

**Line Conventions and Drawings.**—American National Standard ANSI/ASME Y14.2-2014 establishes line and lettering practices for engineering drawings. The line conventions and the symbols for section lining are as shown in [Table 2](#) and [Table 3](#).

Approximate width of THICK lines for metric drawings is 0.6 mm, and for inch drawings, 0.032 inch. Approximate width of THIN lines for metric drawings is 0.3 mm, and for inch drawings, 0.016 inch. These approximate line widths are intended to differentiate between THICK and THIN lines and are not values influencing acceptance or rejection of drawings. Basic line conventions in ISO are established in ISO 128-20: 1996. Lines intended to comply with ISO standards use widths of 0.13 mm, 0.18 mm, 0.25 mm, 0.35 mm, 0.5 mm, 0.7 mm, 1 mm, 1.4 mm and 2 mm, but again may deviate as long as lines are consistent in width and it is possible to differentiate “unambiguously” between two adjacent lines with different widths.

Note: This table includes the most commonly used symbols; for additional symbols, refer to the standard.

**Surface Texture Symbols.**—A detailed explanation of the use of surface-texture symbols from American National Standard ANSI/ASME Y14.36 begins on page 815, while ISO surface-texture techniques, standardized in ISO 1302, are explained beginning on page 822.

**Geometric Dimensioning and Tolerancing (GD&T).**—ASME Y14.5-2018, “Dimensioning and Tolerancing,” covers dimensioning, tolerancing, and similar practices for engineering drawings and related documentation. The mathematical definitions of dimensioning and tolerancing principles are given in the standard ANSI/ASME Y14.5.1M-1994 (R2012). ISO standards ISO 8015, ISO 1101 and ISO 26921 contain a detailed explanation of ISO geometric dimensioning and tolerancing practices. Those ISO practices involving GD&T and other selected ISO standard practices are shown in contrast to ANSI/ASME practices where applicable.

Geometric dimensioning and tolerancing provides a comprehensive system for symbolically defining the geometrical tolerance zone within which features must be contained. It provides an accurate transmission of design specifications among the three primary users of engineering drawings: design, manufacturing, and quality assurance groups. Some techniques introduced in ASME Y14.5-2018 have been accepted by ISO. These techniques include projected tolerance zone, the three-plane datum concept, total runout tolerance, multiple datums, and datum targets. Although Y14.5 follows ISO practice closely, there are still differences between ISO and US practice. Summaries of commonly used symbols in ASME Y14.5 and ISO standards are given in Table 4 and Table 5, respectively.

One major area of disagreement is the ISO “principle of independency” versus the “Taylor principle.” Y14.5 and standard US practice both follow the Taylor principle, in which a geometric tolerancing zone may not extend beyond the boundary (or envelope) of perfect form at MMC (maximum material condition). This boundary is prescribed to control variations as well as the size of individual features. The US definition of independency further defines features of size as being independent and not required to maintain a perfect relationship with other features. The “envelope principle” is optional in treatment of these principles. A summary of the application of ASME geometric control symbols and their use with basic dimensions and modifiers is given in Table 6.

ASME Y14.5 features metric SI units (the International System of Units), but customary units may be used without violating any principles. On drawings where all dimensions are either in millimeters or in inches, individual identification of linear units is not required. However, the drawing should contain a note stating “*Unless otherwise specified, all dimensions are in millimeters*” (or *in inches*, as applicable). According to Y14.5, all dimensions are applicable at a temperature of 20°C (68°F) unless otherwise specified. Compensation may be made for measurements taken at other temperatures.

Angular units are expressed in degrees and decimals of a degree (35.4) or in degrees (°), minutes (′), and seconds (″), as in 35° 25′ 10″. Where decimal degrees less than one are specified, a zero shall precede the decimal value. A 90-degree angle is implied where center lines and depicting features are shown on a drawing at right angles and no angle is specified. A 90-degree BASIC angle applies where center lines of features in a pattern or surface shown at right angles on a drawing are located or defined by basic dimensions and no angle is specified.

Basic to all US practice is that orthographic drawing views are arranged in 3rd angle projection while Europe and Asia generally follow ISO practices that default to 1st angle projection. In 1st angle projection, the orientation of the views is reversed from US practice. See Fig. 1a for 3rd angle projection and Fig. 1b for 1st angle projection. Note the graphical symbol at the bottom of each, which indicates the projection system in use for the drawing. ANSI, ASME and ISO practice allow the other projection system, but the use of non-default practice must be declared by use of the graphical symbol.

**Table 6. ASME Geometric Control Symbols ASME Y14.5-2018**

Type <sup>a</sup>	Geometric Characteristics		Pertains To	Basic Dimensions	Feature Modifier	Datum Modifier
Form	—	Straightness	Only individual feature	Not applicable	See Note 1	No datum
	▭	Flatness			Modifier not applicable	
	○	Circularity				
	⊘	Cylindricity				
Profile	⌒	Profile of a Line	Individual or related	Yes if related	See Note 1	See Note 1
	⌒	Profile of a Surface				
Orientation	∠	Angularity	Always related feature(s)	Yes	See Note 1	See Note 1
	⊥	Perpendicularity		Not applicable		
	∥	Parallelism		Yes		
Location	⊕	Position		Yes		
Runout	↗	Circular Runout <sup>b</sup>		Not applicable	Only RFS	
	↗↘	Total Runout <sup>b</sup>				

Note 1: Default RFS unless MMC or LMC explicitly stated.

<sup>a</sup>Five types of geometric control, when datums are indicated, when basic dimensions are required, and when MMC and LMC modifiers may be used.

<sup>b</sup>Arrowheads may be filled in or not.

### ANSI/ASME and ISO Orthographic Projections

Fig. 1a. ANSI/ASME—Orthographic Projection Following Third Angle Projection

Fig. 1b. ISO—Orthographic Projection Following First Angle Projection

US ASME Y14.5-2018 and ISO practice use a preceding 0 before millimeter dimension values less than 1. Unlike US practice, ISO requires a comma as a decimal placeholder where US practice would use a decimal point, compare Fig. 2a and Fig. 2c. For decimal inch dimensioning, a zero is NOT used before the decimal for values less than 1 inch, Fig. 2b.

Fig. 2a. US Practice,  
Metric Dimensions

Fig. 2b. US Practice,  
Inch Dimensions

Fig. 2c. ISO Practice

When dimensioning per US default practice, unless otherwise specified, dimension lines are broken and dimension text remains horizontal, hence read from the bottom of the drawing, see Fig. 3a. ISO dimensioning practices default to aligned text with dimensions placed above an unbroken dimension line, see Fig. 3b.

Fig. 3a. Default US Practice

Fig. 3b. Default ISO Practice

### Standard Drafting Definitions

The following terms are defined as their use applies to ASME Y14.5. Where ISO practice in actual use differs, the definitions are expanded to clarify the contrasting practices.

**Datum Feature:** The feature of a part that is used to establish a datum, identified with either a datum feature or datum target symbols, see Fig. 4.

Fig. 4. Datum Feature Symbol

**Datum Identifier:** The graphic symbol on a drawing used to indicate the datum feature.

**Specified Datum Feature:** A datum is the origin from which the location or other geometric characteristics of features of a part are established.

**Datum Reference Frame:** Sufficient features on a part are chosen to position the part in relationship to as many as three planes. The three planes are mutually perpendicular and together are called the datum reference frame. The planes follow an order of precedence and allow the part to be immobilized. This immobilization in turn creates measurable relationships among features.

**Datum Simulator:** Formed by the datum feature contacting a precision surface such as a surface plate, gage surface or by a mandrel contacting the datum. Thus, the plane formed

by contact restricts motion and constitutes the specific reference surface from which measurements are taken and dimensions verified. The datum simulator is the practical embodiment of the datum feature during manufacturing and quality assurance.

*Datum Target:* A specified point, line, or area on a part, used to establish a datum; see page 631.

*Degrees of Freedom:* The six directions of movement or translation are called degrees of freedom in a three-dimensional environment. They are up-down, left-right, fore-aft, roll, pitch, and yaw, see Fig. 5.

Fig. 5. Degrees of Freedom (Movement) that Must be Controlled, Depending on the Design Requirements

*Dimension, Basic:* A numerical value used to describe the theoretically exact size, orientation, location, or optionally, the profile, of a feature or datum or datum target. Basic dimensions are indicated by a rectangle around the dimension and are not toleranced directly or by default, see Fig. 6. The specific dimensional limits are determined by the permissible variations as established by the tolerance zone specified in the feature control frame. A dimension is only considered basic for the geometric control to which it is related.

Fig. 6. Basic Dimensions

*Dimension, Origin:* A symbol used to indicate the origin and direction of a dimension between two features. The dimension originates from the symbol with the dimension tolerance zone being applied at the other feature, see Fig. 7.

*Dimension, Reference:* A dimension, usually without tolerance, used for information purposes only. Considered to be auxiliary information and not governing production or inspection operations. A reference dimension is a repeat of a dimension or is derived from a calculation or combination of other values shown on the drawing or on related drawings.

*Feature Control Frame [Tolerance Frame]:* Specification on a drawing that indicates the type of geometric control for the feature, the tolerance for the control, and the related datums, if applicable, see Fig. 8.

*Feature:* The general term applied to a physical portion of a part, such as a surface, hole, pin, tab, or slot. In ISO practice, depending on how the tolerance frame leader line is attached to the feature, different interpretations may be invoked as to whether the reference is to a line or surface, or an axis or median planer.

Fig. 7. Dimension Origin Symbol

Fig. 8. Feature Control Frame and Datum Order of Precedence

When an ISO tolerance frame leader line terminates on the outline of the feature, it indicates that the control is a line or the surface itself (Fig. 9a.) When an ISO tolerance frame leader line terminates on a dimension, the axis or medium plane of the dimensioned feature is being controlled. Either inside or outside dimension lines may be used (Fig. 9b.)

Fig. 9a. ISO Tolerance Frame Leader Line Terminating on the Outline of the Feature

Fig. 9b. ISO Tolerance Frame Leader Line Terminating on a Dimension

**Feature of Size, Regular:** One cylindrical or spherical surface, a circular element, and a set of two opposed parallel elements or opposed parallel surfaces, each of which is associated with a directly tolerated dimension.

**Feature of Size, Irregular:** A directly tolerated feature or collection of features that may contain or be contained by an actual mating envelope that is a) a sphere, cylinder, or pair of parallel planes; or b) other than a sphere, cylinder, or pair of parallel planes.

**Least Material Boundary (LMB):** The limit defined by a tolerance or combination of tolerances that exist on or inside the material of a feature or features.

**Least Material Condition (LMC):** The condition in which a feature of size contains the least amount of material within the stated limits of size, for example, upper limit or maximum hole diameter and lower limit or minimum shaft diameter.

**Limits, Upper and Lower (UL and LL):** The arithmetic values representing the maximum and minimum size allowable for a dimension or tolerance. The upper limit represents the maximum size allowable. The lower limit represents the minimum size allowable.

**Maximum Material Boundary (MMB):** The limit defined by a tolerance or combination of tolerances that exist on or outside the material of a feature or features.

**Maximum Material Condition (MMC):** The condition in which a feature of size contains the maximum amount of material within the stated limits of size. For example, the lower limit of a hole is the minimum hole diameter. The upper limit of a shaft is the maximum shaft diameter.

**Position:** Formerly called true position, position is the theoretically exact location of a feature established by basic dimensions. In ISO practice a basic dimension is called a theoretically exact dimension (TED). A positional tolerance is indicated by the position symbol, a tolerance value, applicable material condition modifiers, and appropriate datum references placed in a feature control frame.

**Regardless of Feature Size (RFS):** The term used to indicate that a geometric tolerance or datum reference applies at any increment of size of the feature within its tolerance limits. RFS is the default condition unless MMC or LMC is specified. The concept is now the default in ASME Y14.5-2018, unless specifically stated otherwise. Thus the symbol for RFS is no longer supported in ASME Y14.5-2018.

**Regardless of Material Boundary (RMB):** indicates that a datum feature simulator progresses from MMB toward LMB until it makes maximum contact with the extremities of a feature(s). See *Datum Simulator* on page 627.

**Size, Actual:** The term indicating the size of a feature as produced.

**Tolerance Zone Symmetry:** In geometric tolerancing, the tolerance value stated in the feature control frame is always a single value. Unless otherwise specified, it is assumed that boundaries created by the stated tolerance are bilateral and equidistant about the perfect form control specified. See Fig. 10a for default zone. If desired, the tolerance may be specified as unilateral or unequally bilateral. See Fig. 10b and Fig. 10c for external and internal unilateral zones, and Fig. 10d for an example of a bilateral asymmetrical zone.

### Tolerance Zone Symmetry Examples

Fig. 10a. Default Symmetrical Tolerance Zone About Perfect Form

Fig. 10b. External Unilateral Tolerance Zone About Perfect Form

Fig. 10c. Internal Unilateral Tolerance Zone About Perfect Form

Fig. 10d. Bilateral Asymmetrical Tolerance Zone About Perfect Form

\* Added for clarification and is not part of the specification.

**Tolerance, Bilateral:** A tolerance where variation is permitted in both directions from the specified dimension. Bilateral tolerances may be equal or unequal.

*Tolerance, Geometric:* The general term applied to the category of tolerances used to control form, profile, orientation, location, and runout.

*Tolerance, Unilateral:* A tolerance where variation is permitted in only one direction from the specified dimension.

*True Geometric Counterpart:* Theoretically perfect plane of a specified datum feature.

*Virtual Condition:* A constant boundary generated by the collective effects of the feature size, its specified MMC or LMC material condition, and the geometric tolerance for that condition.

**Datum Referencing.**—A datum indicates the origin of a dimensional relationship between a toleranced feature and a designated feature or features on a part. The designated feature serves as a datum feature, whereas its true geometric counterpart establishes the datum plane. Because measurements cannot be made from a true geometric counterpart, which is theoretical, a datum is assumed to exist in and be simulated by the associated processing equipment.

For example, machine tables and surface plates, although not true planes, are of such quality that they are used to simulate the datums from which measurements are taken and dimensions are verified. When magnified, flat surfaces of manufactured parts are seen to have irregularities, so that contact is made with a datum plane formed at a number of surface extremities or high points. Sufficient datum features, those most important to the design of the part, are chosen to position the part in relation to a set of three mutually perpendicular planes, the datum reference frame. This reference frame exists only in theory and not on the part. Therefore, it is necessary to establish a method for simulating the theoretical reference frame from existing features of the part. This simulation is accomplished by positioning the part on appropriate datum features to adequately relate the part to the reference frame and to restrict the degrees of freedom of the part in relation to it.

These reference frame planes are simulated in a mutually perpendicular relationship to provide direction as well as the origin for related dimensions and measurements. Thus, when the part is positioned on the datum reference frame (by physical contact between each datum feature and its counterpart in the associated processing equipment), dimensions related to the datum reference frame by a feature control frame are thereby mutually perpendicular. This theoretical reference frame constitutes the three-plane dimensioning system used for datum referencing.

Depending on the degrees of freedom that must be controlled, a simple reference frame may suffice. At other times, additional datum reference frames may be necessary where physical separation occurs or the functional relationship of features requires that datum reference frames be applied at specific locations on the part. Each feature control frame must contain the datum feature references that are applicable.

*Datum Targets:* Datum targets are used to establish a datum plane. They may be points, lines or surface areas. Datum targets are used when the datum feature contains irregularities, other features block the surface or the entire surface cannot be used. Examples where datum targets may be indicated include uneven surfaces, forgings and castings, weldments, non-planar surfaces or surfaces subject to warping or distortion. The datum target symbol is located outside the part outline with a leader directed to the target point, area or line. The targets are dimensionally located on the part using basic or toleranced dimensions. If basic dimensions are used, established tooling or gaging tolerances apply.

A solid leader line from the symbol to the target is used for visible or near side locations, with a dashed leader line used for hidden or far side locations. The datum target symbol is divided horizontally into two halves. The top half contains the target point area if applicable; the bottom half contains a datum feature identifying letter and target number. Target numbers indicate the quantity required to define a primary, secondary, or tertiary datum. If a target point or target line is indicated, the top half is left blank. Datum targets and datum features may be combined to form the datum reference frame, see Fig. 11.

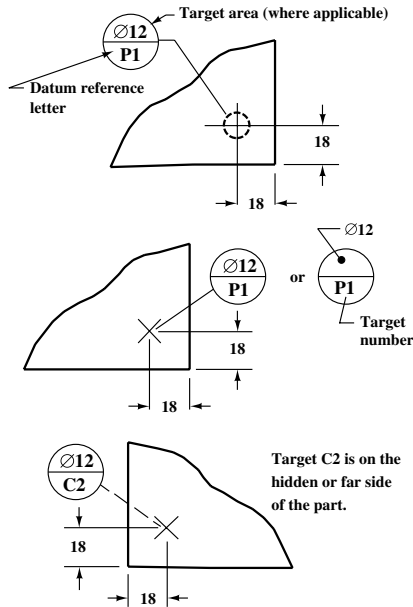

Fig. 11. Datum Target Symbols

**Datum Target Points:** A datum target point is indicated by the symbol “X,” which is dimensionally located on a direct view of the surface. Where there is no direct view, the point location is dimensioned on multiple views.

**Datum Target Lines:** A datum target line is dimensionally located on an edge view of the surface using a phantom line on the direct view. Where there is no direct view, the location is dimensioned on multiple views. Where the length of the datum target line must be controlled, its length and location are dimensioned.

**Datum Target Areas:** Where it is determined that an area or areas of flat contact are necessary to ensure establishment of the datum, and where spherical or pointed pins would be inadequate, a target area of the desired shape is specified. Examples include the need to span holes, finishing irregularities, or rough surface conditions. The datum target area may be indicated with the “X” symbol as with a datum point, but the area of contact is specified in the upper half of the datum target symbol. Datum target areas may additionally be specified by defining controlling dimensions and drawing the contact area on the feature with section lines inside a phantom outline of the desired shape.

**Positional Tolerance.**—A positional tolerance defines a zone within which the center, axis, or center plane of a feature of size is permitted to vary from true (theoretically exact) position. Basic dimensions establish the true position from specified datum features and between interrelated features. A positional tolerance is indicated by the position symbol, a tolerance, and appropriate datum references placed in a feature control frame.

**Modifiers:** In certain geometric tolerances, modifiers in the form of additional symbols may be used to further refine the level of control. The use of the MMC and LMC modifiers

has been common practice for many years. Several new modifiers introduced with the 1994 US standard include free state, tangent plane and statistical tolerancing, see Fig. 12. New modifiers introduced in the 2009 standard include MMB, LMB, and RMB.

(F)	(M)	(L)	(T)	(P)	(U)	ST	CF
Free State	MMC and MMB	LMC and LMB	Tangent Plane	Projected Tolerance Zone	Unequally Disposed	Statistical Tolerance	Continuous Feature

Fig. 12. Tolerance Modifiers

**Projected Tolerance Zone:** Application of this concept is recommended where any variation in perpendicularity of the threaded or press-fit holes could cause fasteners such as screws, studs, or pins to interfere with mating parts. An interference with subsequent parts can occur even though the hole axes are inclined within allowable limits. This interference occurs because, without a projected tolerance zone, a positional tolerance is applied solely to the depth of threaded or press-fit holes. Unlike the floating fastener application involving clearance holes only, the attitude of a fixed fastener is restrained by the inclination of the produced hole into which it assembles.

With a projected tolerance zone equal to the thickness of the mating part, the inclinational error is accounted for in both parts. In other words, the projected zone is an extension of the tolerance zone begun inside the hole and projected out, in this case 14 mm, on the same axis within the specified tolerance of location. The minimum extent and direction of the projected tolerance zone is shown as a value in the feature control frame. The zone may be shown in a drawing view as a dimensioned value with a heavy chain line drawn closely adjacent to an extension of the center line of the hole, see Fig. 13.

It has been noted that the projected tolerance zone illustration shown here differs slightly from that shown in ASME Y14.5-2018. However, it is believed that the illustration shown here is a more realistic portrayal of the intent of the text in the standard.

**Statistical Tolerance:** The statistical tolerancing symbol is a modifier that may be used to indicate that a tolerance is controlled statistically as opposed to being controlled arithmetically. With arithmetic control, assembly tolerances are typically divided arithmetically among the individual components of the assembly. This division results in the assumption that assemblies based on “worst case” conditions would be guaranteed to fit because the worst case set of parts fits — so that anything better would fit as well. When this technique is restrictive, statistical tolerancing, via the symbol, may be specified in the feature control frame as a method of increasing tolerances for individual parts. This procedure may reduce manufacturing costs because its use changes the assumption that statistical process control may make a statistically significant quantity of parts fit, but not absolutely all. The technique should only be used when sound statistical methods are employed.

**Tangent Plane:** When it is desirable to control the surface of a feature by the contacting or high points of the surface, a tangent plane symbol is added as a modifier to the tolerance in the feature control frame, see Fig. 14.

**Free State:** The free state modifier symbol is used when the geometric tolerance applies to the feature in its “free state,” or after removal of any forces used in the manufacturing process. With removal of forces, the part may distort due to gravity, flexibility, springback, or other release of internal stresses developed during fabrication. Typical applications include parts with extremely thin walls and non-rigid parts made of rubber or plastics. The modifier is placed in the tolerance portion of the feature control frame and follows any other modifier.

Fig. 13. Projected Tolerance Zone Application

Fig. 14. Tangent Plane Modifier

The above examples are just a few of the numerous concepts and related symbols covered by ASME Y14.5-2018. Refer to the standard for a complete discussion with further examples of the application of geometric dimensioning and tolerancing principles.

**GD&T and CAD Models.**—ASME Y14.5-2018 and all earlier editions are usable on modern CAD systems. However, the primary concepts are still communicated visually among design, manufacturing and quality stakeholders via annotation applied to engineering drawings, be they on paper or depicted on a computer monitor. Effectively, there is no difference between specifications communicated manually on paper using a pencil and those applied to a drawing on a CAD system, the latter being for all practical purposes an electronic drawing board. As such, utilization of the tolerancing information still requires that a person read the specifications, interpret them and manually apply the information in manufacturing and/or quality systems. That manual process has begun to change with the introduction of ANSI/ASME Y14.41-2012, Digital Production Definition Data Practices, and its international version ISO 16792:2006, Digital Production Definition Data Practices.

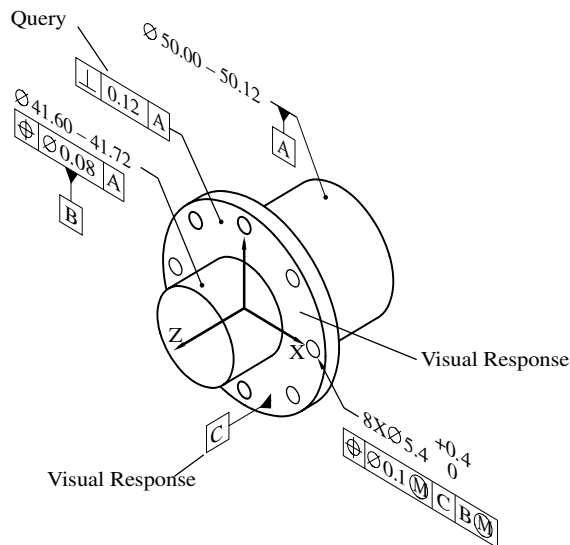

Fig. 15. Visual Response to a Tolerance Query on a 3D CAD System  
Compliant with ASME Y14.41-2012

These standards define use of ASME GD&T practices and ISO GD&T practices, respectively, in a digital environment where specifications are embedded directly into the product definition data set as part of product lifecycle management (PLM). Embedded GD&T is generally called “eGD&T” (electronic geometric dimensioning & tolerancing). Once incorporated into the data set, the specifications can be selectively queried for visual display as needed on a computer screen or an engineering drawing, see Fig. 15. Perhaps more importantly, the embedded tolerancing information can be directly accessed by software for tolerance analysis, process planning, or any other applications designed to utilize the geometric and tolerancing information as part of product lifecycle management. As these standards are adopted by CAD vendors and fully implemented, their promise is for a more expedient, more accurate design and analysis process.

Both standards define how current GD&T concepts are applied to digital models. Both standards also explain where rules have changed to account for differing requirements between 2D-based annotation and 3D annotations.

**Digital Product Definition Data Practices Terms.**—The following terms are defined in both ANSI/ASME Y14.41 and ISO 16792. In ISO 16792, rules are modified to recognize ISO drawing practices where those practices differ from predominately US practice as illustrated in ANSI/ASME Y14.41-2012. Rules in both standards cover not only data sets with models only, but also those data sets with models and drawings. See the respective standards for complete rules and definitions.

*Annotation:* Dimensions, tolerances, notes, text, or symbols visible without any manual or external manipulation.

*Attribute:* A dimension, tolerance, note, text, or symbol required to complete the product definition or feature of the product that is not visible but available upon interrogating the model.

*Design Model:* The portion of the data set that contains model and supplemental geometry.

*Geometric Element:* A graphic entity used in a data set. For example: point, line, plane, surface, solid, model coordinate system or crosshatching.

*Management Data:* The data required for the release, control, and storage of product definition data as well as other relevant engineering data.

*Model:* A combination of design model, annotation and attributes that describes a product, see Fig. 16.

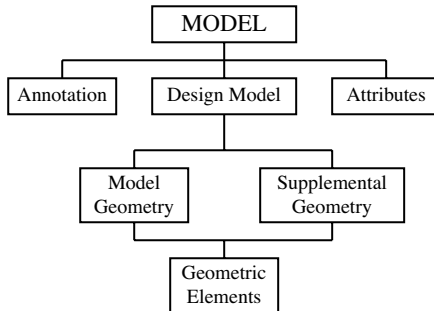

Fig. 16. Content of a Digital Model (ANSI/ASME Y14.41-2012)

*Model Value:* The numerical value derived by interrogating the model that quantifies the form and spatial relationships of the geometry composing a design model or assembly of models to the precision (number of decimal places) of the computer system.

*Model Geometry:* Geometric elements in product definition data which represent a designed product.

*Product Definition Data:* Data elements required to completely define a product.

*Product Definition Data Set:* A collection of one or more computer files that discloses (directly or by reference), by means of graphic or textual presentations, or combinations of both, the physical and functional requirements of an item, see Fig. 17.

*Query:* A means of interrogating a digital element or the relationship between digital elements, see Fig. 17.

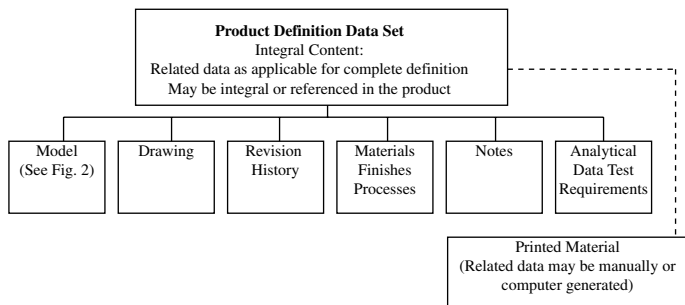

Fig. 17. Product Definition Data Set (ANSI/ASME Y14.41-2012)

*Supplemental Geometry:* Geometric elements included in product definition data to communicate design requirements but not intended to represent a portion of the manufactured product.

### Checking Designs and Drawings

In order for production designs to be maintained at the highest level of consistency, a set of suggestions for checking models and drawings is provided below. The suggestions first concentrate on a review of the design parameters in a global sense, then on a detailed review of the drawings and/or model itself. It is recommended that these suggestions be followed in parts based on responsibility, by engineers, checkers, designers, detailers and any others involved in producing, reviewing and approving engineering models and drawings.

**Design Parameters.—Inspecting a New Design:** When a new design is involved, first carefully inspect the general design and its parts in relationship to the assemblies as a whole, ascertaining that parts function correctly and assemble under all material conditions. Additionally, determine if the parts have the proper relative proportions and that the general design satisfies constraints for strength, rigidity, bearing areas, appearance, manufacturability, ergonomics of assembly, direction of motion, no unnecessary interferences, etc. Generate a digital simulation physical rapid prototype if necessary. If the design appears to be unsatisfactory in any aspect, or improvements appear to be possible, notify the person responsible for that aspect of the design.

*Checking for Strength:* Physically inspect the design for strength, rigidity, and appearance. Compare it with other designs used in similar service whenever possible, giving preference to the known working designs in such a comparison, unless the known designs are examples of unsatisfactory parts. If there is any question, perform applicable analysis on the model or, if required, manually compute the stresses and deformations. If the new design is for a larger version of an existing device, ascertain that any standard parts necessarily increased in size will continue to be sufficiently strong to bear increased service loads.

*Materials Specified:* For the design, consider the material specification in relationship to the various manufacturing process options available, such as molding, forging, a weldment, or other method with which to form the rough shape. Then consider the machining operations to see whether changes in form or design will reduce the number of operations or reduce the machining cost. Parts should be designed with reference to the economical use of material, and whenever possible, utilize standard stock sizes and material readily obtainable from local sources. In the case of alloy steel, special bronze, and similar or exotic materials, confirm that the material can be obtained in the required size.

*Checking Casting Designs:* In checking castings, the form of the pattern is studied, the methods of molding, the method of supporting and venting the cores, and the effect of draft and rough molding on clearances. Undue metal thickness should be avoided, as well as extreme differences between thick and thin sections in the same casting.

All metal thicknesses should be specified, so that appropriate chaplets can be selected for supporting cores. Ample fillets and rounds should be provided and properly dimensioned directly or by note. Cores should be designed so that they can be secured in the mold without crushing or causing interference.

Allowances should be made for swelling, shrinkage, or misalignment of cores to ensure adequate machinability. Material should be added to surfaces destined to be finished.

On large castings, sufficient extra material should be provided for finishing to permit "clean up" to net size in case of warpage.

**Checking Drawings.**—The following are some rules-of-thumb and general guidelines to keep in mind when creating and reviewing engineering drawings and data models.

*Checking the Technique Used in Making the Drawing:* Inspect the drawing to see that all regular, auxiliary and section views are made in such a way as to illustrate the most descriptive views of the form of the piece and its relationship to other parts. Selection of type and quantity of views on a drawing serve as both a carrier of the dimensional values and to represent accurately the visual nature of the part. Ultimately, drawings must communicate design intent, both numerically and visually.

*Checking Dimensions in General:* In general, all dimensions should be checked for correctness. If manually drawn, dimensions should also be scaled to determine if the drawing is to scale. Where any dimension is "not-to-scale," it is indicated by underlining the offending dimension. This is the standard technique for indicating not-to-scale. While most CAD systems automatically indicate not-to-scale dimensions, some do not. Not-to-scale dimensions are problematic on CAD drawings and models as they are indicative of dimension values not matching the geometry. In the case of a CAD drawing dimension being not-to-scale, it too should be underlined. However, this may be a serious concern, and may demand immediate correction. More and more, CAD geometry drives downstream applications such as numerical control or tolerance analysis. Hence, errors in CAD geometry cannot be tolerated if accurate downstream results are expected.

**ASME and ISO Drawing Checklists.**—The following checklists represent questions based on industry practice and standards for engineering drawings and, unless noted, apply to both inch and metric drawings and models and both ASME Y14.5 and ISO methodology.

*Model Checklist:* Are features built within dimensional limits and to appropriate material conditions (MMC, LMC, nominal)?

Are features built to sufficient numerical accuracy?

Are fillets and rounds added to all non-finished corners of castings and forgings?

On as-cast models, is machining allowance added to surfaces destined to be finished?

Has allowance for wrench clearance been built into locations of bolts and other fasteners requiring tools?

*Drawing Checklist:* Are all dimensions indicated only once to avoid potentially misinterpreted redundant dimensioning?

Are all auxiliary and section views labeled?

Are general notes added to address default conditions such as fillets and rounds, numerical significance, default tolerances?

Are all finish marks indicated where appropriate?

Are clearance hole diameters clearly specified to avoid potential look-up errors?

Are there sufficient views so that no assumptions need be made about any feature or dimension?

If following US practice, are all dimensions, notes and other text readable from the bottom of the drawing?

If following ISO practice, is all dimensional text aligned with each dimension on the drawing?

When dimensioning in metric, are preceding 0s shown for values less than 1, and trailing 0s not shown for integers? (e.g. 0.11 and 10)

When heat treatment is required, the heat treatment should be specified.

When dimension in inches, are preceding 0s not shown for values less than 1, and trailing 0s added for consistent significant digits? (e.g. .11 and 10.00)

If dimensioning symbols are used, such as depth, diameter, radius, etc., are the symbols placed before the dimensional value?

Are quantities specified for all dimensions or features occurring in multiple locations (via 2X or TWO TIMES)?

Are threaded holes specified by tap drill and thread specifications to avoid potential look-up errors?

Are all occurrences of dimensional and non-dimensional text to consistent size or per company policy?

Are dimensions to hidden lines and those directly to object lines minimized unless impossible to avoid?

Are dimensions shown in a view depicting the true shape projection of the feature?

Do all dimensions account for tolerance, either directly or indirectly, via note or block tolerance?

Does the selection of paper size match the complexity of the part to avoid over-crowding via a size too small or wasted space via a size too large?

Are dimensions shown in a form that minimizes unnecessary calculations by readers of the drawing?

Are views aligned left-to-right and bottom-to-top, and arranged properly for 3rd angle projection (or 1st angle projection)?

Is the primary view the most descriptive view possible?

Is chain dimensioning minimized to avoid "stacking" of tolerances?

Are holes and other round features and parts located by their centers?

Are witness lines (extension lines) used with dimensions rather than dimensioning directly to features?

Is the drawing title correct and the drawing number or file name in the correct format?

**Arrangement of Views.**—A drawing may show one or more views of an object arranged according to a definite plan. In the United States, the general practice is to place the top view above the front view, and the end view next to whatever end it represents. For example, if a view of the left-hand end is considered important, the end view is placed to the left of the front view. If a right-hand view is also necessary, it is placed to the right of the front view. If a bottom view is needed, it is placed below the front view.

The view obtained by looking at an object from above is a *plan* view. The view obtained by looking at the object from its side and showing a vertical face is an elevation, which may be either a *front elevation* or an *end elevation* (also known as side elevation).

*Third-angle and First-angle Projection:* If the views are placed with the plan above the front elevation, the right-hand end view to the right and the left-hand end view (when drawn) to the left, this is known as *third-angle projection*. In ISO practice, it is the custom to use what is known as *first-angle projection*. With this method, the front elevation is placed at the top, the plan view at the bottom, the right-hand end view at the left, and the left-hand end view at the right. The first-angle projection is also generally employed in architectural and structural work, as in drawings of bridges, etc. See Fig. 1a and Fig. 1b on page 626.

## ALLOWANCES AND TOLERANCES FOR FITS

## Limits and Fits

Fits between cylindrical parts, i.e., cylindrical fits, govern the proper assembly and performance of many mechanisms. Clearance fits permit relative freedom of motion between a shaft and a hole—axially, radially, or both. Interference fits secure a certain amount of tightness between parts, whether these are meant to remain permanently assembled or to be taken apart from time to time. Or again, two parts may be required to fit together snugly—without apparent tightness or looseness. The designer's problem is to specify these different types of fits in such a way that the shop can produce them. Establishing the specifications requires the adoption of two manufacturing limits for the hole and two for the shaft, and, hence, the adoption of a manufacturing tolerance on each part.

In selecting and specifying limits and fits for various applications, it is essential in the interests of interchangeable manufacturing that 1) standard definitions of terms relating to limits and fits be used; 2) preferred basic sizes be selected wherever possible to reduce material and tooling costs; 3) limits be based upon a series of preferred tolerances and allowances; and 4) a uniform system of applying tolerances (preferably unilateral) be used. These principles have been incorporated in both the American and British standards for limits and fits. Information about these standards is given beginning on page 646.

**Basic Size.**—The basic size of a screw thread or machine part is the theoretical or nominal standard size from which variations are made. For example, a shaft may have a *basic* diameter of 2 inches, but a maximum variation of minus 0.010 inch may be permitted. The minimum hole should be of basic size wherever the use of standard tools represents the greatest economy. The maximum shaft should be of basic size wherever the use of standard purchased material, without further machining, represents the greatest economy, even though special tools are required to machine the mating part.

**Tolerances.**—Tolerance is the amount of variation permitted on dimensions or surfaces of machine parts. The tolerance is equal to the difference between the maximum and minimum limits of any specified dimension. For example, if the maximum limit for the diameter of a shaft is 2.000 inches and its minimum limit 1.990 inches, the tolerance for this diameter is 0.010 inch. The extent of these tolerances is established by determining the maximum and minimum clearances required on operating surfaces. As applied to the fitting of machine parts, the word tolerance means the amount that duplicate parts are allowed to vary in size in connection with manufacturing operations, owing to unavoidable imperfections of workmanship. Tolerance may also be defined as the amount that duplicate parts are permitted to vary in size to secure sufficient accuracy without unnecessary refinement. The terms “tolerance” and “allowance” are often used interchangeably, but, according to common usage, *allowance* is a difference in dimensions prescribed to secure various classes of fits between different parts.

For information on factors involved in and various methods for calculating tolerances, see *Tolerance Analysis and Assignment* on page 684.

**Unilateral and Bilateral Tolerances.**—The term “unilateral tolerance” means that the total tolerance, as related to a basic dimension, is in *one* direction only. For example, if the basic dimension were 1 inch and the tolerance were expressed as  $1.000 - 0.002$ , or as  $1.000 + 0.002$ , these would be unilateral tolerances because the total tolerance in each is in one direction. On the contrary, if the tolerance were divided, so as to be partly plus and partly minus, it would be classed as “bilateral.”

Thus,  $1.000 \begin{matrix} +0.001 \\ -0.001 \end{matrix}$

is an example of bilateral tolerance, because the total tolerance of 0.002 is given in two directions—plus and minus.

When unilateral tolerances are used, one of the following three methods should be used to express them:

1) Specify, limiting dimensions only as

Diameter of hole: 2.250, 2.252

Diameter of shaft: 2.249, 2.247

2) One limiting size may be specified with its tolerances as

Diameter of hole: 2.250 + 0.002, -0.000

Diameter of shaft: 2.249 + 0.000, -0.002

3) The nominal size may be specified for both parts, with a notation showing both allowance and tolerance, as

Diameter of hole:  $2\frac{1}{4} + 0.002, -0.000$

Diameter of shaft:  $2\frac{1}{4} - 0.001, -0.003$

Bilateral tolerances should be specified as such, usually with plus and minus tolerances of equal amount. An example of the expression of bilateral tolerances is

$$2 \pm 0.001 \quad \text{or} \quad \begin{array}{c} +0.001 \\ 2 \\ -0.001 \end{array}$$

**Application of Tolerances.**—According to common practice, tolerances are applied in such a way as to show the permissible amount of dimensional variation in the direction that is less dangerous. When a variation in either direction is equally dangerous, a bilateral tolerance should be given. When a variation in one direction is more dangerous than a variation in another, a unilateral tolerance should be given in the less dangerous direction.

For nonmating surfaces, or atmospheric fits, the tolerances may be bilateral or unilateral, depending entirely upon the nature of the variations that develop in manufacture. On mating surfaces, with few exceptions, the tolerances should be unilateral.

Where tolerances are required on the distances between holes, usually they should be bilateral, as variation in either direction is normally equally dangerous. The variation in the distance between shafts carrying gears, however, should always be unilateral and plus; otherwise, the gears might run too tight. A slight increase in the backlash between gears is seldom of much importance.

One exception to the use of unilateral tolerances on mating surfaces occurs when tapers are involved; either bilateral or unilateral tolerances may then prove advisable, depending upon conditions. These tolerances should be determined in the same manner as the tolerances on the distances between holes. When a variation either in or out of the position of the mating taper surfaces is equally dangerous, the tolerances should be bilateral. When a variation in one direction is of less danger than a variation in the opposite direction, the tolerance should be unilateral and in the less dangerous direction.

**Locating Tolerance Dimensions.**—Only one dimension in the same straight line can be controlled within fixed limits. That dimension is the distance between the cutting surface of the tool and the locating or registering surface of the part being machined. Therefore, it is incorrect to locate any point or surface with tolerances from more than one point in the same straight line.

Every part of a mechanism must be located in each plane. Every operating part must be located with proper operating allowances. After such requirements of location are met, all other surfaces should have liberal clearances. Dimensions should be given between those points or surfaces that it is essential to hold in a specific relation to each other. This restriction applies particularly to those surfaces in each plane that control the location of other component parts. Many dimensions are relatively unimportant in this respect. It is good practice to establish a common locating point in each plane and give, as far as possible, all such dimensions from these common locating points. The locating points on the drawing, the locating or registering points used for machining the surfaces and the locating points for measuring should all be identical.

The initial dimensions placed on component drawings should be the exact dimensions that would be used if it were possible to work without tolerances. Tolerances should be given in that direction in which variations will cause the least harm or danger. When a variation in either direction is equally dangerous, the tolerances should be of equal amount in both directions, or bilateral. The initial clearance, or allowance, between operating parts should be as small as the operation of the mechanism will permit. The maximum clearance should be as great as the proper functioning of the mechanism will permit.

**Direction of Tolerances on Gages.**—The extreme sizes for all plain limit gages shall not exceed the extreme limits of the part to be gaged. All variations in the gages, whatever their cause or purpose, shall bring these gages within these extreme limits.

The data for gage tolerances on page 673 cover gages to inspect workpieces held to tolerances in the American National Standard ANSI B4.4M-1981 (Withdrawn).

