\frac{n_2}{n_1}\right)^3$$

When two similar fans are compared:

$$\frac{Q_2}{Q_1} = \left(\frac{n_2}{n_1}\right)\left(\frac{D_2}{D_1}\right)^3 \quad \frac{P_2}{P_1} = \left(\frac{p_2 Q_2}{p_1 Q_1}\right)$$

Sizing of fans and blowers is similar in process to that of pumps, where graphs are commonly used. The performance graph is usually a constant-speed plot with capacity on the X axis and a variety of performance factors on the Y axis. As part of the selection process, a graph of the system is also generated, with capacity as the X axis and head (energy loss in the system) on the Y axis. As with pumps, the operating point of a fan is found at the intersection of the performance graph and the system graph. When multiple system curves are applicable, as with variable duct geometry or variable static pressure, there will be multiple operating points. When multiple performance curves are available, as with adjustable impeller vane angle, damper control, or variable speed, there will be multiple operating points. A slightly undersized fan is preferable to an oversized fan because of lower cost and increased stability.

Operating a fan or blower at much lower than rated capacity can result in pulsations and instability due to a variety of factors. This should be avoided. To ensure stable fan and blower operation, the engineer should select an operating point where the slope of the pressure/capacity performance curve has opposite sign as the system curve. This is usually the case, except at or above design capacity. Pulsation can be avoided by selecting an operating point to the right of the surge point. If this is not possible, speed control, impeller geometry control, inlet dampers, exhaust dampers, and bleed lines may be employed. Changing a fan's speed cannot be used to stabilize a fan operating in an unstable condition. According to affinity, if an operating point for a fan is in an unstable region to the left of the peak, it will remain in an unstable region at any speed.

Multiple fans may be called for in some applications to avoid pressure buildup in a space or to fit a space constraint. When demand or system conditions are highly variable, multiple fans may serve the need better than a single fan. Because operating point is based on capacity, if capacity varies the operating point will move along the performance curve and may depart from reasonable efficiency for the fan or blower. In these cases, one fan is sized for one operating point, and additional fans are called into service as needed to provide additional capacity. Fans or blowers in parallel and series follow the same additive rules as pumps. Instability can occur in parallel fan systems when the combined performance curve intersects the system curve at a point where the individual operating points are widely separated. In that condition, the fans may suddenly exchange loading and shock the mechanism and/or ductwork. To avoid this, fans in parallel must be carefully matched to the system.

**Compressors.**—When significant air pressure must be generated, in excess of 10 psig (68.9 kPa), a compressor is employed. The most common pressures range from 60 to 110 psig (413.7–758.4 kPa). There are many standards covering compressors, including those by ANSI, ASME, API, SAE, and CAGI.

*Compression of Air:* The formula for the relationship between pressure, temperature, and volume of air just given indicates that when the pressure remains constant the volume is directly proportional to the absolute temperature. If the temperature remains constant,

the volume is inversely proportional to the absolute pressure. Theoretically, air (as well as other gases) can be expanded or compressed according to different laws.

*Adiabatic Expansion or Compression* takes place when the air is expanded or compressed without transmission of heat to or from it, as, for example, if the air could be expanded or compressed in a cylinder of an absolutely nonconducting material.

- Let:  $P_1$  = initial absolute pressure in pounds per square foot  
 $V_1$  = initial volume in cubic feet  
 $T_1$  = initial absolute temperature in degrees R  
 $P_2$  = absolute pressure in pounds per square foot, after compression  
 $V_2$  = volume in cubic feet, after compression  
 $T_2$  = absolute temperature in degrees R, after compression

Then:

$$\frac{V_2}{V_1} = \left(\frac{P_1}{P_2}\right)^{0.71} \quad \frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{1.41} \quad \frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{0.41}$$

$$\frac{V_2}{V_1} = \left(\frac{T_1}{T_2}\right)^{2.46} \quad \frac{P_2}{P_1} = \left(\frac{T_2}{T_1}\right)^{3.46} \quad \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{0.29}$$

These formulas are also applicable if all pressures are in pounds per square inch; if all volumes are in cubic inches; or if any other consistent set of units is used for pressure or volume.

*Example 1:* A volume of 165 cubic feet of air, at a pressure of 15 pounds per square inch, is compressed adiabatically to a pressure of 80 pounds per square inch. What will be the volume at this pressure?

$$V_2 = V_1 \left(\frac{P_1}{P_2}\right)^{0.71} = 165 \left(\frac{15}{80}\right)^{0.71} = 50 \text{ cubic feet, approx.}$$

*Isothermal Expansion or Compression* takes place when a gas is expanded or compressed with an addition or transmission of sufficient heat to maintain a constant temperature.

- Let:  $P_1$  = initial absolute pressure in pounds per square foot  
 $V_1$  = initial volume in cubic feet  
 $P_2$  = absolute pressure in pounds per square foot, after compression  
 $V_2$  = volume in cubic feet, after compression  
 $R = 53.3$   
 $T$  = temperature in degrees Rankine maintained during isothermal expansion or contraction

Then:

$$P_1 \times V_1 = P_2 \times V_2 = RT$$

*Example 2:* The same volume of air as in *Example 1* is compressed isothermally from 15 to 80 pounds per square inch. What will be the volume after compression?

$$V_2 = \frac{P_1 \times V_1}{P_2} = \frac{15 \times 165}{80} = 31 \text{ cubic feet}$$

*Work Required in Compression of Air:* The total work required for compression and expulsion of air, adiabatically compressed, is:

$$\text{Total work in foot-pounds} = 2.44 P_1 V_1 \left[ \left(\frac{P_2}{P_1}\right)^{0.29} - 1 \right]$$

$P_1$  = initial absolute pressure in pounds per square foot;  $P_2$  = absolute pressure in pounds per square foot, after compression; and,  $V_1$  = initial volume in cubic feet.

The total work required for isothermal compression is:

$$\text{Total work in foot-pounds} = P_1 V_1 \log_e \frac{V_1}{V_2}$$

in which  $P_1$ ,  $P_2$ , and  $V_1$  denote the same quantities as in the previous equation, and  $V_2$  = volume of air in cubic feet, after compression.

The work required to compress air isothermally, that is, when the heat of compression is removed as rapidly as produced, is considerably less than the work required for compressing air adiabatically, or when all the heat is retained. In practice, neither of these two theoretical extremes is obtainable, but the power required for air compression is about the median between the powers that would be required for each. The accompanying table gives the average number of foot-pounds of work required to compress air.

*Horsepower Required to Compress Air:* In the accompanying tables is given the horsepower required to compress one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures, for one-, two-, and three-stage compression. The formula for calculating the horsepower required to compress, adiabatically, a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144NPVn}{33,000(n-1)} \left[ \left( \frac{P_2}{P} \right)^{\frac{n-1}{n}} - 1 \right]$$

where  $N$  = number of stages in which compression is accomplished

$P$  = atmospheric pressure in pounds per square inch

$P_2$  = absolute terminal pressure in pounds per square inch

$V$  = volume of air, in cubic feet, compressed per minute, at atmospheric pressure

$n$  = exponent of the compression curve = 1.41 for adiabatic compression

For different methods of compression and for one cubic foot of air per minute, this formula may be simplified as follows:

For one-stage compression:  $\text{HP} = 0.015P(R^{0.29} - 1)$

For two-stage compression:  $\text{HP} = 0.030P(R^{0.145} - 1)$

For three-stage compression:  $\text{HP} = 0.045P(R^{0.0975} - 1)$

For four-stage compression:  $\text{HP} = 0.060P(R^{0.0725} - 1)$

In these latter formulas  $R = \frac{P_2}{P}$  = number of atmospheres to be compressed

The formula for calculating the horsepower required to compress isothermally a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144PV}{33000} \left( \log_e \frac{P_2}{P} \right)$$

Natural logarithms are obtained by multiplying common logarithms by 2.30259 or by using a handheld calculator.

The work and power required for air compression can be found in [Table 35](#) to [Table 38](#).

Stress and heat are what limits the maximum compression of any single stage of a compressor. The volumetric efficiency drops as pressure rise increases, further limiting the maximum compression of a single stage. Multi-stage compressors are used when a single stage cannot develop enough pressure. Multi-stage axial compressors use a series of axial fans to deliver very large flow rates. Perfect intercooling is impractical, so it is important to note that for every 10°F temperature increase, the horsepower requirement increases nearly 1%.

**Table 35. Foot-pounds of Work Required in Compression of Air  
Initial Pressure = 1 atmosphere = 14.7 Pounds per Square Inch**

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

**Table 37. Horsepower Required to Compress Air, Two-Stage Compression**

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

*Compressor Types:* Compressors can be centrifugal, multi-stage centrifugal, multi-stage axial, or positive displacement. Centrifugal compressors are similar to centrifugal blowers. Positive displacement compressors are essentially positive displacement pumps, used to deliver high pressures at moderate flow rates. These compressors can employ a variety of mechanisms, like pistons, lobes, screws, and vanes. Small positive displacement compressors are often sold to homes and businesses.

Positive displacement compressors compress a fixed amount of gas within a closed chamber by decreasing its volume. Volumetric efficiency is affected by leakage and mechanical losses. Positive displacement compressors tend to be selected for low to moderate flow applications with high compression requirements. Compressor types in this category include: reciprocating piston, rotary vane, rolling piston, rotary twin screw, and orbiting scroll compressors. Screw compressors are commonly used in the range between 100 and 150 psig. Reciprocating compressors can be either single acting or double acting, and are commonly used for pressures in excess of 200 psig. These types of compressors deliver a pulsating flow of gas, unlike other types of compressors. Multi-stage positive displacement compressors with intercooling are common at pressures exceeding 80 psig.

Many state laws and general good practice requires the use of an appropriately sized relief valve ahead of the first stop valve in positive displacement compressors. This relief valve should be set to release at 125 percent of the maximum discharge pressure of the compressor, or at the maximum working pressure of the compressor, whichever is lower.

Dynamic compressors impart momentum to the gas by means of a spinning rotor. This momentum energy is converted to pressure energy when the gas is slowed again. This is a constant flow process. Dynamic compressors are subject to the fan laws, and the specific speed is used to select the geometry. Dynamic compressors tend to be selected for moderate to high flow applications with low to moderate compression requirements. Multi-stage dynamic compressors can provide high flow and high compression.