**Allowance for Forced Fits.**—The allowance per inch of diameter usually ranges from 0.001 inch to 0.0025 inch (0.0254-0.0635 mm), 0.0015 inch (0.0381 mm) being a fair average. Ordinarily the allowance per inch decreases as the diameter increases; thus the total allowance for a diameter of 2 inches (50.8 mm) might be 0.004 inch (0.102 mm), whereas for a diameter of 8 inches (203.2 mm) the total allowance might not be over 0.009 or 0.010 inch (0.23 or 0.25 mm). The parts to be assembled by forced fits are usually made cylindrical, although sometimes they are slightly tapered. Advantages of the taper form are: the possibility of abrasion of the fitted surfaces is reduced; less pressure is required in assembling; and parts are more readily separated when renewal is required. On the other hand, the taper fit is less reliable because, if it loosens, the entire fit is free with but little axial movement. Some lubricant, such as white lead and lard oil mixed to the consistency of paint, should be applied to the pin and bore before assembling, to reduce the tendency toward abrasion.

**Pressure for Forced Fits.**—The pressure required for assembling cylindrical parts depends not only upon the allowance for the fit, but also upon the area of the fitted surfaces, the pressure increasing in proportion to the distance that the inner member is forced in. The approximate ultimate pressure in tons can be determined by the use of the following formula in conjunction with the accompanying table of *Pressure Factors for Forced Fits*. Assuming that  $A$  = area of surface in contact in "fit";  $a$  = total allowance in inches;  $P$  = ultimate pressure required, in tons;  $F$  = pressure factor based upon assumption that the diameter of the hub is twice the diameter of the bore, that the shaft is of machine steel, and that the hub is of cast iron:

$$P = \frac{A \times a \times F}{2}$$

**Pressure Factors for Forced Fits**

Diameter, Inches	Pressure Factor	Diameter, Inches	Pressure Factor	Diameter, Inches	Pressure Factor	Diameter, Inches	Pressure Factor	Diameter, Inches	Pressure Factor
1	500	3½	132	6	75	9	48.7	14	30.5
1¼	395	3¾	123	6¼	72	9½	46.0	14½	29.4
1½	325	4	115	6½	69	10	43.5	15	28.3
1¾	276	4¼	108	6¾	66	10½	41.3	15½	27.4
2	240	4½	101	7	64	11	39.3	16	26.5
2¼	212	4¾	96	7¼	61	11½	37.5	16½	25.6
2½	189	5	91	7½	59	12	35.9	17	24.8
2¾	171	5¼	86	7¾	57	12½	34.4	17½	24.1
3	156	5½	82	8	55	13	33.0	18	23.4
3¼	143	5¾	78	8½	52	13½	31.7	...	...

**Allowance for Given Pressure.**—By transposing the preceding formula, the approximate allowance for a required ultimate tonnage can be determined. Thus,  $a = \frac{2P}{AF}$ . The average ultimate pressure in tons commonly used ranges from 7 to 10 times the diameter in inches.

**Expansion Fits.**—In assembling certain classes of work requiring a very tight fit, the inner member is contracted by sub-zero cooling to permit insertion into the outer member and a tight fit is obtained as the temperature rises and the inner part expands. To obtain the sub-zero temperature, solid carbon dioxide or “dry ice” has been used, but its temperature of about  $-109^{\circ}\text{F}$  ( $-78^{\circ}\text{C}$ ) below zero will not contract some parts sufficiently to permit insertion in holes or recesses. Greater contraction may be obtained by using high purity liquid nitrogen which has a temperature of about  $-320^{\circ}\text{F}$  ( $-196^{\circ}\text{C}$ ) below zero. During a temperature reduction from  $75^{\circ}\text{F}$  to  $-321^{\circ}\text{F}$  ( $220^{\circ}\text{C}$  difference), the shrinkage per inch of diameter varies from about 0.002 to 0.003 inch for steel; 0.0042 inch for aluminum alloys; 0.0046 inch for magnesium alloys; 0.0033 inch for copper alloys; 0.0023 inch for monel metal; and 0.0017 inch for cast iron (not alloyed). The cooling equipment may vary from an insulated bucket to a special automatic unit, depending upon the kind and quantity of work. One type of unit is so arranged that parts are precooled by vapors from the liquid nitrogen before immersion. With another type, cooling is entirely by the vapor method.

**Shrinkage Fits.**—General practice seems to favor a smaller allowance for shrinkage fits than for forced fits, although in many shops the allowances are practically the same for each, and, for some classes of work, shrinkage allowances exceed those for forced fits. The shrinkage allowance also varies to a great extent with the form and construction of the part that has to be shrunk into place. The thickness or amount of metal around the hole is the most important factor. The way in which the metal is distributed also has an influence on the results. Shrinkage allowances for locomotive driving wheel tires adopted by the American Railway Master Mechanics Association are as follows:

Center diameter, inches	38	44	50	56	62	66
Allowances, inches	0.040	0.047	0.053	0.060	0.066	0.070

Whether parts are to be assembled by forced or shrinkage fits depends upon conditions. For example, to press a tire over its wheel center, without heating, would ordinarily be a rather difficult job. On the other hand, pins, etc., are easily and quickly forced into place with a hydraulic press, and there is the additional advantage of knowing the exact pressure required in assembling, whereas there is more or less uncertainty connected with a shrinkage fit, unless the stresses are calculated. Tests to determine the difference in the quality of shrinkage and forced fits showed that the resistance of a shrinkage fit to slippage for an axial pull was 3.66 times greater than that of a forced fit, and, in rotation or torsion, 3.2 times greater. In each comparative test, dimensions and allowances were equal.

**Allowances for Shrinkage Fits.**—The most important point to consider when calculating shrinkage fits is the stress in the hub at the bore, which depends chiefly upon the shrinkage allowance. If the allowance is excessive, the elastic limit of the material will be exceeded, and permanent set will occur, or, in extreme conditions, the ultimate strength of the metal will be exceeded and the hub will burst. The intensity of the grip of the fit and the resistance to slippage depend mainly upon the thickness of the hub; the greater the thickness, the stronger the grip, and *vice versa*. Assuming the modulus of elasticity for steel to be 30,000,000 ( $206.8 \times 10^6$  MPa) and for cast iron 15,000,000 ( $103.4 \times 10^6$  MPa), the shrinkage allowance per inch (mm) of nominal diameter can be determined by the following formula, in which  $A$  = allowance per inch (mm) of diameter;  $T$  = true tangential tensile stress at inner surface of outer member, psi (MPa);  $C$  = factor taken from one of the accompanying Table 1, Table 2, and Table 3.

For a cast-iron hub and steel shaft:

$$\text{US } A = \frac{T(2+C)}{30,000,000} \quad (1a) \quad \text{metric } A = 25.4 \frac{T(2+C)}{206.843 \times 10^9} \quad (1b)$$

When both hub and shaft are of steel:

$$\text{US } A = \frac{T(1+C)}{30,000,000} \quad (2a) \quad \text{metric } A = 25.4 \frac{T(1+C)}{206.843 \times 10^9} \quad (2b)$$

If the shaft is solid, the factor  $C$  is taken from Table 1; if it is hollow and the hub is of steel, factor  $C$  is taken from Table 2; if it is hollow and the hub is of cast iron, the factor is taken from Table 3.

**Table 1. Factors for Calculating Shrinkage Fit Allowances for Steel Shafts and Steel or Cast-Iron Hubs**

Ratio of Diameters $\frac{D_2}{D_1}$	Steel Hub	Cast-iron Hub	Ratio of Diameters $\frac{D_2}{D_1}$	Steel Hub	Cast-iron Hub
	$C$			$C$	
1.5	0.227	0.234	2.8	0.410	0.432
1.6	0.255	0.263	3.0	0.421	0.444
1.8	0.299	0.311	3.2	0.430	0.455
2.0	0.333	0.348	3.4	0.438	0.463
2.2	0.359	0.377	3.6	0.444	0.471
2.4	0.380	0.399	3.8	0.450	0.477
2.6	0.397	0.417	4.0	0.455	0.482

Values of factor  $C$  for solid steel shafts of nominal diameter  $D_1$ , and hubs of steel or cast iron of nominal external and internal diameters  $D_2$  and  $D_1$ , respectively.

*Example 1:* A steel crank web 375 mm outside diameter is to be shrunk on a 250 mm solid steel shaft. Required is the allowance per mm of shaft diameter to produce a maximum tensile stress in the crank of 170 MPa, assuming the stresses in the crank to be equivalent to those in a ring of the diameter given.

The ratio of the external to the internal diameters equals  $375 \div 250 = 1.5$ ;  $T = 170$  MPa; from Table 1,  $C = 0.227$ . Substituting in Formula (2b):

$$A = 25.4 \frac{170 \times (1 + 0.227)}{206843} = 0.026 \text{ mm}$$

*Example 2:* Find the allowance per mm of diameter for a 250 mm shaft having a 125 mm axial through hole, other conditions being the same as in Example 1.

The ratio of external to internal diameters of the hub equals  $375 \div 250 = 1.5$ , as before, and the ratio of external to internal diameters of the shaft equals  $250 \div 125 = 2$ . From Table 2, we find that factor  $C = 0.455$ ;  $T = 170$  MPa. Substituting these values in Formula (2b):

$$A = 25.4 \frac{170(1 + 0.455)}{206843} = 0.030 \text{ mm}$$

The allowance is increased, as compared with Example 1, because the hollow shaft is more compressible.

*Example 3:* If the crank web in Example 1 is of cast iron and 28 MPa is the maximum tensile stress in the hub, what is the allowance per mm of diameter?

$$\frac{D_2}{D_1} = 1.5 \quad T = 28$$

In Table 1, we find that  $C = 0.234$ . Substituting in Formula (1b), for cast-iron hubs,  $A = 0.0076$  mm, which, owing to the lower tensile strength of cast iron, is about one-third the shrinkage allowance in Example 1, although the stress is two-thirds of the elastic limit.

<sup>a</sup> Values of factor  $C$  for hollow steel shafts and cast-iron hubs. Notation as in Table 2.

**Temperatures for Shrinkage Fits.**—The temperature to which the outer member in a shrinkage fit should be heated for clearance in assembling the parts depends on the total expansion required and on the coefficient  $\alpha$  of linear expansion of the metal (i.e., the increase in length of any section of the metal in any direction for an increase in temperature of 1 degree F). The total expansion in diameter that is required consists of the total allowance for shrinkage and an added amount for clearance. The value of the coefficient  $\alpha$  is, for nickel-steel, 0.000007; for steel in general, 0.0000065; for cast iron, 0.0000062. As an example, take an outer member of steel to be expanded 0.005 inch per inch of internal diameter, 0.001 being the shrinkage allowance and the remainder for clearance. Then

$$\alpha \times t^{\circ} = 0.005$$

$$t = \frac{0.005}{0.0000065} = 769 \text{ degrees F}$$

The value  $t$  is the number of degrees F that the temperature of the member must be raised above that of the room temperature.

### ANSI/ASME Standard Limits and Fits

This American National Standard for Preferred Limits and Fits for Cylindrical Parts, ANSI/ASME B4.1-1967 (2009; out of print), presents definitions of terms applying to fits between plain (non threaded) cylindrical parts and makes recommendations on preferred sizes, allowances, tolerances, and fits for use wherever they are applicable. As of 2009, this standard was in accord with the recommendations of American-British-Canadian (ABC) conferences up to a diameter of 20 inches, with experimental work thereafter carried on with the objective of reaching agreement in the range above 20 inches. The recommendations in the standard are presented for guidance and for use where they might serve to improve and simplify products, practices, and facilities. They have practical application for a wide range of products.

Note: At the time of this publication, even though ANSI/ASME B4.1-1967 was no longer officially in print, it was still available for reference and not yet revised or superseded.

**Factors Affecting Selection of Fits.**—Many factors, such as length of engagement, bearing load, speed, lubrication, temperature, humidity, and materials must be taken into consideration in the selection of fits for a particular application, and modifications in the ANSI/ASME recommendations may be required to satisfy extreme conditions. Subsequent adjustments may also be found desirable as a result of experience in a particular application to suit critical functional requirements or to permit optimum manufacturing economy.

**Definitions.**—The following terms are defined in this standard:

**Nominal Size:** The nominal size is the designation used for the purpose of general identification.

**Dimension:** A dimension is a geometrical characteristic such as diameter, length, angle, or center distance.

**Size:** Size is a designation of magnitude. When a value is assigned to a dimension, it is referred to as the size of that dimension. (It is recognized that the words “dimension” and “size” are both used at times to convey the meaning of magnitude.)

**Allowance:** An allowance is a prescribed difference between the maximum material limits of mating parts. (See definition of *Fit*). It is a minimum clearance (positive allowance) or maximum interference (negative allowance) between such parts.

**Tolerance:** A tolerance is the total permissible variation of a size. The tolerance is the difference between the limits of size.

**Basic Size:** The basic size is that size from which the limits of size are derived by the application of allowances and tolerances.

**Design Size:** The design size is the basic size with allowance applied, from which the limits of size are derived by the application of tolerances. Where there is no allowance, the design size is the same as the basic size.

*Actual Size:* An actual size is a measured size.

*Limits of Size:* The limits of size are the applicable maximum and minimum sizes.

*Maximum Material Limit:* A maximum material limit is that limit of size that provides the maximum amount of material for the part. Normally it is the maximum limit of size of an external dimension or the minimum limit of size of an internal dimension.\*

*Minimum Material Limit:* A minimum material limit is that limit of size that provides the minimum amount of material for the part. Normally it is the minimum limit of size of an external dimension or the maximum limit of size of an internal dimension.\*

*Tolerance Limit:* A tolerance limit is the variation, positive or negative, by which a size is permitted to depart from the design size.

*Unilateral Tolerance:* A unilateral tolerance is a tolerance in which variation is permitted in only one direction from the design size.

*Bilateral Tolerance:* A bilateral tolerance is a tolerance in which variation is permitted in both directions from the design size.

*Unilateral Tolerance System:* A design plan that uses only unilateral tolerances is known as a Unilateral Tolerance System.

*Bilateral Tolerance System:* A design plan that uses only bilateral tolerances is known as a Bilateral Tolerance System.

**Fits.**—*Fit:* Fit is the general term used to signify the range of tightness that may result from the application of a specific combination of allowances and tolerances in the design of mating parts.

*Actual Fit:* The actual fit between two mating parts is the relation existing between them with respect to the amount of clearance or interference that is present when they are assembled. (Fits are of three general types: clearance, transition, and interference.)

*Clearance Fit:* A clearance fit is one having limits of size so specified that a clearance always results when mating parts are assembled.

*Interference Fit:* An interference fit is one having limits of size so specified that an interference always results when mating parts are assembled.

*Transition Fit:* A transition fit is one having limits of size so specified that either a clearance or an interference may result when mating parts are assembled.

*Basic Hole System:* A basic hole system is a system of fits in which the design size of the hole is the basic size and the allowance, if any, is applied to the shaft.

*Basic Shaft System:* A basic shaft system is a system of fits in which the design size of the shaft is the basic size and the allowance, if any, is applied to the hole.

**Preferred Basic Sizes.**—In specifying fits, the basic size of mating parts shall be chosen from the decimal series or the fractional series in [Table 4](#).

**Preferred Series for Tolerances and Allowances.**—All fundamental tolerances and allowances of all shafts and holes have been taken from the series given in [Table 5](#).

**Standard Tolerances.**—The series of standard tolerances shown in [Table 6](#) are so arranged that for any one grade they represent approximately similar production difficulties throughout the range of sizes. This table provides a suitable range from which appropriate tolerances for holes and shafts can be selected and enables standard gages to be used. The tolerances shown in [Table 6](#) have been used in the succeeding tables for different classes of fits.

[Table 7](#) graphically illustrates the range of tolerance grades that various machining processes may produce under normal conditions.

\* An example of exceptions: an exterior corner radius where the maximum radius is the minimum material limit and the minimum radius is the maximum material limit.

**ANSI/ASME Standard Fits.**—Table 8a through Table 12 inclusive show a series of standard types and classes of fits on a unilateral hole basis, such that the fit produced by mating parts in any one class will produce approximately similar performance throughout the range of sizes. These tables prescribe the fit for any given size, or type of fit; they also prescribe the standard limits for the mating parts that will produce the fit. The fits listed in these tables contain all those that appear in the approved American-British-Canadian proposal.

**Selection of Fits:** In selecting limits of size for any application, the type of fit is determined first, based on the use or service required from the equipment being designed; then the limits of size of the mating parts are established, to insure that the desired fit will be produced.

Theoretically, an infinite number of fits could be chosen, but the number of standard fits shown in the accompanying tables should cover most applications.

**Designation of Standard Fits:** Standard fits are designated by means of the following symbols which, facilitate reference to classes of fit for educational purposes. The symbols are not intended to be shown on manufacturing drawings; instead, sizes should be specified on drawings.

The letter symbols used to designate standard fits are as follows:

RC = Running or Sliding Clearance Fit      LC = Locational Clearance Fit

LT = Transition Clearance or Interference Fit

LN = Locational Interference Fit

FN = Force or Shrink Fit

These letter symbols are used in conjunction with numbers representing the class of fit; thus FN 4 represents a Class 4 force fit.

Each of these symbols (two letters and a number) represents a complete fit for which the minimum and maximum clearance or interference and the limits of size for the mating parts are given directly in the tables.

**Description of Fits.**—The classes of fits are arranged in three general groups: running and sliding fits, locational fits, and force fits.

*Running and Sliding Fits (RC):* Running and sliding fits, for which limits of clearance are given in Table 8a, are intended to provide a similar running performance, with suitable lubrication allowance, throughout the range of sizes. The clearances for the first two classes, used chiefly as slide fits, increase more slowly with the diameter than for the other classes so that accurate location is maintained even at the expense of free relative motion.

These fits may be described as follows:

RC 1 *Close sliding fits* are intended for the accurate location of parts that must assemble without perceptible play.

RC 2 *Sliding fits* are intended for accurate location, but with greater maximum clearance than class RC 1. Parts made to this fit move and turn easily but are not intended to run freely, and in the larger sizes may seize with small temperature changes.

RC 3 *Precision running fits* are about the closest fits that can be expected to run freely and are intended for precision work at slow speeds and light journal pressures, but they are not suitable where appreciable temperature differences are likely to be encountered.

RC 4 *Close running fits* are intended chiefly for running fits on accurate machinery with moderate surface speeds and journal pressures, where accurate location and minimum play are desired.

RC 5 and RC 6 *Medium running fits* are intended for higher running speeds, or heavy journal pressures, or both.

RC 7 *Free running fits* are intended for use where accuracy is not essential, or where large temperature variations are likely to be encountered, or under both these conditions.

RC 8 and RC 9 *Loose running fits* are intended for use where wide commercial tolerances may be necessary, together with an allowance, on the external member.

*Locational Fits (LC, LT, and LN):* Locational fits are intended to determine only the location of the mating parts; they may provide rigid or accurate location, as with interference fits, or provide some freedom of location, as with clearance fits. Accordingly, they are divided into three groups: clearance fits (LC), transition fits (LT), and interference fits (LN).

These are described as follows:

LC *Locational clearance fits* are intended for parts that are normally stationary but that can be freely assembled or disassembled. They range from snug fits for parts requiring accuracy of location, through the medium clearance fits for parts such as spigots, to the looser fastener fits where freedom of assembly is of prime importance.

LT *Locational transition fits* are a compromise between clearance and interference fits for applications where accuracy of location is important but either a small amount of clearance or interference is permissible.

LN *Locational interference fits* are used where accuracy of location is of prime importance, and for parts requiring rigidity and alignment with no special requirements for bore pressure. Such fits are not intended for parts designed to transmit frictional loads from one part to another by virtue of the tightness of fit. These conditions are covered by force fits.

*Force Fits (FN):* Force or shrink fits constitute a special type of interference fit, normally characterized by maintenance of constant bore pressures throughout the range of sizes. The interference, therefore, varies almost directly with diameter, and the difference

between its minimum and maximum value is small to maintain the resulting pressures within reasonable limits.

These fits are described as follows:

FN 1 *Light drive fits* are those requiring light assembly pressures and produce more or less permanent assemblies. They are suitable for thin sections or long fits, or in cast-iron external members.

FN 2 *Medium drive fits* are suitable for ordinary steel parts or for shrink fits on light sections. They are about the tightest fits that can be used with high-grade cast-iron external members.

FN 3 *Heavy drive fits* are suitable for heavier steel parts or for shrink fits in medium sections.

FN 4 and FN 5 *Force fits* are suitable for parts that can be highly stressed or for shrink fits where the heavy pressing forces required are impractical.

**Graphical Representation of Limits and Fits.**—A visual comparison of the hole and shaft tolerances and the clearances or interferences provided by the various types and classes of fits can be obtained from the diagrams on page 652. These diagrams have been drawn to scale for a nominal diameter of 1 inch.

**Use of Standard Fit Tables.**—*Example 1:* A Class RC 1 fit is to be used in assembling a mating hole and shaft of 2-inch nominal diameter. This class of fit was selected because the application required accurate location of the parts with no perceptible play (see *Description of Fits*, RC 1 close sliding fits). From the data in Table 8a, establish the limits of size and clearance of the hole and shaft.

Maximum hole =  $2 + 0.0005 = 2.0005$ ; minimum hole = 2 inches

Maximum shaft =  $2 - 0.0004 = 1.9996$ ; minimum shaft =  $2 - 0.0007 = 1.9993$  inches

Minimum clearance = 0.0004; maximum clearance = 0.0012 inch

**Modified Standard Fits.**—Fits having the same limits of clearance or interference as those shown in Table 8a to Table 12 may sometimes have to be produced by using holes or shafts having limits of size other than those shown in these tables. These modifications may be accomplished by using either a *Bilateral Hole System (Symbol B)* or a *Basic Shaft System (Symbol S)*. Both methods will result in nonstandard holes and shafts.

*Bilateral Hole Fits (Symbol B):* The common situation is where holes are produced with fixed tools such as drills or reamers; to provide a longer wear life for such tools, a bilateral tolerance is desired.

The symbols used for these fits are identical with those used for standard fits except that they are followed by the letter B. Thus, LC 4B is a clearance locational fit Class 4, except that it is produced with a bilateral hole.

The limits of clearance or interference are identical with those shown in Table 8a to Table 12 for the corresponding fits.

The hole tolerance, however, is changed so that the plus limit is that for one grade finer than the value shown in the tables and the minus limit equals the amount by which the plus limit was lowered. The shaft limits are both lowered by the same amount as the lower limit of size of the hole. The finer grade of tolerance required to make these modifications may be obtained from Table 6. For example, an LC 4B fit for a 6-inch diameter hole would have tolerance limits of  $+4.0, -2.0 (+0.0040$  inch,  $-0.0020$  inch); the shaft would have tolerance limits of  $-2.0, -6.0 (-0.0020$  inch,  $-0.0060$  inch).

*Basic Shaft Fits (Symbol S)* For these fits, the maximum size of the shaft is basic. The limits of clearance or interference are identical with those shown in Table 8a to Table 12 for the corresponding fits, and the symbols used for these fits are identical with those used for standard fits except that they are followed by the letter S. Thus, LC 4S is a clearance locational fit Class 4, except that it is produced on a basic shaft basis.

The limits for hole and shaft as given in Table 8a to Table 12 are increased for clearance fits (*decreased* for transition or interference fits) by the value of the upper shaft limit, that is, by the amount required to change the maximum shaft to the basic size.

**Graphical Representation of ANSI/ASME Standard Limits and Fits**  
 ANSI/ASME B4.1-1967 (2009; out of print)

Diagrams show disposition of hole and shaft tolerances (in thousandths of an inch) with respect to basic size (0) for a diameter of 1 inch.

<sup>a</sup> Pairs of values shown represent minimum and maximum amounts of clearance resulting from application of standard tolerance limits.

Tolerance limits in **Table 8a** and **Table 8b** are added to or subtracted from basic size (as indicated by + or - sign) to obtain maximum and minimum sizes of mating parts.

All data above heavy lines are in accord with ABC agreements. Symbols H5, g4, etc., are hole and shaft designations in ABC system. Limits for sizes above 19.69 inches are also given in the ANSI/ASME Standard.

All data in this table are in accordance with American-British-Canadian (ABC) agreements.

Limits for sizes above 19.69 inches are not covered by ABC agreements but are given in the ANSI/ASME Standard.

Symbols H7, p6, etc., are hole and shaft designations in the ABC system.

Tolerance limits given in body of table are added or subtracted to basic size (as indicated by + or - sign) to obtain maximum and minimum sizes of mating parts.

### ANSI/ASME Preferred Metric Limits and Fits

This standard ANSI/ASME B4.2-1978 (R2009) describes the ISO system of metric limits and fits for mating parts as approved for general engineering usage in the United States.

It establishes 1) the designation symbols used to define dimensional limits on drawings, material stock, related tools, gages, etc.; 2) the preferred basic sizes (first and second choices); 3) the preferred tolerance zones (first, second, and third choices); 4) the preferred limits and fits for sizes (first choice only) up to and including 500 millimeters; and 5) the definitions of related terms.

The general terms "hole" and "shaft" can also be taken to refer to the space containing or contained by two parallel faces of any part, such as the width of a slot or the thickness of a key.

**Definitions.**—The most important terms relating to limits and fits are shown in Fig. 1 and are defined as follows:

**Basic Size:** The size to which limits of deviation are assigned. The basic size is the same for both members of a fit. For example, it is designated by the numbers 40 in 40H7.

**Deviation:** The algebraic difference between a size and the corresponding basic size.

**Upper Deviation:** The algebraic difference between the maximum limit of size and the corresponding basic size.

**Lower Deviation:** The algebraic difference between the minimum limit of size and the corresponding basic size.

**Fundamental Deviation:** That one of the two deviations closest to the basic size. For example, it is designated by the letter H in 40H7.

**Tolerance:** The difference between the maximum and minimum size limits on a part.

**Tolerance Zone:** A zone representing the tolerance and its position in relation to the basic size.

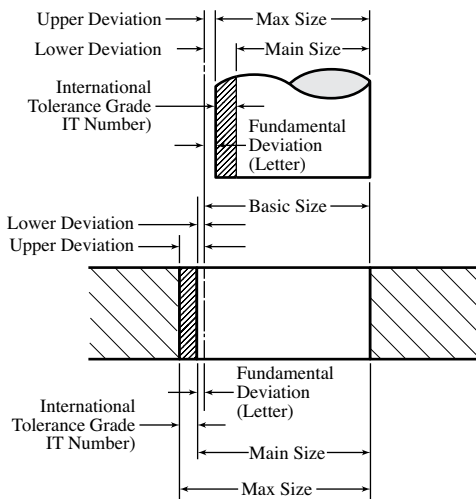

Fig. 1. Illustration of Definitions

**International Tolerance Grade (IT):** A group of tolerances that vary depending on the basic size, but that provide the same relative level of accuracy within a given grade. For example, International Tolerance Grade is designated by the number 7 in 40H7 or as IT7.

**Hole Basis:** The system of fits where the minimum hole size is basic. The fundamental deviation for a hole basis system is H.

**Shaft Basis:** The system of fits where the maximum shaft size is basic. The fundamental deviation for a shaft basis system is h.

**Clearance Fit:** The relationship between assembled parts when clearance occurs under all tolerance conditions.

**Interference Fit:** The relationship between assembled parts when interference occurs under all tolerance conditions.

**Transition Fit:** The relationship between assembled parts when either a clearance or an interference fit can result, depending on the tolerance conditions of the mating parts.

**Tolerances Designation.**—An “International Tolerance Grade” establishes the magnitude of the tolerance zone or the amount of part size variation allowed for external and internal dimensions alike (see Fig. 1). Tolerances are expressed in grade numbers that are consistent with International Tolerance Grades identified by the prefix IT, such as IT6, IT11, etc. A smaller grade number provides a smaller tolerance zone.

A fundamental deviation establishes the position of the tolerance zone with respect to the basic size (see Fig. 1). Fundamental deviations are expressed by tolerance position letters. Capital letters are used for internal dimensions and lowercase or small letters for external dimensions.

*Symbols:* By combining the IT grade number and the tolerance position letter, the tolerance symbol is established that identifies the actual maximum and minimum limits of the part. The toleranced size is thus defined by the basic size of the part followed by a symbol composed of a letter and a number, such as 40H7, 40f7, etc.

A fit is indicated by the basic size common to both components, followed by a symbol corresponding to each component, the internal part symbol preceding the external part symbol, such as 40H8/f7.

Some methods of designating tolerances on drawings are:

$$40H8 \qquad 40H8 \begin{pmatrix} 40.039 \\ 40.000 \end{pmatrix} \qquad \begin{pmatrix} 40.039 \\ 40.000 \end{pmatrix} 40H8$$

The values in parentheses indicate reference only.

**Preferred Metric Fits.**—First-choice tolerance zones are used to establish preferred fits in ANSI/ASME B4.2, *Preferred Metric Limits and Fits*, as shown in Fig. 2 and Fig. 3. A complete listing of first-, second-, and third- choice tolerance zones is given in the Standard.

Hole basis fits have a fundamental deviation of H on the hole, and shaft basis fits have a fundamental deviation of *h* on the shaft; they are shown in Fig. 2 for hole basis and Fig. 3 for shaft basis fits. A description of both types of fits, which have the same relative fit condition, is given in Table 1. Normally, the hole basis system is preferred; however, when a common shaft mates with several holes, the shaft basis system should be used.

The hole basis and shaft basis fits shown in the table *Description of Preferred Fits* on page 664 are combined with the first-choice preferred metric sizes from Table 1, page 688, to form Table 2, Table 3, Table 4, and Table 5, in which specific limits as well as the resultant fits are tabulated.

If the required size is not found tabulated in Table 2 through Table 5, then the preferred fit can be calculated from numerical values given in an appendix of ANSI/ASME B4.2-1978 (R2009). It is anticipated that other fit conditions may be necessary to meet special requirements, and a preferred fit can be loosened or tightened simply by selecting a standard tolerance zone as given in the Standard. Information on how to calculate limit dimensions, clearances, and interferences for nonpreferred fits and sizes can be found in an appendix of this Standard.

*Conversion of Fits:* It may sometimes be necessary or desirable to modify the tolerance zone on one or both of two mating parts yet still keep the total tolerance and fit condition the same. Examples of this appear in Table 1 on page 664 when converting from a hole basis fit to a shaft basis fit. The corresponding fits are identical, yet the individual tolerance zones are different.

To convert from one type of fit to another, reverse the fundamental deviations between the shaft and hole, keeping the IT grade the same on each individual part. The examples below represent preferred fits from Table 1 for a 60-mm basic size. These fits have the same maximum clearance (0.520) and the same minimum clearance (0.140).

Hole basis, loose running fit, values from Table 2

$$\text{Hole } 60H11 \begin{pmatrix} 60.190 \\ 60.000 \end{pmatrix} \qquad \text{Shaft } 60c11 \begin{pmatrix} 59.860 \\ 59.670 \end{pmatrix} \qquad \text{Fit } 60H11/c11 \begin{pmatrix} 0.520 \\ 0.140 \end{pmatrix}$$

Hole basis, loose running fit, values from Table 4

$$\text{Hole } 60C11 \begin{pmatrix} 60.330 \\ 60.140 \end{pmatrix} \qquad \text{Shaft } 60h11 \begin{pmatrix} 60.000 \\ 59.810 \end{pmatrix} \qquad \text{Fit } 60C11/h11 \begin{pmatrix} 0.520 \\ 0.140 \end{pmatrix}$$

Fig. 2. Preferred Hole Basis Fits

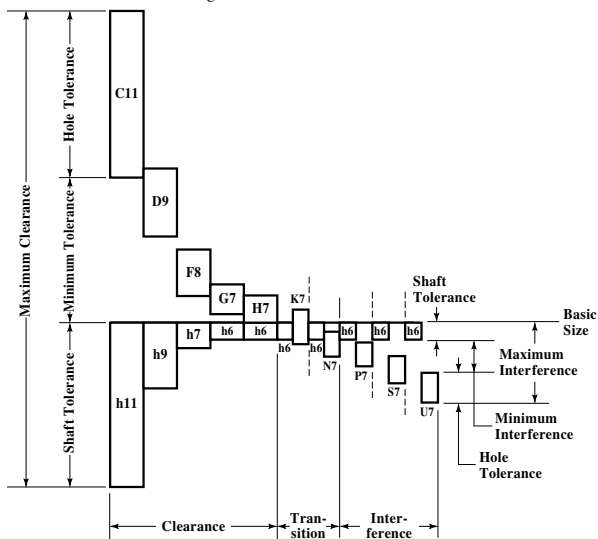

Fig. 3. Preferred Shaft Basis Fits

Table 1. Description of Preferred Fits

	ISO SYMBOL		DESCRIPTION	
	Hole Basis	Shaft Basis		
Clearance Fits	H11/c11	C11/h11	<i>Loose running</i> fit for wide commercial tolerances or allowances on external members.	↑ More Clearance
	H9/d9	D9/h9	<i>Free running</i> fit not for use where accuracy is essential, but good for large temperature variations, high running speeds, or heavy journal pressures.	
	H8/f7	F8/h7	<i>Close Running</i> fit for running on accurate machines and for accurate moderate speeds and journal pressures.	
	H7/g6	G7/h6	<i>Sliding fit</i> not intended to run freely but to move and turn freely and locate accurately.	
	H7/h6	H7/h6	<i>Locational clearance</i> fit provides snug fit for locating stationary parts but can be freely assembled and disassembled.	
Transition Fits	H7/k6	K7/h6	<i>Locational transition</i> fit for accurate location, a compromise between clearance and Interference.	↓ More Interference
	H7/n6	N7/h6	<i>Locational transition</i> fit for more accurate location where greater interference is permissible.	
Interference Fits	H7/p6 <sup>a</sup>	P7/h6	<i>Locational interference</i> fit for parts requiring rigidity and alignment with prime accuracy of location but without special bore pressure requirements.	
	H7/s6	S7/h6	<i>Medium drive</i> fit for ordinary steel parts or shrink fits on light sections, the tightest fit usable with cast iron.	
	H7/u6	U7/h6	<i>Force</i> fit suitable for parts which can be highly stressed or for shrink fits where the heavy pressing forces required are impractical.	

<sup>a</sup> Transition fit for basic sizes in range from 0 through 3 mm.

<sup>a</sup> The sizes shown are first-choice basic sizes (see Table 1, page 688). Preferred fits for other sizes can be calculated from data given in ANSI/ASME B4.2-1978 (R2009).

<sup>b</sup> All fits shown in this table have clearance.

All dimensions are in millimeters.

<sup>a</sup> The sizes shown are first-choice basic sizes (see Table 1, page 688). Preferred fits for other sizes can be calculated from data given in ANSI/ASME B4.2-1978 (R2009).

<sup>b</sup> A plus sign indicates clearance; a minus sign indicates interference.

All dimensions are in millimeters.

<sup>a</sup> The sizes shown are first-choice basic sizes (see Table 1, page 688). Preferred fits for other sizes can be calculated from data given in ANSI/ASME B4.2-1978 (R2009).

<sup>b</sup> All fits shown in this table have clearance.

All dimensions are in millimeters.

<sup>a</sup> The sizes shown are first-choice basic sizes (see Table 1, page 688). Preferred fits for other sizes can be calculated from data given in ANSI/ASME B4.2-1978 (R2009).

<sup>b</sup> A plus sign indicates clearance; a minus sign indicates interference.

All dimensions are in millimeters.

**Table 6. American National Standard Gagemakers Tolerances**  
 ANSI B4.4M-1981 (Withdrawn)

Gagemakers Tolerance			Workpiece Tolerance	
Class	ISO Symbol <sup>a</sup>	IT Grade	Recommended Gage Usage	
			ZM	0.05 IT11
YM	0.05 IT9	IT9	Gages recommended to be used to inspect workpieces held to internal (hole) tolerances D9 and H9 and to external (shaft) tolerances d9 and h9.	
XM	0.05 IT8	IT8	Precision gages recommended to be used to inspect workpieces held to internal (hole) tolerances F8 and H8.	
XXM	0.05 IT7	IT7	Recommended to be used for gages to inspect workpieces held to internal (hole) tolerances G7, H7, K7, N7, P7, S7, and U7, and to external (shaft) tolerances f7 and h7.	
XXXM	0.05 IT6	IT6	High-precision gages recommended to be used to inspect workpieces held to external (shaft) tolerances g6, h6, k6, n6, p6, s6, and u6.	

<sup>a</sup> Gagemakers tolerance is equal to 5 percent of workpiece tolerance or 5 percent of applicable IT grade value. See Table 7.

For workpiece tolerance class values, see previous Table 2 through Table 5, inclusive.

400	500	0.0200	0.0077	0.0048	0.0031	0.0020

All dimensions are in millimeters. For closer gagemakers tolerance classes than Class XXXM, specify 5 percent of IT5, IT4, or IT3 and use the designation 0.05 IT5, 0.05 IT4, etc.

Fig. 4. Relationship between Gagemakers Tolerance, Wear Allowance and Workpiece Tolerance

**Applications**

Many factors such as length of engagement, bearing load, speed, lubrication, operating temperatures, humidity, surface texture, and materials must be taken into account in fit selections for a particular application.

Choice of other than the preferred fits might be considered necessary to satisfy extreme conditions. Subsequent adjustments might also be desired as the result of experience in a particular application to suit critical functional requirements or to permit optimum manufacturing economy. Selection of a departure from these recommendations will depend upon consideration of the engineering and economic factors that might be involved; however, the benefits to be derived from the use of preferred fits should not be overlooked.

A general guide to machining processes that may normally be expected to produce work within the tolerances indicated by the IT grades given in ANSI/ASME B4.2-1978 (R2009) is shown in Table 8. Practical usage of the various IT tolerance grades is shown in Table 9.

							For Fits						For Large Manufacturing Tolerances					

**ISO Metric Limits and Fits**

Based on ISO Recommendation R286, this British Standard BS 4500:1969 is intended to provide a comprehensive range of metric limits and fits for engineering purposes, and meets the requirements of metrication in the United Kingdom. Sizes up to 3,150 mm are covered by the Standard, but the condensed information presented here embraces dimensions up to 500 mm only. The system is based on a series of tolerances graded to suit all classes of work from the finest to the most coarse, and the different types of fits that can be obtained range from coarse clearance to heavy interference. In the Standard, only cylindrical parts, designated holes and shafts are referred to explicitly, but it is emphasized that the recommendations

apply equally well to other sections, and the general terms *hole* and *shaft* can be taken to mean the space contained by or containing two parallel faces or tangent planes of any part, such as the width of a slot or the thickness of a key. It is also strongly emphasized that the grades series of tolerances are intended for the most general application and should be used wherever possible whether the features of the component involved are members of a fit or not.

**Definitions.**—The definitions given in the Standard include the following:

*Limits of Size:* The maximum and minimum sizes permitted for a feature.

*Basic Size:* The reference size to which the limits of size are fixed. The basic size is the same for both members of a fit.

*Upper Deviation:* The algebraic difference between the maximum limit of size and the corresponding basic size. It is designated as “ES” for a hole and as “es” for a shaft, which stands for the French term *écart supérieur*.

*Lower Deviation:* The algebraic difference between the minimum limit of size and the corresponding basic size. It is designated as “EI” for a hole and as “ei” for a shaft, which stands for the French term *écart inférieur*.

*Zero Line:* In a graphical representation of limits and fits, the straight line to which the deviations are referred. The zero line is the line of zero deviation and represents the basic size.

*Tolerance:* The difference between the maximum limit of size and the minimum limit of size. It is an absolute value without sign.

*Tolerance Zone:* In a graphical representation of tolerances, the zone comprised between the two lines representing the limits of tolerance and defined by its magnitude (tolerance) and by its position in relation to the zero line.

*Fundamental Deviation:* That one of the two deviations, being the one nearest to the zero line, which is conventionally chosen to define the position of the tolerance zone in relation to the zero line.

*Shaft-Basis System of Fits:* A system of fits in which the different clearances and interferences are obtained by associating various holes with a single shaft. In the ISO system, the basic shaft is the shaft the upper deviation of which is zero.

*Hole-Basis System of Fits:* A system of fits in which the different clearances and interferences are obtained by associating various shafts with a single hole. In the ISO system, the basic hole is the hole the lower deviation of which is zero.

**Selected Limits of Tolerance, and Fits.**—The number of fit combinations that can be built up with the ISO system is very large. However, experience shows that the majority of fits required for usual engineering products can be provided by a limited selection of tolerances. Limits of tolerance for selected holes are shown in [Table 1](#) and for shafts in [Table 2](#). Selected fits, based on combinations of the selected hole and shaft tolerances, are given in [Table 3](#).

**Tolerances and Fundamental Deviations.**—There are 18 tolerance grades intended to meet the requirements of different classes of work, and they are designated IT01, IT0, and IT1 to IT16. (IT stands for ISO series of tolerances.) [Table 4](#) shows the standardized numerical values for the 18 tolerance grades, which are known as standard tolerances. The system provides 27 fundamental deviations for sizes up to and including 500 mm, and [Table 5a](#) and [Table 5b](#) contain the values for shafts and [Table 6a](#) and [Table 6b](#) for holes. Uppercase (capital) letters designate hole deviations, and the same letters in lower case designate shaft deviations. The deviation  $j_s$  ( $J_s$  for holes) is provided to meet the need for symmetrical bilateral tolerances. In this instance, there is no fundamental deviation, and the tolerance zone, of whatever magnitude, is equally disposed about the zero line.

**Calculated Limits of Tolerance.**—The deviations and fundamental tolerances provided by the ISO system can be combined in any way that appears necessary to give a required fit. Thus, for example, the deviations H (basic hole) and f (clearance shaft) could

be associated, and with each of these deviations any one of the tolerance grades IT01 to IT16 could be used. All the limits of tolerance that the system is capable of providing for sizes up to and including 500 mm can be calculated from the standard tolerances given in Table 4, and the fundamental deviations given in Table 5a, Table 5b, Table 6a and Table 6b. The range includes limits of tolerance for shafts and holes used in small high-precision work and horology.

The system provides for the use of either hole-basis or shaft-basis fits, and the Standard includes details of procedures for converting from one type of fit to the other.

The limits of tolerance for a shaft or hole are designated by the appropriate letter indicating the fundamental deviation, followed by a suffix number denoting the tolerance grade. This suffix number is the numerical part of the tolerance grade designation. Thus, a hole tolerance with deviation H and tolerance grade IT7 is designated H7. Likewise, a shaft with deviation p and tolerance grade IT6 is designated p6. The limits of size of a component feature are defined by the basic size, say, 45 mm, followed by the appropriate tolerance designation, for example, 45 H7 or 45 p6. A fit is indicated by combining the basic size common to both features with the designation appropriate to each of them, for example, 45 H7-p6 or 45 H7/p6.

When calculating the limits of size for a shaft, the upper deviation  $es$ , or the lower deviation  $ei$ , is first obtained from Table 5a or Table 5b, depending on the particular letter designation, and nominal dimension. If an upper deviation has been determined, the lower deviation  $ei = es - IT$ . The IT value is obtained from Table 4 for the particular tolerance grade being applied. If a lower deviation has been obtained from Table 5a or Table 5b, the upper deviation  $es = ei + IT$ . When the upper deviation ES has been determined for a hole from Table 6a or Table 6b, the lower deviation EI = ES - IT. If a lower deviation EI has been obtained from Table 6a, then the upper deviation ES = EI + IT.

The upper deviations for holes K, M, and N with tolerance grades up to and including IT8, and for holes P to ZC with tolerance grades up to and including IT7 must be calculated by adding the delta ( $\Delta$ ) values given in Table 6b as indicated.

*Example 1:* The limits of size for a part of 133 mm basic size with a tolerance designation g9 are derived as follows:

From Table 5a, the upper deviation ( $es$ ) is  $-0.014$  mm. From Table 4, the tolerance grade (IT9) is 0.100 mm. The lower deviation ( $ei$ ) =  $es - IT = 0.114$  mm, and the limits of size are thus 132.986 and 132.886 mm.

*Example 2:* The limits of size for a part 20 mm in size, with tolerance designation D3, are derived as follows: From Table 6a, the lower deviation (EI) is  $+0.065$  mm. From Table 4, the tolerance grade (IT3) is 0.004 mm. The upper deviation (ES) =  $EI + IT = 0.069$  mm, and thus the limits of size for the part are 20.069 and 20.065 mm.

*Example 3:* The limits of size for a part 32 mm in size, with tolerance designation M5, which involves a delta value, are obtained as follows: From Table 6a, the upper deviation ES is  $-0.009$  mm +  $\Delta = -0.005$  mm. (The delta value given at the end of Table 6b for this size and grade IT5 is 0.004 mm.) From Table 4, the tolerance grade (IT5) is 0.011 mm. The lower deviation (EI) =  $ES - IT = -0.016$  mm, and thus the limits of size for the part are 31.995 and 31.984 mm.

Where the designations h and H or  $j_s$  and  $J_s$  are used, it is only necessary to refer to Table 4. For h and H, the fundamental deviation is always zero, and the disposition of the tolerance is always negative (−) for a shaft and positive (+) for a hole.

*Example 4:* The limits for a part 40 mm in size, designated h8 are derived as follows: From Table 4, the tolerance grade (IT8) is 0.039 mm, and the limits are therefore 40.000 and 39.961 mm.

*Example 5:* The limits for a part 60 mm in size, designated  $j_s7$  or  $J_s7$  are derived as follows: From Table 4, the tolerance grade (IT7) is 0.030 mm, and this value is divided equally about the basic size to give limits of 60.015 and 59.985 mm.

<sup>a</sup> Not applicable to sizes up to 1 mm.<sup>b</sup> In grades 7 to 11, the two symmetrical deviations ±IT/2 should be rounded if the IT value in micrometers is an odd value by replacing it with the even value immediately below. For example, if IT = 175, replace it by 174.

<sup>a</sup> Special case: for M6, ES = -9 for sizes from 250 to 315 mm, instead of -11.

<sup>b</sup> Not applicable to sizes up to 1 mm.

<sup>c</sup> In grades 7 to 11, the two symmetrical deviations ±IT/2 should be rounded if the IT value in micrometers is an odd value by replacing it with the even value below. For example, if IT = 175, replace it by 174.

<sup>d</sup> When calculating deviations for holes K, M, and N with tolerance grades up to and including IT8, and holes P to ZC with tolerance grades up to and including IT7, the delta (Δ) values are added to the upper deviation ES. For example, for 25 P7, ES = -0.022 + 0.008 = -0.014 mm.

**Table 6b. British Standard Fundamental Deviations for Holes BS 4500:1969**

The dimensions are given in 0.001 mm, except the nominal sizes, which are in millimeters.

### Tolerance Analysis and Assignment

All parts are produced with some amount of variation, or difference, between the intended geometry and features of the part produced. While variation is unavoidable and expected, the challenge is determining an acceptable amount. The amount and type of variation is called *tolerance*. Part feature tolerances are not assigned arbitrarily, but rather are specified by designers with good understanding of manufacturing process capabilities, cost limitations, and assembly and functional requirements. Good design allows for the broadest tolerances possible that meet all requirements, resulting in parts that are easier and less costly to produce. Overly restrictive tolerances limit manufacturers to unnecessarily precise methods, driving up costs, which can be impacted dramatically by small differences in tolerances.

Tolerance analysis and tolerance assignment are bottom-up and top-down approaches, respectively, to calculating tolerances, and typically they are used in iterative fashion. Tolerance assignment is done at the design stage, to meet assembly and functional requirements. Tolerance analysis is performed later, on preliminary or final part tolerances, to detect any needed design improvements and changes in tolerance assignments. Predicting the results of variations may be an end in itself, but more often, the goal is to select the best tolerances throughout an assembly to meet design requirements.

**The Tolerance Stack-Up Chain.**—Tolerance stack-up calculations analyze the effects that tolerances have on function and guide tolerance assignment. A tolerance stack-up chain diagram is created first to clearly identify the assembly dimension to be solved and each part dimension contributing to the stack-up, as is shown in Fig. 5.

Fig. 5. Tolerance Stack-Up Chain Diagram, Related Specifications, and Dimension Data

From the diagram, a tolerance stack-up equation is derived. In dimension labeling, a sign convention denotes direction: positive for up or right; negative for down or left. The assembly dimension can then be solved, as in the following example, written in general form:

$$A = -B - C - D + E + F + G \quad (1)$$

Clear, unambiguous part definition, as provided by geometric dimensioning and tolerancing, is required for accurate tolerance analysis. Care must be taken to ensure the effects of geometric variation are included in dimensions expressed numerically. Any sources of variation allowed by referenced drawings must be included in the stack-up equation.

**Tolerance Analysis Calculation Methods.**—For solving analysis or assignment problems, four methods of tolerance stack-up calculation are common.

**Worst-Case:** During analysis, the worst-case method predicts the largest variation in the assembly dimension and requires the smallest tolerances be assigned. Worst-case calculations are appropriate when every feature is inspected to screen from use any out-of-specification parts, and/or when there are few (approximately seven or fewer) dimensions in the chain. Benefits of this analytical method are its simplicity and speed.

A tolerance stack-up calculation is performed twice, resulting in the maximum value on the first pass and the minimum value on the second pass. Thus, the general stack-up equation is expressed as two separate equations, with each dimension represented by its maximum and minimum values. The default is to put maximum values on the first line and minimum on the second; this is reversed for contributing dimensions with negative signs.

$$A_{\max} = -B_{\min} - C_{\min} - D_{\min} + E_{\max} + F_{\max} + G_{\max} \quad (2a)$$

$$A_{\min} = -B_{\max} - C_{\max} - D_{\max} + E_{\min} + F_{\min} + G_{\min} \quad (2b)$$

*Example:* Predict the minimum and maximum assembly dimensions for the stack-up diagram and dimensions given in Fig. 5 using the worst-case method.

*Solution:* Using Equations (2a) and (2b):

$$A_{\max} = -0.375 - 0.5858 - 1.749 + 0.1875 + 1.755 + 0.9395 = 0.1722$$

$$A_{\min} = -0.376 - 0.5906 - 1.751 + 0.1825 + 1.745 + 0.9355 = 0.1454$$

*Statistical:* This approach produces likely values and ranges, predicts smaller assembly variations, and permits larger tolerances to be assigned. While it does not guarantee conformity to requirements, conformance and defect rates can be predicted. Statistical calculations are appropriate when many dimensions are contributing to a stack-up chain or when it can be assumed that the contributing dimensions follow normal distributions, such as when statistical process control (SPC) is used (see *STATISTICAL ANALYSIS OF MANUFACTURING DATA* on page 136 for statistics terminology used here). The assembly dimension  $A$  is modeled as a normal distribution, with assembly mean ( $\mu_A$ ) and assembly standard deviation ( $\sigma_A$ ) calculated using the general stack-up equations written in statistical form:

Assembly mean ( $\mu_A$ ):

$$\mu_A = -\mu_B - \mu_C - \mu_D + \mu_E + \mu_F + \mu_G \quad (3)$$

Assembly standard deviation ( $\sigma_A$ ):

$$\sigma_A = \sqrt{\sigma_B^2 + \sigma_C^2 + \sigma_D^2 + \sigma_E^2 + \sigma_F^2 + \sigma_G^2} \quad (4)$$

*Example:* Use the statistical method to determine the range of assembly dimension values, between which 99 percent of assembly dimensions are expected to fall, for the stack-up diagram and dimensions given in Fig. 5. Manufacturing data show the contributing dimensions are well modeled as normal distributions using the parameters included in the figure.

*Solution:* Model assembly dimension  $A$  as a normal distribution with parameters calculated using Equations (3) and (4):

$$\mu_A = -0.375464 - 0.588126 - 1.750128 + 0.185147 + 1.750748 + 0.937331 = 0.159508$$

$$\sigma_A = \sqrt{0.000106^2 + 0.001004^2 + 0.000203^2 + 0.000874^2 + 0.001200^2 + 0.000517^2} = 0.001879$$

99 percent of the area under the normal distribution curve falls within the range of  $\pm 2.5758\sigma$ . Upper and lower limits of this range for assembly dimension  $A$  are calculated as:

$$A_{\text{upper}} = 0.159508 + (2.5758)(0.001879) = 0.164348$$

$$A_{\text{lower}} = 0.159508 - (2.5758)(0.001879) = 0.154668$$

Therefore, 99 percent of assembly dimensions are expected to measure between 0.154668 and 0.164348.

*Root Sum of Squares (RSS):* This method belongs somewhere between the worst-case and statistical methods in terms of when applicable and the desired characteristics of the result. RSS is technically a statistical method with several simplifying assumptions applied. Each contributing dimension is modeled as a normal distribution, with mean ( $\mu$ ) and standard deviation ( $\sigma$ ) calculated from the maximum and minimum values.

Each contributing dimension mean ( $\mu$ ) is calculated as:

$$\mu = \frac{\text{Max} + \text{Min}}{2} \quad (5)$$

Each contributing dimension standard deviation ( $\sigma$ ) is calculated as:

$$\sigma = \frac{\text{Max} - \text{Min}}{6} \quad (6)$$

The calculations for assembly mean ( $\mu_A$ ) and assembly standard deviation ( $\sigma_A$ ) are the same as in the statistical method; see Equations (3) and (4). The assembly dimension is then predicted to fall between the limits:

$$A_{\max} = \mu_A + 3\sigma_A \quad (7a)$$

$$A_{\min} = \mu_A - 3\sigma_A \quad (7b)$$

*Example:* Predict the minimum and maximum assembly dimension for the stack-up diagram and dimensions given in Fig. 5. Assume manufacturing data are not available for this example and apply the RSS method.

*Solution:* Using Equations (5) and (6), calculate a mean and standard deviation to use as model parameters for each of the contributing dimensions in Fig. 5. Starting with B:

$\mu = \frac{0.376 + 0.375}{2} = 0.3755$ $\sigma = \frac{0.376 - 0.375}{6} = 0.000167$	Dim	Mean ( $\mu$ )	Standard Deviation ( $\sigma$ )
	B	0.3755	0.000167
	C	0.5882	0.000800
	D	1.75	0.000333
	E	0.185	0.000833
	F	1.75	0.001667
	G	0.9375	0.000667

Repeating this calculation for dimensions C through G produces the table values shown. Next, the assembly dimension parameters are calculated using Equations (3) and (4):

$$\mu_A = -0.3755 - 0.5882 - 1.75 + 0.185 + 1.75 + 0.9375 = 0.1588$$

$$\sigma_A = \sqrt{0.000167^2 + 0.000800^2 + 0.000333^2 + 0.000833^2 + 0.001667^2 + 0.000667^2} = 0.002167$$

Finally, the assembly limits are calculated using Equations (7a) and (7b):

$$A_{\max} = 0.1588 + (3)(0.002167) = 0.165301$$

$$A_{\min} = 0.1588 - (3)(0.002167) = 0.152299$$

Therefore, assemblies are expected to measure between 0.152299 and 0.165301.

*Monte Carlo Simulation:* This random-number-based calculation method attempts to model variation realistically. The simulation runs numerous cases and builds a probability distribution for the stack-up, which is used to predict results, including defect rates. For each case, contributing dimensions in the stack-up chain are randomly chosen according to their statistical distribution (normal, uniform, or otherwise). The dimensions are combined according to the stack-up equation, which may be nonlinear.

**Tolerance Assignment.**—This is the process of distributing the “tolerance budget” among contributing dimensions of the stack-up chain to manage costs and meet target quality levels. As explained above, analysis produces one solution (assembly dimension) from several inputs (dimensions of contributing parts), whereas assignment attempts to produce several contributing part dimensions from one assembly dimension. There are infinite ways to assign part tolerances to achieve a desired assembly tolerance (thus, analytical solutions usually are not possible), with several methods for assigning tolerances being most common.

*Even Assignment:* Part feature tolerances are assigned equally among assignable tolerances to stay within the required assembly tolerance.

*Proportional Scaling:* Preliminary tolerances are assigned and analyzed. If the assembly tolerance exceeds the allowed amount, assignable part feature tolerances are scaled down proportionally as needed.

*Weight Factors:* Weight factors, determined on the basis of manufacturing difficulty, are allocated to each assignable tolerance. The assembly tolerance budget is divided across each tolerance proportional to its weight factor.

*Cost Minimization:* A cost-versus-tolerance relationship is determined for each contributing dimension. The optimization algorithm varies and compares the tolerances of each dimension to arrive at the combination that minimizes total cost.

*Total Cost Minimization:* This method loosens tolerances to reduce cost while considering the cost of lower yields due to production of some number of defective parts.

### Preferred Numbers

Preferred numbers are series of numbers selected to be used for standardization purposes in preference to any other numbers. Their use will lead to simplified practice, and they should be employed whenever possible for individual standard sizes and ratings, or for a series, in applications similar to the following:

- 1) Important or characteristic linear dimensions such as diameters and lengths, areas, volume, weights, capacities.
- 2) Ratings of machinery and apparatus in horsepower, kilowatts, kilovolt-amperes, voltages, currents, speeds, power-factors, pressures, heat units, temperatures, gas or liquid-flow units, weight-handling capacities, etc.
- 3) Characteristic ratios of figures for all kinds of units.

**American National Standard for Preferred Numbers.**—ANSI Standard Z17.1-1973 covers basic series of preferred numbers which are independent of any measurement system and therefore can be used with metric or customary units. This standard has been withdrawn with no superseding standard specified.

The numbers are rounded values of the following five geometric series of numbers:  $10^{N/5}$ ,  $10^{N/10}$ ,  $10^{N/20}$ ,  $10^{N/40}$ , and  $10^{N/80}$ , where  $N$  is an integer in the series 0, 1, 2, 3, etc. The designations used for the five series are respectively R5, R10, R20, R40, and R80, where R stands for Renard (Charles Renard, originator of the first preferred number system) and the number indicates the root of 10 on which the particular series is based.

The R5 series gives 5 numbers approximately 60 percent apart, the R10 series gives 10 numbers approximately 25 percent apart, the R20 series gives 20 numbers approximately 12 percent apart, the R40 series gives 40 numbers approximately 6 percent apart, and the R80 series gives 80 numbers approximately 3 percent apart. The number of sizes for a given purpose can be minimized by using the R5 series first and then adding sizes from the R10 and R20 series as needed. The R40 and R80 series are used principally for expressing tolerances in sizes based on preferred numbers. Preferred numbers below 1 are formed by dividing the given numbers by 10, 100, etc., and numbers above 10 are obtained by multiplying the given numbers by 10, 100, etc. Sizes graded according to the system may not be exactly proportional to one another because preferred numbers may differ from calculated values by +1.26 percent to -1.01 percent. Deviations from preferred numbers are used in some instances — for example, where whole numbers are needed, such as 32 instead of 31.5 for the number of teeth in a gear.

**Basic Series of Preferred Numbers ANSI Z17.1-1973**

Series Designation								
R5	R10	R20	R40	R40	R80	R80	R80	R80
Preferred Numbers								
1.00	1.00	1.00	1.00	3.15	1.00	1.80	3.15	5.60

**Preferred Metric Sizes.**—American National Standard ANSI B32.4M-1980 (R1994), presents series of preferred metric sizes for round, square, rectangular, and hexagonal metal products. **Table 1** gives preferred metric diameters from 1 to 320 millimeters for round metal products. Wherever possible, sizes should be selected from the Preferred Series shown in the table. A Second Preference Series is also shown. A Third Preference Series not shown in the table is: 1.3, 2.1, 2.4, 2.6, 3.2, 3.8, 4.2, 4.8, 7.5, 8.5, 9.5, 36, 85, and 95. This standard has now been consolidated into ANSI/ASME B32.100-2016, see *Metric Sizes for Flat Metal Products* on page 2708.

ANSI/ASME B4.2-1978 (R2009) states that the basic size of mating parts should be chosen from the first choice sizes listed in **Table 1**. Most of the Preferred Series sizes are derived from the American National Standard “10 series” of preferred numbers (see *American National Standard for Preferred Numbers* on page 687). Most of the Second Preference Series are derived from the “20 series” of preferred numbers. Third Preference sizes are generally from the “40 series” of preferred numbers.

For preferred metric diameters less than 1 millimeter, preferred across flat metric sizes of square and hexagon metal products, preferred across flat metric sizes of rectangular metal products, and preferred metric lengths of metal products, reference should be made to the Standard.

**Preferred Metric Sizes for Metal Products.**—See *Metric Sizes for Flat Metal Products* on page 2708.

**British Standard Preferred Numbers and Preferred Sizes.**—This British Standard, PD 6481:1977 1983, gives recommendations for the use of preferred numbers and preferred sizes for functional characteristics and dimensions of various products.

The preferred number system is internationally standardized in ISO 3. It is also referred to as the Renard, or R, series (see *American National Standard for Preferred Numbers* on page 687).

The series in the preferred number system are geometric series, that is, there is a constant ratio between each figure and the succeeding one, within a decimal framework. Thus, the R5 series has five steps between 1 and 10, the R10 series has 10 steps between 1 and 10, the R20 series, 20 steps, and the R40 series, 40 steps, giving increases between steps of approximately 60, 25, 12, and 6 percent, respectively.

The preferred size series have been developed from the preferred number series by rounding off the inconvenient numbers in the basic series and adjusting for linear measurement in millimeters. These series are shown in Table 2.

After taking all normal considerations into account, it is recommended that (a) for ranges of values of the primary *functional* characteristics (outputs and capacities) of a series of products, the preferred number series R5 to R40 (see page 687) should be used, and (b) whenever linear sizes are concerned, the preferred sizes as given in the following table should be used. The presentation of preferred sizes gives designers and users a logical selection and the benefits of rational variety reduction.

The second-choice size given should only be used when it is not possible to use the first choice, and the third choice should be applied only if a size from the second choice cannot be selected. With this procedure, common usage will tend to be concentrated on a limited range of sizes, and a contribution is thus made to variety reduction. However, the decision to use a particular size cannot be taken on the basis that one is first choice and the other not. Account must be taken of the effect on the design, the availability of tools, and other relevant factors.

**Table 2. British Standard Preferred Sizes, PD 6481: 1977 (1983)**

	4.5		20	19	64			64	120								
5		4.8		21													
			22														

For dimensions above 300, each series continues in a similar manner, i.e., the intervals between each series number are the same as between 200 and 300.

## MEASURING, INSTRUMENTS, AND INSPECTION METHODS

## Reading Verniers and Micrometers

**Reading a Vernier.**—A general rule for taking readings with a vernier scale is as follows: Note the number of inches and subdivisions of an inch that the zero mark of the vernier scale has moved along the true scale, and then add to this reading as many thousandths, hundredths, or whatever fractional part of an inch the vernier reads to, as there are spaces between the vernier zero and that line on the vernier coinciding with one on the true scale. For example, if the zero line of a vernier that reads to thousandths is slightly beyond the 0.5 inch division on the main or true scale, as shown in Fig. 1, and graduation line 10 on the vernier exactly coincides with one on the true scale, the reading is  $0.5 + 0.010$  or 0.510 inch. In order to determine the reading or fractional part of an inch that can be obtained by a vernier, multiply the denominator of the finest subdivision given on the true scale by the total number of divisions on the vernier. For example, if one inch on the true scale is divided into 40 parts or fortieths (as in Fig. 1), and the vernier into twenty-five parts, the vernier will read to thousandths of an inch, as  $25 \times 40 = 1000$ . Similarly, if there are sixteen divisions to the inch on the true scale and a total of eight on the vernier, the latter will enable readings to be taken within  $\frac{1}{128}$  of an inch, as  $8 \times 16 = 128$ .

Fig. 1. Inch Vernier

Fig. 2. Protractor with Vernier Scale

If the vernier is on a protractor, note the whole number of degrees passed by the vernier zero mark and then count the spaces between the vernier zero and the line coinciding with a graduation on the protractor scale. If the vernier indicates angles within five minutes or one-twelfth degree (as in Fig. 2), the number of spaces multiplied by 5 will, of course, give the number of minutes to be added to the whole number of degrees. The reading of the protractor set as illustrated would be 14 whole degrees (the number passed by the zero mark on the vernier) plus 30 minutes, as the graduation 30 on the vernier is the only one to the right of the vernier zero that exactly coincides with a line on the protractor scale. It will be

noted that there are duplicate scales on the vernier, one being to the right and the other to the left of zero. The left-hand scale is used when the vernier zero is moved to the left of the zero of the protractor scale, whereas the right-hand graduations are used when the movement is to the right.

**Reading a Metric Vernier.**—The smallest graduation on the bar (true or main scale) of the metric vernier gage shown in Fig. 1, is 0.5 millimeter. The scale is numbered at each twentieth division, and thus increments of 10, 20, 30, 40 millimeters, etc., are indicated. There are 25 divisions on the vernier scale, occupying the same length as 24 divisions on the bar, which is 12 millimeters. Therefore, one division on the vernier scale equals one twenty-fifth of 12 millimeters =  $0.04 \times 12 = 0.48$  millimeter. Thus, the difference between one bar division (0.50 mm) and one vernier division (2.48 mm) is  $0.50 - 0.48 = 0.02$  millimeter, which is the minimum measuring increment that the gage provides. To permit direct readings, the vernier scale has graduations to represent tenths of a millimeter (0.1 mm) and fiftieths of a millimeter (0.02 mm).

Fig. 1. Metric Vernier

To read a vernier gage, first note how many millimeters the zero line on the vernier is from the zero line on the bar. Next, find the graduation on the vernier scale that exactly coincides with a graduation line on the bar, and note the value of the vernier scale graduation. This value is added to the value obtained from the bar, and the result is the total reading.

In the example shown in Fig. 1, the vernier zero is just past the 40.5 millimeters graduation on the bar. The 0.18 millimeter line on the vernier coincides with a line on the bar, and the total reading is therefore  $40.5 + 0.18 = 40.68$  mm.

**Dual Metric-Inch Vernier.**—The vernier gage shown in Fig. 2 has separate metric 50-division, and inch 25-division vernier scales to permit measurements in either system.

On the bar, the smallest metric graduation is 1 millimeter, and the 50 divisions of the vernier occupy the same length as 49 divisions on the bar, which is 49 mm. Therefore, one division on the vernier scale equals one-fiftieth of 49 millimeters =  $0.02 \times 49 = 0.98$  mm. Thus, the difference between one bar division (1.0 mm) and one vernier division (0.98 mm) is 0.02 mm, which is the minimum measuring increment the gage provides.

The vernier scale is graduated for direct reading to 0.02 mm. In Fig. 2, the vernier zero is just past the 27 mm graduation on the bar, and the 0.42 mm graduation on the vernier coincides with a line on the bar. The total reading is therefore 27.42 mm.

The smallest inch graduation on the bar is 0.025 inch, and the 25 vernier divisions occupy the same length as 49 bar divisions, which is 1.225 inches. Therefore, one vernier division equals one twenty-fifth of 1.225 inches =  $0.04 \times 1.225 = 0.049$  inch. Thus, the difference between the length of two bar divisions and a vernier division is  $0.050 - 0.049 = 0.001$  inch. The vernier scale is graduated for direct reading to 0.001 inch. In the example, the vernier zero is past the 1.075 graduation on the bar, and the 0.004 graduation on the vernier coincides with a line on the bar. Thus, the total reading is 1.079 inches.

Fig. 2. Dual Metric-Inch Vernier

**Reading a Micrometer.**—The spindle of an inch-system micrometer has 40 threads per inch, so that one turn moves the spindle axially  $0.025$  inch ( $1 \div 40 = 0.025$ ), equal to the distance between two graduations on the frame. The 25 graduations on the thimble allow the  $0.025$  inch to be further divided, so that turning the thimble through one division moves the spindle axially  $0.001$  inch ( $0.025 \div 25 = 0.001$ ). To read a micrometer, count the number of whole divisions visible on the scale of the frame, multiply this number by 25 (the number of thousandths of an inch that each division represents) and add to the product the number of that division on the thimble coinciding with the axial zero line on the frame. The result will be the diameter expressed in thousandths of an inch. As the numbers 1, 2, 3, etc., opposite every fourth subdivision on the frame indicate hundreds of thousandths, the reading can easily be taken mentally. Suppose the thimble were screwed out so that graduation 2 and three additional subdivisions were visible (as shown in Fig. 3), and that graduation 10 on the thimble coincided with the axial line on the frame. The reading then would be  $0.200 + 0.075 + 0.010$ , or  $0.285$  inch.

Fig. 3. Inch Micrometer

Fig. 4. Inch Micrometer with Vernier

Some micrometers have a vernier scale on the frame in addition to the regular graduations so that measurements within  $0.0001$  part of an inch can be taken. Micrometers of this type are read as follows: First determine the number of thousandths, as with an ordinary micrometer, and then find a line on the vernier scale that exactly coincides with one on the thimble; the number of this line represents the number of ten-thousandths to be added to the number of thousandths obtained by the regular graduations. The reading shown in the illustration, Fig. 4, is  $0.275 + 0.020 + 0.0003 = 0.2953$  inch.

Micrometers graduated according to the English system of measurement ordinarily have a table of decimal equivalents stamped on the sides of the frame so that fractions such as sixty-fourths, thirty-seconds, etc., can readily be converted into decimals.

**Reading a Metric Micrometer.**—The spindle of an ordinary metric micrometer has 2 threads per millimeter, and thus one complete revolution moves the spindle through a distance of 0.5 millimeter. The longitudinal line on the frame is graduated with 1 millimeter divisions and 0.5 millimeter subdivisions. The thimble has 50 graduations, each being 0.01 millimeter (one-hundredth of a millimeter).

To read a metric micrometer, note the number of millimeter divisions visible on the scale of the sleeve, and add the total to the particular division on the thimble that coincides with the axial line on the sleeve. Suppose that the thimble were screwed out so that graduation 5 and one additional 0.5 subdivision were visible (as shown in Fig. 5), and that graduation 28 on the thimble coincided with the axial line on the sleeve. The reading then would be  $5.00 + 0.5 + 0.28 = 5.78$  mm.

Fig. 5. Metric Micrometer

To permit measurements within 0.002 millimeter to be made, some micrometers are provided with a vernier scale on the sleeve in addition to regular graduations. Micrometers of this type are read as follows: First, as with an ordinary micrometer, determine the number of whole millimeters (if any) and the number of hundredths of a millimeter, and then find a line on the sleeve vernier scale that exactly coincides with one on the thimble. The number of this coinciding vernier line represents the number of two-thousandths of a millimeter to be added to the reading already obtained. Thus, for example, a measurement of 2.958 millimeters would be obtained by reading 2.5 millimeters on the sleeve, adding 0.45 millimeter read from the thimble, and then adding 0.008 millimeter as determined by the vernier.

*Note:* 0.01 millimeter = 0.000393 inch, and 0.002 millimeter = 0.000078 inch (78 millionths). Therefore, metric micrometers provide smaller measuring increments than comparable inch unit micrometers—the smallest graduation of an ordinary inch-reading micrometer is 0.001 inch; the vernier type has graduations down to 0.0001 inch. When using either a metric or inch micrometer without a vernier, smaller readings than those graduated may, of course, be obtained by visual interpolation between graduations.

### Sine-Bar Use

The sine-bar is used either for very accurate angular measurements or for locating work at a given angle as, for example, in surface grinding templets, gages, etc. The sine-bar is especially useful in measuring or checking angles when the limit of accuracy is 5 minutes or less. Some bevel protractors are equipped with verniers which read to 5 minutes, but the setting depends upon the alignment of graduations, whereas a sine-bar usually is located by positive contact with precision gage-blocks selected for whatever dimension is required for obtaining a given angle.

**Types of Sine-Bars.**—A sine-bar consists of a hardened, ground and lapped steel bar with very accurate cylindrical plugs of equal diameter attached to or near each end. The form illustrated by Fig. 1 has notched ends for receiving the cylindrical plugs so that they are held firmly against both faces of the notch. The standard center-to-center distance  $C$  between the plugs is either 5 or 10 inches. The upper and lower sides of sine-bars are parallel to the center line of the plugs within very close limits. The body of the sine-bar ordinarily

has several through holes to reduce the weight. In the making of the sine-bar shown in Fig. 2, if too much material is removed from one locating notch, regrinding the shoulder at the opposite end would make it possible to obtain the correct center distance. That is the reason for this change in form. The type of sine-bar illustrated by Fig. 3 has the cylindrical disks or plugs attached to one side. These differences in form or arrangement do not, of course, affect the principle governing the use of the sine-bar. An accurate surface plate or master flat is always used in conjunction with a sine-bar in order to form the base from which the vertical measurements are made.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

**Setting a Sine-Bar to a Given Angle.**—To find the vertical distance  $H$  for setting a sine-bar to the required angle, convert the angle to decimal form on a pocket calculator, take the sine of that angle, and multiply by the distance between the cylinders. For example, if an angle of 31 degrees, 30 minutes is required, the equivalent angle is 31 degrees plus  $\frac{30}{60} = 31 + 0.5$ , or 31.5 degrees. (For conversions from minutes and seconds to decimals of degrees and vice versa, see page 103.) The sine of 31.5 degrees is 0.5225, and multiplying this value by the sine-bar length gives 2.613 inches for the height  $H$ , Fig. 1 and Fig. 3, of the gage blocks.

**Finding Angle when Height  $H$  of Sine-Bar is Known.**—To find the angle equivalent to a given height  $H$ , reverse the above procedure. Thus, if the height  $H$  is 1.4061 in., dividing by 5 gives a sine of 0.28122, which corresponds to an angle of 16.333 degrees, or 16 degrees 20 minutes.

**Checking Angle of Templet or Gage by Using Sine-Bar.**—Place templet or gage on sine-bar as indicated by dotted lines, Fig. 1. Clamps may be used to hold work in place. Place upper end of sine-bar on gage blocks having total height  $H$  corresponding to the required angle. If upper edge  $D$  of work is parallel with surface plate  $E$ , then angle  $A$  of work equals angle  $A$  to which sine-bar is set. Parallelism between edge  $D$  and surface plate may be tested by checking the height at each end with a dial gage or some type of indicating comparator.

**Measuring Angle of Templet or Gage with Sine-Bar.**—To measure such an angle, adjust height of gage blocks and sine-bar until edge  $D$ , Fig. 1, is parallel with surface plate  $E$ ; then find angle corresponding to height  $H$  of gage blocks. For example, if height  $H$  is

2.5939 inches when  $D$  and  $E$  are parallel, the calculator will show that the angle  $A$  of the work is 31 degrees, 15 minutes.

**Checking Taper per Foot with Sine-Bar.**—As an example, assume that the plug gage in Fig. 2 is supposed to have a taper of  $6\frac{1}{8}$  inches per foot and taper is to be checked by using a 5-inch sine-bar. The table of *Tapers per Foot and Corresponding Angles* on page 698 shows that the included angle for a taper of  $6\frac{1}{8}$  inches per foot is 28 degrees 38 minutes 1 second, or 28.6336 degrees from the calculator. For a 5-inch sine-bar, the calculator gives a value of 2.396 inch for the height  $H$  of the gage blocks. Using this height, if the upper surface  $F$  of the plug gage is parallel to the surface plate, the angle corresponds to a taper of  $6\frac{1}{8}$  inches per foot.

**Setting Sine-Bar having Plugs Attached to Side.**—If the lower plug does not rest directly on the surface plate, as in Fig. 3, the height  $H$  for the sine-bar is the difference between heights  $x$  and  $y$ , or the difference between the heights of the plugs; otherwise, the procedure in setting the sine-bar and checking angles is the same as previously described.

**Checking Templets Having Two Angles.**—Assume that angle  $a$  of templet, Fig. 4, is 9 degrees, angle  $b$  is 12 degrees, and that edge  $G$  is parallel to the surface plate. For an angle  $b$  of 12 degrees, the calculator shows that the height  $H$  is 1.03956 inches. For an angle  $a$  of 9 degrees, the difference between measurements  $x$  and  $y$  when the sine-bar is in contact with the upper edge of the templet is 0.78217 inch.

**Sine-Bar Tables to Set Sine-Bars to Given Angle.**—*Machinery's Handbook 31 Digital Edition* contains tables that give constants for sine-bars of 2.5 to 10 inches and 75 to 150 mm length. These constants represent the vertical height  $H$  for setting a sine-bar of the corresponding length to the required angle.

**Using Sine-Bar Tables with Sine-Bars of Other Lengths.**—A sine-bar may sometimes be preferred that is longer (or shorter) than that given in available tables because of its longer working surface or because the longer center distance is conducive to greater precision. To use the sine-bar tables with a sine-bar of another length to obtain the vertical distances  $H$ , multiply the value obtained from the table by the fraction (length of sine-bar used  $\div$  length of sine-bar specified in table).

*Example:* Use the 5-inch sine-bar table to obtain the vertical height  $H$  for setting a 10-inch sine-bar to an angle of 39 degrees. The sine of 39 degrees is 0.62932, hence the vertical height  $H$  for setting a 10-inch sine-bar is 6.2932 inches.

*Solution:* The height  $H$  given for 39 degrees in the 5-inch sine-bar table (*Constants for 5-Inch Sine-Bar* in the *ADDITIONAL* material in the *Machinery's Handbook 31 Digital Edition*) is 3.14660. The corresponding height for a 10-inch sine-bar is  $10\frac{0}{100} \times 3.14660 = 6.2932$  inches.

**Using a Calculator to Determine Sine-Bar Constants for a Given Angle.**—The constant required to set a given angle for a sine-bar of any length can be quickly determined by using a scientific calculator. The required formulas are as follows:

- a) angle  $A$  given in degrees and calculator is set to measure angles in radian      or      a) angle  $A$  is given in radian, or  
 b) angle  $A$  is given in degrees and calculator is set to measure angles in degrees

$$H = L \times \sin\left(A \times \frac{\pi}{180}\right)$$

$$H = L \times \sin(A)$$

where  $L$  = length of the sine-bar       $A$  = angle to which the sine-bar is to be set

$H$  = vertical height to which one end of sine-bar must be set to obtain angle  $A$

$$\pi = 3.141592654$$

In the previous formulas, the height  $H$  and length  $L$  must be given in the same units but may be in either metric or US units. Thus, if  $L$  is given in mm, then  $H$  is in mm; and, if  $L$  is given in inches, then  $H$  is in inches.

**Measuring Tapers with V-Block and Sine-Bar.**—The taper on a conical part may be checked or found by placing the part in a V-block that rests on the surface of a sine-plate or sine-bar as shown in the accompanying diagram. The advantage of this method is that the axis of the V-block may be aligned with the sides of the sine-bar. Thus, when the tapered part is placed in the V-block, it will be aligned perpendicular to the transverse axis of the sine-bar.

The sine-bar is set to angle  $B = (C + A/2)$  where  $A/2$  is one-half the included angle of the tapered part. If  $D$  is the included angle of the precision V-block, the angle  $C$  is calculated from the formula:

$$\sin C = \frac{\sin (A/2)}{\sin (D/2)}$$

If dial indicator readings show no change across all points along the top of the taper surface, then this checks that the angle  $A$  of the taper is correct.

If the indicator readings vary, proceed as follows to find the actual angle of taper: 1) Adjust the angle of the sine-bar until the indicator reading is constant. Then find the new angle  $B'$  as explained in the paragraph *Measuring Angle of Templet or Gage with Sine-Bar* on page 694; and Using the angle  $B'$  calculate the actual half-angle  $A'/2$  of the taper from the formula:

$$\tan \frac{A'}{2} = \frac{\sin B'}{\csc \frac{D}{2} + \cos B'}$$

The taper per foot corresponding to certain half-angles of taper may be found in the table on page 698.

**Dimensioning Tapers.**—At least three methods of dimensioning tapers are in use.

*Standard Tapers:* Give one diameter or width, the length, and insert note on drawing designating the taper by number.

*Special Tapers:* In dimensioning a taper when the slope is specified, the length and only one diameter should be given or the diameters at both ends of the taper should be given and length omitted.

*Precision Work:* In certain cases where very precise measurements are necessary, the taper surface, either external or internal, is specified by giving a diameter at a certain distance from a surface and the slope of the taper.

### Accurate Measurement of Angles and Tapers

When great accuracy is required in the measurement of angles, or when originating tapers, disks are commonly used. The principle of the disk method of taper measurement is that if two disks of unequal diameters are placed either in contact or a certain distance apart, lines tangent to their peripheries will represent an angle or taper, the degree of which depends upon the diameters of the two disks and the distance between them.

The gage shown in the accompanying illustration, which is a form commonly used for originating tapers or measuring angles accurately, is set by means of disks. This gage consists of two adjustable straight edges  $A$  and  $A_1$ , which are in contact with disks  $B$  and  $B_1$ . The angle  $\alpha$  or the taper between the straight edges depends, of course, upon the diameters of the disks and the center distance  $C$ , and, as these three dimensions can be measured accurately, it is possible to set the gage to a given angle within very close limits. Moreover, if a record of the three dimensions is kept, the exact setting of the gage can be reproduced quickly at any time. The following rules may be used for adjusting a gage of this type and cover all problems likely to arise in practice. Disks are also occasionally used for the setting of parts in angular positions when they are to be machined accurately to a given angle; the rules are applicable to these conditions also.

**Measuring Dovetail Slides.**—Dovetail slides that must be machined accurately to a given width are commonly gaged by using pieces of cylindrical rod or wire and measuring as indicated by the dimensions  $x$  and  $y$  of the accompanying illustrations.

The rod or wire used should be small enough so that the point of contact  $e$  is somewhat below the corner or edge of the dovetail.

To obtain dimension  $x$  for measuring male dovetails, add 1 to the cotangent of one-half the dovetail angle  $\alpha$ , multiply by diameter  $D$  of the rods used, and add the product to dimension  $a$ .

$$x = D \left( 1 + \cot \frac{1}{2} \alpha \right) + a \quad c = h \times \cot \alpha$$

To obtain dimension  $y$  for measuring a female dovetail, add 1 to the cotangent of one-half the dovetail angle  $\alpha$ , multiply by diameter  $D$  of the rod used, and subtract the result from dimension  $b$ . Expressing these rules as formulas:

$$y = b - D \left( 1 + \cot \frac{1}{2} \alpha \right)$$

## Tapers per Foot and Corresponding Angles

The amount of taper in a certain length of inches is equal to the taper per foot divided by 12 then multiplied by the given length of the tapered part.

**Rules for Figuring Tapers**

<p><math>D_L</math> = diameter of taper, large end  <math>D_S</math> = diameter of taper, small end  <math>L</math> = length of taper (inches)  <math>TPF</math> = taper per foot  <math>TPI</math> = taper per inch  <math>T</math> = taper in a certain length, in inches</p>		
Given	To Find	Rule
$TPF$	$TPI$	$TPI = TPF/12$
$TPI$	$TPF$	$TPF = TPI \times 12$
$D_L, D_S, L$	$TPF$	$TPF = 12 \frac{D_L - D_S}{L}$
$D_L, L, TPF$	$D_S$	$D_S = D_L - \frac{TPF}{12} L$
$D_S, L, TPF$	$D_L$	$D_L = D_S + \frac{TPF}{12} L$
$D_L, D_S, TPF$	$L$	$L = (D_L - D_S) \frac{12}{TPF}$
$L, TPF$	$T$	$T = \frac{TPF}{12} \times L$

**To find angle  $\alpha$  for given taper  $T$  in inches per foot.—**

*Example:* What angle  $\alpha$  is equivalent to a taper of 1.5 inches per foot?

$$\alpha = 2 \times \arctan (1.5/24) = 7.153^\circ$$

**To find taper per foot  $T$  given angle  $\alpha$  in degrees.—**

$$T = 24 \tan (\alpha/2) \text{ inches per foot}$$

*Example:* What taper  $T$  is equivalent to an angle of  $7.153^\circ$ ?

$$T = 24 \tan (7.153/2) = 1.5 \text{ inches per foot}$$

**To find angle  $\alpha$  given dimensions  $D, d$ , and  $C$ .—**Let  $K$  be the difference in the disk diameters divided by twice the center distance.  $K = (D-d)/(2C)$ , then  $\alpha = 2 \arcsin K$

*Example:* If the disk diameters  $d$  and  $D$  are 1 and 1.5 inches, respectively, and the center distance  $C$  is 5 inches, find the included angle  $\alpha$ .

$$K = (1.5 - 1) / (2 \times 5) = 0.05 \quad \alpha = 2 \times \arcsin 0.05 = 5.732^\circ$$

**To find taper  $T$  measured at right angles to a line through the disk centers given dimensions  $D$ ,  $d$ , and distance  $C$ .**—Find  $K$  using the formula in the previous example,

then  $T = 24K/\sqrt{1 - K^2}$  inches per foot.