*Compressor Sizing:* When sizing a compressor for a given application, one must analyze the piping system to the point of use to account for any pressure drops between it and the compressor. Any pressure loss must be added to the compressor range to make sure the desired pressure is delivered at the point of use. If the pressure drop is significant (exceeding 10 percent) the change in specific weight of the gas should be taken into account.

The maximum capacity of a compressor should exceed the maximum mean air consumption of the system.

Because the maximum capacity of an air compressor will exceed the minimum air consumption in the system, the compressor must modulate its capacity during normal work. This will cause variation of system pressure, or pressure pulsation. As a result, a receiver should be installed after the compressor to stabilize system pressure.

Like with fans and pumps, compressors are usually sized by graphing the characteristic curve. Discharge pressure, head, or pressure ratio is graphed against inlet flow rate. For dynamic compressors, the graph includes values at various speeds and efficiencies. The system curve(s) is then plotted over the characteristic curve(s) and the intersection is the operating point. Multiple operating points may be encountered. Each stage of compression will have its own characteristic curve, and in an ideal case each stage will operate at a high efficiency.

For dynamic compressors, inlet pressure variation has a direct effect on horsepower. To correctly size the compressor drive, the full range of inlet pressures must be considered as well as discharge pressures. Dynamic compressors are subject to a minimum flow rate called the surge limit. Surge is seen to the left of the characteristic curve(s). The demand limits of the application must be considered and operation below the surge limit prevented.

**Gas Conditioning and Stabilization.**—In order to provide consistent, clean, dry gas supply; dryers, filters, oilers, receivers, silencers, and exhaust cleaners are used to condition and stabilize pressurized gas.

*Filters:* Compressed gas used to perform work normally needs to be very clean to avoid fouling the devices in the system. Filters of various types are employed to clean compressed air. Most manufacturers offer a range of high efficiency coalescing compressed air filters for the removal of water and oil aerosols, solid particulates and micro-organisms, and dust filters for the removal of dry particulate and micro-organisms from industrial compressed air systems. Filters are selected and sized based on what contaminant is to be removed, output cleanliness level, pressure capacity, flow capacity, pressure drop, and mounting method. Filters require regular preventative maintenance.

*Dryers:* Compressed air supplies for pneumatic systems normally have moisture removed to prevent fouling and corrosion of the system components. For this purpose, compressed air dryers are employed. Dryer type and size is selected according to required air quality, pressure, dew point, and delivery volume. There are several types of commercial dryers available: refrigerated, desiccant, membrane, and deliquescent.

A refrigerated dryer uses a compressor, heat exchanger, and refrigerant to pull liquid out of the gas. Normally a coalescing prefilter is installed immediately upstream of a refrigerated dryer to remove lubricating oil and other contaminants that have the potential to foul the dryer's heat exchangers.

A desiccant dryer passes compressed air through a pressure vessel filled with a media such as activated alumina, silica gel, molecular sieve or other desiccant material which pulls water out of the gas. Normally the desiccant can be regenerated.

A membrane dryer requires no electricity to operate. Water vapor permeates a membrane of hollow fibers and is swept out with redirected dry air to exhaust, while the bulk of the dry air is passed back into the pressurized system.

Normally a coalescing prefilter is installed immediately upstream of a membrane dryer to remove lubricating oil and other contaminants that have potential to foul the dryer's membrane.

A deliquescent dryer typically consists of a pressure vessel filled with a hygroscopic media that absorbs water vapor. The media gradually dissolves, or deliquesces. The vessel must be regularly drained and new media must be added.

*Lubricators:* In some cases a small amount of oil or other lubricant is added to the compressed air supply to lubricate components like actuators. Manufacturers will specify whether their components are "oil-free" or not.

Lubricators are often combined with filters and regulators to form filter-regulator-lubricator (FRL) units. Lubricators usually introduce a fine mist of lubricant into the air stream with particles in the micron range.

*Receivers:* Most compressed gas systems have gas introduced in a pulsating supply. Receivers are essentially pressure vessels that act as reservoirs for the compressed gas. These reservoirs act to stabilize the system pressure by absorbing pressure pulsations. They also stabilize the system at times of fluctuating demand by supplying excess gas when demand peaks, and storing it when demand drops. Receivers are most effective when placed close to the pressure source in the system. A pressure regulator is placed after the receiver to provide constant pressure to the downstream components. Secondary receivers are often placed near high demand to further stabilize the system pressure. Receivers may have valves at the bottom where collected condensate may be drained.

*Silencers and Exhaust Cleaners:* When air is the gas employed, it is usually exhausted to atmosphere after it is used to perform work. When compressed air is released, significant noise can be produced. Silencers or mufflers are used to minimize this effect. The most common silencers are sintered metal, and they are very effective. Silencers are chosen based on port size, pressure, flow requirement, construction, material, and noise

reduction level. Exhaust cleaners may be required in some cases where contaminants are present. The proper cleaning system will depend on the contaminant type and level, flow rate, pressure, and construction.

**Nozzles.**—These devices include a restriction through which a gas passes from a region of higher pressure to a region of lower pressure, typically atmospheric. Nozzles are used to accelerate and direct a gas to perform some function. Analysis of nozzles is greatly simplified if one assumes that there is zero heat transfer during discharge, or the discharge is adiabatic. Real nozzles are not adiabatic, but this assumption is generally safe to make. Flow rate of gas through a nozzle is calculated using the following equation:

$$\dot{m} = \rho v_n A_n$$

where  $A_n$  is the cross sectional area of the nozzle,  $v_n$  is velocity through the nozzle, and  $\dot{m}$  is the mass flow rate. In the following equations,  $v_n$  and  $p_n$  are nozzle outlet velocity and exit pressure ( $p_n =$  atmospheric normally),  $v_t$  and  $p_t$  are source (tank) velocity and pressure,  $\gamma$  is specific weight, and  $k$  is the adiabatic exponent given in Table 39. Pressures are absolute.

**Table 39. Adiabatic Gas Exponent and Critical Pressure Ratio**

Gas	$k$	Critical Pressure Ratio	Gas	$k$	Critical Pressure Ratio
Air	1.4	0.528	Nitrogen	1.41	0.527
Ammonia	1.32	0.542	Oxygen	1.4	0.528
Carbon Dioxide	1.3	0.546	Propane	1.15	0.574

Flow rate through a converging nozzle reaches a maximum at a critical pressure ratio. At this ratio, the nozzle velocity is equal to the speed of sound for that gas at those conditions. For subsonic flow, an increase in nozzle cross sectional area causes flow velocity to decrease. For supersonic flow, an increase in nozzle area causes flow velocity to increase. To calculate the critical pressure ratio use the following equation:

$$\left(\frac{p'_n}{p_t}\right)_c = \left(\frac{2}{k+1}\right)^{\frac{k}{k-1}}$$

If a converging nozzle's pressure ratio ( $p_n/p_t$ ) is greater than the critical pressure ratio, use the following equation to calculate flow.

$$W = A_n \sqrt{\frac{p_t \gamma_t 2gk}{k+1} \left(\frac{2}{k+1}\right)^{\frac{2}{k-1}}}$$

where  $W$  is the weight flow rate.

If a converging nozzle is not operating above the critical pressure ratio, then velocity is equal to sonic velocity and the following equations are used:

Pressure at the nozzle throat is equal to the critical pressure:

$$p_n = p'_n = p_t \left(\frac{2}{k+1}\right)^{\frac{k}{k+1}}$$

$$\dot{m} = A_n \sqrt{k p_t \rho_t} \left(\frac{2}{k+1}\right)^{\frac{k+1}{2(k-1)}}$$

where subscript  $i$  indicates inlet conditions,  $\dot{m}$  is the mass flow in kg/s,  $A$  is nozzle area in  $m^2$ , and  $p$  is pressure in Pa.

Flow rate faster than the speed of sound is possible with a converging-diverging nozzle. Analysis of this type of nozzle is beyond the scope of this text.

*Velocity of Escaping Compressed Air:* For a large container with a small orifice or hole from which the air escapes, the velocity of escape (theoretical) may be calculated from the formula:

$$v_2 = \sqrt{2g \cdot \frac{k}{k-1} \cdot 53.3(459.7 + F) \left[ 1 - \left( \frac{p_2}{p_1} \right)^{\frac{k-1}{k}} \right]}$$

In this formula,  $v_2$  = velocity of escaping air in feet per second;  $g$  = acceleration due to gravity, 32.16 feet per second squared;  $k$  = 1.41 for adiabatic expansion or compression of air;  $F$  = temperature, degrees F;  $p_2$  = atmospheric pressure = 14.7 pounds per square inch; and  $p_1$  = pressure of air in container, pounds per square inch. In applying the preceding formula, when the ratio  $p_2/p_1$  approximately equals 0.53, under normal temperature conditions at sea level, the escape velocity  $v_2$  will be equal to the velocity of sound. Increasing the pressure  $p_1$  will not increase the velocity of escaping air beyond this limiting velocity unless a special converging-diverging nozzle design is used rather than an orifice.

The accompanying Table 40 provides velocity of escaping air for various values of  $p_1$ . These values were calculated from the preceding formula simplified by substituting the appropriate constants:

$$v_2 = 108.58 \sqrt{(459.7 + F) \left[ 1 - \left( \frac{14.7}{p_1} \right)^{0.29} \right]}$$

**Table 40. Velocity of Escaping Air at 70-Degrees F**

Pressure Above Atmospheric Pressure			Theoretical Velocity, Feet per Second	Pressure Above Atmospheric Pressure			Theoretical Velocity, Feet per Second
Atmospheres	Inches Mercury	lbs per sq. in.		Atmospheres	Inches Mercury	lbs per sq. in.	
0.010	0.30	0.147	134	0.408	12.24	6.00	769
0.068	2.04	1.00	344	0.500	15.00	7.35	833
0.100	3.00	1.47	413	0.544	16.33	8.00	861
0.136	4.08	2.00	477	0.612	18.37	9.00	900
0.204	6.12	3.00	573	0.680	20.41	10.0	935
0.272	8.16	4.00	650	0.816	24.49	12.0	997
0.340	10.20	5.00	714	0.884	26.53	13.0	1025

The theoretical velocities in Table 40 must be reduced by multiplying by a "coefficient of discharge," which varies with the orifice and the pressure. The coefficients in Table 41 are used for orifices in thin plates and short tubes.