*Example:* If disk diameters  $d$  and  $D$  are 1 and 1.5 inches, respectively, and the center distance  $C$  is 5 inches, find the taper per foot.

$$K = (1.5 - 1)/(2 \times 5) = 0.05 \quad T = \frac{24 \times 0.05}{\sqrt{1 - (0.05)^2}} = 1.2015 \text{ inches per foot}$$

**To find center distance  $C$  for a given taper  $T$  in inches per foot.**—

$$C = \frac{D - d}{2} \times \frac{\sqrt{1 + (T/24)^2}}{T/24} \text{ inches}$$

*Example:* Gage is to be set to  $\frac{3}{4}$  inch per foot, and disk diameters are 1.25 and 1.5 inches, respectively. Find the required center distance for the disks.

$$C = \frac{1.5 - 1.25}{2} \times \frac{\sqrt{1 + (0.75/24)^2}}{0.75/24} = 4.002 \text{ inches}$$

**To find center distance  $C$  for a given angle  $\alpha$  and dimensions  $D$  and  $d$ .**

$$C = (D - d)/2 \sin(\alpha/2) \text{ inches}$$

*Example:* If an angle  $\alpha$  of  $20^\circ$  is required, and the disks are 1 and 3 inches in diameter, respectively, find the required center distance  $C$ .

$$C = (3 - 1)/(2 \times \sin 10^\circ) = 5.759 \text{ inches}$$

**To find taper  $T$  measured at right angles to one side.**—When one side is taken as a base line and the taper is measured at right angles to that side, calculate  $K$  as explained above and use the following formula for determining the taper  $T$ :

$$T = 24K \frac{\sqrt{1 - K^2}}{1 - 2K^2} \text{ inches per foot}$$

*Example:* If the disk diameters are 2 and 3 inches, respectively, and the center distance is 5 inches, what is the taper per foot measured at right angles to one side?

$$K = \frac{3 - 2}{2 \times 5} = 0.1 \quad T = 24 \times 0.1 \times \frac{\sqrt{1 - (0.1)^2}}{1 - [2 \times (0.1)^2]} = 2.4367 \text{ in. per ft.}$$

**To find center distance  $C$  when taper  $T$  is measured from one side.**—

$$C = \frac{D - d}{\sqrt{2 - 2/\sqrt{1 + (T/12)^2}}} \text{ inches}$$

*Example:* If the taper measured at right angles to one side is 6.9 inches per foot, and the disks are 2 and 5 inches in diameter, respectively, what is center distance  $C$ ?

$$C = \frac{5 - 2}{\sqrt{2 - 2/\sqrt{1 + (6.9/12)^2}}} = 5.815 \text{ inches.}$$

To find diameter  $D$  of a large disk in contact with a small disk of diameter  $d$  given angle  $\alpha$ .—

$$D = d \times \frac{1 + \sin(\alpha/2)}{1 - \sin(\alpha/2)} \text{ inches}$$

*Example:* The required angle  $\alpha$  is  $15^\circ$ . Find diameter  $D$  of a large disk that is in contact with a standard 1-inch reference disk.

$$D = 1 \times \frac{1 + \sin 7.5^\circ}{1 - \sin 7.5^\circ} = 1.3002 \text{ inches}$$

**Measurement over Pins and Rolls**

**Measurement over Pins.**—When the distance across a bolt circle is too large to measure using ordinary measuring tools, then the required distance may be found from the distance across adjacent or alternate holes using one of the methods that follow:

Fig. 1a.

Fig. 1b.

Fig. 1c.

*Even Number of Holes in Circle:* To measure the unknown distance  $x$  over opposite plugs in a bolt circle of  $n$  holes ( $n$  is even and greater than 4), as shown in Fig. 1a, where  $y$  is the distance over alternate plugs,  $d$  is the diameter of the holes, and  $\theta = 360/n$  is the angle between adjacent holes, use the following general equation for obtaining  $x$ :

$$x = \frac{y - d}{\sin \theta} + d$$

*Example:* In a die that has six  $3/4$ -inch diameter holes equally spaced on a circle, where the distance  $y$  over alternate holes is  $4\frac{1}{2}$  inches, and the angle  $\theta$  between adjacent holes is  $60^\circ$ , then

$$x = \frac{4.500 - 0.7500}{\sin 60^\circ} + 0.7500 = 5.0801$$

In a similar problem, the distance  $c$  over adjacent plugs is given, as shown in Fig. 1b. If the number of holes is even and greater than 4, the distance  $x$  over opposite plugs is given in the following formula:

$$x = 2(c - d) \left( \frac{\sin\left(\frac{180 - \theta}{2}\right)}{\sin \theta} \right) + d$$

where  $d$  and  $\theta$  are as defined above.

**Odd Number of Holes in Circle:** In a circle as shown in Fig. 1c, where the number of holes  $n$  is odd and greater than 3, and the distance  $c$  over adjacent holes is given, then  $\theta$  equals  $360/n$  and the distance  $x$  across the most widely spaced holes is given by:

$$x = \frac{c-d}{\sin \frac{\theta}{4}} + d$$

**Checking a V-Shaped Groove by Measurement Over Pins.**—In checking a groove of the shape shown in Fig. 2, it is necessary to measure the dimension  $X$  over the pins of radius  $R$ . If values for the radius  $R$ , dimension  $Z$ , and the angles  $\alpha$  and  $\beta$  are known, the problem is to determine the distance  $Y$ , to arrive at the required overall dimension for  $X$ . If a line  $AC$  is drawn from the bottom of the V to the center of the pin at the left in Fig. 2, and a line  $CB$  from the center of this pin to its point of tangency with the side of the V, a right-angle triangle is formed in which one side,  $CB$ , is known and one angle,  $CAB$ , can be determined. A line drawn from the center of a circle to the point of intersection of two tangents to the circle bisects the angle made by the tangent lines, and angle  $CAB$  therefore equals  $\frac{1}{2}(\alpha + \beta)$ . The length  $AC$  and the angle  $DAC$  can now be found, and with  $AC$  known in the right-angle triangle  $ADC$ ,  $AD$ , which is equal to  $Y$ , can be found.

Fig. 2.

The value for  $X$  can be obtained from the formula

$$X = Z + 2R \left( \csc \frac{\alpha + \beta}{2} \cos \frac{\alpha - \beta}{2} + 1 \right)$$

For example, if  $R = 0.500$ ,  $Z = 1.824$ ,  $\alpha = 45$  degrees, and  $\beta = 35$  degrees,

$$X = 1.824 + (2 \times 0.5) \left( \csc \frac{45^\circ + 35^\circ}{2} \cos \frac{45^\circ - 35^\circ}{2} + 1 \right)$$

$$X = 1.824 + \csc 40^\circ \cos 5^\circ + 1$$

$$X = 1.824 + 1.5557 \times 0.99619 + 1$$

$$X = 1.824 + 1.550 + 1 = 4.374$$

**Checking Radius of Arc by Measurement Over Rolls.**—The radius  $R$  of large-radius concave and convex gages of the type shown in Fig. 3a, Fig. 3b and Fig. 3c can be checked by measurement  $L$  over two rolls with the gage resting on the rolls as shown. If the diameter of the rolls  $D$ , the length  $L$ , and the height  $H$  of the top of the arc above the surface plate (for the concave gage, Fig. 3a) are known or can be measured, the radius  $R$  of the workpiece to be checked can be calculated trigonometrically, as follows.

Referring to Fig. 3a for the concave gage, if  $L$  and  $D$  are known,  $cb$  can be found, and if  $H$  and  $D$  are known,  $ce$  can be found. With  $cb$  and  $ce$  known,  $ab$  can be found by means of a diagram as shown in Fig. 3c.

In diagram Fig. 3c,  $cb$  and  $ce$  are shown at right angles as in Fig. 3a. A line is drawn connecting points  $b$  and  $e$ , and line  $ce$  is extended to the right. A line is now drawn from point  $b$  perpendicular to  $be$  and intersecting the extension of  $ce$  at point  $f$ . A semicircle can now be drawn through points  $b$ ,  $e$ , and  $f$  with point  $a$  as the center. Triangles  $bce$  and  $bcf$  are similar and have a common side. Thus  $ce:bc::bc:cf$ . With  $ce$  and  $bc$  known,  $cf$  can be found from this proportion and, hence,  $ef$ , which is the diameter of the semicircle and radius  $ab$ . Then  $R = ab + D/2$ .

Fig. 3a.

Fig. 3b.

Fig. 3c.

The procedure for the convex gage is similar. The distances  $cb$  and  $ce$  are readily found, and from these two distances  $ab$  is computed on the basis of similar triangles as before. Radius  $R$  is then readily found.

The derived formulas for concave and convex gages are as follows:

Formulas:

$$R = \frac{(L - D)^2}{8(H - D)} + \frac{H}{2} \quad (\text{Concave gage Fig. 3a})$$

$$R = \frac{(L - D)^2}{8D} \quad (\text{Convex gage Fig. 3b})$$

For example: For Fig. 3a, let  $L = 17.8$ ,  $D = 3.20$ , and  $H = 5.72$ , then

$$R = \frac{(17.8 - 3.20)^2}{8(5.72 - 3.20)} + \frac{5.72}{2} = \frac{(14.60)^2}{8 \times 2.52} + 2.86$$

$$R = \frac{213.16}{20.16} + 2.86 = 13.43$$

For Fig. 3b, let  $L = 22.28$  and  $D = 3.40$ , then

$$R = \frac{(22.28 - 3.40)^2}{8 \times 3.40} = \frac{356.45}{27.20} = 13.1$$

### Checking Shaft Conditions

**Checking for Various Shaft Conditions.**—An indicating height gage, together with V-blocks can be used to check shafts for ovality, taper, straightness (bending or curving), and concentricity of features (as shown exaggerated in Fig. 4). If a shaft on which work has been completed shows lack of concentricity, it may be due to the shaft having become bent or bowed because of mishandling or oval or tapered due to poor machine conditions. In checking for concentricity, the first step is to check for ovality, or out-of-roundness, as in Fig. 4a. The shaft is supported in a suitable V-block on a surface table, and the dial indicator plunger is placed over the workpiece, which is then rotated beneath the plunger to obtain readings of the amount of eccentricity.

This procedure (sometimes called clocking, owing to the resemblance of the dial indicator to a clock face) is repeated for other shaft diameters as necessary, and, in addition to making a written record of the measurements, the positions of extreme conditions should be marked on the workpiece for later reference.

Fig. 4.

To check for taper, the shaft is supported in the V-block and the dial indicator is used to measure the maximum height over the shaft at various positions along its length, as shown in Fig. 4b, without turning the workpiece. Again, the shaft should be marked with the reading positions and values, and with the direction of the taper, and a written record should be made of the amount and direction of any taper discovered.

Checking for a bent shaft requires that the shaft be clocked at the shoulder and at the farther end, as shown in Fig. 4c. For a second check, the shaft is rotated only 90° or a quarter turn. When the recorded readings are compared with those from the ovality and taper checks, the three conditions can be distinguished.

To detect a curved or bowed condition, the shaft should be suspended in two V-blocks with only about  $\frac{1}{8}$  inch of each end in each V. Alternatively, the shaft can be placed between centers. The shaft is then clocked at several points, as shown in Fig. 4d, but preferably not at those locations used for the ovality, taper, or crookedness checks. If the single element due to curvature is to be distinguished from the effects of ovality, taper, and crookedness, and its value assessed, great care must be taken to differentiate between the conditions detected by the measurements.

Finally, the amount of eccentricity between one shaft diameter and another may be tested by the setup shown in Fig. 4e. With the indicator plunger in contact with the smaller diameter, close to the shoulder, the shaft is rotated in the V-block and the indicator needle position is monitored to find the maximum and minimum readings.

Curvature, ovality, or crookedness conditions may tend to cancel each other, as shown in Fig. 5, and one or more of these degrees of defectiveness may add themselves to the true eccentricity readings, depending on their angular positions. Fig. 5a shows, for instance, how crookedness and ovality tend to cancel each other, and also shows their effect in falsifying the reading for eccentricity. As the same shaft is turned in the V-block to the position shown in Fig. 5b, the maximum curvature reading could tend to cancel or reduce the maximum eccentricity reading. Where maximum readings for ovality, curvature, or crookedness occur at the same angular position, their values should be subtracted from the eccentricity reading to arrive at a true picture of the shaft condition. Confirmation of eccentricity readings may be obtained by reversing the shaft in the V-block, as shown in Fig. 5c, and clocking the larger diameter of the shaft.

Fig. 5.

**Out-of-Roundness—Lobing.**—With the imposition of finer tolerances and the development of improved measurement methods, it has become apparent that no hole, cylinder, or

sphere can be produced with a perfectly symmetrical round shape. Some of the conditions are diagrammed in Fig. 6, where Fig. 6a shows simple ovality and Fig. 6b shows ovality occurring in two directions. From the observation of such conditions have come the terms lobe and lobing. Fig. 6c shows the three-lobed shape common with centerless-ground components, and Fig. 6d is typical of multi-lobed shapes. In Fig. 6e are shown surface waviness, surface roughness, and out-of-roundness, which often are combined with lobing.

Fig. 6.

In Fig. 6a through Fig. 6d, the cylinder (or hole) diameters are shown at full size, but the lobes are magnified some 10,000 times to make them visible. In precision parts, the deviation from the round condition is usually only in the range of millionths of an inch, although it occasionally can be 0.0001 inch, 0.0002 inch, or more. For instance, a 3-inch-diameter part may have a lobing condition amounting to an inaccuracy of only 30 millionths (0.000030 inch). Even if the distortion (ovality, waviness, roughness) is small, it may cause hum, vibration, heat buildup, and wear, possibly leading to eventual failure of the component or assembly.

Plain elliptical out-of-roundness (two lobes), or any even number of lobes, can be detected by rotating the part on a surface plate under a dial indicator of adequate resolution, or by using an indicating caliper or snap gage. However, supporting such a part in a V-block during measurement will tend to conceal roundness errors. Ovality in a hole can be detected by a dial-type bore gage or internal measuring machine. Parts with odd numbers of lobes require an instrument that can measure the envelope or complete circumference. Plug and ring gages will tell whether a shaft can be assembled into a bearing but not whether there will be a good fit, as illustrated in Fig. 6e.

A standard, 90-degree included-angle V-block can be used to detect and count the number of lobes, but to measure the exact amount of lobing indicated by  $R-r$  in Fig. 7 requires a V-block with an angle  $\alpha$ , which is related to the number of lobes. This angle  $\alpha$  can be calculated from the formula  $2\alpha = 180^\circ - 360^\circ/N$ , where  $N$  is the number of lobes. Thus, for a three-lobe form,  $\alpha$  becomes 30 degrees, and the V-block used should have a 60-degree included angle. The distance  $M$ , which is obtained by rotating the part under the comparator plunger, is converted to a value for the radial variation in cylinder contour by the formula  $M = (R-r)(1 + \csc \alpha)$ .

Fig. 7.

Using a V-block (even of appropriate angle) for parts with odd numbers of lobes will give exaggerated readings when the distance  $R - r$  (Fig. 7) is used as the measure of the amount of out-of-roundness. The accompanying table shows the appropriate V-block angles for various odd numbers of lobes and the factors  $(1 + \csc \alpha)$  by which the readings are increased over the actual out-of-roundness values.

**Table of Lobes, V-Block Angles and Exaggeration Factors in Measuring Out-of-Round Conditions in Shafts**

Number of Lobes	Included Angle of V-Block (deg)	Exaggeration Factor $(1 + \csc \alpha)$
3	60	3.00
5	108	2.24
7	128.57	2.11
9	140	2.06

Measurement of a complete circumference requires special equipment, often incorporating a precision spindle running true within two millionths (0.000002) inch. A stylus attached to the spindle is caused to traverse the internal or external cylinder being inspected, and its divergences are processed electronically to produce a polar chart similar to the wavy outline in Fig. 6e. Electronic circuits provide for the variations due to surface effects to be separated from those of lobing and other departures from the "true" cylinder traced out by the spindle.

### Coordinates for Hole Circles

**Type "A" Hole Circles.**—Type "A" hole circles can be identified by hole number 1 at the top of the hole circle, as shown in Fig. 1a and Fig. 1b. The  $x, y$  coordinates for hole circles of from 3 to 33 holes corresponding to the geometry of Fig. 1a are given in Table 1a, and corresponding to the geometry of Fig. 1b in Table 1b. Holes are numbered in a counterclockwise direction as shown. Coordinates given are based upon a hole circle of (1) unit diameter. For other diameters, multiply the  $x$  and  $y$  coordinates from the table by the hole circle diameter. For example, for a 3-inch or 3-centimeter hole circle diameter, multiply table values by 3. Coordinates are valid in any unit system.

Fig. 1a. Type "A" Circle

Fig. 1b. Type "A" Circle

The origin of the coordinate system in Fig. 1a, marked "Ref", is at the center of the hole circle at position  $x = 0, y = 0$ . The equations for calculating hole coordinates for type "A" circles with the coordinate system origin at the center of the hole circle are as follows:

$$\theta = \frac{360}{n} = \frac{2\pi}{n} \quad x_H = -\frac{D}{2} \sin((H-1)\theta) \quad y_H = -\frac{D}{2} \cos((H-1)\theta) \quad (1a)$$

where  $n$  = number of holes in circle;  $D$  = diameter of hole circle;  $\theta$  = angle between adjacent holes in circle;  $H$  = number (from 1 to  $n$ ) of the current hole;  $x_H$  =  $x$  coordinate at position of hole number  $H$ ; and  $y_H$  =  $y$  coordinate at position of hole number  $H$ .

*Example 1(a):* Calculate the hole coordinates for the 5-hole circle shown in Fig. 1a when circle diameter = 1. Compare the results to the data tabulated in Table 1a.

Hole	$\theta = 360/5 = 72^\circ$	$D = 1$	
1	$x_H = x_1 = -1/2 \times \sin(0) = 0.00000$		$y_1 = -1/2 \times \cos(0) = -0.50000$
2	$x_2 = -1/2 \times \sin(72) = -0.47553$		$y_2 = -1/2 \times \cos(72) = -0.15451$
3	$x_3 = -1/2 \times \sin(144) = -0.29389$		$y_3 = -1/2 \times \cos(144) = 0.40451$
4	$x_4 = -1/2 \times \sin(216) = 0.29389$		$y_4 = -1/2 \times \cos(216) = 0.40451$
5	$x_5 = -1/2 \times \sin(288) = 0.47553$		$y_5 = -1/2 \times \cos(288) = -0.15451$

In Fig. 1b, the origin of the coordinate system (point 0,0) is located at the top left of the figure at the intersection of the two lines labeled "Ref." The center of the hole circle is offset from the coordinate system origin by distance  $X_O$  in the +x direction, and by distance  $Y_O$  in the +y direction. In practice the origin of the coordinate system can be located at any convenient distance from the center of the hole circle. In Fig. 1b, it can be determined by inspection that the distances  $X_O = Y_O = D/2$ . The equations for calculating hole positions of type "A" circles of the Fig. 1b type are almost the same as in Equation (1a), but with the addition of  $X_O$  and  $Y_O$  terms, as follows:

$$\theta = \frac{360}{n} = \frac{2\pi}{n} \quad x_H = -\frac{D}{2} \sin((H-1)\theta) + X_O \quad y_H = -\frac{D}{2} \cos((H-1)\theta) + Y_O \quad (1b)$$

*Example 1(b):* Use results of Example 1 to determine hole coordinates of Fig. 1b for circle diameter = 1, and compare results with Table 1b.

Hole	$\theta = 360/5 = 72^\circ$	$D = 1$	$X_O = D/2 = 0.50000$	$Y_O = D/2 = 0.50000$
1	$x_1 = 0.00000 + X_O = 0.50000$			$y_1 = -0.50000 + Y_O = 0.00000$
2	$x_2 = -0.47553 + X_O = 0.02447$			$y_2 = -0.15451 + Y_O = 0.34549$
3	$x_3 = -0.29389 + X_O = 0.20611$			$y_3 = 0.40451 + Y_O = 0.90451$
4	$x_4 = 0.29389 + X_O = 0.79389$			$y_4 = 0.40451 + Y_O = 0.90451$
5	$x_5 = 0.47553 + X_O = 0.97553$			$y_5 = -0.15451 + Y_O = 0.34549$

**Type "B" Hole Circles.**—Compared to type "A" hole circles, type "B" hole circles, Fig. 2a and Fig. 2b, are arranged such that the circle of holes is rotated about the center of the circle by  $\theta/2$  degrees, that is,  $1/2$  of the angle between adjacent holes. The x,y coordinates for type "B" hole circles of from 3 to 33 holes are given in Table 2a for geometry corresponding to Fig. 2a, and in Table 2b for geometry corresponding to Fig. 2b. Holes are numbered in a counterclockwise direction as shown. Coordinates given are based upon a hole circle of (1) unit diameter. For other diameters, multiply the x and y coordinates from the table by the hole circle diameter. For example, for a 3-inch or 3-centimeter hole circle diameter, multiply table values by 3. Coordinates are valid in any unit system.

Fig. 2a. Type "B" Circle

Fig. 2b. Type "B" Circle

In Fig. 2a, the coordinate system origin, marked "Ref", is at the center of the hole circle at position  $x = 0, y = 0$ . Equations for calculating hole coordinates for type "B" circles with the coordinate system origin at the center of the hole circle as in Fig. 2a are as follows:

$$\theta = \frac{360}{n} = \frac{2\pi}{n} \quad x_H = -\frac{D}{2} \sin\left((H-1)\theta + \frac{\theta}{2}\right) \quad y_H = -\frac{D}{2} \cos\left((H-1)\theta + \frac{\theta}{2}\right) \quad (2a)$$

where  $n$  = number of holes in circle;  $D$  = diameter of hole circle;  $\theta$  = angle between adjacent holes;  $x_H$  =  $x$  coordinate at position of hole number  $H$ ; and,  $y_H$  =  $y$  coordinate at position of hole number  $H$ .

**Example 2(a):** Calculate the hole coordinates for the 5-hole circle shown in Fig. 2a when circle diameter = 1. Compare the results to the data in Table 2a.

Hole	$\theta = 360/5 = 72^\circ$	$\theta/2 = 36^\circ$	$D = 1$
1	$x_1 = -\frac{1}{2} \times \sin(36) = -0.29389$		$y_1 = -\frac{1}{2} \times \cos(36) = -0.40451$
2	$x_2 = -\frac{1}{2} \times \sin(108) = -0.47553$		$y_2 = -\frac{1}{2} \times \cos(108) = 0.15451$
3	$x_3 = -\frac{1}{2} \times \sin(180) = 0.00000$		$y_3 = -\frac{1}{2} \times \cos(180) = 0.50000$
4	$x_4 = -\frac{1}{2} \times \sin(252) = 0.47553$		$y_4 = -\frac{1}{2} \times \cos(252) = 0.15451$
5	$x_5 = -\frac{1}{2} \times \sin(324) = 0.29389$		$y_5 = -\frac{1}{2} \times \cos(324) = -0.40451$

In Fig. 2b, the origin of the coordinate system (point 0,0) is located at the top left of the figure at the intersection of the two lines labeled "Ref." The center of the hole circle is offset from the coordinate system origin by distance  $X_O$  in the  $+x$  direction and by distance  $Y_O$  in the  $+y$  direction. In practice, the origin of the coordinate system can be chosen at any convenient distance from the hole circle origin. In Fig. 2b, it can be determined by inspection that distance  $X_O = Y_O = D/2$ . The equations for calculating hole positions of type "B" circles of the Fig. 2b type are the same as in Equation (2a) but with the addition of  $X_O$  and  $Y_O$  terms, as follows:

$$\theta = \frac{360}{n} = \frac{2\pi}{n} \quad x_H = -\frac{D}{2} \sin\left((H-1)\theta + \frac{\theta}{2}\right) + X_O \quad y_H = -\frac{D}{2} \cos\left((H-1)\theta + \frac{\theta}{2}\right) + Y_O \quad (2b)$$

**Example 2(b):** Use the coordinates obtained in Example 2(a) to determine the hole coordinates of a 5-hole circle shown in Fig. 1b with circle diameter = 1. Compare the results to the data in Table 2b.

Hole	$\theta = 360/5 = 72^\circ$	$\theta/2 = 36^\circ$	$D = 1$	$X_O = D/2 = 0.50000$	$Y_O = D/2 = 0.50000$
1	$x_1 = -\frac{1}{2} \times \sin(36) + 0.50000 = 0.20611$			$y_1 = -\frac{1}{2} \times \cos(36) + 0.50000 = 0.09549$	
2	$x_2 = -\frac{1}{2} \times \sin(108) + 0.50000 = 0.02447$			$y_2 = -\frac{1}{2} \times \cos(108) + 0.50000 = 0.65451$	
3	$x_3 = -\frac{1}{2} \times \sin(180) + 0.50000 = 0.50000$			$y_3 = -\frac{1}{2} \times \cos(180) + 0.50000 = 1.00000$	
4	$x_4 = -\frac{1}{2} \times \sin(252) + 0.50000 = 0.97553$			$y_4 = -\frac{1}{2} \times \cos(252) + 0.50000 = 0.65451$	
5	$x_5 = -\frac{1}{2} \times \sin(324) + 0.50000 = 0.79389$			$y_5 = -\frac{1}{2} \times \cos(324) + 0.50000 = 0.09549$	

**Adapting Hole Coordinate Equations for Different Geometry.**—Hole coordinate values in Table 1a through Table 2b are obtained using the equations given previously, along with the geometry of the corresponding figures. If the geometry does not match that given in one of the previous figures, hole coordinate values from the tables or equations will be incorrect. Fig. 3 illustrates such a case. Fig. 3 resembles a type "A" hole circle (Fig. 1b) with hole number 2 at the top, and it also resembles a type "B" hole circle (Fig. 2b) in which all holes have been rotated  $90^\circ$  clockwise. A closer look also reveals that the positive  $y$  direction in Fig. 3 is opposite that used in Fig. 1b and Fig. 2b. Therefore, to determine the hole coordinates of Fig. 3 it is necessary to create new equations that match the given geometry or to modify the previous equations to match the Fig. 3 geometry.

Fig. 3.

*Example 3(a), Determining Hole Coordinates for Fig. 3:* Write equations for the coordinates of holes 1, 2, and 3 of Fig. 3.

$$\begin{array}{ll} x_1 = 7.5 + 5\cos(30^\circ) = 11.8301 & y_1 = 6.0 + 5\sin(30^\circ) = 8.5000 \\ x_2 = 7.5 + 5\cos(30^\circ + 60^\circ) = 7.5 & y_2 = 6.0 + 5\sin(30^\circ + 60^\circ) = 11.0000 \\ x_3 = 7.5 + 5\cos(30^\circ + 120^\circ) = 3.1699 & y_3 = 6.0 + 5\sin(30^\circ + 120^\circ) = 8.5000 \end{array}$$

*Example 3(b), Modify Equation (2b) for Fig. 3:* In Fig. 3, hole numbering is rotated  $90^\circ$  ( $\pi/2$  radian) in the clockwise (negative) direction relative to Fig. 2b, and the direction of the +y coordinate axis is the reverse, or negative, of that given in Fig. 2b. Equations for Fig. 3 can be obtained from Equation (2b) by

1) subtracting  $90^\circ$  from the angle of each hole in the x and y equations of Equation (2b)

2) multiplying the  $y_H$  equation by  $-1$  to reverse the orientation of the y axis

$$x_H = -\frac{D}{2}\sin\left((H-1)\theta + \frac{\theta}{2} - 90^\circ\right) + X_0 \quad y_H = -\left(-\frac{D}{2}\cos\left((H-1)\theta + \frac{\theta}{2} - 90^\circ\right) + Y_0\right)$$

In Fig. 3,  $\theta = 360/n = 60^\circ$  for 6 holes,  $X_0 = 7.5$ , and  $Y_0 = -6.0$ .

$$\begin{array}{ll} x_1 = -5\sin(30 - 90) + 7.5 = 11.8301 & y_1 = 5\cos(30 - 90) + 6 = 8.5000 \\ x_2 = -5\sin(60 + 30 - 90) + 7.5 = 7.5 & y_2 = 5\cos(60 + 30 - 90) + 6 = 11.0000 \\ x_3 = -5\sin(120 + 30 - 90) + 7.5 = 3.1699 & y_3 = 5\cos(120 + 30 - 90) + 6 = 8.5000 \end{array}$$

**Lengths of Chords on Hole Circle Circumference.**—Table 3 on page 720 gives the lengths of chords for spacing off the circumferences of circles. The object of this table is to make possible the division of the periphery into a number of equal parts without trials with the dividers. Table 3 is calculated for circles having a diameter equal to 1. For circles of other diameters, the length of chord given in the table should be multiplied by the diameter of the circle. Table 3 may be used by toolmakers when setting “buttons” in circular formation and with inch or metric dimensions. See *Coordinates for Hole Circles* on page 708 for more information on this topic.

*Example:* Assume that it is required to divide the periphery of a circle of 20 inches diameter into thirty-two equal parts.

*Solution:* From the table the length of the chord is found to be 0.098017 inch, if the diameter of the circle were 1 inch. With a diameter of 20 inches the length of the chord for one division would be  $20 \times 0.098017 = 1.9603$  inches.

**Another example, in metric units:** For a 100 millimeter diameter requiring 5 equal divisions, the length of the chord for one division would be  $100 \times 0.587785 = 58.7785$  millimeters.

*Example:* Assume that it is required to divide a circle of  $6\frac{1}{2}$  millimeter diameter into seven equal parts. Find the length of the chord required for spacing off the circumference.

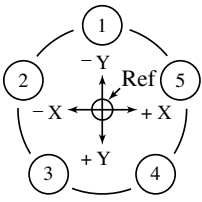

*Solution:* In Table 3, the length of the chord for dividing a circle of 1 millimeter diameter into 7 equal parts is 0.433884 mm. The length of chord for a circle of  $6\frac{1}{2}$  mm diameter is  $6\frac{1}{2} \times 0.433884 = 2.820246$  mm.

*Example:* Assume that it is required to divide a circle having a diameter of  $9\frac{23}{32}$  inches into 15 equal divisions.

*Solution:* In Table 3, the length of the chord for dividing a circle of 1 inch diameter into 15 equal parts is 0.207912 inch. The length of chord for a circle of 9 inches diameter is  $9\frac{23}{32} \times 0.207912 = 2.020645$  inches.

For circles of other diameters, multiply length given in table by diameter of circle.

*Example:* In a drill jig, 8 holes, each  $\frac{1}{2}$  inch diameter, were spaced evenly on a 6-inch diameter circle. To test the accuracy of the jig, plugs were placed in adjacent holes, and the distance over the plugs was measured with a micrometer. What should be the micrometer reading?

*Solution:* The micrometer reading equals the diameter of one plug plus 6 times the chordal distance between adjacent hole centers given in the table above. Thus, the reading should be  $\frac{1}{2} + (6 \times 0.382683) = 2.796098$  inches.

### Gage Blocks

The primary standard for linear measurement is the *gage block*. Gage blocks were originally called Jo-Blocks after their Swedish inventor, Carl Edvard Johansson. These precision lapped blocks are the primary means of establishing measurement traceability to the prime standards located in the national laboratories of every country. The primary length standards are themselves defined by the distance traveled by light in a vacuum over a fixed time period.

The gage block is critical in establishing true traceability and measurement assurance in the dimensional discipline. There are several materials and grades of gage blocks to select from. The most common material in use today is steel. However, there is also Croblox, made by Mitutoyo, a thermally stable material with a very low coefficient of thermal expansion, and ceramic blocks, with extremely good wear capabilities. The average life span of a gage block is approximately 3 years. With proper care and cleaning the gage block may last many years longer but will eventually wear beyond the limits of the allowable tolerances and will need to be replaced.

The size tolerances applied to gage blocks, defined in the ANSI/ASME B89.1.9-2002, are shown in [Table 1a](#) and [Table 1b](#), for inch and metric units, respectively. Nearly all gage blocks are manufactured and calibrated to this standard. B89.1.9 establishes the allowable deviations for size variance as well as flatness and parallelism. It is these controlled dimensions that give the gage block the properties necessary for use as a dimensional standard.

**Table 1a. Maximum Permitted Deviations of Length at Any Point<sup>a</sup> and Tolerance on Variation in Length, Inch<sup>b</sup> ANSI/ASME B89.1.9-2002 (R2012)**

<sup>a</sup> Maximum permitted deviations of length at any point,  $\pm l_e$   $\mu$ m, from nominal length,  $l_e$  mm.

<sup>b</sup> Tolerance,  $t_v$   $\mu$ m, for the variation in length.

1) Always keep gage blocks clean and well oiled when not in direct use. Alcohol is acceptable as a cleaner, but it is always advisable to coat the gage block with a rust inhibitor when placing it back in the case. A very light machine oil is recommended.

2) Take great care when removing gage blocks from the case so as not to nick or damage the working surface. Clean with a soft cloth or chamois and isopropanol. Never touch gage blocks with bare hands. Oil from fingers will cause corrosion on the bare metal surface.

3) Always keep the gage blocks over a soft cloth or chamois when handling or wringing them together. Dropping the gage blocks onto a hard surface or other gage blocks will damage the working surface and cause an error beyond the limits of the tolerance. Always treat gage blocks as highly accurate precision instruments.

4) Should the gage block surface show signs of degradation and the wringing together of blocks become difficult, the surface may need to be deburred. The use of a serrated sintered aluminum oxide deburring stone is recommended to recondition the surface and renew the ability to join the gage blocks through wringing. Caution must be exercised when deburring the surface of gage blocks so it is not damaged instead of repaired.

5) Gently place the gage block flat on the serrated block. With two fingers (using gloves), press down firmly, but not hard, on the gage block and slide it lengthwise over the serrations on the block for three or four strokes until the surface feels very smooth. Turn the gage block over and repeat the movement. Remove and clean the gage block thoroughly.

6) It is important that the serrated sintered aluminum oxide deburring stone is cleaned as well, and metal deposits, oils, and dirt are not allowed to build up on the surface. A cotton packing impregnated with a metal solvent will clean the serrated sintered aluminum oxide deburring stone.

**Calibration and Verification of Gage Blocks.**—The calibration and verification of gage blocks should be completed on a regular basis. This is done to maintain measurement assurance in every good quality program. The quality assurance program will determine

the optimal interval for recalibration of the gage block sets to maintain the appropriate level of measurement assurance. Calibration of the gage blocks should be done by an approved and, if necessary, certified calibration laboratory that provides impartial third party confirmation of the calibrated features of the gage block set.

**Precision Gage Blocks.**—Precision gage blocks are usually purchased in sets containing a specific number of blocks of different sizes. The nominal gage lengths of individual blocks in a set are determined mathematically so that particular desired lengths can be obtained by combining selected blocks. They are made to several different tolerance grades that categorize them as master blocks, calibration blocks, inspection blocks, and workshop blocks. *Master blocks* are employed as basic reference standards; *calibration blocks* are used for high precision gaging work and calibrating inspection blocks; *inspection blocks* are used as toolroom standards and for checking and setting limit and comparator gages, for example. The *workshop blocks* are working gages used as shop standards for direct precision measurements and gaging applications, including sine-bars.

Federal Specification GGG-G-15C, Gage Blocks (see below), lists typical sets and gives details of materials, design, and manufacturing requirements, and tolerance grades. When there is in a set no single block of the exact size wanted, two or more blocks are combined by “wringing” them together. Wringing is achieved by first placing one block crosswise on the other and applying some pressure. Then a swiveling motion is used to twist the blocks to a parallel position, causing them to adhere firmly to one another.

When combining blocks for a given dimension, the object is to use as few blocks as possible to obtain the dimension. The procedure for selecting blocks is based on successively eliminating the right-hand figure of the desired dimension.

*Example:* Referring to inch-size gage block Set Number 1 below, determine the blocks required to obtain 3.6742 inches. *Step 1:* Eliminate 0.0002 by selecting a 0.1002 block. Subtract 0.1002 from 3.6743 = 3.5740. *Step 2:* Eliminate 0.004 by selecting a 0.124 block. Subtract 0.124 from 3.5740 = 3.450. *Step 3:* Eliminate 0.450 with a block this size. Subtract 0.450 from 3.450 = 3.000. *Step 4:* Select a 3.000 inch block. The combined blocks are  $0.1002 + 0.124 + 0.450 + 3.000 = 3.6742$  inches.

**Gage Block Sets, Inch Sizes (Federal Specification GGG-G-15C).**—*Set Number 1 (81 Blocks):* First Series: 0.0001-Inch Increments (9 Blocks), 0.1001 to 0.1009; Second Series: 0.001-Inch Increments (49 Blocks), 0.101 to 0.149; Third Series: 0.050-Inch Increments (19 Blocks), 0.050 to 0.950; Fourth Series: 1.000-Inch Increments (4 Blocks), 1.000- to 4.000-inch.

*Set Numbers 2, 3, and 4:* The specification does not list a set 2 or 3. Gage block *Set Number 4* (88 Blocks), listed in the Specification, is not given here; it is the same as Set Number 1 (81 Blocks) but contains seven additional blocks measuring 0.0625, 0.078125, 0.093750, 0.100025, 0.100050, 0.100075, and 0.109375 inch.

*Set Number 5 (21 Blocks):* First Series: 0.0001-Inch Increments (9 Blocks), 0.0101 to 0.0109; Second Series: 0.001-Inch Increments (11 Blocks), 0.010 to 0.020; One Block 0.01005 inch.

*Set Number 6 (28 Blocks):* First Series: 0.0001-Inch Increments (9 Blocks), 0.0201 to 0.0209; Second Series: 0.001-Inch Increments (9 Blocks), 0.021 to 0.029; Third Series: 0.010-Inch Increments (9 Blocks), 0.010 to 0.090; One Block 0.02005 Inch.

*Long Gage Block Set Number 7 (8 Blocks):* Whole-Inch Series (8 Blocks), 5, 6, 7, 8, 10, 12, 16, 20 inches.

*Set Number 8 (36 Blocks):* First Series: 0.0001-Inch Increments (9 Blocks), 0.1001 to 0.1009; Second Series: 0.001-Inch Increments (11 Blocks), 0.100 to 0.110; Third Series: 0.010-Inch Increments (8 Blocks), 0.120 to 0.190; Fourth Series: 0.100-Inch Increments (4 Blocks), 0.200 to 0.500; Whole-Inch Series (3 Blocks), 1, 2, 4 Inches; One Block 0.050 inch.

*Set Number 9 (20 Blocks):* First Series: 0.0001-Inch Increments (9 Blocks), 0.0501 to 0.0509; Second Series: 0.001-Inch Increments (10 Blocks), 0.050 to 0.059; One Block 0.05005 inch.

**Gage Block Sets, Metric Sizes (Federal Specification GGG-G-15C).**—*Set Number 1M (45 Blocks):* First Series: 0.001-Millimeter Increments (9 Blocks), 1.001 to 1.009; Second Series: 0.01-Millimeter Increments (9 Blocks), 1.01 to 1.09; Third Series: 0.10-Millimeter Increments (9 Blocks), 1.10 to 1.90; Fourth Series: 1.0-Millimeter Increments (9 Blocks), 1.0 to 9.0; Fifth Series: 10-Millimeter Increments (9 Blocks), 10 to 90 mm.

*Set Number 2M (88 Blocks):* First Series: 0.001-Millimeter Increments (9 Blocks), 1.001 to 1.009; Second Series: 0.01-Millimeter Increments (49 Blocks), 1.01 to 1.49; Third Series: 0.50-Millimeter Increments (19 Blocks), 0.5 to 9.5; Fourth Series: 10-Millimeter Increments (10 Blocks), 10 to 100; One Block 1.0005 mm.

*Set Number 3M:* Gage block Set Number 3M (112 Blocks) is not given here. It is similar to Set Number 2M (88 Blocks), and the chief difference is the inclusion of a larger number of blocks in the 0.5-millimeter increment series up to 24.5 mm.

*Set Number 4M (45 Blocks):* First Series: 0.001-Millimeter Increments (9 Blocks), 2.001 to 2.009; Second Series: 0.01-Millimeter Increments (9 Blocks), 2.01 to 2.09; Third Series: 0.10-Millimeter Increments (9 Blocks), 2.1 to 2.9; Fourth Series: 1-Millimeter Increments (9 Blocks), 1.0 to 9.0; Fifth Series: 10-Millimeter Increments (9 Blocks), 10 to 90 mm.

*Set Numbers 5M, 6M, 7M:* Set Numbers 5M (88 Blocks), 6M (112 Blocks), and 7M (17 Blocks) are not listed here.

*Long Gage Block Set Number 8M (8 Blocks):* Whole-Millimeter Series (8 Blocks), 125, 150, 175, 200, 250, 300, 400, 500 mm.

### Surface Plates

The surface plate is the primary plane from which all vertical measurements are made. The quality and dependability of this surface is one of the most critical elements in dimensional inspection measurement. Originally made from cast iron, the present-day granite plate was first developed during World War II because most metal was being used in the war effort. Faced with a need to check precision parts, Mr. Wallace Herman, a metal working and monument shop owner, decided to investigate the use of granite as a suitable replacement for the then-common cast-iron surface plate and manufactured the first granite surface plate in his shop in Dayton, Ohio.

Although surface plates have changed in their design and materials, the basic concept has remained the same. The stability and precision that can be achieved with granite is actually far superior to cast iron and is much easier to maintain. With the proper care and maintenance, a well-made surface plate can last for generations and always remain within the parameters of the grade to which it was originally made, or even better.

**Materials and Grades of Surface Plates.**—The selection of a surface plate is driven directly by the specific application the plate will be used for. A plate, for instance, that will be used in a very large machining facility would be primarily concerned with the load-bearing properties and secondarily in surface flatness accuracy, although both are important concerns. A surface plate that will be used in a metrology laboratory or high precision inspection department with a high volume of work would be concerned with high accuracy and surface wear properties. In each case the material and design would be considered for the application in mind before a selection is made and a purchase initiated.

The material properties of the granite is what makes the difference in the performance of surface plates. The differences in the various types of granite are considered in Table 1, based on Federal Specification GGG-P-463c, Plate, Surface (Granite) (Inch and Metric).

**Table 1. Granite Rock Types, Physical Properties, and Mineral Components GGG-P-463c**

Rock Type	Natural Color	Texture	Mineral Constituents, Descending Order Of Abundance	Modulus of Elasticity	
				10 <sup>6</sup> psi	GPa
Biotite granite	Bluish gray	Fine-grained	Orthoclase, smoky quartz, <sup>a</sup> oligoclase, albite, biotite, muscovite, magnetite and zircon	3.5–7.0	24.1–48.2
	Light gray	Medium-grained	Oligoclase, orthoclase and microcline, quartz, biotite, apatite and zircon	3.5–7.0	24.1–48.2
	Pink		Orthoclase with a small amount of microcline, plagioclase, quartz <sup>a</sup> , biotite, magnetite, and garnet	5.0–9.0	34.4–62.0
Biotite hornblende granite	Reddish brown	Fine-grained	Orthoclase and microcline, quartz <sup>a</sup> , hornblende, biotite, plagioclase and magnetite	6.0–9.0	41.3–62.0
Biotite-muscovite	Light gray	Medium- to fine-grained	Microcline, quartz, plagioclase, biotite, muscovite and magnetite	5.0–7.0	34.4–48.2
Diabase	Dark gray	Fine-grained	Plagioclase, pyroxene and magnetite	9.0–12.0	62.0–82.7
Hypersthene Gabbro			Plagioclase, pyroxene, hornblende, magnetite and biotite	10.0–12.0	68.9–82.7
Muscovite-biotite granite-gneiss	Light gray	Medium-grained	Microcline and orthoclase, oligoclase, quartz, rutile, muscovite	3.5–8.0	24.1–55.1

<sup>a</sup> 28 to 32% quartz by volume. In certain conditions, high quartz content tends to increase wear life.

As indicated in Table 1, fine-grained pink granite containing a small amount of quartz has a lower modulus of elasticity and therefore a lower load bearing per square foot capacity. The presence of large quartz crystals, however, results in a high degree of wearability by providing an ultra-smooth surface finish with increased surface hardness that resists wear on the granite and the precision ground and lapped instruments used on it. Although the load-bearing properties are lower than those of black or dark gray granite, this can be compensated for by increasing the thickness of the plate.

As a result of the increased wearability of pink granite, the interval between lapping compared to fine-grained black granite can be as much as five times as long. This is an important consideration when planning the maintenance costs and downtime involved in maintaining a production schedule.

The precision lapped and calibrated granite surface plate is a high-precision piece of equipment and must be maintained as such. Great care should be taken at all times to protect the surface, and attention to cleanliness is critical in the life span of the surface plate. It is essential that the surface be protected from the buildup of dirt, grease, airborne grime and oils. The plate should be covered when not in use to avoid accidentally dropping objects on the surface and chipping or cracking the precision finished surface.

All surface plates should be installed and supported according to the manufacturer's design and recommendations. Plates up to and including 6–12 feet are supported in a three-point non-distortable support system of hard rubber pads that are installed during manufacturing and remain in place during lapping and finishing. These pads are critical in the correct support of the surface plate and must never be removed or repositioned. Always make sure the surface plate is resting on these pads, and never support the plate by its ledges or under the four corners as this will cause deformation of the surface and introduce errors beyond the tolerance limits.

Surface plates made to meet standard guidelines and accuracy parameters established over the last fifty years and published in documents such as the Federal Specification GGG-P-463c will be manufactured in certain pre-designed sizes. These designs have been analyzed for dimensional stability and dependability and will, with proper care, provide dependable measurement assurance for many years. There are manufacturers that will special order surface plates in a wide variety of sizes and configurations to meet the needs

of specialized applications, and have engineering staffs that will design a surface plate to meet those needs. However, most applications and manufacturers' products fall under the design guidelines of the tables in the GGG-P-463c Federal Specification.

**Table 2a. Standard Sizes for Rectangular Granite Surface Plates GGG-P-463c**

Inch				Metric

**Table 2b. Standard Sizes for Round Granite Surface Plates GGG-P-463c**

Inch		Millimeter	
Diameter (inch)	Area (ft <sup>2</sup> )	Diameter (mm)	Area (m <sup>2</sup> )
12	0.8	300	0.071
18	1.8	450	0.159
24	3.1	600	0.283
36	7.1	900	0.636
48	48	1200	1.131

*Thickness:* For rectangular and round surface plates, specify thickness only if essential; see Appendix 30 and inch and metric versions of Tables XI and XII of GGG-P-463c.

Surface plate grades are established in the Federal Specifications and are the guidelines by which the plates are calibrated. The flatness tolerances in microinches for standard inch-dimension plates, listed in Table 3a., are obtained through the standard formula:

$$\text{Total flatness tolerance for inch - dimension grade AA plates} = 40 + \frac{D^2}{25} \mu\text{in.}$$

where  $D$  = diagonal or diameter of the plate in inches. The calculated flatness tolerance for grade AA is rounded to the nearest  $25\mu\text{in.}$

**For metric plate sizes, the total flatness tolerance of grade AA plates in micrometers is:**

$$\text{Total flatness tolerance for metric grade AA plates} = 1 + 1.62D^2 \cdot 10^{-6} \mu\text{m}$$

**where  $D$  = diagonal or diameter of the plate in millimeters.**

For both the inch and metric plates, the tolerances of the A and B grades are 2 and 4 times, respectively, those for grade AA.

Table 3a and Table 3b, adapted from Federal Specification GGG-P-463c, contain the calculated tolerances for the standard size and grades of rectangular and round surface plates.

**Table 3a. Total Flatness Tolerance, Rectangular Surface Plates GGG-P-463c**

Rectangular Plates									
Inch Sizes, Tolerances in Microinches					Millimeter Sizes, Tolerances in Micrometers				
Width (inch)	Length (inch)	Grade AA	Grade A	Grade B	Width (mm)	Length (mm)	Grade AA	Grade A	Grade B

**Table 3b. Total Flatness Tolerance, Round Surface Plates GGG-P-463c**

Round Plates							
Inch Sizes, Tolerances in Microinches				Millimeter Sizes, Tolerances in Micrometers			
Diameter (inch)	Grade AA	Grade A	Grade B	Diameter (mm)	Grade AA	Grade A	Grade B
12	50	100	200	300	1.1	2.3	4.6
18	50	100	200	450	1.3	2.5	5.3
24	75	150	300	600	1.6	3.2	6.3
36	100	200	400	900	2.3	4.6	9.2
48	125	250	500	1200	3.3	6.6	13.2

**Calibration of Surface Plates.**—Surface plates, like other precision instruments, will drift out of tolerance in time and need to be periodically checked and even adjusted to maintain accuracy. For a surface plate, this adjustment involves lapping the surface and physically removing material until the entire surface is once again flat to within the limits of the grade to which it was made. This is a labor-intensive adjustment that should only be attempted by a trained technician with the appropriate tools. An untrained technician, even with the proper lapping tools and compounds, may cause more harm than good when attempting such an adjustment.

However, with proper care and cleaning, a surface plate may not need lapping at every calibration. Completing the calibration process will give the quality assurance program the data needed to identify wear patterns on a surface plate and have the proper maintenance completed before an out of tolerance condition occurs, thereby avoiding a costly failure impact analysis and reinspection of parts, or even a recall of finished parts from a customer. The calibration process is a cost-effective alternative to these undesirable effects.

Fig. 1 illustrates the “Union Jack” or eight line pattern that is used to analyze the overall flatness of the surface plate working area. Each line is measured independently, and the positive and negative elevations are recorded at predetermined intervals. The peak to valley

flatness is calculated from the recorded data. This method was developed by JC Moody while working for Sandia Corporation, and the resulting plot of the data points is referred to as a Moody Plot. There are many software packages available that simplify the process of calculating this plot and provide a detailed printout of the data in a graphical format.

Fig. 1. Union Jack Pattern

**Repeat-o-Meter Method (Fed. Spec. GGG-P-463c)** The easiest and quickest method of monitoring for surface plate wear and tolerance adherence is the Repeat-o-Meter method. A *repeat reading gage* similar in design to the one shown in Fig. 2 is used to establish the variation in flatness of the surface plate.

Fig. 2. Repeat Reading Gage from Federal Specification GGG-P-463c

The gage is placed at the center of the surface plate, and the indicator is set to zero. The eight-line Union Jack pattern, Fig. 1, is then scanned in the sequence defined in the Federal Specification GGG-P-463c. The result of the maximum reading minus the minimum reading shall not exceed the flatness tolerance expressed in Table 4a and Table 4b for inch- and millimeter-sized plates, respectively.

**Table 4a. Tolerance for Repeat Reading of Measurement (microinches)**

Diagonal / Diameter Range		Grade AA	Grade A	Grade B	Obtained
Over	Thru	Full Indicator Movement (FIM), microinches			
...	30	35	60	110	When not specified
30	60	45	70	120	
60	90	60	80	160	
90	120	75	100	200	
120	150	90	120	240	
150	...	100	140	280	When specified
All Sizes		25	50	100	

**Table 4b. Tolerance for Repeat Reading of Measurement (micrometers)**

Diagonal / Diameter Range (mm)		Grade AA	Grade A	Grade B	Obtained
Over	Thru	Full Indicator Movement (FIM), micrometers			
...	800	35	60	110	When not specified
800	1500	45	70	120	
1500	2200	60	80	160	
2200	3000	75	100	200	
3000	3800	90	120	240	
3800	...	100	140	280	
All Sizes		0.6	1.3	2.5	When specified

*Note for Table 4a and Table 4b:* If it is intended that small objects be measured on large surface plates, it should be noted that a larger tolerance in flatness over small areas is permitted on larger plates.

All points on the work surface shall be contained between two parallel planes, the roof plane and the base plane. The distance between these planes shall be no greater than that specified in the tolerance table for the respective grades.

**Autocollimator Calibration (Ref NAVAIR 17-20MD-14, 1 MAY 1995).**— Calibration of a surface plate by autocollimator is one of the most accurate and relatively quickest methods in use today. The method has been in use since the advent of the autocollimator in the 1940s but was refined by JC Moody with the development of the Moody Plot analysis method that utilized the data collected on perimeters, diagonals and bisectors. The resulting pattern resembles the “Union Jack” and is referred to as such.

Autocollimators today have been enhanced with the inclusion of CCD devices, digital readouts, computer interfacing, and automatic data collection that calculates the deviations and analyzes the results in a fraction of the time previously required, producing a full color graphical diagram of the surface plate variances.

Fig. 3 and Fig. 4 show the positioning of the turning mirrors used when performing the surface plate calibration with an autocollimator.

Fig. 3. Placement of the First Turning Mirror and Retroreflector: TO 33K6-4-137-1

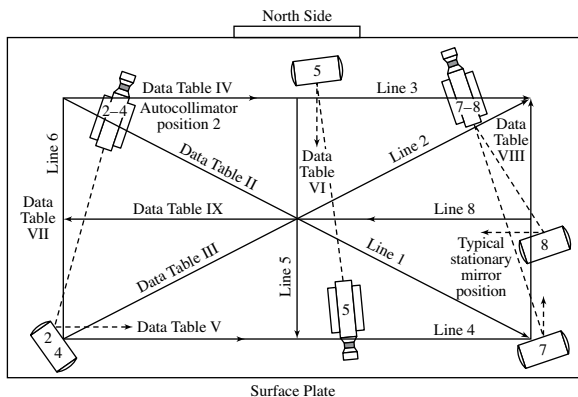

Fig. 4. Turning Mirror Placement for Remaining Lines: TO 33K6-4-137-1

**Interferometer Calibration (Ref TO 33K6-4-10-1 30 April 2006).**—Calibration of a surface plate can also be accomplished using a laser interferometer. The laser offers the absolute lowest uncertainty in the calibration process, and, although it takes more time than either of the other methods, it is sometimes required by some customers doing military or government contract work. There are several models and methods available on the market today. The general process will be covered, but familiarity with the particular model being used is necessary to complete the full calibration procedure.

The process is much the same as the autocollimator calibration method using turning mirrors. The laser tripod and laser head are located as close to the line being shot as possible. Move the tripod and realign the laser interferometer for each line during calibration. If available, use the turning mirrors to facilitate the alignment of the beam. As with any high-precision physical measurements, air currents and vibrations will affect the indications. Take precautions to minimize these affects. Clean the surface plate twice with surface plate cleaner and once again with ethyl alcohol prior to beginning the calibration process.

Mark the surface with lines as shown in Fig. 5 below. The lines will be either 3 or 4 inches away from the edge of the surface plate, depending on the size of the plate. The North side of the plate will always be the side bearing the manufacturer's label or the previous calibration label.

Fig. 5. Reference Lines for Union Jack 1

Clamp the straight edge to the surface plate in the position shown in Fig. 6 below. The straightedge will always be offset from the center of the line so that the centerline of the mirror will travel directly above the center of the reference line.

Place the interferometer and retroreflector on the reference line closest to the laser head. Direct the beam through the interferometer optics and, using the vertical and horizontal adjustments on the tripod head, adjust until the beam returns through the optics and registers a strong beam strength on the beam strength indicator.

Slide the retroreflector to the far end of the reference line and use the rotation adjustment on the tripod head to swing the beam back into alignment with the laser head until once again the beam strength indicator shows a strong beam strength. Using this method of Translate Near / Rotate Far you will be able to align the beam with the path of the reference line. Patience will be required, and the manufacturer will also have information regarding the best method for the specific model being used.

Fig. 6. Placement of the Straightedge for Measurement of the First Reference Line

Once the alignment of the first reference line has been completed, take the measurements at the stations recommended by the software calculations. The number of stations will change according to the size of the surface plate and the length of the footpad used for the retroreflector. Record the values at each station along the first reference line then return to the first position and verify that the reading repeats before proceeding to the next line. Great care must be taken to ensure a clean plate and footpad, free of residue or buildup. A very small amount of dirt or dust can cause an out of tolerance condition and result in many wasted hours of failure impact analysis and possibly recall of parts to be reinspected unnecessarily.

When the data from all the reference lines has been collected, the interferometer software will calculate the overall flatness of the plate and make the determination as to whether or not the plate meets the specific grade to which it has been assigned or needs to be lapped to meet tolerance limits. If there is a failure determination, the plate will need to be lapped and reshot to collect the "As Left" data and close the calibration event with an acceptance of the calibration data.

Lapping a surface plate is a very specific skill and should not be attempted by an amateur or enthusiastic technician however good the intentions may be. Lapping requires specialized tools and compounds as well as skill. An inexperienced technician attempting to lap a surface plate may well cause more damage than is already present. Always consult an experienced and proven professional in this field.

**V-Blocks**

The V-block is a precision holding jig or fixture devised as a tool or to enable the precision and repeatable positioning of a cylindrical work piece. The V-block enables drilling, grinding, or milling operations on a robust and precision platform as compared to the vise or other simple holding devices.

In 1902, Elmer Cobb and Eugene Spaulding of Portland, Maine patented a Machinists' V-block to expand their capability to hold and drill extended workpieces. The V-blocks were machined with a large channel on one side and a pair of smaller channels on the other to accommodate the various diameters that were encountered in the basic work done in the machine shop of the era. Each block had a hole in the center to allow the passage of a drill through the work piece. The blocks were a matched set that were secured together by two rods that aligned the blocks together and allowed them to slide open or to be closed together to support work of varying lengths.

Fig. 1. Machinists' V-Block, Patented 1902 by Cobb and Spaulding

In 1923, Gustave Hines invented a device that incorporated a scale along the linear side of the work piece, and locked the work into a scaled collar that could be rotated accurately throughout 180°. The device provided a drill guide that would accurately measure distances between centerlines of holes, and provide rotational accuracy.

Gustave Hines 1923 Innovation

**Classification.**—The Federal Specification GGG-V-191D 1971 “V Blocks and Clamps” was developed to provide the acceptable criteria for items to be purchased under contract by the US Government or Department of Defense. This specification has been superseded by Federal Specification A-A-51150B and since canceled. However, these and related standards are still referenced by many manufacturers of precision V-blocks and were the initial guidelines for the manufacturing and specification of the tool.

*Federal Specification Coverage:* This specification covers only the types, styles and grades generally purchased by the Federal Government, and does not include all types, styles, and grades which are commercially available.

### **Type, Style, and Grade**

*Type I—Single V-Groove (page 735)*

*Style 2:* Double level clamping

*Style 3:* Reversible clamping yoke

*Style 4:* Magnetic clamping (mild steel and brass laminated)

*Style 5:* Ribbed, without clamping

*Style 6:* Plain without clamping

*Grades:* Grade A: Steel (alloy); Grade B: Mild Steel (and brass laminated for style 4); and Grade C: Cast Steel.

*Type II—Double V-Groove (page 738)*

*Style 1:* Single level clamping

*Grades:* Grade A: Steel (alloy); and Grade B: Cast Iron (class 40 iron).

*Type III—Quadruple V-Groove (page 739)*

*Style 1:* Single level clamping

*Grades:* Grade A: Steel (alloy); and Grade B: Cast Iron (class 40 iron).

*Type IV—Combination, Top and End V-Grooves (page 741)*

*Style 1:* Single level clamping

*Grades:* Grade A: Steel (alloy)

**Material.**—*Note:* Grade and surface finish specifications are a representation of all governing standards in use today.

*Grade A Blocks:* Grade A blocks shall be steel or steel alloy and shall have a surface hardness of 58 to 65 RC on the Rockwell C scale.

*Grade B Blocks:* Grade B blocks shall be a good quality mild steel, free from porosity and other injurious defects and have a surface hardness of 40 to 45 on the Rockwell C scale.

*Grade C Blocks:* Grade C blocks shall be a good quality cast steel free of porosity or other injurious defects and shall have a surface hardness of 150 to 180 BHN (Brinell Hardness Number).

*Precision Granite Blocks:* Precision granite V-blocks shall be made from a close grained uniform texture granite free from flaws or fissures and inclusions of softer material. Granite V-blocks shall adhere to either Grade A or B accuracy. Grade A and matched sets are to be provided in a protective case.

*Finished Surfaces:* Surfaces of the V-grooves, tops sides, bottom, V-groove relief slots, and clamp engaging grooves shall have finished surfaces measured in micrometers arithmetical average (A.A.) or roughness average (Ra) in accordance with ANSI/ASME B46.1-2009. All other surfaces shall be finished in accordance with normal manufacturer's standard commercial practice.

*Surface Finish, Grades A and B, Style 4, Blocks:* Surface of V-groove relief slots and clamp engaging grooves (when applicable) on blocks shall have a surface roughness not greater than 125  $\mu\text{in}$  (3.175  $\mu\text{m}$ ). All other finished surfaces shall have a surface roughness not greater than 32  $\mu\text{in}$  (0.81  $\mu\text{m}$ ) Ra.

*Surface Finish, Grade B (except Style 4), and Grade C Blocks:* Surface of V-groove(s). The V-grooves relief slots and clamp engaging grooves (when applicable) on blocks shall have a surface roughness not greater than 125  $\mu\text{in}$  (3.175  $\mu\text{m}$ ) Ra. All other finished surfaces shall have a surface roughness not greater than 63  $\mu\text{in}$  (1.600  $\mu\text{m}$ ) Ra.

*Surface Edges:* Edges of all exterior surfaces, including corners, shall be rounded or beveled not less than 0.010 inch and shall be free from fins and burrs.

**Tolerance.**—All Grade A; and Style 4, Grade B, mild steel laminated with brass, shall have a ground finish on the ends, sides, top, bottom, and the V-groove(s). The V-grooves shall be centered with the sides, square with the sides and ends, and parallel to the bottom within 0.0003 in. All surfaces shall be square with each other within 0.0003 in.

Grade B (except Style 4) and Grade C shall have a machined or ground finish. The V-groove(s) shall be parallel and centered with the sides to within 0.002 in. The ends shall be square with the sides within 0.002 in. and the sides shall be square with the top and the bottom within 0.002 in. The V-grooves shall be 45° each side of the center perpendicular plane for all grades. When specified, Grade B or C blocks shall be furnished with tolerances as specified for Grade A blocks.

When the V-blocks are provided in matched sets, they shall be clearly marked to identify them as such and shall be identical to each other within 0.0002 in. on all critical features.

**V-Block Design.**—Each V-block shall have a 90° V-groove 45° from center perpendicular plane cut lengthwise on the top, or top and end, or top and bottom, for the type specified. A slot shall be provided at the apex of the V-groove for chip relief. The exception being with the Type III V-blocks which shall be furnished without the chip relief unless otherwise specified.

When V-blocks are furnished in “matched pairs” they shall be marked to readily identify them as a pair. Clamping grooves shall be provided along the full length of the sides of Styles 1 and 2 blocks for engaging the clamps.

**Clamps.**—The clamps shall consist essentially of a yoke and one or two screws for the style specified, and shall be of a size to accommodate the maximum size round stock specified in the respective tables. The Clamp shall be made of good quality steel or iron and sufficiently robust to provide adequate support and security of the work piece in the V-block during drilling and grinding operations. When engaged in the clamping grooves, the clamp should not extend past the side faces of the block. When provided with matched sets the clamp shall be applicable to either member of the set. The screws for the clamping device shall be right handed thread conforming to ANSI/ASME B1.2 or FED-STD-H28.

**Yokes.**—Yokes shall be made of good quality steel or iron and sufficiently robust to provide adequate support and security of the work piece in the V-block during drilling and grinding operations and should not extend past the side faces of the block. V-block and yoke screws for Type 1 Style 3 shall be threaded in accordance with ANSI/ASME B1.2 or FED-STD-H28 or the equivalent and shall be a Class 2 fit. When the yoke is in place it shall bisect the 90° V-groove. The yokes when engaged in the clamping grooves shall stand in an upright position.

Yokes for the style 3 blocks shall have a slot on each end to engage the two adjusting screws. The yoke shall be designed so that the pads bisect the 90° V-groove to allow the yoke to secure stock that does not extend above the V-groove. When inverted the yoke shall be able to secure stock of the maximum size specified.

**Screws.**—All screws shall be made of steel of such quality as to withstand hard usage. Screw heads shall be knurled and provided with a hole through the center for tightening with a pin or rod. All screws shall conform to the ANSI/ASME B1.2 or FED-STD-H28 or equivalent and shall be a class 2 fit.

**Type 1, Style 2.**—Type 1 V-blocks are of the single V type. The Style 2 V-block shall have two clamping grooves on each side to accommodate clamping from minimum to the full range of the capacity of the V-groove. The block shall be similar to Fig. 2 and conform to the dimensions shown in Table 1. Style 2 V-blocks can be furnished in matched pairs and the clamps shall be suitable for use with either V-block.

Fig. 2. Type 1, Style 2

**Table 1. Accuracy and Dimensions, Type 1, Style 2**

Grade and Designating Size		Permitted Deviations (inch)					
		Flatness of Working Faces	End/Side Square to Base	Parallelism of Opposite Faces	Parallelism of "V" to Base and Sides	"V" Centrality	Matching Tolerance over "V" Length
Grade A	1	0.00015	0.0002	0.0002	0.0003	0.0003	0.0002
	2	0.0001	0.0002	0.0002	0.0003	0.0003	0.0002

	Length	Width	Height	Maximum Capacity
1	3.000	2.500	2.500	2.500
2	2.500	3.000	2.000	2.000

All dimensions are in inches.

**Type 1, Style 3.**—Style 3, reversible clamping yoke. Style 3 blocks shall be similar to Fig. 3, conform to dimensions and accuracies shown in Table 2 for the sizes specified and be designed to facilitate clamping to a machine table or plate. The top surface shall have 4 drilled and tapped holes, one near each corner, to accommodate the yoke screws. If the blocks are furnished in matched pairs the yokes and screws shall be suitable for use with either block of the matched pair.

5	6.000	6.000	6.000	4.500
6	8.000	8.000	8.000	6.375

All dimensions are in inches.

**Type 1, Style 4, Magnetic Clamping Blocks.**—Style 4, magnetic clamping blocks shall be similar to Fig. 4 and conform to the dimensions and accuracies shown in Table 3. Magnetic clamping V-blocks shall be either made of mild steel laminated with brass or an assembly of mild steel with an embedded magnetic core that can be disengaged to allow positioning of work piece. Style 4 magnetic clamping blocks shall have a ground finish on the sides, top, bottom, and V-grooves.

Fig. 4. Type 1, Style 4 Magnetic Clamping V Blocks

Fig. 5. Type 1, Style 5 Ribbed without Clamps

**Type 1, Style 5, Ribbed without Clamps.**—The Style 5 block shall be designed without clamping capability for the work piece. The block shall be similar in design to Fig. 5 and conform to the dimensions and accuracies shown in Table 4. The Style 5 block shall be of ribbed design to provide strength with light weight. There may be lightening holes in the webbing section to reduce weight without affecting the performance capabilities. The Style 5 block shall be of a design as to facilitate clamping to a machine table or plate.

**Table 3. Accuracy and Dimensions for Type 1, Style 4  
Magnetic Clamping V-Block**

Grade	Permitted Deviations (inch)					
	Flatness of Working Faces	End/Side Square to Base	Parallelism of opposite faces	Parallelism of "V" to Base and Side	"V" Centrality	Matching tolerance
Grades A, B	0.0001	0.0002	0.0002	0.0003	0.0003	0.0002
Grade C	0.0004	0.002	0.001	0.002	0.002	0.001
Grade Characteristics						
Grade A, B	<ul style="list-style-type: none"> <li>• Up to 2.125"</li> <li>• Mild steel with embedded magnetic core, or laminated mild steel with brass</li> <li>• Surface finish NTE 32<math>\mu</math>in      • Material hardness for mild steel 50–62 RC</li> </ul>					
Grade C	<ul style="list-style-type: none"> <li>• Up to 2.125"</li> <li>• Mild steel with embedded magnetic core, or laminated mild steel with brass</li> <li>• Surface finish NTE 63<math>\mu</math>in      • Material hardness 40–45 RC Steel</li> </ul>					

All Grades, Designating Size	Nominal Dimensions			
	Length	Width	Height	Maximum Capacity
1	1.750	2.375	1.875	2.125
2	2.375	1.875	1.750	1.625
3	2.500	2.500	1.750	2.250
4	3.750	2.375	1.750	2.125

All dimensions in inches.

Due to the nature of the material, special consideration has been given to the granite V-blocks and the general recommended dimensions are given in Table 4. Higher accuracy granite V-blocks are commercially available and manufacturers' tolerances apply.

All dimensions in inches.

**Type 1, Style 6, Plain, without Clamps.**—Type 1, Style 6 V-block shall be designed similar to the style shown in Fig. 6 and conform to the dimensions and accuracies described in Table 5. The Style 6 block shall be designed plain with a chip relief at the apex of the V-groove. The block shall be furnished in a set of three suitable for general machine shop use.

Fig. 6. Type 1, Style 6  
General Machine Shop Support V-Block

6	11.81	4.13	4.13	0.600 to 4.10

All dimensions in inches.

**Type II, Double V-Blocks.**—The Type II, Double V-Blocks shall be designed to incorporate two V-grooves, as in Fig. 7a, Fig. 7b, and Fig. 7c, on one block machined on opposite sides, and both conforming to the dimensions and accuracies shown in Table 6. Nominal dimensions shown in Table 6 do not encompass all configurations available but define the tolerances that need to be adhered to and define the design parameters. In the case that the design furnishes two V-grooves of different sizes, the accuracy tolerances of the larger size shall apply to both.

The Type II, Double V-Block shall be furnished individually or in matched pairs and shall conform to Grade A or Grade B accuracy tolerances and shall come furnished with a clamp or clamps sufficiently robust to enable adequate security of work piece during average drilling or grinding operations. If furnished in matched pairs the clamps shall be usable on either member of the matched set. The clamps shall be designed to engage a single clamping groove along the outer face of the block.

All dimensions in inches.

**Type III, Quadruple V-Groove Block.**—The Type III, Quadruple Groove Block shall have four V-grooves, one on each of the four sides. This type shall be furnished in Grade A or B. Grade A shall be of a steel alloy and conform to the dimensions and accuracy tolerances defined in [Table 7](#).

Fig. 8. Type III, Style 1 Quadruple V-Block

Fig. 9. Type III, Style 2 Quadruple V-Block

Fig. 10. Type IV, Style 1 Combination Top and End V-Block

The Grade B Type III shall be of fine grained cast steel and conform to the dimensions and tolerances defined in Table 8. The nominal dimensions referenced in Table 7 and Table 8 do not represent the full extent of options available. Tolerances are defined as the minimum acceptable. Higher accuracy V-blocks of the Type III Style 1 and 2 may be available.

**Table 7. Type III, Style 1  
Quadruple V-Groove Block**

1	2.000	1.500	1.500	1.125

All dimensions in inches

**Type III, Style 2, Quadruple V-Block.**—Type III, Style 2, Quadruple V-Block is designed for a robust precision support of the work piece. This style V-block is not furnished with clamp or yoke and may be made of either mild steel or fine grain cast steel. The Type III, Style 2 block may be designed with uniform V-groove capability or a range of capacities. The tolerance of the Style 2 V-block will conform to those shown in Table 8, however the nominal dimensions and accuracies referenced in Table 8 do not represent the full extent of options available. Manufacturers' tolerances are always applied.

**Table 8. Type III, Style 2  
Quadruple V-Block**

Grade	Permitted Deviations (inch)

3	120	120	35	30 × 1 – 40 × 1 – 50 × 1 – 60 × 1		
4	120	120	60	30 × 1 – 40 × 1 – 50 × 1 – 60 × 1		
5	150	150	75	40 × 1 – 50 × 1 – 60 × 1 – 70 × 1		
6	200	200	100	60 × 1 – 70 × 1 – 80 × 1 – 100 × 1		

Dimensions of deviations are in inches; Nominal dimensions are in mm.

**Type IV, Combination Top and End V-Groove Block.**—The Type IV, Combination Top and End V-Groove Block shall be furnished in individual blocks consisting of one block, one clamp and one securing screw which is similar to the design illustrated in Fig. 10. The V-block shall be so designed that when turned on side or end that there shall be no interference from the sliding clamp. One end of the block shall be stepped and this end shall contain a V-groove and clamping grooves at right angle to the base. The blocks shall be designed to facilitate clamping to a machine bed or plate and have two tapped holes in the base and one on each side for mounting purposes.

**Style 1, Single Level Clamping.**—The Type IV, Style 1 Block shall be similar in design to the one shown in Fig. 10 and shall conform to the dimensions and tolerances as defined in Table 9. The Type IV, Style 1 shall be offered in Grade A configuration. Grade A tolerance shall be applied to the perpendicular secondary V-groove as it is to the primary V-groove.

**Table 9. Combination Top and End V-Groove Block**

Grade	Permitted Deviations (inch)					
	Flatness of Working Faces	End/Side Square to Base	Parallelism of Opposite Faces	Parallelism of "V" to Base and Side	"V" Centrality	Matching Tolerance

Characteristics	<ul style="list-style-type: none"> <li>• Steel alloy</li> <li>• Surface finish NTE 32<math>\mu</math>in</li> <li>• Material hardness 50–62 RC</li> </ul>					

Designating Size	Nominal Dimensions (inch)			
	Length	Width	Height	Maximum Capacity
1	3.625	1.875	1.875	1.3125

All dimensions in inches

**Metric Products.**—Products manufactured to metric dimensions (SI units) shall be considered on an equal basis with those manufactured to the inch units, providing they fall within the applicable tolerance conversions. The British Standard BS 3731:1987 provides specific requirements for hollow or solid, single or double V-groove blocks made from cast iron or steel, and solid V-blocks made from granite. Two grades of accuracy are defined, Grade 1 and Grade 2. Provisions are made for matched sets as well.

**British Standard V-Block Designs, BS 3731**

<sup>a</sup> Length C (side view) not shown.

160	26	42	42	42	42	2	26	20
200	28	46	46	46	46	2	28	24

Note: Intermediate sizes should be made to the accuracy specified for the next smaller designated size. Double V-blocks should be made to the accuracy specified for the larger designating size.

**Recommended General Dimensions for Steel, Cast Iron,  
and Granite V-Blocks BS 3731**

Max Dia., mm	Width A, mm	Height B, mm	Length C, mm	Max Dia., mm	Width A, mm	Height B, mm	Length C, mm
Cast Iron Hollow V-Block				Solid Steel or Cast Iron			
63	80	60	35	40	50	40	25
80	100	75	40	85	100	70	50
100	130	90	45	Solid Granite V-Block			
125	150	100	50	50	75	75	75
160	180	130	60	75	100	100	100
200	220	160	70	85	150	150	150
Double V-Block				125	200	200	200
20 and 25	32	32	42				
20 and 40	40	40	50				

### Calibration of V-Blocks

**Calibration Description.**—Calibration of the V-block shall be accomplished at intervals determined by either National Conference of Standards Laboratories (NCSL) Recommended Practices found in RP-1 “Establishment and Adjustment of Calibration Intervals” or the responsible facilities Quality Assurance Manual. Calibration intervals are designed to provide an acceptable level of assurance to adherence to original manufacturer’s specifications. Calibration of all precision measurement equipment is critical to providing measurement assurance to the quality system and maintaining a sound, robust manufacturing process and quality system.

**Table 11. Tolerance Limits per Grade**

Test Instrument (TI) Characteristics	Range	Performance Specification for Accuracy	Test Method
Ends/sides Squareness To Each Other	Up to 5 in.	Grade A – 200 $\mu$ in Grade B – 0.002 in.	Verified with Electronic Indicator
	Over 5 in.	Grade A – 500 $\mu$ in Grade B – 0.002 in.	
Parallelism of V to Base	Up to 5 in.	Grade A – 300 $\mu$ in Grade B – 0.002 in.	
	Over 5 in.	Grade A – 500 $\mu$ in Grade B – 0.002 in.	
V Centrality	Up to 5 in.	Grade A – 300 $\mu$ in Grade B – 0.002 in.	
	Over 5 in.	Grade A – 500 $\mu$ in Grade B – 0.002 in.	
Flatness of Working Faces		Grade A – 100 $\mu$ in Grade B – 500 $\mu$ in	
Matching Tolerance	Less than 6.00 in.	Grade A – 200 $\mu$ in Grade A – 300 $\mu$ in	
	Over 6.00 in.	Grade B – 500 $\mu$ in	

*Note:* Tolerances listed in Table 11 are a representation of the standard tolerances recommended by the GGG-V-191D -1971, AFMETCAL (Air Force Metrology & Calibration Program) and general commercial manufacturing. Be advised that not all features are calibrated on all types and styles of V-blocks. Manufacturer’s tolerances shall be applied when provided. The actual use of the V-block should be taken into consideration when selecting the features to be calibrated.

**Table 12. Equipment Requirements**

Item	Minimum Use Specifications	Calibration Equipment Examples
Surface Plate	Range: 24 × 36 inch, Grade AA, 100 $\mu$ in overall Flatness	Per Fed Spec GGG-P-463
Electronic Indicator	Range: $\pm 0.010$ , Accuracy: $\pm 0.00001$ in.	Mahr-Federal, Model 832 Digital Electronic Amplifier w/ EHE-2056 LVDT
Precision Cylindrical Gage	Range: 0.5 in. dia. × 3 in L; Accuracy: Class XX	Van Keuren, Extra Length Reversible Plug Gage
	Range: 1.00 in dia. × 2 in. L; Accuracy: Class XX	Van Keuren, Reversible Plug Gage
Granite Master Square	Range: 9 in. L × 12 in. H × 3 in. W Accuracy: Grade AA 25 $\mu$ in/6 in.	L.S.Starrett Granite Tri-Square
Squarol	Range: 0.375 in. to 5.00 in	Squarol Squareness Checker Model #700
Sine Plate	Range: 6 × 6 inch; Accuracy: $\pm 200$ $\mu$ in	Taft Pierce Model 9123-1

**Table 12.** (Continued) **Equipment Requirements**

Item	Minimum Use Specifications	Calibration Equipment Examples
Alternative Equipment Requirements		
SquareMaster	Range: 0 in. to 12 in.; Accuracy $\pm 50 \mu\text{in}$ over 12.00 in.	PMC/Mercury SquareMaster Model VSQ-12
Master Square	Range 3 in. W $\times$ 5 in. L $\times$ 12 in. H	SquareMaster Master Square
Cylindrical Square	Range to fit max diameter of UUT. (Example: 5 in. $\times$ 12 in.); Accuracy: 100 $\mu\text{in}$	Taft Pierce Model 9143

**Preliminary Operations.**—Review and become familiar with the entire procedure before proceeding with the calibration process. Alternative standards may be substituted for the ones listed in **Table 12. Equipment Requirements**. Thorough consideration must be paid to the *Accuracy Ratio*, *Total Accuracy Ratio (TAR)*, and *Measurement Uncertainties* introduced when substituting standards. Some standards represented do not offer a 4:1 TAR. If this is an unacceptable condition according to your particular quality assurance system then measures must be taken to calculate the uncertainty and introduce this into your uncertainty budget, or determine the acceptable tolerance limits through *Guard Banding* or similar method to satisfy the requirements of your quality system.

- Allow all the components to stabilize a minimum of 4 hours to the temperature of the calibration area before beginning the procedure.
- Clean and closely inspect all critical surfaces for nicks and burrs. Carefully stone with fine hard Arkansas stone to remove any incursions.
- Turn on electronic indicator and allow to warm up for a minimum of 30 minutes before proceeding.

### Calibration Procedure

*Note:* Document the results of all measurements and tests for future reference, Trend Analysis, Root Cause Analysis or Calibration Interval Adjustment.

**Sides Square To Each Other.**—1) Set up equipment as shown in **Fig. 11**.

- Special attention must be paid to establishing ZERO indication at the height of the V-block (UUT or Unit Under Test) sides to be measured. The SQUAROL (squareness checker) is rotated so the crest of the radius is indicated by the lowest reading on the Electronic Indicator. Plus and Minus travel must be available on the indicator head.

Fig. 11.

2) Set the electronic indicator to the appropriate range to measure the Squareness of the Side A of the UUT.

- $\pm 0.0002$  in. for Grade A. ( $\pm 0.0005$  over 5 in.)
- $\pm 0.002$  in. for Grade B (or C)

3) Set the gage head of the electronic indicator against the granite square master at the appropriate height to measure side A of the UUT at approximately 90% of its vertical height. Rotate the Squarol to seek the lowest indication. Using the fine adjust of the Squarol to bring the reading close to the zero indication. Assure that plus and minus travel can be realized.

- 4) Zero the indicator with the electronic fine adjust to set the final zero indication.
- 5) Remove the granite square master and replace with the UUT (Side A) as shown in Fig. 12. Side A is determined arbitrarily, but once established, must be maintained throughout the procedure to determine the relationship of all sides to each other.

Fig. 12.

6) Rotate the Squarol to seek the lowest indication. Verify that the indication is within the tolerance limits for the UUT as defined in Table 11. Record the indication as Side A to Base Squariness.

7) It may be necessary to place a parallel bar or right-angle iron behind the UUT to secure the UUT in place while obtaining indication. This will not affect the accuracy of the measurement as long as the measurement is repeatable and consistent.

8) Reverse the UUT and repeat Items 1) through 6) for Side B. Record indication as Side B to Base Squariness.

9) Rotate UUT 90° clockwise and repeat Item 6) and record indication as End A to Base Squariness.

10) Rotate UUT 180° clockwise and repeat Item 6) and record indication as End B to Base Squariness.

11) The End measurements will not be applicable to all styles and types due to design features. In that case disregard Items 8) and 9).

12) Rotate the UUT so that Side A is down and the indication is of Base to Side A.

13) Repeat Items 6) through 9) for remaining three sides (End A, End B, Top)

14) Rotate the UUT so that Side B is down and the indication is of Base to Side B.

15) Rotate the UUT so End A is down and the indication is Base to End A.

16) Repeat Items 6) through 9) for remaining three sides. (Side A, Side B Top)

17) Repeat process for End B if applicable.

18) All readings must be within limits defined in Table 11.

**Parallelism of V to Base.**—1) Select the appropriate size precision cylindrical gage or cylindrical square for the UUT being calibrated. The appropriate size gage should contact the V-groove near the center of the working surface. Leave approximately half the length of the cylindrical gage extended over one end of the UUT as shown in Fig. 13.