**Table 41. Coefficients of Discharge**

Type of Orifice	Pressures in Atmospheres Above Atmospheric Pressure			
	0.01	0.1	0.5	1
Orifice in thin plate	0.65	0.64	0.57	0.54
Orifice in short tube	0.83	0.82	0.71	0.67

### Vacuum

Vacuum is any pressure lower than atmospheric. It can be measured in psi or Pa as a negative gauge pressure, or as a positive absolute pressure. Other common units for vacuum are inches of mercury (inHg), millimeters of mercury (mmHg), millibar, and torr. A perfect vacuum has zero absolute pressure, or -14.7 psi (-29.92 inHg). Flow in low to medium vacuum (down to  $10^{-4}$  torr) is characterized as viscous flow, while in high (below  $10^{-4}$  torr) and ultra-high vacuum (below  $10^{-8}$  torr) it is characterized as molecular flow.

**Tubing and Fittings for Vacuum Applications.**—Tubing and fittings used for vacuum applications must be rated for vacuum use to prevent collapse. When working with vacuum, the resistance to flow created by tubing and fittings is discussed in terms of conductance. Conductance can be calculated as follows:

$$C = \frac{Q}{\Delta p}$$

where  $C$  is conductance in l/sec,  $p$  is pressure in torr, and  $Q$  is flow rate in torr-l/sec. For dry air at 20°C in the molecular flow region of vacuum, estimate conductance of long tubes as follows:

$$C = 75 \frac{D^3}{L}$$

where  $L$  is tube length in inches,  $D$  is tube inner diameter in inches, and  $C$  is in l/sec.

Effective pumping speed at the end of a tube with conductance  $C$  can be calculated using the following equation:

$$\frac{1}{S_{eff}} = \frac{1}{C} + \frac{1}{S}$$

where  $S$  is the pumping speed of the pump by itself, and  $C$  is conductance of the tube.

The conductance of tubes in series and parallel can be combined according to the following equations.

Conductance changes with pressure, so effective pumping speed is best calculated piecemeal at incremental pressures.

$C_p = C_1 + C_2$  where  $C_p$  is the conductance of tubes 1 and 2 in parallel.

$\frac{1}{C_s} = \frac{1}{C_1} + \frac{1}{C_2}$  where  $C_s$  is the conductance of tubes 1 and 2 in series.

**Vacuum Pumps and Generators.**—Vacuum pumps are essentially compressors in reverse. Where deep or continuous vacuum is required on a large evacuation volume, it is common to use a fast evacuation pump to remove the gas, and then a deep vacuum pump is used to reach the desired vacuum level. Vacuum deeper than -14.7psi (-29.92 inHg) is not possible.

Vacuum generators usually use a venturi to generate vacuum when compressed air is supplied. Single and multi-stage units are widely available to generate vacuum as deep as -25 inHg (-85 kPa). Suction flow for vacuum generators is moderate, with values of 7 SCFM (200 l/min) commercially available. Vacuum generators consume compressed air, so these tend to be more costly to run than vacuum pumps. Vacuum generators are sometimes combined into devices called "vacuum ejectors" which provide a puff of positive air pressure when the vacuum is halted. This provides a positive release function when picking and placing components using vacuum.

*Types of Vacuum Pumps:* Vacuum pumps can employ pistons, vanes, and lobes like compressors or pumps. There are also turbomolecular pumps, diffuser pumps, chemical reaction pumps, gettering pumps, ion pumps, and cryogenic pumps. Vacuum pumps tend to fall into two main categories: transfer pumps and capture pumps.

Coarse vacuum pumps used for rapid evacuation are commonly rotary vane-type positive displacement pumps. These pumps are usually flooded with oil, which lubricates, cools, and seals the pump. The oil is discharged with the gas. To achieve deep vacuum, vane pumps in series are sometimes used, as are screw pumps. Where the presence of oil is objectionable, multi-stage oil-free pumps are employed, but are not as efficient as oil sealed pumps.

Turbomolecular pumps in general use rotors to accelerate gas molecules, similar to centrifugal pumps. Drag pumps are an example of this type of vacuum pump.

Diffuser, or jet pumps are the most commonly used type of vacuum pump for high vacuum applications. In these pumps, a high velocity jet of fluid is used to transfer momentum to gas in a channel. This type of pump can sustain a vacuum level up to 1 torr, but must be used in combination with an evacuation pump. Multi-stage diffuser pumps are available.

Cryogenic pumps cool gases until they condense into a liquid or solid. In practice, a cooled pump is used, rather than cooling an entire reservoir or chamber. Helium is often used as the refrigerant, and cooling to temperatures of 10 Kelvin are possible.

Gettering pumps use specially treated surfaces, called "gettering" surfaces. In vacuum, these surfaces are capable of holding greater amounts of gas than would occupy a section of free space of the same cross sectional area. Ion pumps use electron bombardment to ionize inert gases that would not normally be affected by gettering surfaces.

*Selection Factors:* The type of pump or generator required by an application depends on whether the system must provide rapid evacuation, long term maintenance of vacuum, high suction flow rate, and/or deep vacuum. Diffuser pumps cannot be exposed to gas at atmospheric pressure once they are at operating temperature. To prevent the risk of damage, a system of valves must be engineered to prevent this condition. Filters should always be used with vacuum generators to protect them from contamination.

*Sizing Vacuum Pumps and Generators:* Vacuum pump performance is rated in terms of throughput, pumping speed, and vacuum pressure capability. They are rated for either intermittent or continuous duty. Throughput is the product of volumetric flow rate and pressure. Pumping speed has units of volume/time and is the mean volume flow through the cross section of the inlet port of a vacuum pump.

Determination of the pumping speed is described in ISO 21360-1. Vacuum pump performance curves are plots of pumping speed as a function of inlet pressure. The lowest pressure that can be achieved by a vacuum pump can be calculated using the following equation:

$$p_{\min} = p_0 e^{\left(\frac{-S_{\text{eff}} t}{V}\right)} + \frac{Q_o}{S_{\text{eff}}} + \frac{Q_D}{S_{\text{eff}}} + \frac{Q_K}{S_{\text{eff}}}$$

where  $p_{\min}$  is the deepest vacuum achievable,  $p_0$  is the initial pressure,  $t$  is time,  $S_{\text{eff}}$  is the effective pumping speed, and  $V$  is the evacuation volume.  $Q_o$ ,  $Q_D$ , and  $Q_K$  are outgassing, diffusion, and permeation flow rates.

The time required to reach a certain pressure depends on the pumping speed, the volume being evacuated, and the initial pressure. It can be calculated using the following equation. Effective pumping speed changes as the pressure decreases, so the following equations are best applied piecemeal using pumping speed values at increments as the pressure varies.

$$t = \frac{V}{S_{\text{eff}}} \ln\left(\frac{p_0}{p_1}\right)$$

where  $t$  is pumpdown time,  $V$  is volume,  $S_{\text{eff}}$  is effective pumping speed,  $p_0$  is initial pressure (absolute), and  $p_1$  is final pressure.

Minimum achievable pressure is affected by ambient air pressure according to the following relationship:

$$P'_{\min} = P_{atm} \frac{P_r}{29.92}$$

where  $P'_{\min}$  is the adjusted achievable vacuum (psi),  $P_{atm}$  is atmospheric pressure (psi), and  $P_r$  is the rated achievable vacuum (inHg). Most vacuum pumps are rated at sea level atmospheric pressure.

Vacuum generators are sized according to the level of vacuum required and the required suction flow rate.

Vacuum level generated is often expressed as a percentage of input pressure. Input tube diameter and air pressure must be known. A variety of options are available, including ejection, vacuum monitoring, and valving. Multi-stage generators are used to create deeper vacuum than single stage units. Some vacuum generators are optimized for high flow, while others for deep vacuum. Deep vacuum is desirable when picking up a heavy object with a leak-free seal. High suction flow is desirable when picking up objects where a leak-free seal is not possible.

*Vacuum Accessories:* Many accessories are used with vacuum pumps and generators to filter, regulate, control, exploit, measure, and stabilize vacuum. It is important to note that vacuum rated greases must be used when grease is exposed to vacuum.

*Filters:* Filters are critical when using vacuum, because contaminants can be sucked into the vacuum lines and damage the pump, generator, valve, or other components. Selection is based on body type, tube diameter, and maximum particle size that can pass through the filter. Fine filters are typically used with vacuum systems. They must be regularly replaced or cleaned to prevent clogging.

*Regulators:* Like pressure regulators, these devices are essential for limiting and stabilizing vacuum pressure in a circuit. They may be manually or automatically controlled. These devices are outfitted with a gauge or digital readout. Vacuum regulators are sized with respect to range and accuracy of measurement, maximum flow rate, and port size.

*Valves:* Many pressure valves can be used to control vacuum. However, if the valve uses air pressure to cause switching, an external pilot line with positive pressure must be provided.

*Grippers:* There are a wide variety of grippers available for the purpose of picking up objects with vacuum. Their primary purpose is to provide a leak-free seal to maximize the effect of the vacuum system. Compliant grippers include suction cups, bellows, and vacuum pads of all shapes and sizes. Miniature valves are often used in applications with multiple grippers to restrict flow if no part is present.

*Measurement:* Vacuum gauges and switches are used to measure the level of vacuum. They may be analog or digital, and measure in absolute or gauge pressure.

*Level Compensators:* These compliant devices are used when multiple grippers are employed in picking up a part. They provide some degree of shock and vibration dampening. Level compensators are available in a wide variety of sizes and stroke lengths.

## Abbreviations for Scientific and Engineering Terms

ANSI/ASME Y14.38-2007 (R2013) (Continued)

Indicated horsepower-hour	iph	Pound-force foot	lbr · ft or lb-ft
Intermediate pressure	ip	Pound-force inch	lbr · in or lb-in
Internal	intl	Pound-force per square foot	lbr/ft <sup>2</sup> or psf
Kilovolt-ampere hour	KVA-h or kVah	Pound-force per square inch	lbr/in <sup>2</sup> or psi
Kilowatt-hour meter	kwhm	Pound per horsepower	lb/hp or php
Latitude	lat	Power factor	pf
Least common multiple	lcm	Quart	qt
Liquid	liq	Reactive volt-ampere meter	rva
Logarithm (common)	log	Revolution per minute	r/min or rpm
Logarithm (natural)	ln	Revolution per second	r/s or rps
Low pressure	lp	Root mean square	rms
Lumen per watt	lm/W or lpw	Round	rnd
Magnetomotive force	mmf	Secant	sec
Mathematics (ical)	math	Second	s or sec
Maximum	max	Sine	sin
Mean effective pressure	mep	Specific gravity	sp gr
Melting point	mp	Specific heat	sp ht
Meter	m	Square	sq
Meter-kilogram-second (system)	mks	Square centimeter	cm <sup>2</sup> or sq cm
Microfarad	μF	Square foot	ft <sup>2</sup> or sq ft
Mile	mi	Square inch	in <sup>2</sup> or sq in
Mile per hour	mi/h or mph	Square kilometer	km <sup>2</sup> or sq km
Milliampere	mA	Square root of mean square	rms
Minimum	min	Standard	std
Molecular weight	mol wt	Tangent	tan
Molecule	mo	Temperature	temp
National Electrical Code	NEC	Tensile strength	ts
Ounce	oz	Versed sine	vers
Ounce-inch	oz-in	Volt	V
Pennyweight	dwt	Watt	W
Pint	pt	Watt-hour	Wh
Potential	pot	Week	wk
Potential difference	pd	Weight	wt
Pound	lb	Yard	yd

## Alternative abbreviations conforming to the practice of the International Electrotechnical Commission.

Ampere	A	Kilovolt-ampere	kVA	Microfarad	μF	Volt	V
Ampere-hour	Ah	Kilowatt	kW	Microwatt	μW	Volt-ampere	VA
Coulomb	C			Milliampere	mA	Volt-coulomb	VC
Farad	F	Kilowatt-hour	kWh	Millifarad	mF	Watt	W
Henry	H	Megawatt	MW	Millihenry	mH	Watt-hour	Wh
Joule	J	Megaohm	MΩ	Millivolt	mV		
Kilovolt	kV	Microampere	μA	Ohm	Ω		

Only the most commonly used terms have been included. These forms are recommended for those whose familiarity with the terms used makes possible a maximum of abbreviations. For others, less contracted combinations made up from this list may be used. For example, the list gives the abbreviation of the term "feet per second" as "fps." To some, however, ft per sec will be more easily understood.

Abbreviations should be used sparingly and only where their meaning will be clear. If there is any doubt, then spell out the term or unit of measurement.

The following points are good practice when preparing engineering documentation. Terms denoting units of measurement should be abbreviated in text only when preceded by the amounts indicated in numerals: "several inches," "one inch," "12 in." A sentence should not begin with a numeral followed by an abbreviation. The use of conventional signs for abbreviations in text should be avoided: use "lb," not "#" or "in," not ".

Symbols for the chemical elements are listed in the table on page 368.

## Mathematical Signs and Commonly Used Abbreviations

+	Plus (sign of addition)	$\pi$	Pi (3.1416)
+	Positive	$\Sigma$	Sigma (sign of summation)
-	Minus (sign of subtraction)	$\omega$	Omega
-	Negative	$g$	Acceleration due to gravity (32.16 ft/s <sup>2</sup> or 9.81 m/s <sup>2</sup> )
$\pm$ ( $\mp$ )	Plus or minus (minus or plus)	$i$ (or $j$ )	Imaginary quantity ( $\sqrt{-1}$ )
$\times$	Multiplied by (multiplication sign)	sin	Sine
$\cdot$	Multiplied by (multiplication sign)	cos	Cosine
$\div$	Divided by (division sign)	tan	Tangent
$/$	Divided by (division sign)	cot	Cotangent
:	Is to (in proportion)	sec	Secant
=	Equals	csc	Cosecant
$\neq$	Is not equal to	vers	Versed sine
$\equiv$	Is identical to	covers	Covered sine
$\approx$ or $\cong$	Approximately equals	$\sin^{-1} a$	Angle the sine of which is $a$
>	Greater than	$\arcsin a$ or $\sin^{-1} a$	Angle the sine of which is $a$
<	Less than	$(\sin a)^{-1}$	Reciprocal of $\sin a$ ( $1 \div \sin a$ )
$\geq$	Greater than or equal to	$\sin^n x$	$n$ th power of $\sin x$
$\leq$	Less than or equal to	$\sinh x$	Hyperbolic sine of $x$
$\rightarrow$	Approaches as a limit; implies	$\cosh x$	Hyperbolic cosine of $x$
$\infty$	Varies directly as	$\Delta$	Delta (increment of)
$\therefore$	Therefore	$\delta$	Delta (variation of)
$\therefore$	Therefore	$d$	Differential (in calculus)
$\therefore$	Therefore	$\partial$	Partial differentiation (in calculus)
$\sqrt{a}$	Square root of $a$	$\int$	Integral (in calculus)
$\sqrt[3]{a}$	Cube root of $a$	$\int_a^b$	Integral between the limits $a$ and $b$
$\sqrt[n]{a}$	$n$ th root of $a$ (also $a^{1/n}$ )	$n!$	Factorial, $n(n-1)\dots(2)(1)$ ; $0! = 1$ ; $1! = 1$ Ex: $5! = 5 \times 4 \times 3 \times 2 \times 1 = 120$
$a^2$	$a$ squared (2nd power of $a$ )	$\angle$	Angle
$a^3$	$a$ cubed (3rd power of $a$ )	$\perp$	Right angle
$a^4$	4th power of $a$	$\perp$	Perpendicular to
$a^n$	$n$ th power of $a$	$\Delta$	Triangle
$a^{-n}$	$1 \div a^n$	$\bigcirc$	Circle
$\frac{1}{n}$	Reciprocal value of $n$	$\square$	Parallelogram
log	Logarithm	$^\circ$	Degree (circular arc or temperature)
$\log_e$	Natural or Napierian logarithm	'	Minutes or feet
ln	Natural or Napierian logarithm	"	Seconds or inches
$e$	Base of natural logarithms (2.71828)	$a'$	$a$ prime
lim	Limit value (of an expression)	$a''$	$a$ double prime
$\infty$	Infinity	$a_1$	$a$ sub one
$\alpha$	Alpha	$a_2$	$a$ sub two
$\beta$	Beta	$a_n$	$a$ sub $n$
$\gamma$	Gamma	( )	Parentheses
$\theta$	Theta	[ ]	Brackets
$\phi$	Phi	{ }	Braces
$\mu$	Mu (coefficient of friction)	$ K $	Absolute value of $K$ , size of $K$ irrespective of sign

## Letter Symbols for Mechanics and Time-Related Phenomena

ANSI/ASME Y10.3M-1984

Acceleration, angular	$\alpha$ (alpha)	Height	$h$
Acceleration, due to gravity	$g$	Inertia, moment of	$I$ or $J$
Acceleration, linear	$a$	Inertia, polar (area) moment of <sup>a</sup>	$J$
Amplitude <sup>a</sup>	$A$	Inertia, product (area) moment of <sup>a</sup>	$I_{xy}$
		Length	$L$ or $l$
	$\alpha$ (alpha)	Load per unit distance <sup>a</sup>	$q$ or $w$
	$\beta$ (beta)	Load, total <sup>a</sup>	$P$ or $W$
Angle	$\gamma$ (gamma)	Mass	$m$
	$\theta$ (theta)	Moment of force, including bending moment	$M$
	$\phi$ (phi)	Neutral axis, distance to extreme fiber from <sup>a</sup>	$c$
	$\psi$ (psi)	Period	$T$
Angle, solid	$\Omega$ (omega)	Poisson's ratio	$\mu$ (mu) or $\nu$ (nu)
Angular frequency	$\omega$ (omega)	Power	$P$
Angular momentum	$L$	Pressure, normal force per unit area	$p$
Angular velocity	$\omega$ (omega)	Radius	$r$
Arc length	$s$	Revolutions per unit of time	$n$
Area	$A$	Second moment of area (second axial moment of area)	$I_a$
Axes, through any point <sup>a</sup>	$X-X$ , $Y-Y$ , or $Z-Z$	Second polar moment of area	$I_p$ or $J$
Bulk modulus	$K$	Section modulus	$Z$
Breadth (width)	$b$	Shear force in beam section <sup>a</sup>	$V$
Coefficient of expansion, linear <sup>a</sup>	$\alpha$ (alpha)	Spring constant (load per unit deflection) <sup>a</sup>	$k$
Coefficient of friction	$\mu$ (mu)	Static moment of any area about a given axis <sup>a</sup>	$Q$
Concentrated load (same as force)	$F$	Strain, normal	$\epsilon$ (epsilon)
Deflection of beam, max <sup>a</sup>	$\delta$ (delta)	Strain, shear	$\gamma$ (gamma)
Density	$\rho$ (rho)	Stress, concentration factor <sup>a</sup>	$K$
Depth	$d$ , $\delta$ (delta), or $t$	Stress, normal	$\sigma$ (sigma)
Diameter	$D$ or $d$	Stress, shear	$\tau$ (tau)
Displacement <sup>a</sup>	$u$ , $v$ , $w$	Temperature, absolute <sup>b</sup>	$T$ , or $\theta$ (theta)
Distance, linear <sup>a</sup>	$s$	Temperature <sup>b</sup>	$t$ , or $\theta$ (theta)
Eccentricity of application of load <sup>a</sup>	$e$	Thickness	$d$ , $\delta$ (delta), or $t$
Efficiency <sup>a</sup>	$\eta$ (eta)	Time	$t$
Elasticity, modulus of	$E$	Torque	$T$
Elasticity, modulus of, in shear	$G$	Velocity, linear	$v$
Elongation, total <sup>a</sup>	$\delta$ (delta)	Volume	$V$
Energy, kinetic	$E_k$ , $K$ , $T$	Wavelength	$\lambda$ (lambda)
Energy, potential	$E_p$ , $V$ , or $\Phi$ (phi)	Weight	$W$
Factor of safety <sup>a</sup>	$N$ or $n$	Weight per unit volume	$\gamma$ (gamma)
Force or load, concentrated	$F$	Work	$W$
Frequency	$f$		
Gyration, radius of <sup>a</sup>	$k$

## MEASURING UNITS

## Metric Systems of Measurement

A metric system of measurement was first established in France in the years following the French Revolution, and various systems of metric units have been developed since that time. All metric unit systems are based, at least in part, on the International Metric Standards, which are the meter and kilogram, or decimal multiples or submultiples of these standards.