*Note:* Larger V-blocks will require the use of cylindrical squares of various diameters to accomplish the engagement at the center of the working surface. Special care should be taken in handling these precision standards to avoid nicking or damaging the fine lapped surfaces. Adaptation of the methods used herein can be made to accomplish the calibration of larger V-blocks without reducing confidence levels associated with the readings taken.

Fig. 13. V-Block with Cylindrical Gage Installed

2) Place the contact point on top of the cylindrical gage as close as possible and directly above the end of the V-block. Seek the top of the cylinder by sweeping across the radius and observing the maximum indication.

3) Zero the electronic indicator at the high point of the sweep.

4) Move the gage head to the end of the cylindrical gage. Indicate the peak of the radius and note the reading.

5) Rotate the cylindrical gage or square 180° and repeat **Items 2)** through **4)**.

6) Do not adjust the zero setting of the electronic indicator from **Item 5)**.

*Note:* If the cylindrical gage or cylindrical square being used covers  $\frac{3}{4}$  of the V-groove then Gage or Square does not have to be moved to the other end.

7) Remove the cylindrical gage or cylindrical square being used and place it on the opposite end of the V-groove with the same end facing out.

8) Place the contact point on top of the cylindrical gage as close as possible and directly above the end of the V-block. Seek the top of the Cylinder by sweeping across the radius and observing the maximum indication. Note this reading.

9) Move the gage head to the end of the cylindrical gage. Indicate the peak of the radius and note the reading.

10) Rotate the cylindrical gage or square 180° and repeat **Items 8)** through **9)** retaining the original zero setting position.

11) Record the largest reading found as the maximum error of Parallelism of V to Base. Reading shall fall within the Tolerance Limits defined in **Table 11**.

12) Lay UUT on Side A and perform **Items 1)** through **11)** to calibrate Parallelism of V-Groove to Side A.

13) Lay UUT on Side B and perform **Items 1)** through **11)** to calibrate Parallelism of V-Groove to Side B.

14) Repeat **Items 1)** through **13)** for V-groove opposite and all remaining V-grooves if unit is Type 2, Style 1; Type 3, Style 1 or 2; or Type 4, Style 1.

a) Double V-Groove Block Tolerance is to be derived from the tolerance of the larger of the two V-grooves.

b) The Type III Style 2 Quadruple V-Block is generally produced in the B Grade and the applicable tolerance shall be applied to all V-grooves inclusive. Grade A tolerances shall apply to all V-grooves in a Grade A Quadruple Type III Style 2 regardless of the size of the V-groove unless otherwise specified by the manufacturer.

15) If V-blocks are a matched pair the maximum deviation between the members may not exceed the tolerance limits as defined in **Table 11**.

16) All dimensions must be indicated in matched sets.

17) Place both members of the set side by side on the surface plate with the V-groove up as shown in **Fig. 14**. The clamp or yoke is not installed for this measurement.

18) Place the contact point at the upper left corner of V-Block 1 and zero the indicator at that point.

19) Indicate the top surface of the V-block and confirm the flatness of the block. If there are any erroneous readings, immediately check the V-block base for nicks or burrs that could be affecting the reading. Gently remove nicks or burrs with a hard Arkansas stone.

20) Move the contact point to V-Block 2. Do not change the zero setting and indicate the top surface of V-Block 2 and confirm that the readings are within the tolerance limits as defined in [Table 11](#) for matched sets.

21) Rotate the UUT set so that Side A is now on the surface plate and place the contact point in the same relative position as with the TOP measurement.

Fig. 14. Matched V-Block Setup TOP VIEW

22) Indicate the entire surface of V-Block 1, once again observing for any abnormalities that may indicate a nick or burr on the side opposite.

23) Move the contact point to the starting point on V-Block 2 and observe the deviation from the zero setting. Indicate the entire surface of V-Block 2 and note the maximum deviation from zero.

24) Verify that all readings are within the tolerance limits as defined in [Table 11](#).

25) Rotate the UUT set so that the TOP is now on the surface plate.

26) Place the contact point in the same relative starting position as previously used. If the V-Block Set has a lapped or flat ground surface, indicate the entire surface observing any abnormalities and deviations in accordance with the tolerance table. If the UUT has a double rail supporting system, only indicate the sections that come into contact with the surface plate under normal use.

27) Move the contact point to V-Block 2 starting point and observe the initial deviation from zero. Indicate the applicable surface area and verify that all deviations are within the tolerance limits as defined in [Table 11](#).

28) Rotate the UUT set to the final side and repeat [Items 21\)](#) through [24\)](#).

29) Place UUT set on End A and repeat [Items 21\)](#) through [24\)](#).

30) Place UUT set on End B and repeat [Items 21\)](#) through [24\)](#).

**V-Groove Centrality.**—1) The V-Groove Centrality is not calibrated in all types and styles. Centrality of the V-Groove is only applicable if the V-block can be set on its side with no interference when the clamp or yoke is installed.

a) Precision granite V-blocks are generally produced in laboratory grade accuracies and require special attention in handling to avoid damage to the standards and V-blocks.

b) Type 1 Style 5 are sometimes large and require special care in handling due to the weight of the UUT and the size of the standard use in this calibration. Care must be taken when securing a large cylindrical square into the V-groove so no nicks or burrs are raised in the lapped surface.

2) Using the same cylindrical gage or cylindrical square as in [Parallelism of V to Base: Items through 13\)](#), lay the UUT on Side A as shown in [Fig. 15](#).

3) Place the contact point on top of the cylindrical gage close to the end of the V-block. Seek the top of the Cylinder by sweeping across the radius and observing the maximum indication. Zero the electronic indicator.

4) Without disturbing the position of the cylindrical gage mounted in the V-groove, rotate the setup over and lay the UUT on Side B.

5) Place the contact point on top of the cylindrical gage as close as possible to the same distance from the end of the V-block as in [Item 3](#)). Seek the top of the cylinder by sweeping across the radius and observing the maximum indication. This reading must be within the tolerance limits defined in [Table 11](#).

Fig. 15. V-Block Indicate Side A

6) Rotate the cylindrical gage  $180^\circ$  and repeat [Items 2](#)) through [5](#)). This reading must be within the tolerance limits defined in [Table 11](#).

7) Repeat the process for the opposite end, and for each remaining V-groove on the UUT.

8) If the UUT is a matched set, the maximum deviation must not exceed the limits for matched sets as defined in [Table 11](#).

**Flatness of Working Surfaces.**—1) Place UUT onto sine plate as shown in [Fig. 16](#) and seat well against the end bar. Assure that no nicks or burrs are present on either the plate or end bar that could affect the reading.

2) Set up the Sine Plate to an angle of  $45^\circ$

3) Place the contact point of the electronic indicator into the V-groove at the upper left position of the first line as shown in the **Top View of Surface** of [Fig. 16](#) and zero the electronic indicator at this position.

Fig. 16. Flatness of Working Surface Set Up

4) Sweep the surface along the lines shown from the throat of the V-groove to the outer edge Left to Right (or End A to End B)

5) Verify that all readings are within the tolerance limits as defined in [Table 11](#).

6) Rotate the V-block so the side opposite is now parallel to the surface plate and repeat [Items 3](#)) through [5](#)), working from End B to End A.

7) Record all readings on a permanent record and retain for use by the QA system.

8) Remove all standards. Clean and return to protected storage condition. Remove UUT from set up and store in appropriate protective containers or stations.

### Parallel Bars

*Parallel bars* are used for workpiece support during layout, machining, and inspection operations. Parallel bars are made from either steel, cast iron, or granite, come in a wide range of sizes and are either used alone or in matched pairs. In general, there are four types of parallel bars: Type I, Solid; Type II, Ribbed; Type III, Box; Type IV, Adjustable. Although the parallel bar is a relatively simple tool, it is still considered a precision instrument and must be handled with the same attention to care and handling as other precision ground and finished supporting gages. Most precision parallels are made from heat-treated steel and hardened to 55 to 60 on the C Rockwell scale. Generally, they have a finish of 8  $\mu$ in Ra with a fine finish free from all grind marks, chatter, or cracks. Granite parallel bars are also very desirable in an environment where thermal expansion is a consideration or where steel or cast iron would not be acceptable. Granite parallel bars are made to a very high degree of accuracy and can be used in a precision inspection setup.

**Type I, Solid.**—Type I parallel bars are designed to be used independently as an individual bar to aid in inspection setups. They can be used as a reference surface or to establish a vertical plane perpendicular to a base plane. They can also be used as an extended support plane, when used in matched pairs, to establish an elevated plane that is parallel to the base plane. Type I parallel bars have four finished sides that shall not vary from a true plane by more than 0.0002 inch per foot (0.005mm/300mm). The adjacent sides will be square to each other within 0.0005 inch (0.012mm). Type I parallel bars will appear similar to Fig. 1 and will meet the tolerance specifications stated in Table 1.

Fig. 1. Parallel Bars, Type I, Solid

**Table 1. Steel and Cast-Iron Parallel Bar Tolerances, Inch Sizes**

Size <sup>a</sup>	Tolerance Limits			Width/Height Variance Matched Pairs (in.)

35 to 75	0.0050	0.0050	0.0100	0.0100

<sup>a</sup> Size as applicable to either width or height dimension specified by the manufacturer.

Some common size configurations available from most manufacturers of Type I precision parallel bars appear in Table 2. This is a representation of sizes that are available; however, it is possible to have parallel bars custom made to a special order for a particular application. In that case, either the tolerance specifications of the engineering drawing or the specifications defined in the Federal Specification GGG-P-61a shall apply. It is at the discretion of the designing engineer which tolerances will apply in this case.

Table 2. Common Sizes of Parallel Bars

Width and Height (in.)	Length $\pm 0.002$ (in.)	Width and Height (in.)	Length $\pm 0.002$ (in.)	Width and Height (in.)	Length $\pm 0.002$ (in.)
$\frac{1}{8} - 1$	6	$\frac{7}{16} - \frac{7}{8}$	6	$\frac{1}{2} - 1\frac{1}{2}$	12
$\frac{1}{8} - 1\frac{3}{16}$	6	$\frac{1}{2} - \frac{5}{8}$	6	$\frac{1}{2} - 2$	12
$\frac{3}{16} - \frac{7}{8}$	6	$\frac{1}{2} - \frac{3}{4}$	6	$1\frac{1}{16} - 1\frac{1}{4}$	12
$\frac{3}{16} - 1\frac{1}{8}$	6	$\frac{1}{2} - 1\frac{3}{16}$	6	$\frac{3}{4} - 1$	12
$\frac{1}{4} - \frac{3}{8}$	6	$\frac{1}{2} - 1$	6	$\frac{3}{4} - 2$	12
$\frac{1}{4} - \frac{1}{2}$	6	$\frac{1}{4} - \frac{3}{8}$	9	$1 - 1\frac{1}{2}$	12
$\frac{1}{4} - \frac{5}{8}$	6	$\frac{1}{2} - \frac{5}{8}$	9	$1 - 2$	12
$\frac{1}{4} - \frac{3}{4}$	6	$\frac{1}{2} - 1$	9	$1 - 3$	12
$\frac{1}{4} - 1$	6	$\frac{1}{2} - 1\frac{1}{4}$	9	$1\frac{1}{4} - 1\frac{3}{4}$	12
$\frac{3}{8} - \frac{1}{2}$	6	$\frac{1}{2} - 1\frac{1}{2}$	9	$1\frac{1}{4} - 2\frac{1}{2}$	12
$\frac{3}{8} - \frac{3}{4}$	6	$\frac{3}{4} - 1$	9	$1\frac{1}{2} - 2$	12
$\frac{3}{8} - \frac{7}{8}$	6	$\frac{3}{4} - 1\frac{1}{2}$	9	$1\frac{1}{2} - 3$	12
$\frac{3}{8} - 1$	6	$\frac{3}{8} - 1$	12		

**Type II, Ribbed.**—The Type II parallel bars are rectangular in cross section and made from a cast gray iron. The casting is ribbed to provide lightness while maintaining strength and rigidity. The ribbing on the Type II parallel bar extends to the outer surfaces of the bar and becomes an integral part of the working surface. The working surfaces of the Type II have a fine ground surface that will not exceed a value of 16  $\mu\text{in Ra}$ . All the sharp edges are removed, and the surface is free from all machining marks such as grind chatter or burn. The Type II parallel bar is finished on the four sides of its length. The ends not being considered working surfaces are not finished for work applications. The Type II parallel bar is a much more rugged design than the Type I and is designed to support workpieces of larger dimensions. Type II parallel bars are commonly available in sizes up to 4 by 8 inches with a length of 36 inches. Although larger in overall size, the Type II still maintains a very close tolerance in straightness, parallelism, and squareness.

Fig. 2. Parallel Bars, Type II, Ribbed

After each bar is cast and rough ground, it is subject to a seasoning or aging process. This process can either be natural or artificial. The aging process is necessary to provide long term stability after finish grinding. Once the bar is aged and seasoned, the final dimensions will remain stable and not warp or twist for many years. Well-made and seasoned castings have been known to be in service for nearly 100 years and still hold their original geometry. Type II parallel bars will appear similar to Fig. 2 and will conform to the

tolerances defined in Table 3. Squareness and parallelism tolerances are Total Indicated Readings (TIR) over the full length of the bar.

The following table shows some common sizes that are readily available from most manufacturers of precision parallel bars. These are representative of the sizes that may be available in the general market, and almost any size or combination may be specially made for a specific application.

**Table 3. Tolerance Limits for Type II - Ribbed Parallel Bars**

Size	Tolerance Limits			Width/Height Variance Matched Pairs
	Straightness	Parallelism	Squareness	
Inch Sizes				
(inch)	(inch)	(inch)	(inch)	(inch)
1½ × 3 × 24	0.0002	0.0005	0.0005	0.0005
2 × 4 × 24	0.0002	0.0005	0.0005	0.0005
2½ × 5 × 24	0.0002	0.0005	0.0005	0.0005
3 × 6 × 36	0.0002	0.0005	0.0005	0.0005
4 × 8 × 36	0.0002	0.0005	0.0005	0.0005
Millimeter Sizes				
(mm)	(mm)	(mm)	(mm)	(mm)
35 × 75 × 600	0.005	0.013	0.013	0.013
50 × 100 × 600	0.005	0.013	0.013	0.013
50 × 152 × 600	0.005	0.013	0.013	0.013
75 × 150 × 1000	0.005	0.013	0.013	0.013
100 × 200 × 1000	0.005	0.013	0.013	0.013

**Type III, Box Parallel.**—The Type III “Box” Parallel is designed to provide a wide working surface. The Type III can either be square or rectangular in cross section. The rectangular design will have a rib running through the middle the entire length. This provides support to the two larger surfaces. The surfaces of all six sides will be finish ground to an average of 16 μinch Ra and all sharp edges will be removed. The ground surfaces will all be free from grind chatter marks and grind burn marks.

Fig. 3. Type III, Box Parallel

The Type III parallel bar, after casting and rough grinding, will be subject to a seasoning or aging process. This process can either be artificial or natural, and insures the stability of the material after the grinding process. The finished Type III parallel bars will have a material hardness of 180 BHN (Brinell Hardness Number) checked with a 10mm ball and a 3000 Kg load.

Each of the six working surfaces will not vary from a true plane (straightness) by more than 0.0002 inch per foot. The opposite sides and ends will be parallel to each other within 0.0005 inch. All adjacent sides will be square to each other within 0.0005 inch as well. The

size as specified will also be within 0.0005 inch. The Type III box parallel will appear similar to Fig. 3. Tolerances are given in Table 4.

**Table 4. Tolerance Limits for Type III Box Parallel**

Size (in.)	Straightness (in.)	Squareness (in.)	Parallelism (in.)
4 × 4 × 6	0.0001	0.0005	0.0005
4 × 6 × 6	0.0001	0.0005	0.0005
5 × 8 × 12	0.0002	0.0005	0.0005
10 × 10 × 10	0.0001	0.0005	0.0005

**Type IV, Adjustable Parallel.**—The adjustable parallel is a precision parallel that is adjustable to any height within a specified range. This design allows a flexibility in the use of the parallel that the other designs do not possess. The adjustable parallel is made of close-grained, seasoned cast iron. After initial casting and rough machining, the members of the parallel are subject to an aging or seasoning process that can either be natural or artificial. When complete, the member will have a hardness value of no less than 87 RB on the Rockwell B scale. The final machining on the adjustable parallel shall have a finish of 16  $\mu\text{in}$  Ra on the working surfaces and a 32  $\mu\text{in}$  Ra on the sides. The sides of the adjustable parallel are not designed to be working surfaces.

Fig. 4. Type IV, Adjustable Parallel

The adjustable parallel is made of two pieces. One piece is a fixed member machined with a dovetail slot, and the other a sliding member machined with a dovetail that fits into the slot and slides smoothly. It is this feature that gives the adjustable parallel the ability to be adjusted to any height within the range specified. The width of the bearing surface between the two members will be  $\frac{1}{2}$  the total thickness of the parallel. The two members are held in place and fixed by a locking screw arrangement that secures the two members and prevents them from moving or slipping after they have been set. Adjustable parallels are supplied in either individual pieces or in sets that cover a wide range. The adjustable parallel will conform to the tolerances defined in Table 5 and will appear similar to Fig. 4. A bilateral tolerance will be applied to the parallelism and flatness

**Table 5. Tolerance Limits for Type IV - Adjustable Parallel**

Size (range) (in.)	Length (in.)	Thickness (in.)	Parallelism (in.)	Straightness (flatness) (in.)	Lock Screws
0.375–0.500	1.750	9/32	0.0005	0.00005	1
0.500–0.6875	2.125	9/32	0.0005	0.00005	1
0.6875–0.9375	2.6875	9/32	0.0007	0.00007	1
0.9375–1.3125	3.5625	9/32	0.0007	0.00009	2
1.3125–1.750	4.1875	9/32	0.0009	0.00010	2
1.750–2.250	5.0625	9/32	0.0009	0.00012	2

**Granite Parallel, High-Precision.**—The granite parallel is designed for the very high precision applications where thermal or magnetic properties must be taken into consideration. The granite parallel is made with a much tighter tolerance than the cast-iron or steel

parallels. The configuration is basically the same as the Type I solid parallel; the only difference is in the material and the tolerance limits. The granite parallel is supplied in either individual members or matched sets. Granite parallels must meet the tolerances defined in the table below and will appear similar to Fig. 1.

**Table 6. Tolerance Limits - Granite Parallel**

Size (in.)	Grade AA	Grade A	Grade B
	Flatness and Parallelism	Flatness and Parallelism	Flatness and Parallelism
0.5 × 1 × 6	0.000025	0.00005	0.00010
0.750 × 1 × 6	0.00003	0.00006	N/A
0.750 × 1.5 × 9	0.00004	0.00008	0.00010
1 × 2 × 12	0.00006	0.00010	N/A
1.5 × 3 × 18	0.00015	0.00030	N/A
2 × 4 × 24	0.00020	0.00040	N/A
1.5 × 4 × 30	0.00025	0.00040	N/A

**Calibration, Precision Parallel Bars, Naval Air Systems and Air Force Metrology.**—

It is commonly understood that wear and naturally occurring damage will affect the performance of all precision measuring equipment. Identifying an out of tolerance condition before it can impact a critical measurement is the primary goal of calibration. Parallel bars are no exception to this rule. A precision-ground steel or cast-iron parallel bar may become worn or even deformed from daily wear or excessive forces applied. A granite parallel can also show evidence of wear, and, due to the extremely close tolerances applied to granite parallel bars, the monitoring of these instruments is even more critical. It is not extremely difficult to perform the calibration of the parallel bar, and it can be achieved in a relatively short period of time in a temperature-controlled environment on a clean surface plate with an electronic indicator, a height transfer standard, and a few gage blocks. The features that will be observed are flatness, parallelism, and height and width of matched pairs. The exact height and width of individual parallel bars is not a critical feature, but in this status they can only be used independently.

As an additional note, a Pratt & Whitney Supermicrometer can be used to measure the exact height and width of a set of matched parallel bars, but, in the absence of this instrument, the same results can be achieved with the instruments listed above. The uncertainty of the measurement is effectively the same, and the confidence in the results is just as high with either method.

**Flatness (Straightness) Calibration Method.**—In any calibration, the first steps are to ensure a clean working surface and a proper setup of the standards and measuring instruments. To that end, the first step is to clean the surface plate thoroughly with an approved surface plate cleaner and place the electronic indicator next to the working surface. The indicator should be powered up and allowed to warm up. The surface plate should be of an accuracy grade to provide a surface flatness deviation no greater than 0.00005" within the working surface that will be used. The *UUT* or *Unit Under Test* should be cleaned and, as a preliminary step to calibration, deburred with a clean ultra-fine hard Arkansas stone or gage block deburring stone. Only the edges should be stoned as this is where most burrs will occur. However, all edges, corners and surfaces should be observed to ensure that no damage or burring is present before proceeding.

For precision cast-iron or steel parallel bars, the UUT will be set up on two gage blocks of the same size and accuracy grade. A 2.000" gage block is recommended as a minimum. This will allow access to both sides of the parallel bar when taking data to determine the flatness of each side. It is important that the gage blocks are placed at the correct points to support the UUT without any sagging effect on the bar. These are called *Airy points* and are calculated by a simple formula:

$$\text{Airy point separation distance} = 0.554L, \text{ where } L \text{ is the length of the UUT.}$$

*Example:* For a 12.00" UUT, the gage blocks should be placed  $0.554 \times 12.00 = 6.650$  inches apart and located  $(12.00 - 6.650)/2 = 2.675$  inches from each end, as shown in Fig. 5. This distance should be very close to the calculated distance, but it does not have to be exact. Establishing the distance using a machinists' rule within  $0.100''$  is sufficient.

Fig. 5. Parallel Bar Flatness Setup

The UUT will be marked at five points equally spaced along the distance of each surface. The marks should be done with a felt-tipped marker or other suitable method. By general convention, the largest parallel surfaces are designated A and B. The two smaller surfaces are C and D. The markings A1 through D1 and A2 through D2 should be aligned with one another. A datasheet similar to the one shown in Table 7 should be created to collect the data and aid in the calculations of the deviations.

With the UUT placed on the gage blocks as shown, configure the electronic indicator to measure "over" and set the indicator amplifier range to  $\pm 0.0002$  with a resolution of  $0.00001''$ . It is recommended, however, to begin the readings at a slightly higher range and dial the scale in to a more sensitive resolution to determine the magnitude of the error. This will keep the readings on scale. Take the final readings in the highest sensitivity scale.

Place the indicator contact point on the UUT at the A1 position and zero the amplifier. All readings will have the x1 position as the zero point (A1, B1, C1, D1). All deviations will be from this point.

Sweep the surface of the UUT, recording on the datasheet the deviation as indicated at each of the calibration points. Ensure that each point does not exceed the documented tolerance for the type, style, grade, and size of the UUT.

When Side A has been scanned, adjust the electronic indicator contact point for "Under" measurements, place the contact point at the B1 calibration point and zero the indicator amplifier. This measurement is taken from the underside of the UUT, and the data collected will be used to calculate the parallelism of the two sides A to B. Once again, sweep the surface and record the deviations of the surface at each of the designated calibration points. Verify that all readings for sides A and B are within the tolerance limits assigned to the UUT.

Parallelism will be calculated from the sum of the deviations of each side. Calculate the sum of the deviations at each calibration point for surfaces A and B. The sum of the deviations will reveal the parallelism of the two surfaces. Verify that the values calculated are within the assigned tolerances for the UUT.

Carefully move the UUT to the adjacent sides (C and D) with side C up and repeat the sequence to determine the flatness and parallelism for sides C and D. Once complete and the values have been determined to be within the assigned tolerance limits, remove the UUT from the gage blocks and place on the surface plate. If this is a matched set of parallel bars, place the second member on the gage blocks as for the first member and complete the sequence for the second member.

**Height and Width, Matched Sets.**—The calibration of height and width of matched sets of steel or cast-iron parallel bars is a relatively simple process. Place the two parallel bars side by side on the surface plate in the same orientation, that is, with the same side up and the predefined calibration points adjacent to each other. One parallel bar will be designated as “A” and the other as “B”.

Position the height transfer gage next to the parallel bars and dial the transfer gage to the dimension of the side under test. Zero the electronic indicator on the transfer gage. Pull back the indicator probe off the land of the transfer gage and then replace it onto the land and ensure the zero setting repeats. If it does not repeat, re-zero the indicator amplifier and repeat the reading. Verify the zero setting in this manner until the reading repeats three times in a row with no variation. Then move the indicator probe to the surface of the “A” parallel bar and observe the deviation from zero reading. Sweep the entire surface and verify that all readings fall within the tolerance limits defined for the type and grade under test. Return the indicator probe to the transfer gage land and confirm that the zero point has not shifted before accepting the readings observed. If the zero point has shifted, it will be necessary to repeat the zero point setup and take the readings from the parallel bar again. If the readings are acceptable, proceed to the “B” parallel bar and verify that the deviation from zero reading is within the tolerance limits defined and the deviation from the “A” block is not beyond the limits for the type and grade under test.

Fig. 6. Parallel Bar Matched Set, Height and Width Calibration

Size limitations for granite parallel bars are not as rigid as those for individual bars, acceptable limits for size being  $\pm 1/32$  inch. However, the tolerance for size of matched sets is the same as that for steel and cast iron. The calibration procedure for granite parallel bars is the same as that for steel and cast iron.

As a final note, it should be mentioned that a Pratt & Whitney Supermicrometer can also be used to calibrate the height and width of a parallel bar or a matched set of parallel bars. The Supermicrometer is set up using a gage block or gage block stack to the precise dimension of either the height or width of the parallel bar and zeroed at that point. The gage block is then removed, and the parallel bar is set on the elevating table between the anvils of the Supermicrometer and supported by two flattened rounds. The parallel bar is then measured at the first calibration point and the reading compared to the tolerance limits to assure compliance. The bar is then measured at each remaining calibration point, verifying at each point the compliance to the tolerance limits. This same process is then completed for the "B" parallel bar in the matched set, and the values obtained in the measurement of the "A" bar are compared to assure that deviations in the matched sizes are within the tolerance limits. This method is very good for smaller parallel bar matched sets if a Supermicrometer is available.

### Right-Angle Plates

Right-angle plates or knees, as they are more generally referred to, are divided into six different types as defined in Federal Specification GGG-P-441A. Right-angle plates are used in both machining applications and the setup and inspection of machined parts and assemblies. The plate material is usually high grade, fine-grained, controlled-process iron or iron alloy castings. These castings are always of uniform quality, free from blow holes, porosity or other material inconsistencies, and defects. All castings after being rough cut are stress-relieved to assure dimensional stability and become more stable as they age. With proper care and surface maintenance, angle plates can perform for many years. Fine angle plates over 50 years old are still in service.

**Right-Angle Plate Grades.**—Most right-angle plates are manufactured to meet the guidelines and tolerances laid out in the GGG-P-441A or IS 2554:1971 (India Standards Bureau). While these two governing documents may differ slightly, they both achieve the goal of establishing dimensional guidelines and tolerances that enable the manufacturer to produce a dependably consistent product with values and accuracies that customers require to maintain a high degree of measurement confidence in their quality systems.

Angle plates come in grades according to the surface finish that is applied and the dimensional accuracies that they are manufactured to. The assigned grade is in direct

correlation to the quality and accuracy of the angle plate. Federal Specification GGG-P-441A specifies three *Grades* of surface finish applied to right-angle plates. In addition, there are six distinct *Types* of angle plates that have unique properties according to their specifically designed target uses in the manufacturing process.

*Grade A* angle plates are the highest grade and are used in precise applications where the smallest deviation from square (90°) is required. These plates are used in various industries for clamping and holding work in a vertical position. The scraped surface is beneficial for supporting work in a very precise vertical plane and facilitating the dispersion of lubricants and coolants during the manufacturing process. Grade A plates are required to have working surfaces that are fine precision-scraped with relief spots to prevent sticking of gage blocks or precision-lapped instruments. These relief spots allow the surface to be controlled to a high degree of flatness. Each square inch of surface on a Grade A plate has 15 to 18 spotting cavities, from 0.0002" to 0.0005" deep, and a bearing surface of 20 to 40 percent. The bearing area does not deviate from the mean plane by more than 0.0001 inch in over 24 inches, and no more than 0.0002 inch in up to 60 inches, as per [Table 1](#). No square inch may vary from the adjacent area by more than 0.0001" per square foot. The adjacent working surfaces on any Grade A angle plate shall not vary from square by more than 0.0001" in every 8". This equates to 2.5 arc seconds. These angle plates make excellent fixturing for high precision shaping, milling, grinding, drilling, or boring operations.

**Table 1. Maximum Permissible Deviation of Bearing Area from Main Plane (GGG-P-441A)**

Maximum dimension of working surface, inches		Maximum permissible deviation of bearing areas from mean plane, inch	
Above	To and including	Grades A and B	Grade C
2½	12	0.0001	0.0002
12	24		
24	36	0.0002	0.0004
36	48		0.0006
48	60		0.0008

*Grade B* plates are made to meet requirements of precision inspection and calibration operations. Although the style of the plate can accommodate uses in any of the manufacturing practices, the precision-ground surface finish lends itself to inspection applications on the surface plate and use in calibration laboratories, high precision inspection stations, or situations where a fine precision-ground finish is desired and the highest degree of accuracy necessary. The Grade B angle plate has a working surface that is precision ground to a roughness average value of not more than 16 microinches for plates less than 64 square inches and 32 microinches for larger plates. The precision-ground surface of the Grade B plate is well suited to the applications involved in the inspection process of high accuracy, tight tolerance, precision-made parts. The fine-ground finish offers a precise surface that does not deviate from the mean plane by more than 0.0001 inch in over 24 inches, and no more than 0.0002 inch in up to 60 inches, as per [Table 1](#). No adjacent areas shall vary with each other by more than 0.0001 inch per square foot. The aspect that is most critical about the angle plate is the control of squareness and the ability to pass on the accuracy to the parts being machined or inspected. All adjacent working surfaces will not vary from square by more than 0.0001 inch in every 8 inches. This high degree of accuracy in the Grade A and Grade B angle plates provides the measurement assurance necessary to inspect precision parts and calibrate precision measuring instruments.

*Grade C* angle plates are the workhorses of the plate grades. They are designed to have a smooth machined finish and controlled to not exceed a surface roughness of 32 r.m.s. The bearing area of the working surface shall not exceed a deviation from the mean plane any greater than between 0.0002 to 0.0008 inch depending on the size of the bearing area, as per [Table 1](#). Furthermore, no adjacent square foot may deviate from another by more than

0.0003 inch per square foot. This ensures that the bearing surface is tightly controlled in the graduation of allowable error and will not deviate from the mean plane beyond the allowable limits. Deviation beyond the allowable graduation limits will introduce an error in the surface flatness beyond the functional limits. This flatness deviation control enables the surface of the angle plate to support the workpiece in such a manner as not to introduce errors due to nonuniform support beneath the workpiece or squareness errors from the adjacent sides.

*IS 2554:1971 Grades:* Standard sizes and accuracy of angle plates specified by IS 2554:1971 (India Standards Bureau) are given in [Table 2a](#) and [Table 2b](#).

**Table 2a. Sizes and Accuracy of Slotted Angle Plates Metric Sizes (IS 2554:1971)**

Size (mm) $L \times B \times H$	Accuracy in Microns, $\mu\text{m}$

**Angle Plate Types.**—The right-angle plate is further divided into *Types* and *Classes*, each type having unique characteristics and uses. Types I, II, and III angle plates or knees are intended to be used by craftsmen for ordinary machine shop operations; Types IV, V, and VI are intended to be used principally by toolmakers and for precision type work.

*Type I: Class 1-Plain Right-Angle Plate and Class 2-Slotted Right-Angle Plate:* The Type I Class 1 angle plate has two members with the outside surfaces at right angles to each other. Both the working surfaces and the ends are machined square to within the tolerance limits assigned to their grade, (Fig. 1a). Type I Class 2 plates are similar to Class 1 with the vertical and horizontal slots provided on one or both faces, (Fig. 1b).

Fig. 1a. Type I Class 1-Plain

Fig. 1b. Type I Class 2-Slotted

Fig. 1c. Type I Class 3,  
Measuring-Plain

All the right-angle plates of the various types have ribbing of sufficient thickness to assure maximum support for flatness, squareness, and stability. Class 1 plates of approximately 10 to 12 inches will have at least 2 ribs, those of 16 to 24 inches at least 3 ribs, and those of 36 inches and above a minimum of 4 ribs in their design.

Plates weighing over 75 pounds are designed with lifting holes in the ribbing or threaded holes for the placement of lifting eyes.

*Type I, Class 3, Measuring Plane Right-Angle Plate:* The Type I Class 3 angle plate, Fig. 1c, is designed to establish a measuring plane for production or inspection functions. It has two outside working surfaces that are at right angles to each other. The working surfaces are finished according to the grade specified and are the only two faces designed for functional operation. Unless specifically ordered otherwise, the sides and ends will be finish ground only, and these surfaces are not to be used to determine or establish squareness. The rib provides support between the ends of the plate and is cored out to provide a good hand gripping surface without sacrificing the stabilizing effect of the rib. The short base member "Y" is provided with a suitable hole so the plate may be bolted to the table of a machine or a tapped hole in a surface plate.

*Type II, Inside Right-Angle Plate:* The Type II right-angle plate is an inside right angle that is constructed with the same adherence to squareness and finish as the outside angle plates, Fig. 2. The inside angle plate is an inverted T-shaped casting formed by a base and a perpendicular member of approximately the same thickness. One side of the perpendicular, the adjacent top side of the base, and the bottom of the base are the three working surfaces and are all finished in accordance to the grade specified. The opposite ends and opposite sides are machined parallel and square to their respective working surfaces.

Fig. 2. Type II, Inside Right-Angle Plate

Fig. 3. Type III, Universal Right-Angle Plates

*Type III, Universal Right-Angle Plate:* By far the most versatile and useful right-angle plate in the machine shop is the Type III universal right-angle plate, Fig. 3. The Type III has two outside working surfaces at right angles and all adjacent sides are ground and finished to the same tolerance assigned to the main working surfaces. This provides a full range of positioning capabilities and makes the universal right angle just as accurate on its side as it is resting on its main working surface. All opposite sides are parallel within 0.0002 inch per foot. The universal right angle has a rib located between the ends that is square in configuration and provides support and stability to the main working surfaces while providing additional working surfaces that can be utilized for work support due to the accuracy assigned to the entire plate. The rib is hollowed out to provide good hand grip without sacrificing the stabilizing characteristics.

*Type IV: Machinist's Adjustable Angle Plate:* The Type IV adjustable angle plate, Fig. 4, is designed to allow rotation of the workpiece through 360°. The workpiece support table is adjustable from zero horizontal to 90° vertical in 10° increments. Basically, the Type IV machinist's adjustable angle plate consists of a tilting table mounted on a rotary table base. The base has heavy lugs or bolt slots to accommodate mounting the plate on machine tools. The bottom of the base is machined true flat, parallel to the top plate and square to the vertical axis. The base is the true foundation of the plate and must be manufactured to the tightest of tolerances. All accuracies extend from the craftsmanship that is put into the base work of the Type IV plate. The top of the rotary base is graduated in one degree increments for the full 360° and is marked at least every 10° for a minimum of plus and minus 90° from zero (0°). Most plates are marked around the full 360° in 10° major divisions with 1× minor divisions, permanently engraved or etched on a chrome or brightly finished face for ease of reading and maintenance. The standard rotary accuracy to which all Type IV plates are made is ±2.5 minutes, noncumulative. This tolerance maintains the accuracy ratio necessary to maintain a good measurement assurance level in your quality system.

The tilting table consists of two plates joined together at one end by a precision hinge and provided with an adjustable and positive locking mechanism. The bottom plate is attached to the base at the vertical axis. This plate will swivel through 360° freely and will also have a positive locking mechanism. The bottom of the plate is marked with a permanent line for accurate positioning in relation to the graduations on the base. The top plate is made in one piece as a casting and has T-slots milled in from the solid plate, as shown in Fig. 4.

The top plate is adjustable up to 90° and the positive locking mechanism is robust enough to secure the workpiece into position during milling, drilling, or boring operations without movement. The top plate is made with a protractor integrated into the design that is marked from 0° (horizontal) to 90° (vertical) with major scale indications at every 10°. Minor scale graduations may be indicated at 1° increments. The noncumulative error between graduations of the protractor is no greater than ±2.5 minutes, which allows for a high level of confidence in the measurements and operations made with this plate.

Fig. 4. Type IV, Machinist's Adjustable Angle Plate

Fig. 5. Type V, Toolmaker's Adjustable Knee

*Type V, Toolmaker's Adjustable Angle Plate:* The toolmaker's adjustable knee or adjustable angle plate extends the capabilities of the right-angle plate and allows for precise adjustment of the support table or bearing surface from  $0^\circ$  (horizontal) through  $90^\circ$  (vertical), Fig. 5. The same tolerances in regard to flatness and squareness apply to the bearing surface and the base.

The toolmaker's adjustable knee is constructed of a plate, finished to the tolerances determined by the class specified, and a right-angle iron with two ribs. The right-angle iron and the plate are joined together by a precision hinge that has the capability to be secured at any position within the arc from  $0^\circ$  to  $90^\circ$ . The two ribs are of sufficient thickness to provide stability and support enough to withstand the forces applied during boring, milling, drilling, or grinding operations. The locking mechanism must be capable of maintaining its locked position under the same circumstances. The table is provided with T-slots for the mounting of the workpiece.

The quadrant scale of the adjustable angle plate is divided into 90 divisions and a vernier scale. The vernier scale is graduated into 5 minute divisions from 0 to 60 minutes on either side of the zero index. The 0 (zero index) and every 15 minute index thereafter on both sides of 0 is clearly marked with the corresponding number, and the 5 minute divisions are clearly readable. The quadrant scale has 1 degree divisions from  $0^\circ$  to  $90^\circ$ . The zero index and every  $10^\circ$  index following will be clearly marked with the corresponding number. A tolerance not to exceed plus or minus 2 minutes, noncumulative, is given for the error between any two graduations.

Due to its specialized nature, the toolmaker's adjustable angle plate usually is only manufactured in one size according to the GGG-P-441A Federal Specification.

*Type VI: Toolmaker's Non-Adjustable Angle Plate:* The Type VI toolmaker's nonadjustable right-angle plate is different from the other types in that it has two members. These members have two working surfaces at right angles to each other as well as a finished pad on the back of both working surfaces. The design is of sufficient thickness along with the ribbing to insure rigidity and stability in all operations and applications.

Fig. 6. Type VI, Toolmaker's Non-Adjustable Knee

Both front sides and the back side pads are considered functional working surfaces and will be manufactured according to the grade specified. The working surfaces, the opposite sides, and the opposite ends are all machined parallel to each other and square to their respective working surfaces. All machined surfaces will meet the tolerance limits assigned to the specified grade for finish, flatness, squareness, and parallelism. The Type VI toolmaker's nonadjustable right-angle plate will appear similar to Fig. 6.

**Calibration and Maintenance of Right-Angle Plates.**—In many machine shops and quality assurance programs, right-angle plates are not calibrated and are considered “Calibration Not Required” or “Reference Only” instruments that are not placed into the calibration recall system. Inevitably, this practice may lead to unknown error in a manufacturing operation or inspection procedure. However, calibration of a right-angle plate may be an investment in quality if it becomes evident that an angle plate that has worn

out of squareness or flatness is introducing error in a machining operation or inspection process. There are several calibration procedures and methods for verifying the accuracy of the right-angle plate.

**Flatness Calibration:** The first feature that should be calibrated is the flatness of the working surfaces. The tolerances for the calibration of any individual right-angle plate is defined by the manufacturer and in their absence the GGG-P-441A shall provide an acceptable calibration tolerance. For Type I, II and VI angle plates, the setup for the flatness calibration will appear similar to Fig. 7.

Fig. 7. Calibration of Surface Flatness

Place the angle plate (the *Test Instrument*, or *TI*) on the leveling plate, as shown, and use a jack stand or similar device to support the TI in position. A bubble level can assist in leveling the plate. When the plate has been leveled, use the electronic indicator to measure the surface following the pattern shown in the Detail A of Fig. 7. This pattern is generally called the Union Jack in that it resembles the stripes on the British flag.

Observe the readings and record the *maximum plus* and the *maximum minus* readings overall. Subtract the maximum minus reading from the maximum plus reading; the result is the overall flatness of the surface. This value must meet the manufacturer's tolerance limits for the model under test or the tolerances specified in the GGG-P-441A. The same process is performed for the side opposite and the sides of the TI. All readings must meet the tolerances stated by the manufacturer or the GGG-P-441A standard. Flatness is only checked on TIs that require external hardware for support and leveling on the surface plate. On units not requiring external support, such as Type III plates, flatness is checked as a function of the parallelism calibration.

**Parallelism Calibration (Type III Right-Angle)** The Type III universal right-angle plate has a parallelism tolerance due to the unique design of this unit. As discussed previously, the Type III is finished on all sides and is square and parallel to all working surfaces and sides opposite.

General Parallelism Tolerances	
Size Range	Total Indicator Reading
> 2.5 to 24 inches	0.0004 inch TIR
> 24 to 36 inches	0.0008 inch TIR
> 36 to 48 inches	0.0012 inch TIR
> 48 to 60 inches	0.0016 inch TIR

Before beginning the calibration process, attention must be paid to the surface condition to be certain that no burrs or damage to the edges or surface is present that might affect the outcome of the measurements. A super fine-grained "hard Arkansas stone" may be used

to remove any burrs on the edges or surfaces prior to beginning the calibration process. After the right-angle plate is clean and free from burrs, the TI is placed on the surface plate as shown in Fig. 8. There is no need for a leveling plate as the side opposite is finished and parallel to the working surface, and the parallelism feature is what is being indicated.