In 1795, a metric system called the centimeter-gram-second (cgs) system was proposed, and it was adopted in France in 1799. In 1873, the British Association for the Advancement of Science recommended the use of the cgs system, and since then it has been widely used in all branches of science throughout the world. From the base units in the cgs system are derived the following:

*Unit of velocity* = 1 centimeter per second

*Acceleration due to gravity (at Paris)* = 981 centimeters per second per second

*Unit of force* = 1 dyne =  $\frac{1}{981}$  gram

*Unit of work* = 1 erg = 1 dyne-centimeter

*Unit of power* = 1 watt = 10,000,000 ergs per second

Another metric system, called the MKS (meter-kilogram-second) system of units, was proposed by Professor G. Giorgi in 1902. In 1935, the International Electrotechnical Commission (IEC) accepted his recommendation that this system of units of mechanics be linked with the electromagnetic units by the adoption of a fourth base unit. In 1950, the IEC adopted the ampere, the unit of electric current, as the fourth unit, and the MKSA system thus came into being.

A gravitational system of metric units, known as the technical system, is based on the meter, the kilogram as a force, and the second. It has been widely used in engineering. Because the standard of force is defined as the weight of the mass of the standard kilogram, the fundamental unit of force varies due to the difference in gravitational pull at different locations around the earth. By international agreement, a standard value for acceleration due to gravity was chosen (9.81 meters per second squared) that for all practical measurements is approximately the same as the local value at the point of measurement.

**International System of Units (SI).**—The Conférence Générale des Poids et Mesures (CGPM) is the body responsible for all international matters concerning the metric system, which was originally based on the four MKSA units for: length (*meter*), time (*second*), mass (*kilogram*), and electric current (*ampere*). In 1954, a unit for temperature (*kelvin*) and another for luminous intensity (*candela*) were added.

Over the years, these standards have been refined and redefined. In 1960, the CGPM formally renamed the metric system the *Système International d'Unités* (abbreviated SI in all languages). In 1971, the 14th CGPM adopted a seventh base unit, the *mole*, for the amount of substance in a physical sample. In 2011, CGPM stated its intention of defining all seven base units with “the explicit-constant formulation,” where all units would be defined indirectly through their relation to a fundamental physical constant, as had been done for the speed of light. For several more years, only three of the seven *base units*—the meter, candela, and second—were as yet defined in terms of fundamental physical constants. But in May 2019, the other four base units—the mole, ampere, kelvin, and kilogram—were redefined, no longer based on physical objects, but on universal physical constants.

**Table 1. SI Base Units**

Quantity	Name	Symbol
Length	meter	m
Mass	kilogram	kg
Time	second	s
Electric Current	ampere	A
Luminous Intensity	candela	cd
Thermodynamic Temperature	kelvin	K
Amount of Substance	mole	mol

**Definitions of Base Units**

**Meter (m):** The base unit of length, equal to the path length traveled by light in a vacuum during a time interval of  $3.3356410 \times 10^{-9}$  s (derived from the precise measurement of light's speed,  $c = 299,792,458$  m/s). This value was adopted in 1983, based on the newly defined value for the speed of light, made possible by the technology developed at the National Institute of Standards and Technology (NIST).

**Kilogram (kg):** The base unit of mass, related to the most precise measurement to date of the Planck constant  $h$ , which is the energy carried by a photon to its frequency, and measured as  $6.6260702 \times 10^{-34}$  kg m<sup>2</sup>/s<sup>2</sup>. It is with respect to this invariant of nature that the precise standard for the kilogram is given.

**Second (s):** The duration of  $9.1926318 \times 10^9$  periods of the radiation, corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom, is the element used for the atomic clock due to its stability.

**Ampere (A):** The base unit of electric current, measured as current flow per unit of time. One ampere (*amp*) is equal to one coulomb per second. One elementary electric charge ( $e$ ) is equal to  $1.60218 \times 10^{-19}$  coulomb (that is,  $1 \text{ C} = 6.241 \times 10^{18} e$ ).

**Candela (cd):** The base unit for photometry, which is the science of measuring light perceived by the human eye. The candela (cd) is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency  $540 \times 10^{12}$  hertz. The human eye is most sensitive to this frequency (greenish-yellow light). One cd has a radiant intensity of 1/683 watt per steradian.

**Kelvin (K):** The base unit of thermodynamic temperature, defined by taking the fixed numerical value of the Boltzmann constant  $k$  to be  $1.380649 \times 10^{-23}$  J·K<sup>-1</sup>.

**Mole (mol):** The base unit for the amount of a chemical substance consisting of exactly  $6.02214076 \times 10^{23}$  constitutive particles. This number is the Avogadro constant  $N_A = 6.02214076 \times 10^{23}$  mol<sup>-1</sup>. (Previously, 1 mole was linked to the number of atoms in 12.1 g of the carbon-12 isotope.)

From the base units, come the SI derived units, as shown in [Table 2](#).

**Table 2. SI Derived Units**

Quantity	Name	Symbol
Area	square meter	m <sup>2</sup>
Volume	cubic meter	m <sup>3</sup>
Speed, Velocity	meter per second	m/s
Acceleration	meter per second squared	m/s <sup>2</sup>
Wave Number	reciprocal meter	m <sup>-1</sup>
Mass Density	kilogram per cubic meter	kg/m <sup>3</sup>
Specific Volume	cubic meter per kilogram	m <sup>3</sup> /kg
Current Density	ampere per square meter	A/m <sup>2</sup>
Magnetic Field Strength	ampere per meter	A/m
Amount-of-Substance Concentration	mole per cubic meter	mol/m <sup>3</sup>
Luminance	candle per square meter	cd/m <sup>2</sup>
Mass Fraction	kilogram per kilogram	kg/kg

**Table 3. SI Derived Units with Special Names and Symbols**

Quantity	Name and Derived Units	Symbol
Plane Angle	radian, m/m	rad
Solid Angle	steradian, m <sup>2</sup> /m <sup>2</sup>	sr

**Standard of Length and the US Customary Unit System**

Among all units of measure, the history of standard of length traces a clear path from the less scientific approach of physical object standards used in past centuries to the today's precise standards, based on physical constants on an atomic level.

The primary Imperial yard was set by the British Weights and Measures Act of 1824. But it was partially destroyed in a fire in 1834, and replaced by a new standard, made of an alloy of copper, tin, and zinc. Between 1845 and 1855, forty copies of the Imperial yard were cast. Bronze yard No. 11 went to the United States, an exact copy of the British Imperial yard, in both form and material.

By an Act of Congress, in 1866, the US legally recognized the meter as a standard of length equal to  $39/39.37 = 0.9144$  yard; for commercial purposes, 1 meter = 39.37 inches.

The Treaty of the Meter was signed in 1875, and the International Bureau of Weights and Measures (BIPM) in Severs, France, created 30 prototype line standards of platinum iridium. In 1889, United States received Nos. 27 and 21 prototype meters from BIPM. No. 27 was used as a standard for the U.S. metric system from 1889 to 1960, but then a new standard was adopted, based not on an object whose dimensions could change over time but on a physical constant related the number of wavelengths krypton-86 emits during a specific energy level transition. In 1983 the meter was again redefined, described now in terms of the speed of light. In 2019, the standard was once more updated, based on an even more precise measurement of the speed of light. Prototype meter No. 27 is now kept in the NIST museum.

According to U.S. 1988 Law on Metrification, the country would phase out the imperial and US customary unit, replacing them with their metric equivalents. As of 2018, the use of the metric system in trade and commerce was mandatory in all countries except the United States, Myanmar, and Liberia.

The meter has gone through several restandardizations. In 1983, the modern base unit was set as that length equal to the path length traveled by light in a vacuum during a time interval of  $3.3356410 \times 10^{-9}$  second. The new meter represents the most advanced ideas of physical measurement, much like the second is based on the Cs 133 atomic clock.

Each new meter represented the most advanced ideas of standards, so it seemed that greater stability, as well as higher accuracy, would be secured by accepting the international meter as a fundamental standard of length. The director of national standard laboratory of the United States entered into agreement effective July 1, 1959, whereby the equivalent of 1 yard = 0.9144 meter and 1 avoirdupois pound = 0.45359237 kilogram, where adapted. In the United States, the SI metric system of units is predominantly used in the fields of physics, chemistry, and other sciences; however, U.S. customary units are still widely used in industry and by the general public.

### Fundamental Constants

Name	Symbol	USCS units	SI units
Avogadro's number	$N_A$		$6.022 \times 10^{23} \text{ mol}^{-1}$
Boltzman constant	$k$	$5.65 \times 10^{-24} \text{ ft}\cdot\text{lb}_f/\text{°R}$	$1.38065 \times 10^{-23} \text{ J/K}$
Faraday Constant	$F$		96,485 C/mol
Gravitational constant	$g$	$32.174 \text{ lb}_m\text{-ft}/\text{lb}_f\text{-sec}^2$	$9.80667 \text{ m/sec}^2$
Gravitational constant	$G$	$5.65 \times 10^{-24} \text{ ft}\cdot\text{lb}_f/\text{°R}$	$6.672 \times 10^{-11} \text{ N}\cdot\text{m}^2/\text{kg}^2$
Specific gas constant	$R$	$53.3 \text{ ft}\cdot\text{lb}_f/\text{lb}_m\text{-°R}$	287 J/kg·K
Universal gas constant	$R$	$1545 \text{ ft}\cdot\text{lb}_f/\text{lbmol}\text{-°R}$	8314 J/kmol·K
Volume (molal ideal gas)	$V$	$359 \text{ ft}^3/\text{lbmol}$	$22.41 \text{ m}^3/\text{kmol}$
Pressure, atmospheric	$P$	$14.696 \text{ lb}_f/\text{in}^2$	$101,330 \text{ Pa (N/m}^2)$
Temperature, standard	$T$	32°F	0°C
Density			
Air at 32°F (0°C)		$0.0805 \text{ lb}_m/\text{ft}^3$	$1.29 \text{ kg/m}^3$
Air at 70°F (20°C), 1 atm		$0.0749 \text{ lb}_m/\text{ft}^3$	$1.20 \text{ kg/m}^3$
Sea water		$64 \text{ lb}_m/\text{ft}^3$	$1025 \text{ kg/m}^3$
Fresh water		$62.4 \text{ lb}_m/\text{ft}^3$	$1000 \text{ kg/m}^3$
Mercury		$849 \text{ lb}_m/\text{ft}^3$	$13600 \text{ kg/m}^3$
Earth		$345 \text{ lb}_m/\text{ft}^3$	$5520 \text{ kg/m}^3$

*Example:* A tape measure reads 17 feet 8 inches. How many inches is this? *Solution:* Read down the first column of Table 3 to find 10 ft 0 in = 120 inches. Next, find the intersection of the 7 ft row and the 8 inch column to get 92 inches. Add both results to get 120 inches + 92 inches = 212 inches.

*Example:* Convert  $7\frac{3}{4}$  inches to feet. *Solution:* From Table 4, find 70 inches = 5.8333 feet and add to that  $8\frac{3}{4}$  inches = 0.7292 feet found in Table 5 at the intersection of the  $\frac{3}{4}$  inch row and the 8 inch column. Thus,  $7\frac{3}{4}$  inches = 5.8333 + 0.7292 = 6.5625 feet.

<sup>a</sup>Reading left to right from all "Fractional" and "Decimal Inches" columns to "Millimeters" columns: conversion values are exact. Reading right to left from the "Millimeters" columns: whole number millimeters conversions to "Decimal Inches" are rounded to 9 decimal places.

<sup>b</sup>A bar over a group of digits indicates they repeat indefinitely; for example,  $0.08\overline{33} = 0.08333\dots$

**Table 8a. Inches to Millimeters Conversion**

inch	mm	inch	mm	inch	mm	inch	mm	inch	mm	inch	mm
10	254.00000	1	25.40000	0.1	2.54000	.01	0.25400	0.001	0.02540	0.0001	0.00254
20	508.00000	2	50.80000	0.2	5.08000	.02	0.50800	0.002	0.05080	0.0002	0.00508
30	762.00000	3	76.20000	0.3	7.62000	.03	0.76200	0.003	0.07620	0.0003	0.00762
40	1,016.00000	4	101.60000	0.4	10.16000	.04	1.01600	0.004	0.10160	0.0004	0.01016
50	1,270.00000	5	127.00000	0.5	12.70000	.05	1.27000	0.005	0.12700	0.0005	0.01270
60	1,524.00000	6	152.40000	0.6	15.24000	.06	1.52400	0.006	0.15240	0.0006	0.01524
70	1,778.00000	7	177.80000	0.7	17.78000	.07	1.77800	0.007	0.17780	0.0007	0.01778
80	2,032.00000	8	203.20000	0.8	20.32000	.08	2.03200	0.008	0.20320	0.0008	0.02032
90	2,286.00000	9	228.60000	0.9	22.86000	.09	2.28600	0.009	0.22860	0.0009	0.02286
100	2,540.00000	10	254.00000	1.0	25.40000	.10	2.54000	0.010	0.25400	0.0010	0.02540

All values in this table are exact. For inches to centimeters, shift decimal point in mm column one place to left and read centimeters; thus, for example, 40 in. = 1016 mm = 101.6 cm.

**Table 8b. Millimeters to Inches Conversion**

mm	inch	mm	inch	mm	inch	mm	inch	mm	inch	mm	inch
100	3.93701	10	0.39370	1	0.03937	0.1	0.00394	0.01	.00039	0.001	0.0004

500	19.68504	50	1.96850	5	0.19685	0.5	0.01969	0.05	.00197	0.005	0.0020
600	23.62205	60	2.36220	6	0.23622	0.6	0.02362	0.06	.00236	0.006	0.0024
700	27.55906	70	2.75591	7	0.27559	0.7	0.02756	0.07	.00276	0.007	0.0028
800	31.49606	80	3.14961	8	0.31496	0.8	0.03150	0.08	.00315	0.008	0.0031
900	35.43307	90	3.54331	9	0.35433	0.9	0.03543	0.09	.00354	0.009	0.0035
1,000	39.37008	100	3.93701	10	0.39370	1.0	0.03937	0.10	.00394	0.010	0.0039

Based on 1 inch = 25.4 millimeters, exactly. For centimeters to inches, shift decimal point of centimeter value one place to right and enter mm column; thus, for example, 70 cm = 700 mm = 27.55906 inches.

**Table 9. Feet to Millimeters Conversion**

feet	mm	feet	mm	feet	mm	feet	mm	feet	mm
100	30,480	10	3,048	1	304.8	0.1	30.48	0.01	3.048
200	60,960	20	6,096	2	609.6	0.2	60.96	0.02	6.096
300	91,440	30	9,144	3	914.4	0.3	91.44	0.03	9.144
400	121,920	40	12,192	4	1,219.2	0.4	121.92	0.04	12.192
500	152,400	50	15,240	5	1,524.0	0.5	152.40	0.05	15.240
600	182,880	60	18,288	6	1,828.8	0.6	182.88	0.06	18.288
700	213,360	70	21,336	7	2,133.6	0.7	213.36	0.07	21.336
800	243,840	80	24,384	8	2,438.4	0.8	243.84	0.08	24.384
900	274,320	90	27,432	9	2,743.2	0.9	274.32	0.09	27.432
1,000	304,800	100	30,480	10	3,048.0	1.0	304.80	0.10	30.480

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact.

*Example 1:* Convert 293 feet,  $5\frac{7}{64}$  inches to mm.

200 ft	=	60,960.0	mm
90 ft	=	27,432.0	mm
3 ft	=	914.4	mm
5	inch	=	127.0 mm
$\frac{7}{64}$	inch	=	18.653 mm
293 ft $5\frac{7}{64}$ inch	=	89,452.053	mm

*Example 2:* Convert 71.86 feet to mm.

70.0	feet	=	21,336.0	mm
1.0	feet	=	304.8	mm
0.80	feet	=	243.84	mm
<u>0.06</u>	feet	=	<u>18.288</u>	mm
71.86	feet	=	21,902.928	mm

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. *Example:* Convert  $2\frac{21}{64}$  inches to millimeters. *Solution:* From the first page of this table, find 20 inches = 508.0 millimeters and add to that  $1\frac{21}{64}$  inches = 34.528125 millimeters found at the intersection of the 1-inch column and the row containing  $\frac{21}{64}$  inch. Thus,  $2\frac{21}{64}$  inches = 508.0 + 34.528125 = 542.528125 mm, exactly.

Based on 1 inch = 25.4 millimeters, exactly. All values in this table are exact. Use [Table 8a](#) to obtain whole inch and other decimal equivalents to add to decimal equivalents above. *Example:* Convert 10.9983 in. to mm. *Solution:* 10.9983 in. = 254.0 + 25.3492 + 0.00762 = 279.35682 mm.

480	12.192	12.2174	12.2428	12.2682	12.2936	12.319	12.3444	12.3698	12.3952	12.4206
490	12.446	12.4714	12.4968	12.5222	12.5476	12.573	12.5984	12.6238	12.6492	12.6746
500	12.7	12.7254	12.7508	12.7762	12.8016	12.827	12.8524	12.8778	12.9032	12.9286

Use the small table below to convert microinches to micrometers for ranges higher than given in the main table above. Appropriate quantities chosen from both tables are simply added to obtain the higher converted value:

μin.	μm	μin.	μm	μin.	μm	μin.	μm	μin.	μm
600	15.24	800	20.32	1000	25.4	1500	38.1	2100	53.34
700	17.78	900	22.86	1200	30.48	1800	45.72	2400	60.96

Both tables based on 1 microinch = 0.0254 micrometer, exactly. All values in both parts of this table are exact; figures to the right of the last place figures are all zeros.

*Example:* Convert 1375 μin. to μm:

$$\text{From lower portion of Table 13a: } 1200 \mu\text{in.} = 30.48 \mu\text{m}$$

$$\text{From upper portion of Table 13a: } \frac{175 \mu\text{in.}}{1375 \mu\text{in.}} = \frac{4.445 \mu\text{m}}{34.925 \mu\text{m}}$$

Table 13b. Micrometers (Microns) to Microinches Conversion

4.90	192.9134	193.3071	193.7008	194.0945	194.4882	194.8819	195.2756	195.6693	196.0630	196.4567
5.00	196.8504	197.2441	197.6378	198.0315	198.4252	198.8189	199.2126	199.6063	200.0000	200.3937

The table given below can be used with the preceding main table to obtain higher converted values, simply by adding appropriate quantities chosen from each table:

$\mu\text{m}$	$\mu\text{in.}$	$\mu\text{m}$	$\mu\text{in.}$	$\mu\text{m}$	$\mu\text{in.}$	$\mu\text{m}$	$\mu\text{in.}$
10	393.7008	20	787.4016	30	1181.1024	40	1574.8032
15	590.5512	25	984.2520	35	1378.9528	45	1771.6535
						50	1968.5039
						55	2165.3543

Both portions of Table 13b are based on 1 micron = 0.0254 micrometer, exactly.