Fig. 8. Measuring Flatness/Parallelism of Type III Right-Angle Plate

Using the electronic indicator as before, indicate the surface in the Union Jack pattern and record the maximum plus and the maximum minus readings overall. In general, it is a good idea to zero the electronic indicator in the center of the Union Jack and take the readings from that point. This provides an easily repeated starting point and an overall numerical picture of the parallelism of the surface. As before, subtract the minimum reading from the maximum; the result must meet the tolerance limits specified by the manufacturer or GGG-P-441A. Repeat this process for the remaining sides. All results must meet the stated tolerances.

*Squareness Calibration (Preferred Method)* The simplest method that can be used to verify the squareness of the Type III universal right-angle plate, as well as the squareness of the other types, is quite sufficient when done properly to meet the accuracy ratio that is required for a high confidence level measurement. This method provides quantifiable data that can be assigned an uncertainty should the *Quality System* determine this necessary. This method provides a good measurement to verify the squareness value and identify any out of tolerance conditions before the error is passed on into the manufacturing or inspection process.

Place the angle plate (TI) on the surface plate with two 0.1005-inch gage blocks between the face of the angle plate and the face of the granite angle block, as shown in Fig. 9a.

Fig. 9a. Gage Blocks Between TI and Granite Angle Block

Fig. 9b. Gage Blocks Between Rotated TI and Granite Angle Block

Then, beginning with a 0.1000-inch gage block, gently insert the gage block between the TI and the granite angle block at the top edge of the TI. Continue placing increasingly larger gage blocks between the TI and the granite angle block until the next larger gage block cannot be inserted without moving the TI. A gentle force should be applied to make sure the gage block is in direct contact with the granite surface, and as the gage block slides between the TI and the granite there should be no resistance until reaching the gage block size that is too large to go between without moving the granite. Record the size of this block as Block A. Rotate the TI and place the side opposite against the granite angle block as shown in Fig. 9b. Repeat the gage block sequence as above and record the size of the gage block as Block B.

To calculate the squareness of the working faces of the rotated TI follow the formula:

$$\text{Squareness} = \frac{|A - B|}{2}$$

*Example:* Block A = 0.1001 inch and Block B = 0.1009 inch.

*Solution:* The calculation would be 0.1001 minus 0.1009 divided by 2. The result being (–)0.0004 in overall squareness of the working surfaces to a perfect perpendicular plane.

Repeat the sequence for all remaining sides opposite. All results must meet the tolerances specified by the manufacturer or the GGG-P-441A standard. If for any reason the results do not meet the specified tolerances, it is possible to have the right-angle plates refurbished at a fraction of the cost of purchasing a new one. It is also possible that the deviations may be acceptable to the quality system, and, if the results are discussed with the Quality Engineer, the decision may be made to accept the unit "As Is" and annotate the deviation for future reference. The unit may also be downgraded to a less critical operation and the previous application be taken over by a new unit of acceptable condition. These decisions must be made by the quality engineers or quality managers and follow the guidelines of the quality system in place.

### Measurements Using Light

**Measuring by Light-wave Interference Bands.**—Surface variations as small as two millionths (0.000002) inch can be detected by light-wave interference methods, using an optical flat. An optical flat is a transparent block, usually of plate glass, clear fused quartz, or borosilicate glass, the faces of which are finished to extremely fine limits (of the order of 1 to 8 millionths [0.000001 to 0.000008] inch, depending on the application) for flatness. When an optical flat is placed on a "flat" surface, as shown in Fig. 1, any small departure from flatness will result in formation of a wedge-shaped layer of air between the work surface and the underside of the flat.

Light rays reflected from the work surface and underside of the flat either interfere with or reinforce each other. Interference of two reflections results when the air gap measures exactly half a wavelength of the light used and produces a dark band across the work surface when viewed perpendicularly, under monochromatic helium light. A light band is produced halfway between the dark bands when the rays reinforce each other. With the 0.0000232-inch-wavelength helium light used, the dark bands occur where the optical flat and work surface are separated by 11.6 millionths (0.0000116) inch, or multiples thereof.

Fig. 1.

For instance, at a distance of seven dark bands from the point of contact, as shown in Fig. 1, the underface of the optical flat is separated from the work surface by a distance of  $7 \times 0.0000116$  inch or  $0.0000812$  inch. The bands are separated more widely and the indications become increasingly distorted as the viewing angle departs from the perpendicular. If the bands appear straight, equally spaced and parallel with each other, the work surface is flat. Convex or concave surfaces cause the bands to curve correspondingly, and a cylindrical tendency in the work surface will produce unevenly spaced, straight bands.

See also *Interpreting Optical Flat Fringe Patterns* on page 791.

**Interferometer.**—The interferometer is an instrument of great precision for measuring exceedingly small movements, distances, or displacements, by means of the interference of two beams of light. Instruments of this type are used by physicists and by the makers of astronomical instruments requiring great accuracy. Prior to the introduction of the interferometer, the compound microscope had to be used in connection with very delicate measurements of length. The microscope, however, could not be used for objects smaller than one-half a wavelength of light. Two physicists (Professors Michelson and Morley) developed the *interferometer* for accomplishing in the laboratory what was beyond the range of the compound microscope. This instrument consisted principally of a system of optical mirrors arranged in such a way as to let the waves of light from a suitable source pass between and through them, the waves in the course of their travel being divided and reflected a certain number of times, thus making it possible to measure objects ten times smaller than was possible with the best compound microscope obtainable. Professor C.W. Chamberlain of Denison University invented another instrument known as the *compound interferometer*, which is much more sensitive than the one previously referred to; in fact, it is claimed that it will measure a distance as small as one twenty-millionth of an inch. These compound interferometers have been constructed in several different forms.

An important practical application of the interferometer is in measuring precision gages by a fundamental method of measurement. The use of this optical apparatus is a scientific undertaking, requiring considerable time and involving complex calculations. For this reason all commercial methods of checking accuracy must be comparative, and the taking of fundamental measurements is necessarily confined to the basic or primary standards, such as are used to a very limited extent for checking working masters, where the greatest possible degree of accuracy is required. The interferometer is used to assist in determining the number of light waves of known wavelength (or color) which at a given instant are between two planes coinciding with the opposite faces of a gage block or whatever part is to be measured. When this number is known, the thickness can be computed because the lengths of the light waves used have been determined with almost absolute precision. The light, therefore, becomes a scale with divisions — approximately two hundred-thousandths inch apart.

**MICROMETER, VERNIER, AND DIAL CALIPERS****Micrometer Calipers**

**Classification.**—The definition of the various classifications of micrometers was established in the Federal Specification GGG-C-105 and provided the basic requirements that were to be met by manufactures for sale to the Federal Supply Service, General Services Administration. As stated in the GGG-C-105C (1987); Federal Specifications do not include all varieties of the commodity as indicated by the title of this specification or which are commercially available, but intend to cover only those generally used by the Federal Government. This Federal Specification would become the guideline for manufacturers throughout the United States. Not only was the Federal Government a large consumer of the precision measurement instruments produced by domestic manufacturers, but the establishment of the design and accuracies provided a direction for further development and responded to the needs of the growing quality systems that were, by necessity, playing a greater and greater role in the manufacturing of high quality parts and systems. As the complexity of the systems grew, the greater the need for precision measurement instruments that could provide the measurement assurance needed to support those systems. Establishing the design and accuracies for these instruments was a necessary step and provided the foundation for all future developments.

**Types, Classes, and Styles**

*Type I—Caliper, Micrometer, Outside (page 767)*

*Class 1: Enameled (I-Beam or Hollow Tubular) Frame*

*Style A: Solid Anvil*

*Style B: Interchangeable Anvil*

*Style C: Tubing, Ball Anvil*

*Style D: Tubing, Upright Anvil*

*Class 2: Finished Frame*

*Style A: Solid Anvil*

*Style B: Paper Gage*

*Style C: Tubing, Ball Anvil*

*Style D: Thread*

*Type II—Caliper, Micrometer, Inside (page 776)*

*Class 1: With Jaws*

*Class 2: Rod and Sleeve*

*Class 3: Tubular*

*Style A: Interchangeable Head*

*Style B: Fixed Head*

*Type III—Gage, Depth, Micrometer (page 780)*

*Class 1: Interchangeable Measuring Rods*

*Style A: Full base*

*Style B: Half base*

*Type IV—Micrometer Heads*

*Class 1: High Accuracy Mechanical*

*Class 2: High Accuracy Digital*

*Class 3: Extended Travel*

**Construction Requirements.**—*Materials:* The micrometer spindles and anvils and component parts of the Type II and Type III caliper micrometers and gages having utile measuring surfaces shall be made of high grade tool steel or alloy steel. The source stock shall be assured of a refined crystal structure with a uniform carbide distribution, and shall be sound and free of injurious porosity, soft spots, hard spots and other defects. All materials shall meet the minimum requirements for hardness, stability and strength.

**Resolution:** Micrometers using the inch system shall have a least significant digit of 0.001 in., 0.0001 in., or 0.00005 in. Micrometers using the SI (metric) system shall have a least significant digit of 0.01 mm, 0.002 mm, or 0.001 mm.

**Finish:** Unless otherwise specified, the frames and graduated components of Type I Class 2 micrometers and the thimble and barrels of all inside, depth, and micrometer heads shall have either a dull (non-glare) or satin chrome finish. All other exposed surfaces, excepting Type I Class 1 frames, shall have a ground finish. The surface roughness of all ground surfaces excepting direct measuring surfaces shall not exceed  $32\ \mu\text{in}$  ( $0.8\ \mu\text{m}$ ) Ra, and shall be coated to prevent corrosion. The Type I Class 1 frames shall have either a smooth or ripple enamel coating.

**Identification:** The Type I, Class 1 frame shall have a manufacturer's pad of smooth machined finish. All instruments shall be permanently and legibly marked with the manufacturer's name or trademark, so the source of manufacture can be easily determined, part number, and range of the instrument.

**Adjustments:** Each type, style and class shall provide a method for adjustment due to wear of the measuring faces and/or wear between the spindle screw and the nut. Regular calibration and adjustment of the nut will maintain the accuracy of the micrometer. This is especially true in higher accuracy instruments.

**Micrometer Screw Spindle:** The screw spindle is a critical component of the micrometer. The true accuracy of the instrument derives from the accuracy of the manufacturing of the threaded (screw) section of the spindle. The screw spindle material will be a stabilized high grade tool steel or alloy steel. The spindle screw section will be precision ground and have a hardness of no less than 62 RC on the Rockwell C scale. The exposed spindle section will have a fine ground finish with a surface finish of no greater than  $32\ \mu\text{in}$  ( $0.08\ \mu\text{m}$ ) Ra. The fit between the spindle and the bearing including the nut, shall be free-turning and exhibiting no side shake, end shake or backlash.

**Measuring Faces:** The spindle and anvil of all Type I, Class 1 and Class 2, micrometers shall be at minimum made of a stabilized high grade tool steel or alloy steel and have a hardness of no less than 62 RC. Alternatively, the measuring faces can be made of tungsten carbide with a hardness value of 92 RA on the Rockwell A scale. The tungsten carbide surfaces are preferred and provide a greatly improved life span for the measuring surfaces.

**Graduations:** The graduations shall have a depth reduced below the surface of the barrel and thimble and shall be of contrasting color. Variations in the width of the graduated lines on the barrel, thimble or vernier shall not exceed 0.001 inch.

### Outside Micrometers

**Type I, Caliper Micrometer.**—**Size and Range:** The size of an outside micrometer caliper is defined as the maximum cylindrical diameter measurement that can be obtained by that particular instrument. The range is defined as the span of obtainable measurements from the minimum to maximum capacity of the particular micrometer.

**Design:** The basic features of the micrometer design shall consist of a frame, micrometer screw spindle, barrel and thimble, adjusting nut, either a lock-ring or lever type spindle lock, and a ratchet or friction stop, as shown in Fig. 1. Higher accuracy micrometers will include a vernier scale on the barrel that enables the reading of measurements to 1/10,000 of an inch (0.002 mm).

Fig. 1. Design Features of Type I, Class 1 Micrometer

**Frame:** Frames of all outside micrometers in sizes from  $\frac{1}{2}$  inch to 4 inch shall be of steel. Frames of micrometers from 5 inch and greater shall be of steel, tubular steel or malleable iron.

The Type I, Class 1 enameled frame shall have a cutaway back (Fig. 2a), long tapered back (Fig. 2b), or C-type Back (Fig. 2c), of either I-beam or hollow tubular steel frame construction, and shall have either a smooth or rippled enameled finish.

Fig. 2a. Cut-Away Back

Fig. 2b. Long Taper Back

Fig. 2c. C-Type Back

**Flexure:** The cross section design and material used in the frame shall be, in combination, of sufficient design, that when a force of 2 pounds (10 N) is applied in parallel to the spindle axis upon the anvil, that a flexure of the frame shall not exceed the tolerance as specified in Table 8a and Table 8b.

**Micrometer Screw Spindle:** The entire micrometer screw spindle shall be hardened and stabilized to no less than 62 RC from a high grade or alloy steel. The thread form and all surfaces shall be precision ground and smoothly lapped. The thread form shall conform to ANSI/ASME B1.3-2007 (R2017), "Screw Thread Gaging Systems for Acceptability: Inch and Metric Screw Threads", and be a UN 40 pitch for English measurements and a M 0.5 mm pitch for SI (metric) measurements. The cylindrical portion of micrometer screw spindle shall be a free turning fit to the frame bearing without bind or shake and move smoothly and freely through the entire length of travel. There shall be no backlash between the threaded portion and the nut and at the maximum reading, there shall be no less than 0.240 inch engagement of the nut on the threaded portion of the screw spindle. The thread lead shall be sufficiently accurate throughout the entire length so as to permit compliance to the tolerances defined in Table 8a and Table 8b. The diameter of the spindle shall be no less than 0.1875 ( $\frac{3}{16}$ ) inch for  $\frac{1}{2}$  inch micrometers, and no less than 0.2343 ( $\frac{15}{64}$ ) inch

(5.9 mm) for 1.00 inch (25.0 mm) and larger micrometers. The diameter of the anvil and spindle measuring face shall be equal in diameter to within 0.0015 inch (0.038 mm).

**Barrel and Thimble:** The diameter of the graduated surface of the barrel shall be not less than 0.406 ( $1\frac{1}{32}$ ) inch (10.31 mm). The angle of the bevel at the graduated end of the thimble shall not be more than 20 degrees as measured from the barrel. The beveled end of the thimble at the reading end shall be sharp but dulled to prevent injury to the operator. The major diameter opposite the reading end shall be diamond knurled to facilitate ease of operation. The radial clearance from the barrel to the reading end of the thimble shall not exceed 0.020 and shall be concentric and constant throughout the range of travel. When set at 0.000, 0.025, 0.050 inch . . . , etc., the reading edge shall bisect the graduation line exactly. Throughout the range of travel, there shall be no more than  $\frac{2}{3}$  of the line visible at any point. The barrel shall be constructed so as to prevent dust and foreign matter from coming into contact with the spindle screw.

**Adjusting Nut:** The micrometer design shall provide an adjusting nut to compensate for wear between the spindle screw and the fixed nut. There shall as well be a means provided to compensate as well for wear of the measuring surfaces. This is generally accomplished through adjustment of the barrel or by disengaging the spindle screw from the thimble and resetting the zero indication of the micrometer. Both adjustment of the barrel and the adjusting nut shall be such that they remain secure after resetting and will not impair the original accuracy of the instrument. Disengaging the spindle screw and resetting the zero indication are more advanced adjustments and would require a recalibration of the micrometer before returning to service. Micrometers with a friction-adjusting sleeve on the barrel shall have no less than  $3\frac{1}{2}$  and no more than 15 in-lb torque on the friction sleeve. Spanner wrench, keys or other specialized devices shall be provided by the manufacturer of each micrometer.

**Spindle Lock:** The micrometer shall have a spindle lock which will arrest the spindle at the selected point and not alter the position when engaged. The spindle lock will be either a diamond knurled ring friction lock or a lever operated lock.

**Ratchet or Friction Stop:** The ratchet or friction stop is a device that shall exert a constant and even measuring force on the spindle and effectively removes subjective "feel" of measurements. This device is critical to obtaining an objective measurement and removes a variable in uncertainty analysis by delivering the same force between the spindle and anvil regardless of the operator. The design shall be either the ratchet or friction stop design. It shall be sufficiently knurled to enable satisfactory operation and shall exert a compressive force between the measuring faces of 1 to  $1\frac{1}{2}$  lbs. up to the 6 inch size and 1 to 3 lbs. for larger sizes.

**Measuring Faces of Micrometer Screw Spindle:** The face of the micrometer screw spindle shall be at right angles to the axis at all positions of rotation of the screw spindle. Shall be square and flat and parallel to the anvil and shall maintain this orientation throughout the entire range of travel. The measuring face shall meet the tolerance limits as defined in Table 8a and Table 8b.

**Measuring Faces:** All measuring faces shall be hardened, ground and lapped. The hardness shall be no less than 62 RC and the lapped finish shall be no greater than 4  $\mu$ n Ra. Utile measuring faces can be lapped to recondition them should wear from use cause the surface to exceed the tolerance limits.

**Carbide Measuring Faces:** Some micrometer calipers are furnished with carbide measuring faces. The carbide measuring face tip shall not be less than 0.030 inch thick and shall be an integral part of the spindle and anvil. When provided with carbide measuring faces, both spindle and anvil shall be faced with the carbide tip.

*Graduations: Reference, Graduation and Vernier lines* on the barrel and thimble shall be clearly cut to a width of not more than 0.010 inch and all vernier and graduation lines shall be within 0.001 inch in uniform size. The lines and numbers shall have distinct and clean edges and shall be clearly legible under ordinary service conditions. The barrel and thimble shall be graduated as follows:

*Inch Reading Micrometer:* The graduations on the thimble of the English (inch) reading micrometer shall be divided into 25 divisions each representing 0.001 inch. They shall be numbered as 0, 1, 2, 3, ..., 23, and 24. Zero, then, represents 25 graduations or one full revolution. The barrel is graduated with a longitudinal reference line that runs parallel to the axis of travel of the screw spindle. This reference line is graduated into 40 divisions each representing 0.025 or one full revolution of the thimble. The first graduation shall be numbered 0 (zero) and shall be the zeroing point for all consecutive measurements. After that every fourth division shall be numbered 1, 2, 3, and so on to 9, and 0. These divisions represent 0.100, 0.200, 0.300 and so on throughout the 1.000 inch length of travel. The 0.100 in. lines shall meet the reference line and extend above the line in a manner to designate them as the major 0.100 divisions. The 0.050 in. division lines shall meet the reference line and extend above the line but shall be half the length of the major 0.100 in. lines. The 0.025 in. graduation lines shall also meet the reference line and extend above the line to half the length of the 0.050 division lines. This method establishes a readily visible reference to the exact cumulative value of the reading. The vernier lines for the measurement of  $1/10,000^{\text{th}}$  inch (0.0001) shall be engraved on the upper part of the barrel parallel to the axis of travel of the spindle and extend a sufficient length along the barrel as to provide a reading at any point throughout the entire length of travel. The 10 vernier spaces are equal to nine divisions on the thimble and are numbered 0, 1, 2, 3, ..., 9, and 0.

*Metric Reading Micrometer:* The graduations of metric (SI) reading micrometers are configured in the same manner as the English reading micrometers. However, it must be stressed that manufacturers have developed variations of the basic principal that are equally accurate, and in some cases may be considered a genuine improvement. Slanted minor graduation lines, and split major minor graduations, have both been employed with great success. However, the principle for division of the scale is the same, and provides the amplification of the spindle screw movement necessary to obtain precision and repeatable measurements with the micrometer. The metric micrometer thimble is graduated into 50 divisions, each representing 0.01 mm. These are numbered as 0, 5, 10, 15, ..., 45. The barrel is graduated along the reference line at 0.5 mm intervals. The reference line runs parallel to the axis of travel of the spindle screw. The first of the graduations lines is designated as 0 (zero) and every 10th graduation thereafter is numbered as 5, 10, 15, 20, and 25. The graduation lines representing 1.0 mm shall be meet the reference line and be distinguished by either length or position. The graduation lines representing 0.05 mm shall be distinguished from all other lines again by either length or position, as in the English scale system. The vernier scale shall be as described previously in the section *Inch Reading Micrometer*.

*Accuracy:* All micrometers shall be calibrated at a controlled temperature in a manner and method developed to assure performance parameters are acceptable and within the limits of tolerances as defined in Table 21a and Table 21b. Proper maintenance and periodic calibration are mandatory to maintaining a high confidence level in all precision measuring instruments.

*Reference Setting Standards:* The Type I, Class 1, Styles A and B, and Type I, Class 2, Style A micrometers are furnished with a reference standard for checking and setting the zero reading between the regularly scheduled calibration. These reference standards do not constitute a complete and thorough calibration but may be used to verify the zero setting of the instrument. These setting standards are themselves calibrated to assure adherence to tolerance, and act as a transfer standard during the calibration interval. The

setting standards for the 1.000 inch (25 mm) micrometer shall be either a disk or rod of 1 inch, or 25 mm, respectively. Standards for larger sizes shall be rods. The rods may have either flat and parallel, or spherical ends. The disk, and the ends of the rods, shall have a hardness of no less than 58 RC. The disk shall be concentric in diameter to within 0.00005 inch (0.0012 mm) and shall be within 0.00005 inch (0.0012 mm) of the nominal size. The tolerances for other lengths shall conform to those defined in Table 9.

Tolerances and instructions for calibration of reference standards are given in the section *Calibration of Reference Setting Standards* starting on page 787.

**Type I, Class 1, Style A.**—Type I, Class 1, Style A, *Solid Anvil Micrometers* shall follow a design similar to Fig. 3 and conform to tolerances and requirements of Table 8a and Table 8b and be finished in either a smooth or rippled enamel.

Fig. 3. Type I, Class 1, Style A: Solid Anvil Micrometer

**Type I, Class 1, Style B.**—*Interchangeable Anvil Micrometer* shall be in design similar to Fig. 4 and conform to the tolerances and requirements in Table 8a and Table 8b for accuracy. The anvils of the Type I, Class 1, Style B micrometer shall be designed so as to permit a secure and solid seating that allows no side movement and provides accurate alignment with the spindle measuring face. The anvils will provide a means to compensate for wear of the anvil faces and will be provided in the size ranges defined in Table 1.

Fig. 4. Type I, Class 1, Style B. Interchangeable Anvil. Enamelled (I-beam or Hollow Tubular) Frame. Provided with reference setting standards. Shown with four 1-inch incremental anvils.

**Table 1. Standard Sizes, Type I Class 1 Style B, Interchangeable Anvil Micrometers**

Size Range, Inch		Size Range, mm	
0–4	12–18	0–100	300–450
2–6	16–20	50–150	400–500
6–9	18–24	150–225	450–600
6–12	20–24	150–300	500–600
9–12	24–96	225–300	600–2400
12–16	(in 6 inch increments)	300–400	(in 150 mm increments)

**Type I, Class 1, Style C.**—*Tubing Ball Anvil Micrometer* shall appear similar in design to Fig. 5.

Fig. 5. Type I, Class 1, Style C: Tubing Ball Anvil, Enamelled (I-Beam or Hollow Tubular) Frame, Fixed Ball Anvil

**Size and Range:** The Style C Tubing Ball Anvil Micrometer is generally provided in the  $\frac{1}{2}$  inch or 1 inch (13 mm or 25 mm) range. The range and accuracy of the micrometer is defined in Table 8a and Table 8b. The  $\frac{1}{2}$  inch (13 mm) size micrometer shall conform to the tolerance limits expressed for the 0–1 inch micrometer.

**Anvil:** The measuring face of the anvil shall be a bisected sphere permanently affixed to the frame with the radial center aligned to the projected axis of the spindle. The anvil shall be of such a radius as to permit accurate measurements of the wall thickness of tubing having a minimum inside diameters of 0.3125 inch for the 0 to  $\frac{1}{2}$  inch range. The radius of the anvil for the 0 to 1 inch micrometer shall permit accurate measurement of minimum inside wall thickness diameters of 0.375 inch. For the metric calibrated micrometer, the anvil radius shall be adequate to accurately measure a minimum internal wall diameter of 8 mm for the 13 mm micrometer, and a minimum internal wall diameter of 10 mm for the 25 mm range micrometers.

**Type I, Class 1, Style D.**—The Style D, *Tubing Upright Anvil Micrometer*, shall have the half-C type frame, of I-Beam construction, with the diametrical axis of the anvil perpendicular to the axis of the spindle and in the same plane. The Style D micrometer shall follow in design the example in Fig. 6. Micrometer is provided in 1 inch or 25 mm range.

**Spindle and Anvil:** The measuring face of the spindle will be no less than 0.2343-inch diameter and be flat and parallel to the axis of the anvil. The spindle face shall be perpendicular to the axis of the anvil throughout the rotation and travel of the spindle. The diameter of the anvil shall permit the anvil to freely enter a 0.375-inch diameter hole to a depth of 0.750 inch.

**Type I, Class 2, Finished Frame.**—The Class 2 *Fixed Anvil, Finished Frame Micrometer* shall have a long taper back, cutaway, or C-type frame (see Fig. 2a, Fig. 2b, and Fig. 2c) of a solid rectangular construction. The sides of the frame shall be stamped, engraved or permanently marked in a practicable location in the decimal equivalent of common fractions; 8ths, 16ths, 32nds, 64ths. Stamping, engraving or etching shall be sufficiently deep enough to make characters readily legible in normal operating conditions.

Fig. 6. Type I, Class 1, Style D: Upright Anvil Tubing Micrometer. Enamelled (I-Beam or Hollow Tubular) Frame.

*Finish:* The finish of the Type I, Class 2 frames shall be a dull, non-reflective chrome plating. The utile measuring face of the anvil and spindle shall have a finish not to exceed  $4\ \mu\text{in Ra}$ . The finish of the outer surfaces of the spindle shall not exceed  $32\ \mu\text{in Ra}$ .

*Type I, Class 2, Style A:* The Style A *Solid Anvil Micrometer* is provided in 0–1 inch, 1–2 inch, and 2–3 inch only. The Style A micrometer shall conform to the tolerance limits as defined in [Table 8a](#) and [Table 8b](#) and in design appear similar to [Fig. 7](#).

Fig. 7. Type I, Class 2, Style A: Solid Anvil, Finished Frame Micrometer

*Type I, Class 2, Style B:* The Style B *Paper Gage (Disk) Micrometer* shall be designed with a disk attached to the anvil and spindle of approximately 0.4375 inch diameter. The Style B micrometer is provided in ranges from 0– $\frac{1}{2}$  inch, 0–1 inch, and 1–2 inch. The attached disk may be larger or smaller than recommended diameter. All variations in design shall adhere to the tolerance limits defined in [Table 8a](#) and [Table 8b](#). The Style B micrometer shall follow in design and appear similar to [Fig. 8](#).

Fig. 8. Type I, Class 2, Style B: Paper (Disk) Micrometer

*Type I, Class 2, Style C: The Solid Ball Anvil Tubing Micrometer* is similar in all aspects to the *Type I, Class 1, Style C* with the exception that the frame is a solid rectangular construction. Style C shall adhere to the tolerance limits defined in [Table 8a](#) and [Table 8b](#). The Style C micrometer shall by design appear similar to [Fig. 9](#).

Fig. 9. Type I, Class 2, Style C: Solid Ball Anvil Tubing Micrometer

*Type I, Class 2, Style D, Thread Pitch Micrometer:* The Type I, Class 2, Style D pitch micrometer shall appear similar in design to [Fig. 10](#) for fixed pitch micrometers. The Style D interchangeable anvil pitch micrometers vary in that the design incorporates an adjustable anvil with an anvil lock to allow for resetting the zero indication of the micrometer when changing the matched anvil/spindle pitch sets. The interchangeable anvil pitch micrometer shall appear similar to [Fig. 11](#). Both designs adhere to the tolerance limits defined in [Table 2](#) for the frame design and pitch indication accuracy. The micrometer section of the pitch micrometer shall adhere to the tolerance limits of [Table 8a](#) and [Table 8b](#) for accuracy of the micrometer indication.

*Design:* The design of the Type I, Class 2, Style D pitch micrometer shall be similar to that shown in [Fig. 10](#) or [Fig. 11](#). The frame design, either C-type or rectangular, shall be shaped to permit the measurement of screw thread pitch diameters of Unified thread form threads within size and range of the specific pitch micrometer. The measuring faces of the pitch micrometer consist of a cone (spindle) and a V-groove (anvil) with an inclusive angle the same as the angle of the thread to be measured. The apex of the spindle cone is to be centered and concentric to the axis of the spindle.

**Table 2. Type I, Class 2, Style D Pitch Micrometer Design Specifications**

Size (in.)	Range (in.)	Number of Threads per inch (1/pitch)	Permissible Flexure (in.)	Tolerance on Half Angle of Measuring Faces ( $\pm$ )		Error in Indicated Measurement (max.) (in.)	Error in Spindle/Anvil Alignment (max.) (in.)
				Degree	Minutes		
1/2	0-0.500	48 to 64	0.0001	0	18	0.00010	0.00010
1	0-1	8-13	0.0001	0	5	0.00020	0.00020
1	0-1	14-20	0.0001	0	6	0.00015	0.00015
1	0-1	22-30	0.0001	0	8	0.00015	0.00015
1	0-1	32-40	0.0001	0	12	0.00015	0.00015
2	1-2	4.5-7	0.0001	0	4	0.00025	0.00030

2	1-2	14-20	0.0001	0	6	0.00020	0.00015
2	1-2	22-30	0.0001	0	8	0.00020	0.00015

Fig. 10. Type I, Class 2, Style D: Thread (Fixed Pitch) Micrometer

**Anvil:** The anvil shall be secured in the frame with its axis aligned and concentric to the axis of the micrometer screw spindle. The anvil shall be well seated and secured but allow for a free turning fit with no shake or lateral movement. The end of the anvil facing the spindle cone shall have a V-groove of the same angle as the thread form to be measured. Both the spindle cone and anvil V-groove shall comply with the parameters set forth in Table 2.

Fig. 11. Type I, Class 2, Style D: Interchangeable Anvil Thread (Pitch) Micrometer

**Measuring Surfaces:** The conical surface of the screw spindle and the angular surfaces of the V-groove anvil shall conform to the angular requirements defined in Table 2. The intersection of the apex of the conical screw spindle and the V-groove anvil shall be centered, aligned and in the same plane as the axis of the micrometer screw spindle. The surfaces of the conical spindle and the V-groove anvil shall be ground and lapped and hardened to no less than 62 RC. The surface roughness of these surfaces shall not exceed  $4 \mu\text{m Ra}$ .

### Inside Micrometers

**Type II, Class 1, Inside.**—The Type II, Class 1, *Inside Micrometer with Jaws* shall appear similar in design to Fig. 12 and conform to parameters and accuracy as defined in Table 3.

**Table 3. Type II, Class 1, Inside Micrometer with Jaws**

Size (in.)	Range (in.)	Tolerance (in.)	Radial Alignment (in.)
1	0.200 to 1	0.0002	0.003
1½	0.500 to 1½	0.0002	0.003
2	1 to 2	0.0002	0.003

Fig. 12. Type II, Class 1: Inside Micrometer with Jaws

**Design :** The inside micrometer with jaws shall have a vernier-caliper style measuring jaw, micrometer screw, spindle, barrel and thimble, knurled lock screw, lock device and adjusting screw.

**Jaws :** The inside micrometer vernier-caliper style jaws shall be designed so the measuring surfaces remain parallel throughout the entire range of measurement. The jaws shall travel parallel to the axis of the spindle travel and in the same plane.

**Micrometer Screw:** The Type II, Class 1 inside micrometer shall be driven by a micrometer screw with a lead accuracy throughout its entire length of travel that will permit conformance to the tolerance defined in Table 3. The micrometer screw shall in all aspects adhere to the requirements and performance parameters previously defined for the *Micrometer Screw Spindle* on page 767.

**Spindle:** The Type II, Class 1 inside micrometer shall have a spindle that is not an integral part of the Micrometer Screw. The spindle shall be designed to have only longitudinal movement in the barrel while the micrometer screw is secured to the thimble and free to rotate on the connection to the spindle. The spindle shall have a good free moving fit in the barrel bearing with no shake or bind and shall move smoothly throughout its entire length of travel. The spindle is secured from rotation and guided by the positioning guide and slot.

**Barrel and Thimble:** The barrel and thimble of the Type II, Class 1 inside micrometer shall conform to the design requirements as defined in the previous section *Type I, Caliper Micrometer*. The design requirements for the applicable graduations shall as well be adhered to with the exception of the vernier scale. The numerals for graduations on the barrel shall read in the opposite direction from those on the conventional Type I micrometers as the measurements are reading an internal measurement that will become smaller as the micrometer spindle is drawn outward and larger as it is turned in. The first and every fourth graduation on the barrel along the longitudinal reference line shall

be numbered 0, 9, 8, ... 3, and 2 for the 0.200 to 1 inch range inside micrometer; and 15, 14, 13, ... 6, and 5 for the 0.500 inch through 1.5 inch range inside micrometer. The numerals for graduations on the thimble shall read in the opposite direction from those on a conventional Type I O.D. micrometer.

**Measuring Faces:** The measuring faces on the Type II, Class 1 inside micrometer shall two jaws in the vernier-caliper style designed to be perpendicular to the axis of travel of the micrometer spindle and shall have a radius of curvature no greater than  $\frac{1}{2}$  the diameter if the smallest value of the measuring range. The measuring surfaces shall conform to all design and accuracy requirements defined in the previous section, *Type I, Caliper Micrometer*.

**Type II, Class 2, Rod and Sleeve.**—The Type II, Class 2, *Rod and Sleeve Inside Micrometer* shall follow in design as shown in Fig. 13. The ranges and accuracy shall follow Table 4. The micrometer head is calibrated separately from the length rods and maintains a separate calibration tolerance as shown in Table 4.

Fig. 13. Type II, Class 2: Inside Micrometer: Rod and Sleeve Design

**Table 4. Type II, Class 2, Inside Micrometer Accuracy Tolerance**

Inch			Metric		
Range (inch)	Tolerance		Range (mm)	Tolerance	
	Micrometer Head (inch)	Length Rods (inch)		Micrometer Head (mm)	Length Rods (mm)
1 to 2	0.0002	0.0003	1 to 2	0.0002	0.0003
2 to 8	0.0002	0.0004	25 to 50	0.005	0.0075

8 to 32	0.0002	0.001	50 to 300	0.005	0.0125
8 to 36	0.0002	0.001	200 to 900	0.005	0.025

**Design:** The Type II, Class 2 inside micrometer shall essentially consist of a micrometer head, measuring (length) rods, spacing collars, a knurled locking screw to secure micrometer head in place after obtaining measurement and an extension handle in some designs to optimize handling of unit in deeper bores or smaller diameters.

**Micrometer Head :** The micrometer head consists of a micrometer screw barrel and thimble graduated in design as defined for the Type I outside micrometer (see *Graduations* on page 767) with the exception of the vernier lines.

For Type II, Class 2 inside micrometers designed to inch scale:

- in the 1 to 2 inch range, graduations shall be from 0 to 0.250 inch on the barrel
- in the 2 to 8 inch, and 2 to 12 inch range, graduations will be from 0 to 0.500 inch
- in the 8 to 32 or 36 inch range, graduations will be from 0 to 1.000 inch distance

For Type II, Class 2 inside micrometer designed to the metric scale:

- in the 25 to 50mm range, graduations shall be from 0 to 7mm on the barrel
- in the 50 to 200mm, and 50 to 300mm range, graduations will be from 0 to 13mm
- in the 200 to 800 or 900mm range, graduations will be from 0 to 25mm on the barrel

All Type II, Class 2 micrometer heads shall conform in feature design and finish as previously defined in the *Type I, Caliper Micrometer* general definitions.

*Micrometer Screw, Barrel and Thimble:* The lead of the micrometer screw shall be accurate to within the performance limits as defined in the *Manufacturers' Production Tolerance Tables* on page 781 throughout the entire length of travel. The barrel and thimble shall conform to the design definitions as previously outlined in the *Type I, Caliper Micrometer* section.

*Measuring Rods and Spacing Collars:* A sufficient number of Measuring (length) Rods and Spacing Collars shall be provided to enable the measurement of all distances within the range of each Inside Micrometer Set. The Rods shall be of such design as to provide positive seating with no side motion when assembled with the micrometer head. Length Rods shall provide an adjustable contact point to enable compensation for wear of the measuring face. Each Length Rod shall be plainly, clearly and permanently marked for measurement range.

*Measuring Faces:* The measuring face shall have a radius of curvature less than one-half of the smallest measuring range of the inside micrometer with a surface roughness not to exceed 4  $\mu$ inch Ra. The locating faces on all spacing collars and length rods and micrometer head ends shall have a surface finish not to exceed 8  $\mu$ inch Ra.

**Type II, Class 3, Style A.**—The Type II, Class 3, Style A, *Tubular Inside Micrometer, Interchangeable Head* shall conform to all design feature definitions of the Class 2 inside micrometer with the exception that the length rods shall be tubular in design and conform to the accuracy and length requirements defined in *Table 5*. The Style A inside micrometer shall follow in design and appear similar to *Fig. 14*.

Fig. 14. Type II, Class 3, Style A: Tubular Inside Micrometer with Interchangeable Heads

**Table 5. Type II, Class 3, Style A, Range and Tolerance**

Inch			
Range (inch)	Range of Micrometer Head (inch)	Tolerance

100 to 600	0 to 25	0.005	0.018
100 to 800	0 to 25	0.005	0.022
100 to 1000	0 to 25	0.005	0.022
40 to 800	(two heads) 0 to 13 / 0 to 25	0.005	0.025

*Measuring (Length) Rods:* A sufficient number of length rods of hollow steel tubular construction shall be provided to enable measurement of any dimension within the range of the inside micrometer set. The length rods shall be so designed that they may be mounted on either or both ends of the micrometer head. A cap head measuring face shall be provided to mount to either or both ends of the micrometer head in the case where no length rod is being used. Each rod is to be adjustable by means of a hardened and ground plug at one end that can be turned either into or out of the length rod.

**Type II, Class 3, Style B.**—The Type II, Class 3, Style B, *Tubular Inside Micrometer, Fixed Head* shall be of hollow steel tubular construction with a micrometer head permanently attached. Each unit will be equipped with a thermal isolation grip to negate the effects of thermal expansion from the heat of the hand. The Style B shall follow in design and appear similar to Fig. 15. Accuracy and length requirements are defined in Table 6.

Fig. 15. Type II, Class 3, Style B: Inside Tubular Fixed Micrometer Head

*Type II, Micrometer Head, Adjustments, Measuring Faces:* The Type II, Class 2, Style B inside micrometer uses a micrometer head that adheres in design and function to the features defined in the *Type I, Caliper Micrometer* section. The measuring faces shall have a spherical radius not to exceed  $\frac{1}{2}$  the radius of the smallest measuring range but otherwise adhere to the parameters defined in that section. The adjustment shall be as defined in the *Type I, Caliper Micrometer* section.

**Type III, Micrometer Depth Gage.**—The Type III micrometer depth gage shall be similar in design and function to Fig. 16 below. The Type III depth micrometer consists of a micrometer head, base and interchangeable depth rods. The unit shall be further provided with a ratchet or friction thimble, a clamp ring, spindle lock nut or lever-type spindle lock.

Fig. 16. Type III: Micrometer Depth Gage

**Micrometer Head:** The micrometer head shall be provided in a measuring range of 0–1.000 inch or 0–25 mm. The resolution of the instrument shall be 0.001 inch / 0.01 mm, 0.0001 inch / 0.002 mm (with vernier scale) or 0.00005 inch / 0.001 mm (units equipped

with digital encoders). The graduations on the barrel shall read from the thimble end toward the base to indicate extension of the measuring rod from the base position of zero.

**Base:** The base shall be designed with a measuring surface of no less than  $\frac{3}{8}$  inch, no more than  $\frac{1}{8}$  inch in width, and a length of either 2,  $2\frac{1}{2}$ , 3, 4, 5, or 6 inches. The surface finish shall not exceed 4  $\mu$ m Ra with a surface hardness of not less than 62 RC on the Rockwell C scale. The measuring surface of the base shall be flat to within 0.0001 inch per inch of length.

**Measuring Rods:** The basic micrometer depth gage shall be equipped with three depth measuring rods to provide for the measurement of ranges of 0 to 1, 1 to 2, and 2 to 3 inches or 0 to 25, 25 to 50, and 50 to 75 mm. The depth measuring rods shall be of a design so that one rod at a time can be inserted through a hole in the micrometer screw spindle. The rod seat on the barrel end of the base shall provide a mounting surface parallel to the base measuring surface. When inserted into position the measuring rod shall be held securely into place and pass freely and smoothly throughout the entire range of travel. The measuring rod shall have a means of compensation for wear. The measuring rods shall be straight with a runout when fully extended of no more than 0.003 inch.

**Additional Depth Measuring Rods:** While the basic design requires that the set be provided with three depth measuring rods to reach the range of 0 to 3 inches, additional rods are available in expanded sets. All additional measuring rods shall be of design and performance as defined in this section.

**Accuracy:** All micrometer depth gage micrometer heads and depth measuring rods shall meet the accuracy limits as defined in Table 7. Adjustment to out of tolerance conditions shall be performed before instrument is returned to service.