Example: Convert 23.55  $\mu\text{m}$  to  $\mu\text{in.}$ :

$$\begin{aligned} \text{From above table: } 20.00 \mu\text{m} &= 787.4016 \mu\text{in} \\ \text{From main table: } \frac{3.55 \mu\text{m}}{23.55 \mu\text{m}} &= \frac{139.7638 \mu\text{in}}{927.1654 \mu\text{in}} \end{aligned}$$

1 <i>cubic millimeter</i> = <b>0.001</b> cubic centimeters	
1 <i>hectoliter</i> ( <i>hl</i> ) = <b>100</b> liters	
1 <i>deciliter</i> ( <i>dl</i> ) = <b>10</b> centiliters	
1 <i>centiliter</i> ( <i>cl</i> ) = <b>10</b> milliliters	

## Shipping Measure

For measuring internal capacity of a vessel:

1 *register ton* = 100 cubic feet

For measurement of cargo:

1 *shipping ton* =

Approximately 40 cubic feet of merchandise is considered a shipping ton, unless that bulk would weigh more than 2000 pounds, in which case the freight charge may be based upon weight

40 *cubic feet* =

32.143 US bushels

31.16 Imperial bushels

## British (Imperial) Liquid and Dry Measure

1 <i>British Imperial gallon</i> = 0.1605 cubic foot 277.42 cubic inches 1.2009 US gallon <b>160</b> Imperial fluid ounces <b>4</b> Imperial quarts <b>8</b> Imperial pints <b>4.54609</b> liters
1 <i>quart</i> = <b>2</b> Imperial pints <b>8</b> Imperial gills <b>40</b> Imperial fluid ounces 69.354 cubic inches <b>1.1365225</b> liters
1 <i>pint</i> = <b>4</b> Imperial gills <b>20</b> Imperial fluid ounces 34.678 cubic inches <b>568.26125</b> milliliters
1 <i>gill</i> = <b>5</b> Imperial fluid ounces 8.669 cubic inches 142.07 milliliters

## US Liquid Measure

1 <i>US gallon</i> = 0.13368 cubic foot <b>231</b> cubic inches <b>128</b> US fluid ounces <b>4</b> US quarts <b>8</b> US pints 0.8327 British Imperial gallon <b>3.785411784</b> liters
1 <i>quart</i> = <b>2</b> US pints <b>8</b> US gills <b>32</b> US fluid ounces <b>57.75</b> cubic inches 0.9463529 liters
1 <i>pint</i> = <b>4</b> US gills <b>16</b> US fluid ounces <b>28.875</b> cubic inches 473.176 milliliters
1 <i>gill</i> = <b>1/2</b> cup = <b>4</b> US fluid ounces <b>7.21875</b> cubic inches 118.29 milliliters

Note: Figures in **Bold** indicate exact conversion values

**Pitot Tube.**—A pitot tube is a small, transparent, open tube bent at a right angle. It is a hollow tube that is placed longitudinally in the direction of fluid flow, allowing the flow to enter one end at the fluid's velocity of approach. When the fluids enter the pitot tube, it comes to a stop, and all of the velocity head is converted to pressure head. The difference between the total and static energies is the kinetic energy of the fluid. The velocity of the fluid can be calculated by using the Bernoulli equation.

$$\frac{p_1}{\rho} + \frac{v_1^2}{2} = \frac{p_2}{\rho} \quad v_1 = \sqrt{\frac{2(p_2 - p_1)}{\rho}} \quad (\text{SI}) \quad v_1 = \sqrt{\frac{2(p_2 - p_1)g_c}{\rho}} \quad (\text{US})$$

## Units of Mass and Weight

Table 29. Mass and Weight Conversion Factors

Metric System		Avoirdupois or Commercial Weight	
1 <i>metric ton (t)</i> =		1 <i>gross or long ton</i> =	
<b>1000</b> kilograms		<b>2240</b> pounds	
2204.6223 pounds		1.016 metric ton	
0.9842 gross or long ton (of 2240 pounds)		1016 kilograms	
0.9072 net or short ton (of 2000 pounds)		1 <i>net or short ton</i> = <b>2000</b> pounds	
1 <i>kilogram (kg)</i> =		1 <i>pound</i> = <b>16</b> ounces	
<b>1000</b> grams = <b>10</b> hectograms		<b>7000</b> grains	
2.2046 pounds		<b>0.45359237</b> kilogram	
35.274 ounces avoirdupois		453.6 grams	
1 <i>hectogram (hg)</i> = <b>10</b> dekagrams		1 <i>ounce</i> =	
1 <i>dekagram (dag)</i> = <b>10</b> grams		$\frac{1}{16}$ pound	
1 <i>gram (g)</i> =		16 drachms	
<b>10</b> decigrams		<b>437.5</b> grains	
0.0022046 pound		28,3495 grams	
0.03215 ounce Troy		0.2780139 newton	
0.03527 ounce avoirdupois		1 <i>grain Avoirdupois</i> =	
15.432 grains		<b>1</b> grain apothecaries' weight =	
1 <i>decigram (dg)</i> = <b>10</b> centigrams		<b>1</b> grain Troy weight	
1 <i>centigram (cg)</i> = <b>10</b> milligrams		0.064799 gram	
<b>Troy Weight</b>		<b>Apothecaries' Weight</b>	
Used for Weighing Gold and Silver		1 <i>pound</i> = 12 ounces = 5760 grains	
1 <i>pound Troy</i> =		1 <i>ounce</i> =	
12 ounces Troy = 5760 grains		8 drachms = 480 grains	
$\frac{144}{175}$ avoirdupois pound		31.103 grams	
1 <i>ounce Troy</i> =		1 <i>drachm</i> = 3 scruples = 60 grains	
20 pennyweights = 480 grains		1 <i>scruple</i> = 20 grains	
31.103 grams		<b>Old Weight Measures</b>	
1 <i>pennyweight</i> = 24 grains		Measures for weight seldom used in the United States:	
1 <i>grain Troy</i> =		1 <i>gross or long ton</i> = 20 hundred-weights	
<b>1</b> grain avoirdupois		1 <i>hundred-weight</i> = 4 quarters = 112 pounds	
<b>1</b> grain apothecaries' weight		1 <i>quarter</i> = 28 pounds	
0.0648 gram		1 <i>stone</i> = 14 pounds	
1 <i>carat (used in weighing diamonds)</i> =		1 <i>quintal</i> = 100 pounds	
3.086 grains			
<b>200</b> milligrams = $\frac{1}{5}$ gram			
1 <i>gold karat</i> = $\frac{1}{24}$ proportion pure gold			

Note: Figures in **Bold** indicate exact conversion values

1 newton-meter = 8.850748 pound-inches

**Poundal.**—The expression “poundal” is sometimes used in connection with calculations in mechanics. Many mechanical handbooks, however, do not define it, because of its limited use. A poundal is a unit of force and is defined as that force which, acting on a mass of one pound for one second, produces a velocity of one foot per second. A foot-poundal is a unit of energy equal to the energy resulting when a force of one poundal acts through a distance of one foot. In order to reduce foot-poundals to foot-pounds, multiply the number of foot-poundals by 0.03108. Dividing the number of foot-poundals by 32.16 (acceleration due to gravity) will also give foot-pounds.

### Units of Energy, Power, and Heat

**Table 44a. Energy Conversion Factors**

1 <i>horsepower-hour</i> =	0.746 kilowatt-hour	1,980,000 foot-pounds	2545 Btu (British thermal units)	2.64 pounds of water evaporated at 212°F	17 pounds of water raised from 62° to 212°F
1 <i>kilowatt-hour</i> =	1000 watt-hours	1.34 horsepower-hour	2,655,200 foot-pounds	3,600,000 joules	3415 Btu
				3.54 pounds of water evaporated at 212°F	22.8 pounds of water raised from 62° to 212°F

**Conduction.**—Whenever the molecules of a working substance, whether liquid, solid, or vapor, are restrained so that no appreciable relative translatory motion occurs among them, the kinetic energies of the various molecules will be largely due to vibration. If a temperature difference exists in the working substance, some adjacent molecules will necessarily be at different temperatures, hence will possess different degrees of vibratory motion. In this case the molecule which is vibrating most rapidly will transfer some of its motion to the slower-moving molecule next to it, the one then undergoing a decrease in temperature and the other an increase. In this way, thermal energy will be transferred by the mechanism of conduction from the region of higher to the region of lower temperature. The process will continue spontaneously until the entire system has reached a uniform equilibrium temperature.

In contrast to radiation, conduction only occurs when a working substance is present and when the molecules of that working substance remain practically fixed positions with respect to one another. Thus, conductive heat flow would always occur through solids, but would take place in liquids and vapors only if special conditions prevented or greatly reduced the normal translatory motion of the molecules within these materials.

**Fuel Oil, Coal, and Gas.**—One gallon of fuel oil equals 13.1 pounds of coal, equals 160 cubic feet of natural gas. One barrel of fuel oil equals 0.278 ton of coal, equals 6806 cubic feet of natural gas. One pound of fuel oil equals 1.75 pounds of coal, equals 21.3 cubic feet of natural gas. One pound of coal equals 0.763 gallon of oil, equals 12.2 cubic feet of natural gas. One ton of coal equals 3.6 barrels of oil, equals 24,500 cubic feet of natural gas. The heating value of the average mid-continent fuel oil having a Baume gravity of 26.9 is 19,376 British thermal units per pound of oil, and 143,950 British thermal units per gallon of oil. The specific gravity and the heat value may be expressed approximately by means of a simple formula, as follows: BTU per pound =  $18,650 + 40 \times (\text{Degrees Baume} - 10)$ .

## Units of Temperature

There are two thermometer scales in general use: the Fahrenheit ( $^{\circ}\text{F}$ ), which is used in the United States and in other countries still using the English system of units, and the Celsius ( $^{\circ}\text{C}$ ) or Centigrade used throughout the rest of the world.

In the Fahrenheit thermometer, the freezing point of water is marked at 32 degrees on the scale and the boiling point, at atmospheric pressure, at 212 degrees. The distance between these two points is divided into 180 degrees. On the Celsius scale, the freezing point of water is at 0 degree and the boiling point at 100 degrees. The following formulas may be used for converting temperatures given on any one of the scales to the other scale:

$$^{\circ}\text{F} = \frac{9}{5}^{\circ}\text{C} + 32 \quad \text{C} = \frac{5}{9}(^{\circ}\text{F} - 32)$$

Tables on the pages that follow can be used to convert degrees Celsius into degrees Fahrenheit or vice versa, and to convert the absolute temperatures of Kelvin and Rankine scales. In the event that the conversions are not covered in the tables, use those applicable portions of the formulas given above and in Table 52 for converting.

Table 52. Temperature Conversion Formulas

To Convert	To	Use Formula	To Convert	To	Use Formula
Celsius, $t_C$	K, $t_K$	$t_K = t_C + 273.15$	Kelvin, $t_K$	$^{\circ}\text{C}, t_C$	$t_C = t_K - 273.15$
	$^{\circ}\text{F}, t_F$	$t_F = 1.8t_C + 32$		$^{\circ}\text{F}, t_F$	$t_F = 1.8t_K - 459.67$
	$^{\circ}\text{R}, t_R$	$t_R = 9(t_C + 273.15)/5$		$^{\circ}\text{R}, t_R$	$t_R = 9/5 \times t_K$
Fahrenheit, $t_F$	K, $t_K$	$t_K = (t_F + 459.67)/1.8$	Rankine, $t_R$	K, $t_K$	$t_K = 5/9 \times t_R$
	$^{\circ}\text{C}, t_C$	$t_C = (t_F - 32)/1.8$		$^{\circ}\text{C}, t_C$	$t_C = 5/9 \times t_R - 273.15$
	$^{\circ}\text{R}, t_R$	$t_R = t_F + 459.67$		$^{\circ}\text{F}, t_F$	$t_F = t_R - 459.67$

Kelvin temperatures are expressed by K without use of the degree symbol ( $^{\circ}$ ).

**Absolute Temperature and Absolute Zero.**—A point has been determined on the thermometer scale, by theoretical considerations, that is called the *absolute zero* and beyond which a further decrease in temperature is inconceivable. This point is located at  $-273.15$  degrees Celsius or  $-459.67$  degrees F. A temperature reckoned from this point, instead of from the zero on the ordinary thermometers, is called absolute temperature. The absolute temperature scale corresponding to Celsius is the Kelvin scale; the absolute scale corresponding to Fahrenheit is the Rankine. 0 K and 0  $^{\circ}\text{R}$  are both absolute zero. Conversions from Celsius and Fahrenheit are obtained as follows:

$$\text{K} = ^{\circ}\text{C} + 273.15 \quad ^{\circ}\text{R} = ^{\circ}\text{F} + 459.67$$

**Measures of the Quantity of Thermal Energy.**—The unit of quantity of thermal energy used in the United States is the British thermal unit, which is the quantity of heat or thermal energy required to raise the temperature of one pound of pure water one degree F. (American National Standard abbreviation, Btu; conventional British symbol, B.Th.U.) The French thermal unit, or *kilogram calorie*, is the quantity of heat or thermal energy required to raise the temperature of one kilogram of pure water one degree C. One kilogram calorie = 3.968 British thermal units = 1000 gram calories. The number of foot-pounds of mechanical energy equivalent to one British thermal unit is called the *mechanical equivalent of heat* and equals 778 foot-pounds.

In the modern metric or SI system of units, the unit for thermal energy is the *joule* (J); a commonly used multiple being the kilojoule (kJ), or 1000 joules. See page 2831 for an explanation of the SI system. One kilojoule = 0.9478 Btu. Also in the SI system, the *watt* (W), equal to joule per second (J/s), is used for power, where 1 watt = 3.412 Btu per hour.

Table converts °C → °F and °R, or °F → °C and K. Find "convert from" temperature in **bold** column and read result from °F and °R or °C and K columns. *Example 1:* 183 °C = 361.4 °F and 821.1 °R. *Example 2:* 183 °F = 83.9 °C and 357.0 K.

Stoke (S)	$\frac{\text{cm}^2}{\text{s}}$	ρ	100ρ	$1.45 \times 10^{-5} \rho$	<b>1</b>	100
Centistoke (v)	$\frac{\text{cm}^2}{100\text{s}}$	0.01ρ	ρ	$1.45 \times 10^{-7} \rho$	0.01	<b>1</b>

Table 56b. Additional Viscosity Conversion Factors

Multiply	By	To Obtain	Multiply	By	To Obtain
centipoise	<b>0.001</b>	pascal-second (Pa-s)	pascal-second	<b>1000</b>	centipoise
centistoke	<b>0.000001</b>	meter <sup>2</sup> /second (m <sup>2</sup> /s)	pascal-second	<b>10</b>	poise
stoke	<b>0.0001</b>	meter <sup>2</sup> /second (m <sup>2</sup> /s)	poise	<b>0.1</b>	pascal-second (Pa-s)

ρ = Specific gravity of the oil.

Figures in **bold face** indicate the conversion is exact

## Units of Moment of Inertia and Momentum

Table 57. Moment of Inertia Conversion Factors

Multiply	By	To Obtain
Moment of Inertia and Section Modulus		
moment of inertia [ $\text{kg}\cdot\text{m}^2$ ]	23.73036	pound-foot <sup>2</sup>
moment of inertia [ $\text{kg}\cdot\text{m}^2$ ]	3417.171	pound-inch <sup>2</sup>
moment of inertia [ $\text{lb}\cdot\text{ft}^2$ ]	0.04214011	kilogram-meter <sup>2</sup> ( $\text{kg}\cdot\text{m}^2$ )
moment of inertia [ $\text{lb}\cdot\text{inch}^2$ ]	0.0002926397	kilogram-meter <sup>2</sup> ( $\text{kg}\cdot\text{m}^2$ )
moment of section [foot <sup>4</sup> ]	0.008630975	meter <sup>4</sup> ( $\text{m}^4$ )
moment of section [inch <sup>4</sup> ]	41.62314	centimeter <sup>4</sup>
moment of section [meter <sup>4</sup> ]	115.8618	foot <sup>4</sup>
moment of section [centimeter <sup>4</sup> ]	0.02402510	inch <sup>4</sup>
section modulus [foot <sup>3</sup> ]	0.02831685	meter <sup>3</sup> ( $\text{m}^3$ )
section modulus [inch <sup>3</sup> ]	0.00001638706	meter <sup>3</sup> ( $\text{m}^3$ )
section modulus [meter <sup>3</sup> ]	35.31466	foot <sup>3</sup>
section modulus [meter <sup>3</sup> ]	61,023.76	inch <sup>3</sup>

Table 58. Momentum Conversion Factors

Multiply	By	To Obtain
Momentum		
kilogram-meter/second	7.233011	pound-foot/second
kilogram-meter/second	86.79614	pound-inch/second
pound-foot/second	0.1382550	kilogram-meter/second ( $\text{kg}\cdot\text{m/s}$ )
pound-inch/second	0.01152125	kilogram-meter/second ( $\text{kg}\cdot\text{m/s}$ )

## Miscellaneous Measuring Units

1 *great gross* = 12 gross = 144 dozen1 *gross* = 12 dozen = 144 units1 *dozen* = 12 units1 *quire* = 24 sheets1 *ream* = 20 quires = 480 sheets1 *ream printing paper* = 500 sheets1 *score* = 20 units

**Ohm's Law.**—The following figure represents basic electrical relationships. This chart has been formatted in such a way that each variable has been related to the other three variables. This figure is simply for reference.

Circular Model of Electrical Relations

Key to variables:

V = Voltage (Volts)

R = Resistance (Ohms)

I = Current (Amps)

W = Power (Watts)

**Windchill Temperature.**—Windchill temperature is a measure of the combined cooling effect of wind and temperature. The formula below is used for calculating windchill by the National Weather Service (NWS) in the United States:

$$\text{Windchill Temperature } ^\circ\text{F} = 35.74 + 0.6215T - 35.75(V^{0.16}) + 0.4275T(V^{0.16})$$

where  $T$  = air temperature in  $^\circ\text{F}$

$V$  = wind speed in miles per hour (mph) measured at NWS standard height, 33 feet

The formula calculates the chilling effect of wind on the human body at 5 feet above the ground and assumes no influence caused by sunlight (that is, as if the temperature and wind speed measurements were made at night in clear sky conditions). Windchill temperature is only defined for temperatures at or below 50 degrees F and wind speeds above 3 mph. Bright sunshine may increase the windchill temperature by 10 to 18 degrees F.

#### Wind Velocity to Pressure

$V$	$P$	$V$	$P$	$V$	$P$
5	0.1	35	4.9	65	16.9
10	0.4	40	6.4	70	19.6
15	0.9	45	8.1	75	22.5
20	1.6	50	10.0	80	25.6
25	2.5	55	12.1	100	40.0
30	3.6	60	14.4		

The formula is  $P = 0.004V^2$  where  $V$  = wind velocity, mph;  $P$  = pressure, lbs/sq ft.

#### Phonetic Alphabet

A Alfa	J Juliett	S Sierra	1 One
B Bravo	K Kilo	T Tango	2 Two
C Charlie	L Lima	U Uniform	3 Three
D Delta	M Mike	V Victor	4 Four
E Echo	N November	W Whiskey	5 Five
F Foxtrot	O Oscar	X X-Ray	6 Six
G Golf	P Papa	Y Yankee	7 Seven
H Hotel	Q Quebec	Z Zulu	8 Eight
I India	R Romeo	0 Zero	9 Nine

**Daylight Savings Time.**—The Congress of the United States of America extended Daylight Savings Time (DST) by about a month, effective from 2007. Before 2007, DST began at 2:00 AM on the first Sunday in April and ended at 2:00 AM on the last Sunday in October.

Beginning 2007, DST begins at 2:00 AM on the second Sunday in March and ends at 2:00 AM on the first Sunday in November.

**Bel.**—The *bel* is the fundamental division of a logarithmic scale for expressing the ratio of two amounts of power. The number of bels denoting such a ratio is the logarithm to the base 10 of this ratio. Thus, if  $P_1$  and  $P_2$  are two amounts of power, and  $N$  the number of bels denoting their ratio, then  $N = \log \frac{P_1}{P_2}$  bels.

The *decibel* is one-tenth of a bel and is commonly abbreviated as db. This unit is used extensively in the measurement of sound volume in telephone and radio transmission and reception, and in noise measurements of various kinds.

   grinding 1067–1068  
   groove type 838  
   light cuts 839  
   parallel shoulder type 838  
 Chip flow angle 1203  
 Chip thickness 1196, 1261  
 Chord  
   length for given number of divisions 711  
   length given angle and radius 79, 83, 84–85  
 Chordal addendum 2205, 2224  
   milled, full-depth gear teeth 2222  
   milled bevel gear teeth 2268  
 Chordal distance of bolt circle 82, 711  
 Chordal thickness 2205  
   gear teeth 2221, 2223, 2267  
   milled, full-depth gear teeth 2222, 2223  
   milled bevel gear teeth 2268  
 Chords and diameters of circles 5  
 Chrome 1641  
 Chromium  
   gearing material 2321  
   plating 1609  
   tool steels 447  
 Chucking reamers 909  
   expansion 919  
   rose 910  
 Chucks  
   drill, tapers and threads for 1026  
   hexagonal, for portable tools 1040  
   spindle, for portable tool grinders 1037  
 Circle 49–51  
   center 49  
   chords for dividing circumference of 711  
   general equation 49  
   geometry of 64–65  
   lengths of chords for dividing 711  
   moments of inertia 244  
   radius 49  
   radius of gyration 244