**Table 7. Type III, Micrometer Depth Gage**

**Manufacturers' Production Tolerance Tables**

The *Manufacturers' Production Tolerance Tables*, Table 8a and Table 8b, represent the parameters that are utilized by the original manufacturers of the instruments. These values were defined by the Project Team B89.1.13 of the ASME Standards Committee on Dimensional Metrology. This committee is a representative group of the manufacturing industry that establishes the standards used in the production of micrometers. These standards address the requirements of the American industry and the ISO efforts in the support of international commerce. While these tolerance tables and values are utilized in the manufacturing of the instruments, the calibration of the individual instruments is slightly different and does not always include all the geometrical parameters that are taken into consideration during the manufacturing process.

### Calipers, Vernier and Dial

**Classification.**—The definition of the classifications of vernier calipers was established in the GGG-C-111 standard and provides the basic requirements that were to be met by manufacturers supplying such calipers to the Federal Supply Service, General Services Administration. While the Federal Specifications do not include all varieties of the calipers commercially available, it does provide a guideline for manufacturers. Dial and digital calipers follow the general design features as illustrated in Fig. 17, Fig. 18, and Fig. 20. Any variation in designs must incorporate all aspects and necessary measurement capabilities as defined in the original government specification.

Fig. 17. Original Design: Type 1, Class 1 with Fine Adjust Carrier, Gib, Lock Screw and Fine Adjust Screw and Nut

**Type and Classes.**—Calipers and gages shall be of the following types, classes, and styles, as specified:

*Type 1—Calipers, vernier*

*Class 1: Inch measure*

*Class 2: Metric measure*

*Class 3: Inch-metric measure*

Fig. 18. Type 1, Class 3—Inch/Metric Dual Scale with Vernier Scale Flush to Edge of Main Scale

**Construction Requirements.**—*Materials:* The beam and all measuring surfaces having direct contact with the work shall be made of high grade tool steel. The measuring faces may be made of Tool Steel with Carbide inserts. All materials shall be sound and free of injurious porosity, soft spots, hard spots and other defects. All parts subject to wear, breakage or distortion shall be replaceable.

*Main-scale Member (Beam):* The main-scale member, or beam, of the Type 1 caliper shall be graduated as defined herein for each design variant. The main-scale shall be of a cross sectional area as to provide stability without undue weight when the instrument is used to make measurements at the maximum range. The measuring face and slide locating edge shall be straight within 0.0003 inch for each linear foot of the beam length. The total tolerance for the instrument (if over 12 inch) shall not be accumulated in any 12 inch increment and all deviation in straightness shall be evenly distributed along the entire length of the instrument.

*Slide:* The slide or moveable jaw shall be machined to receive the main-scale beam and shall have a fit and surface finish so as to allow the slide to move through the entire length of the beam without lateral shake or bind when not locked into position. The locating side of the slot shall be square with the measuring plane within 0.0003 inch along the full length of the contact surface. The opposite side of the moveable jaw shall be fitted with a nib or knife edge inside measuring jaw and a locking screw.

*Vernier Plate:* The vernier plate shall either overlap or be flush with the edge of the main scale. The overlap of the main scale shall be no less than 1/64 inch and straight with 0.002 inch in the full length. The vernier plate shall be beveled to prevent parallax error. If the scale is installed flush along the edge of the main scale, the edge of the Vernier Plate shall slide easily along the main scale. The edges of both the main scale and the vernier plate shall extend fully to the edges. The Plate shall be held in place with two screws through elongated mounting holes to allow no less than 0.010 inch longitudinal adjustment.

*Measuring Contacts:* The measuring contacts shall have a surface finish of 8  $\mu$ in Ra or better and have a hardness value of no less than 60 to 65 RC (Rockwell C scale).

**Scale and Graduations.**—All calipers regardless of Type or Class will have a *main scale* and a *Vernier scale* or dial. The vernier scale shall be a direct reading scale so that when aligned with the zero point of the data scale, the first division of the vernier scale will appear below the first mark on the main scale. All vernier scale graduation spacing is a precise fraction smaller than the marks on the main scale. All graduations shall be machine cut or etched between 0.003 to 0.006 in width and from 0.001 to 0.003 inch in depth and shall not vary in width on the main scale or the vernier scale by more than 0.001 inch. The edges of the graduations shall be straight and not vary more than 0.0002 inch throughout the full length of the graduations along the full length of the instrument. The graduations shall be sharp and well defined and contrast with the surrounding area through chemical etching or other similar methods so that the graduations are distinct and easily readable to enable the use of the instrument under normal working conditions. The graduations will be parallel to each other and square to the locating edge of the main scale within 0.0004 inch. The vernier scale graduations shall be parallel and square to the reading edge of the vernier plate or scale within 0.0002 inch. The index of both the main and vernier scales will be located referencing the measuring contacts planes so as to be direct reading.

**Inch Graduated Instruments.**—*Main Scale:* The inch graduated instruments will be graduated to read in thousandths of an inch increments. Each inch of the main scale shall be represented with a graduation mark representing the inch incremental value. Each inch segment shall be subdivided into ten increments of 0.100 inch. Each 0.100 inch increment shall be further divided into 4 increments of 0.025 inch each for 100 divisions per inch instruments or two divisions of 0.050 inch for 50 divisions per inch instruments. Each graduation of the main scale within the first foot shall be accurately located to the reference zero index within 0.0003 inch. With each additional foot length of the main scale and

additional 0.0003 inch shall be acceptable with no total tolerance accumulated within any single foot of main scale length. All graduations within any 1 inch increment shall be accurately located in that inch increment within 0.0002 inch.

**Vernier Scale:** The inch vernier scale shall be divided into either 25 minor divisions each equivalent to one twenty-fifth of the main scale minor division or twenty five thousandths of an inch or 50 divisions each equivalent to one fiftieth of the main scale minor division or fifty thousandths of an inch. On either scale each alignment of the vernier scale mark to the main scale is equivalent to one thousandths of an inch. The graduated length for the 25 division inch graduated vernier scale shall be either 0.6000 or 1.2250 inch  $\pm 0.0002$  and are divided into 25 equal increments accurately spaced to within  $\pm 0.0002$  inch. All graduations shall be of a length so as to be easily discernible with the graduations for 0 (zero) and each 0.005 inch having extra length to enable them to be easily distinguished. The 0 (zero) index and each 0.005 inch increment shall be clearly marked with the incremental value. The vernier scales that are divided into 50 increments shall have a length of either 1.225 or 2.450  $\pm 0.0002$  with each increment accurately spaced to within 0.0002 inch. Each instrument shall be marked with the scaled value.

**Metric Graduated Instruments.—Main Scale:** The metric graduated instruments will be graduated to read in 1/50 mm (0.02mm) increments. Each centimeter of the main scale shall be represented with a graduation mark representing the incremental value. For instruments with 25 increment vernier scales, the main scale shall be graduated in centimeters, millimeters and half-millimeters. Each centimeter segment shall be subdivided into ten increments of 1 millimeter each. Each 1 millimeter increment shall be further divided into 2 increments of 1/2 millimeter each for 20 divisions per centimeter. Centimeters shall be numbered from zero with easily read numerals. The graduation lines for cm, 1/2 cm, mm, and 1/2 mm shall have length of descending order. All graduation lines shall be clearly marked as described in the previous *Scale and Graduations and Inch Graduated Instruments* sections, and be easily readable under normal operating conditions.

Instruments with 50 increment vernier scales shall have the main scale graduated in centimeters and millimeters with half-millimeters at the manufacturers' option.

Each graduation of the main scale within the first 30 cm shall be accurately located to the reference zero index within 0.008 mm. With each additional 30 cm length of the main scale and additional 0.008 mm shall be acceptable with no total tolerance accumulated within any single 30 cm of main scale length. All graduations within any 1 cm increment shall be accurately located in that centimeter increment within 0.005 mm.

**Vernier Scale:** Vernier scales for metric instruments divided into 25 increments shall have a graduated length of 12 mm or 24.5 mm,  $\pm 0.005$  mm and scales divided into 50 increments shall have a graduated length of 24.5 mm or 49 mm,  $\pm 0.005$  mm.

Fig. 19. Common Metric Vernier Caliper Scale Markings

The metric vernier scale most generally found in the current market shall be divided into 10 divisions or 0.1 mm, each division further divided into 5 minor divisions equivalent to a resolution of 0.02 mm. The spacing and location from zero shall be accurate to within 0.005 mm. All graduations shall be of a length so as to be easily discernible with the graduations for 0 (zero) and each 0.1 mm having extra length to enable them to be easily

distinguished. The 0 (zero) index and each major division shall be clearly marked with the numerical incremental value.

**Dial Caliper.**—The dial caliper uses a precise rack and pinion movement that drives an indicating hand to provide a direct reading on a circular dial. This precision movement eliminates the necessity to visually read the vernier scale and negates the effects of subjective observation.

Fig. 20. Dial Caliper – Fine Adjust Wheel and Gib Slide Screws for Accuracy Adjustment

The movement, when adjusted properly and calibrated will provide a measurement with a higher level of confidence than the vernier scale. Typically the indicating hand rotates once every 0.100 in or 1 mm and provides a resolution of 0.001 inch or 0.02 millimeter. The main scale still indicates the major divisions that are added to the reading taken from the dial indication. An additional feature of the dial caliper is that the dial is designed to be rotatable beneath the pointer allowing the operator to “set” the caliper at a known value and zero the indicator and make “differential measurements” from the known value. This function was not possible with the original vernier caliper.

**Digital Caliper.**—The most current refinement in the instrument is in the replacement of the dial movement or vernier scale with a digital display. The dial rack and pinion movement or vernier scale has been replaced with the application of a linear encoder that allows switching between millimeters and inches on demand, zeroing the scale at any point along the scale for differential measurements and electronically “holding” a measurement possibly taken in an awkward position where the digital display may not be visible. Many digital calipers offer a *serial data output* function that allows the operator to capture collected data in a spreadsheet or dedicated controller for analysis and more accurate records collection.

Fig. 21. Digital Caliper – Average Feature Configuration

### Calibration of Reference Setting Standards

#### Preliminary Operations

- 1) Review and become familiar with the entire calibration procedure before beginning the calibration process. Ensure familiarity with setup and operation of all standards involved in the procedure.
- 2) Always observe safe operating methods for all standards, whether electrical, physical, mechanical, or dimensional; exercise caution in handling of all precision standards.
- 3) Ensure measuring surfaces are clean and free of nicks and burrs that could affect the accuracy of the measurements. Observe the rod ends for any possible damage and observe the unit for bending or any condition that may affect the parallelism of the measuring surfaces. If any condition of concern is observed, light stoning with a hard Arkansas stone can be used with care to remove any nicks or burrs.
- 4) Bring the UUT (Unit Under Test) into the controlled environment 12 hours prior to beginning the calibration process. Allow all standards and UUT to stabilize to common temperature.

#### Typical Equipment Requirements

Name	Minimum Use Specifications	Recommended Measurement Standards	Alternative
Universal Horizontal Measuring Machine	Range: 0 to 24 inch Accuracy: $\pm 30 \mu\text{in}$	Mahr-Federal 828	Mahr Linear 1200
Gage Block Set	Range: 0.050 to 4.000 inch 2.0 to 450 mm	Starrett Webber SC 81.A1 Starrett Webber S2C 88.MA1	Mitutoyo 516-401-16 Mitutoyo 516-442-10
Gage Block Set (Long Block)	5 to 84 inch 125 to 500 mm	Starrett Webber SS 8.A1X Starrett Webber SS 8. MA1X	Mitutoyo 516-762-16 Mitutoyo 516-753-10
Height Transfer Gage	Range: 1 to 48 inch	Starrett DIGI-CHECK II DHG 49	Mitutoyo Universal Height Master Model 515-513
Electronic Height Indicator	Range: $\pm 0.032$ in. (min.) Accuracy: $\pm 50 \mu\text{in}$ $\pm 0.001$ mm	Mahr Federal Model 832 w/ LVDT	Mitutoyo Analog MU-Checker 519-420A with 519-327 Lever Head
Precision V-Block	Range: Adequate to support UUT in vertical position. Accuracy: Calibrated to specifications of GGG-V-191D (or equivalent)		
Surface Plate	Range: 24 x 36 Accuracy: Grade A	Starrett Crystal Pink EDP 80655	Mitutoyo 517-808

**Reference Setting Standard Calibration Process.**—*Note:* Special care should be taken to clean and apply a protective coating when handling gage blocks or other precision standards with bare hands. The use of clean cotton or vinyl gloves is recommended to prevent corrosive oils from damaging precision surfaces.

The temperature of the calibration environment must be maintained at approximately 23° C (73.4° F) with a fluctuation of no more than  $\pm 0.5^\circ$  C ( $\pm 0.9^\circ$  F) per hour.

1) Calibration of UUT up to 4.000 inch shall be performed on the horizontal measuring machine. All other measurements shall be performed in the vertical position as described in this procedure.

2) Select gage block equal to the size of the UUT. Wringing blocks together to achieve the desired size should be avoided if possible as this method increases possibility of error.

3) Insert the gage block between the anvil and spindle of the universal horizontal measuring machine resting against the anvil. Bring the head (spindle) into contact with

the gage block and gently bring the indicator to the zero indication. Lock the head into position. Seat the gage block, re-zero, and assure the measurement is repeatable.

4) Remove the gage block and replace with the UUT. Assure that the UUT is seated and the measurement is being read at the peak (highest reading) for radius rod ends, or the parallel point (lowest reading) for flat rod ends. Assure radius is centered on the anvil and spindle. Verify the reading is within the tolerance limits as defined in [Table 9](#).

5) Setup the universal horizontal measuring machine for the next size UUT as described in [Items 2](#)) and 3).

6) Repeat measurement as described in [Item 4](#)).

7) Continue the process through the range of the universal horizontal measuring machine or until all UUT in the set have been measured. If the UUT length in the set exceeds the length of the universal horizontal measuring machine, proceed to [Item 8](#)) for the process to measure the remainder of the set up to 40 inch (1000 mm).

Fig. 22. Vertical Measurement of Reference Setting Standard

8) Using a precision V-block, clamp the UUT into the V-block ensuring the rod end is in contact with the surface plate and the UUT is secured in a vertical orientation.

9) Using either a height transfer gage or a gage block, set the electronic indicator to a zero indication. Set the range and resolution of the indicator so as to adequately indicate the deviation from zero in relation to the tolerance limits assigned to the UUT.

10) Repeat the zero indication several times to assure no drift or error has occurred.

11) Move the indicator from the standard to UUT and seek the highest point (for radius ends) or sweep the flat rod end for deviation from nominal and indication of parallelism.

12) Confirm that the indicated deviation is within the tolerance limits as assigned to the UUT in [Table 9](#).

**Table 9. Size and Tolerance for Inch and Metric Reference Standards**  
(ASME B89.1.13-2001)

English		Metric	
Length (in.)	Tolerance (in.)	Length (mm)	Tolerance (mm)
1	$\pm 0.00005$	25	$\pm 0.0012$
2 to 4	$\pm 0.0001$	50 to 125	$\pm 0.002$
5 to 8	$\pm 0.00015$	150 to 200	$\pm 0.003$
9 to 11	$\pm 0.0002$	225 to 275	$\pm 0.004$
12 to 18	$\pm 0.00025$	300 to 425	$\pm 0.005$
19 to 24	$\pm 0.0003$	450 to 575	$\pm 0.006$
25 to 36	$\pm 0.00035$	600 to 750	$\pm 0.007$
37 to 40	$\pm 0.0004$	775 to 900	$\pm 0.008$

13) Repeat [Items 8](#)) through [12](#)) for the remaining reference setting standards in the set.

**Calibration of Outside Micrometers**

Typical equipment requirements for calibration procedures are shown in **Table 10**; a description of the calibration is given in **Table 11**, and various types of monochromatic light sources are given in **Table 12**.

**Table 10. Calibration Equipment Standards**

Item	Minimum Use Specifications	Recommended Equipment
Monochromatic Light	Range: N/A Accuracy: N/A	<sup>a</sup> Helium Discharge: 11.6 μin Length/Fringe Van Keuren L-1A or L-1
Optical Parallel Set	Range: Two optical parallels differing in thickness by 0.0125 in. Accuracy: 10 μin (flat and parallel)	Van Keuren: OP-2B
Gage Block Set	Range: 0.05 to 4 inch 2.0 to 450 mm	Starrett Webber SC 81.A1 Starrett Webber S2C 88. MA1X
Gage Block Set (Long Block Set)	Range: 5 to 84 inch 125 to 500 mm	Starrett Webber SS 8.A1X Starrett Webber SS 8.MA1X
<b>Optional Equipment</b>		
<sup>b</sup> U6 Monochromatic Reflex Interference Viewer	Range: 6 in diameter Accuracy: N/A	<sup>a</sup> Helium Discharge: 11.6 μin Length/Fringe Van Keuren V760300

<sup>a</sup> While the *Helium Discharge Monochromatic Light* is one of the most common frequencies in use, other monochromatic light sources are available (see **Table 12**) and all will produce the same results. The band count is multiplied by the fringe length value to obtain the flatness of the measured surface. See examples in the table *Interpreting Optical Flat Fringe Patterns*.

<sup>b</sup> The U6 Monochromatic Reflex Interference Viewer is used to observe the base flatness of the depth micrometer directly through an optical flat. The same technique of fringe count can be utilized to obtain the flatness as is used for the OD micrometer anvil and spindle.

**Table 11. Calibration Description**

UUT Characteristics	Performance Specifications	Test Method
Flatness	Range: 0 to 54 in. 0 to 300 mm Tolerance: See <b>Fig. 12</b>	Measured with <i>Optical Flat/Parallel</i> converting fringe curvature to an equivalent linear value.
Parallelism	Range: 0 to 1 inch 0 to 25 mm Tolerance: 50 μin. 0.0013 mm	For UUT with 0–1 inch (0–25 mm) range, measured at two positions with optical parallel set.
Length and Linearity	Range: 0 to 54 inch 0 to 1400 mm Tolerance: See <b>Table 21a</b> and <b>Table 21b</b>	Comparative measurement of UUT reading to gage block test setup to test the basic length and micrometer head linearity.

*Note:* The *Minimum Use Specifications* column of **Table 10** represents the principal parameters required for performance of the calibration. References to specific equipment are recommendations only, and in no way constitute an endorsement other than as examples of the appropriate accuracy required to maintain the correct *Test Accuracy Ratio (TAR)* and confidence level in the calibration procedure. It is understood that equivalent equipment produced by other manufacturers is capable of equally satisfactory performance of this procedure.

*Note:* If the UUT uses the metric scale, use test points equivalent to those defined for the English scale so as to test the micrometer at five places in the circumference of the drum and five equally spaced intervals throughout the range of travel of the micrometer spindle screw.

**Table 12. Types of Monochromatic Light Source**

Light Source	Wave Length		Length/Fringe	
	μin	nm	μin	nm
Helium-Neon Laser (bright red)	24.9	632.8	12.5	316.4
Sodium Vapor (yellow)	23.2	589.3	11.6	294.7
Mercury Vapor (green)	21.5	546.1	10.8	273.1
Helium Discharge (yellow-orange)	23.1	587.6	11.6	293.8

**Preliminary Operations.**—Ensure a clean and well illuminated work area, free from drafts, excessive humidity with a stable temperature that does not fluctuate more than  $\pm 2^\circ$  per hour. It is recommended that a stable temperature of  $68^\circ$  F is maintained in the calibration work area.

*Note:* The calibration of OD Micrometers and similar precision measurement devices is accomplished through the use of gage blocks as the length standard. Due to the thermal reactivity of gage blocks, environmental stability is a major consideration in maintaining the confidence in the accuracy of the measurements taken during the calibration.

Calibration of UUT with an accuracy of  $\pm 0.001$  inch or greater can be accurately calibrated in an environment with a temperature fluctuation of  $\pm 4^\circ$  F. Calibration of UUT with a higher accuracy, such as  $\pm 0.0001$  inch, must be accomplished in a stable environment of no greater than  $68^\circ$  F with a temperature fluctuation of no more than  $\pm 2^\circ$  F per hour.

Ensure that the UUT and all associated standards have been allowed to stabilize in the controlled environment for a minimum of 8 hours prior beginning the calibration procedure. This is especially critical for UUT in excess of 10 inches.

Closely examine the UUT for any burrs or nicks on the measuring surfaces that could in any way damage the highly polished precision surface finishes of the gage blocks and optical flats. Damage to these surfaces could degrade or potentially ruin the standard.

Thoroughly clean the UUT and rotate the micrometer through the full range of travel, ensuring smooth movement with no binding or indication of drag or misalignment of the spindle through the support bearing.

*Note:* It is recommended that well-fitting cotton or nitrile gloves be used to reduce thermal transfer and protect from corrosive elements of direct contact.

**Calibration Procedure, Flatness Test (Outside Micrometers).**—UUT used in precision work or any re-lapped anvil or spindle require a flatness test. If the instrument is known to be for general purpose; i.e. tool box issue, diameter measurement where flatness is not a factor, measurement is a non-quantified value, etc., a flatness test would not be required. Calibration records should reflect “flatness not calibrated”.

Ball anvil and tubing micrometers require a flatness test on the spindle only.

- Connect the *Monochromatic Light* to a power source and turn on. Allow a few moments to warm up.
- Position the UUT in the monochromatic light field and place the optical flat on the anvil. Apply slight pressure and gently seat the optical flat until 3 to 5 bands are displayed on the surface. It is important to not apply greater than necessary force or to cause damage to the

optical flat by pressing down if a burr is detected. Scratching the surface of the optical flat can ruin the flat. Caution is required.

- Using the optical flat and monochromatic light, observe interference bands on anvil face.
- Count the number of bands between the lowest ends and the crest of 1 band. Multiply this number by the frequency of the monochromatic light being used. Confirm that the calculated deviation is within the tolerance limits defined in Table 13.

1 band = 11.6 millionths ( $\mu\text{in}$ ) using helium discharge light source (Table 12).

Record the band count, frequency and result.

### Interpreting Optical Flat Fringe Patterns

Fig. 23a.                      Fig. 23b.                      Fig. 23c.                      Fig. 23d.

*Example, Optical Flat Fringe Patterns:* Fig. 23a through Fig. 23d illustrate fringe patterns produced by an optical flat in contact with several test surfaces.

The following illustrates how to interpret the fringe patterns observed to determine deviations in flatness of the unit under test (UUT).

- Convex surface (Fig. 23a): side edges low 11.6  $\mu\text{in}$
- Convex surface (Fig. 23b): side edges low 5.7  $\mu\text{in}$ .
- Nearly flat (Fig. 23c): side edges low 5.7  $\mu\text{in}$ .
- Complex surface (Fig. 23d) both convex and concave: hollow in center, higher each side of center and lower at side edges: error 3  $\mu\text{in}$ .

- Turn over the UUT and repeat preceding steps for the spindle. If this is inconvenient due to size of UUT, remove the spindle to take the reading. Calculate in the same manner as above. Record the reading.
- If UUT is an interchangeable anvil micrometer, repeat measurement for each anvil.
- Note:* If anvil or spindle do not create an image, or are too worn to produce an image, they will need to be sent out to the appropriate vendor for lapping.

**Table 13. Anvil/Spindle Flatness Tolerances per USAF**

Range		Tolerance	
Inches	Millimeters	English UUT (inch)	Metric UUT (millimeters)
0 to 3	0 to 75	0.00005	0.001
4 to 9	100 to 225	0.00008	0.002
10 and above	250 and above	0.0001	0.0025
All with a resolution of 50 in. or 0.001 mm		0.000025	0.0006

**Parallelism Test (Outside Micrometers).**—The anvil and spindle parallelism test is performed on 0–1 inch / 0–25mm micrometers where a high degree of accuracy is required to be maintained. Prior to the parallelism test, the flatness test must be performed to the satisfaction of the tolerance of the UUT.

- It is critical to the accurate measurement that no dirt or dust particles are present. It is highly recommended that several measurements be taken to verify the results of the measurement. Cleaning the anvil and spindle and optical parallel with lint free lens tissue will aid in assuring the accuracy of the measurement.

- Position the thinner optical parallel between the anvil and spindle of the UUT and adjust the UUT until both surfaces are in contact with the optical parallel. Do not exert greater than necessary force in attempting to minimize interference band count. Adjust the optical flat on the anvil end of the UUT to obtain the minimum band image. The optimum number of bands anticipated here is four. This provides an easily read image to calculate the parallelism of the anvil and spindle. Note the number of bands on the anvil face as *count A*.
- Without changing the position of the UUT, carefully turn and observe the number of bands on the spindle face. Note this as *count B*.
- Compute the parallelism of the anvil and spindle over the smaller optical flat as follows. Use the band width of the monochromatic light that is being used;

$$11.6 \times (A + B) = \text{Parallelism (microinches)}$$

where  $A = \text{count A}$ ;  $B = \text{count B}$ ; and 11.6 is the fringe/length of the light source in microinches (Table 12).

- Remove the thinner optical flat and replace with the 0.0125 inch thicker one and repeat the measurement process. To calculate the anvil to spindle parallelism inclusive of the rotation of the spindle, calculate the difference between the two optical flat measurements.
- Verify that the difference between the two sets of measurements is within  $\pm 50 \mu\text{inch}$  or  $\pm 12 \mu\text{m}$ .
- If only one optical flat is available the same measurement can be achieved by using the measurement technique described above but calculated as  $11.6 \times (A - B) = \text{Parallelism (microinches)}$ . The exception being that this method will not take into consideration the rotation of the spindle.

**Linearity Test (Outside Micrometers).**—1) Set the UUT to indicate zero reading using the ratchet or friction thimble, and assure that the reading meets the applicable tolerance limits. If an *Out of Tolerance (OOT)* reading is identified at this time, assure there is no foreign particle or burr on the anvil or spindle. An accurate zero indication must be established at this time as all other measurements will be affected by any error at zero.

*Note:* The micrometer anvil and spindle can be closed over a sheet of clean white paper damp with isopropyl alcohol, which can then be drawn out slowly to remove any obstructing matter. Repeat with a dry paper and observe any smear or smudge that would indicate dirt or foreign matter. Clean until paper comes through with no residue.

2) For *Interchangeable Anvil Micrometers* the appropriate length gage block will be used to establish the zero indication.

3) The recommended size gage blocks used to test the micrometer spindle thread are very important. The recommended test points achieve the testing of the accuracy of the micrometer throughout the entire length and at points evenly distributed around the diameter of the spindle thread. This verifies the accuracy of the lead error of the thread as well as identifying any sections that may have experienced excessive wear or damage. The recommended sizes are as follows:

- a)  $X.210, X.420, X.605, X.815$  and  $1(X).000$  (inch) and  $5.10, 10.20, 15.30, 20.40,$  and  $25.00$  (mm). The micrometer should be tested at zero and full scale.  $X$  represents the applicable length for the UUT range.
- b) When wringing gage blocks together to achieve the desired size, the stack must soak for 1 hour when calibrating UUT with  $0.0001$  inch ( $0.002$  mm) resolution in a range over  $8.000$  inches ( $200$  mm). The soak time does not apply to sizes over  $8.000$  in ( $200$  mm) that do not require wringing.

4) Select the first gage block stack and measure it using the ratchet or friction thimble. Do not rely on feel as the correct and controlled loading of measuring force by the ratchet or friction thimble will give the most accurate and repeatable reading. All other methods are subjective and open to operator influence. Several clicks of the ratchet or applying force until the friction thimble slips and assuring the micrometer is gently seated on the

gage block stack will give an accurate reading. Assure the reading is repeatable. The reading must meet the tolerance limits as defined in [Table 21a](#) and [Table 21b](#) for *Indicated Measurement Error*.

5) Repeat these steps for each remaining gage block stack and record readings for evaluation or trend analysis. Follow all guidelines of the quality assurance programs in place in regards to recording and retaining all data collected and reporting OOT (out of tolerance) conditions.

6) For *Interchangeable Anvil Micrometers*, after calibration of the micrometer spindle thread, repeat [Items 1](#) and [2](#) for each anvil in the set. Once the micrometer spindle thread accuracy has been confirmed, only the zero setting of each interchangeable anvil needs to be calibrated. Verify that each interchangeable anvil meets the tolerance limits assigned and record any OOT conditions before adjusting to meet tolerance limits if necessary.

### Calibration of Depth Micrometers

*Note:* Do not lock the micrometer head without the depth rod installed. This could result in damage to the split ring locking mechanism causing the rods to bind.

**Flatness Calibration.**—1) For *Depth Micrometers* with a resolution of 100  $\mu\text{in}$  (or metric equivalent) or better, the Van Keuren model U6 Monochromatic Reflex Interference Viewer is used to observe the base flatness of the depth micrometer directly through an optical flat. The same technique of fringe count can be utilized to obtain the flatness as is used for the OD micrometer anvil and spindle (*Interpreting Optical Flat Fringe Patterns*).

2) For *Depth Micrometers* with 0.001 inch (0.01 mm) resolution per division, place the UUT on an individual 1.000 in (25 mm) gage block with the depth rod extended through the center relief hole as shown in [Fig. 24](#). Bring the depth rod into contact using the ratchet stop or friction thimble and observe the reading. Repeat this measurement three times ensuring repeatability of the reading. Record the reading as reading *A*.

3) Remove the UUT from the setup and place it on two gage blocks (or stacks) of 1.000 in. (25 mm) as shown in [Fig. 24](#). Bring the depth rod into contact using the ratchet stop or friction thimble as in [Item 2](#)) and observe the reading. Repeat this measurement three times ensuring repeatability of the reading. Record the reading as reading *B*.

Subtract reading *B* from reading *A* and ensure that the result is within the tolerance limits as listed in [Table 14](#).

**Table 14. Depth Micrometer Base Flatness**

Range		Tolerance	
Inches	Millimeters	(inch)	(millimeters)
All with a resolution of 0.0001 in. or 50 $\mu\text{in}$	All with a resolution of 0.0025mm or 0.001mm	0.0001	0.0025
All with a resolution of 0.001 in.	All with a resolution of 0.01 mm	0.001	0.01

*Note:* The *Linearity* of the UUT is checked using the 0–1 inch (0–25 mm) depth rod only. Once the accuracy of the *Micrometer Head* has been verified, the remaining depth rod extensions are calibrated at the zero position only. It is critical to the outcome of the calibration of the entire set that the base zero setting for the micrometer sleeve and thimble be accurate and without error or deviation. Any error in the base zero setting will cause errors to be translated to the depth rod extensions.

**Linearity Calibration (Depth Micrometers).**—1) Select the appropriate gage blocks to make stacks to measure 0.210, 0.420, 0.605, and 0.815 inch, or 5.10, 10.20, 15.30, 20.40, and 25.00 mm. The 1.000 inch (25.00 mm) block will also be used as the micrometer head will be calibrated at zero to full scale. Clean and wring gage blocks assuring no dirt or foreign matter is present.

Fig. 24. Figure 4: Depth Micrometer Base Flatness Measurement

2) Place the UUT on the surface plate and zero against the plate. A calibrated surface plate must be used as it is used to establish the base zero setting and is considered as one of the standards used in the calibration procedure. Record any deviation and assure the reading is within the tolerance limits as defined.

3) Place the first gage block stack (0.210 inch or metric equivalent) on the surface plate and place the UUT on top of the stack. Measure the stack through the center relief hole in the gage block. Observe the reading. Repeat the measurement three times and assure repeatability of the measurement. Verify that the reading is within the tolerance limits.

4) Repeat **Item 3)** for all remaining gage block stacks. Record all readings. If an OOT condition is discovered, adjust the UUT and repeat the linearity calibration to verify the adjusted accuracy.

5) Repeat **Item 2)** for all remaining depth rod extensions. For UUT with resolution of 0.0001 in or better, allow gage block stacks that require wringing to assemble to stabilize for one hour for lengths over 8.00 inch. Stabilization is not required for single block lengths.

#### Calibration of Micrometer Heads

**Linearity Calibration.**—1) Select the appropriate gage blocks as defined in the *Linearity Test (Outside Micrometers)*. As previously the micrometer head will be calibrated at zero to full scale. Clean and wring gage blocks, as appropriate, assuring no dirt or foreign matter is present.

Fig. 25. Micrometer Head Set Up — Vertical in V-Block

2) Mount the micrometer head vertically by the shank into a precision V-block as shown in Fig. 25, and adjust so that the zero position can be achieved making contact with the calibrated surface plate. If a zero position cannot be achieved with the V-block available, use an intermediary gage block of the necessary size so as to achieve contact with the spindle face and set zero on that intermediary block. This is the zero indication and will not be included in the linear measurement. Repeat the zero measurement three times to assure repeatability of the measurement (zero setting) Record the reading as zero. Verify that the reading is within the tolerance limits for the UUT. Raise the micrometer head spindle and insert the first step gage block (0.210 in or metric equivalent) lower the micrometer head until the spindle measuring face makes contact with the gage block stack. The micrometer head has no ratchet stop or friction thimble to control the force applied. It is important to not overdrive the spindle and introduce an error caused by disturbing the setup. It does not require a great amount of force to lift the setup. Care must be taken to apply the measurement gently but firmly. Repeat the measurement three times to assure the repeatability and accuracy of the measurement.

3) Repeat Item 2) for all remaining gage block stacks throughout the full range of the UUT. Record all readings and verify that all readings are within tolerance limits. Adhere to manufacturers' tolerances if different than the tolerance limits listed in *Calibration Tolerance Tables, Table 21a* and *Table 21b*.

### Calibration of Thread Micrometers

*Note: The Thread (Pitch) Micrometer* uses a dedicated set of spindle and anvil contacts that measure the pitch diameter of a thread of a given pitch range. There are fixed anvil micrometers as well as interchangeable anvil/spindle sets. The interchangeable sets come with matched spindle/anvil sets that can be installed into the micrometer frame and then set to zero.

**Linearity Calibration (Fixed Pitch).**—The fixed anvil micrometers usually do not have the capability to reset the zero indication other than the standard barrel adjustment. The calibration of these instruments is achieved by the measurement of master setting thread plug members that are selected to cover, as close as possible, 25, 50 and 75 percent of the range of the UUT.

1) Three calibrated *Master Setting Thread Plug Gages* are selected that cover 25, 50 and 75 percent of the measuring range of the UUT in the range of pitch that the UUT is designed for. (i.e., 8–13 pitch, 16–18 pitch, 18–24 pitch).

2) Mount the pitch micrometer in a micrometer stand to enable easier operation of the UUT and to provide better control of the standard.

3) Gently bring the *Anvil* and *Spindle* together to achieve a zero indication. If zero reading is not exact, adjust the barrel so no error from zero exists. Repeat the zero indication to assure repeatability.

4) Open the micrometer anvil and spindle beyond the point of the first standard pitch diameter and seat the standard against the anvil.

5) Slowly close the micrometer until the spindle cone seats into the thread opposite the supported anvil.

6) Gently roll the standard up and down against the spindle cone to seek the highest point on the diameter. When this point is located, take a measurement of the pitch diameter.

7) Record the measurement and assure that the measurement is within the tolerance limits for the UUT.

*Note:* UUT with the resolution of  $\pm 0.001$  require a Class X master thread setting plug gage. UUT with a resolution of  $\pm 0.0001$  require a class W master thread setting plug gage.

8) Remove the first standard and repeat measurement throughout the remainder of the master thread setting plug gages selected for the UUT.

**Interchangeable Anvil Pitch Micrometer Sets.**—1) *Interchangeable Anvil Pitch Micrometer* sets include several sets of Anvil and Spindle Cone, and V Anvils. These sets are

dedicated to a range of thread pitch. Most sets also include a set of flat anvil and spindle inserts that can be used to calibrate the micrometer exactly the same as a standard micrometer. If this is the case proceed as follows.

- 2) Select the flat anvil and spindle set and install.
- 3) Zero the anvil and spindle and assure repeatability.
- 4) Perform calibration as described in *Linearity Test (Outside Micrometers)*, Item 3) on page 792 using the defined test points to verify the accuracy of the micrometer head.
- 5) Remove the flat anvil and spindle set and install the smallest (highest pitch) dedicated Anvil V and Spindle Cone set. Close anvil and spindle and re zero the micrometer to the new set.
- 6) Select one master thread setting plug gage for the pitch range, preferably at midrange of travel, and measure as described in *Linearity Calibration (Fixed Pitch)* section. Verify that the measurement is within the tolerance limits of the UUT. This measurement verified the accuracy of the flank angle of the cone and V anvil. This measurement can also be performed on an optical comparator. However, the physical measurement should be performed as the final step in the calibration of the interchangeable cone and anvil sets.
- 7) Repeat for all remaining Anvil V and Spindle Cone sets.

#### Calibration of Inside Micrometers

**Caliper Type Inside Micrometer.**—A description of the calibration and equipment requirements for the Type II, Class 1, Inside Micrometer with Jaws are given in Table 15.

**Table 15. Calibration Requirements of the Type II, Class 1, Inside Micrometer with Jaws**

Calibration Description			
UUT Characteristics	Performance Specifications	Test Method	
UUT Length and Linearity	Range: 0.200 to 1.000 inch 0.500 to 1.500 inch 1.000 to 2.000 inch (or metric equivalent)	Comparative measurement of UUT reading to gage block test setup to test the basic length and micrometer head linearity.	
Equipment Requirements			
Description	Minimum Use Specifications	Calibration Equipment	Sub Item
Gage Block Set	Range: $\pm 0.05$ to 4 inch Accuracy: $\pm 12 \mu\text{in}$ from stated value	L.S. Starrett Co. SS 36.A1	L.S. Starrett Co. SS 81.A1

**Calibration Process.**—1) Set the UUT to indicate the minimum reading for the UUT using the ratchet or friction thimble. Assure that the reading indicates the minimum for the UUT model and range. If the reading is observed as off the minimum at this time, assure there is no foreign particle or burr on the anvil or spindle. An accurate zero indication must be established at this time as all other measurements will be affected by any error at zero.

2) The recommended size gage blocks used to test the micrometer spindle thread are very important. The recommended test points achieve the testing of the accuracy of the micrometer throughout the entire length and at points evenly distributed around the diameter of the spindle thread. This verifies the accuracy of the lead error of the thread as well as identifying any sections that may have experienced excessive wear or damage. The recommended sizes are given in Table 16:

**Table 16. Recommended Test Points for Type II, Class 1, Inside Caliper Micrometer**

Size		Range		Recommended Test Points	
(in.)	(mm)	(in.)	(mm)	(in.)	(mm)
1	25	0.200 to 1	5 to 25	0.210, 0.420, 0.605, 0.815 and 1.000	5.10, 10.20, 15.30, 20.40 and 25.00
1½	30	0.500 to 1½	5 to 30	0.510, 0.720, 0.905, 1.115, and 1.500	7.10, 12.20, 17.30, 23.40, and 30.00
2	50	1 to 2	25 to 50	1.210, 1.420, 1.605, 1.815, and 2.000	25.10, 30.20, 35.30, 40.40, and 50.00

Note:

- a) The micrometer should be tested at zero and full scale.
- b) Care must be taken when wringing gage blocks together to achieve the desired size. It is critical to clean the gage blocks thoroughly before wringing and assembling the end blocks to avoid damaging the superior finish of the standard.
- 3) Assemble the first gage block stack and measure it using the ratchet or friction thimble as described in the *Linearity Test (Outside Micrometers)* on page 792. Do not rely on feel as the correct and controlled loading of measuring force by the ratchet or friction thimble will give the most accurate and repeatable reading. Several clicks of the ratchet or applying force until the friction thimble slips and assuring the micrometer is gently seated on the gage block stack will give an accurate reading. Gently rock the micrometer to assure that the Nibs are parallel to the gage block end block faces. Repeat the measurement several times to assure the reading is repeatable. The reading must meet the tolerance limits as defined in *Table 17, Tolerance* column.

**Table 17. Tolerance Table: Type II, Class 1 Inside Micrometer with Jaws**

Size (in.)	Range (in.)	Tolerance (in.)
1	0.200 to 1	±0.001
1½	0.500 to 1½	±0.001
2	1 to 2	±0.001

- 4) Repeat these steps for each remaining gage block stack and record readings for evaluation or trend analysis. Follow all guidelines of the quality assurance programs in place in regards to recording and retaining all data collected and reporting OOT conditions.

Fig. 26. Measure Gage Block Stack Assembled with End Blocks

**Tubular Type Inside Micrometer.**—A description of the calibration and equipment requirements for the tubular type inside micrometer are given in [Table 18](#).

**Table 18. Calibration Requirements of Tubular Type Inside Micrometer**

Calibration Description			
Test Instrument (TI) Characteristics	Performance Specifications	Test Method	
Length	Range: All Accuracy: As listed in <a href="#">Tables 4, 5, and 6</a>	Measured using a standard measuring machine or supermicrometer referenced to gage blocks	
End caps	Range: All Accuracy: $\pm 0.00025$ in		
Extension Rods	Range: All Accuracy: As listed in <a href="#">Tables 4, 5, and 6</a>		
Equipment Requirements			
Description	Minimum Use Specifications	Calibration Equipment	Alternate Selection
Gage Block Set	Range: 0.05 to 4 in Accuracy: $\pm 12 \mu\text{in}$ from stated value	L.S. Starrett Co. SC 36.A1 SC 36.MA1X	L.S. Starrett Co. SC 88.A1X SC 88.MA1X
Gage Block Set	Range: 5 to 20 in Accuracy: $\pm 5 \mu\text{in/in}$	L.S. Starrett Co. SS8.A1X	
Supermicrometer	Range: 0 to 10.00 inch 0 to 250 mm  Accuracy: $20 \mu\text{in}$	Pratt & Whitney Model PC-250	
Standard Measuring Machine	Range: 0 to 148 inch 0 to 1200 mm Accuracy: $50 \mu\text{in}$	Pratt & Whitney Model DMM-1219	

**Preliminary Operations.**—1) UUT shall be brought into the calibration area at least 4 hours prior to beginning the calibration process.

2) Ensure that all working surfaces are clean and free from dust and dirt.

3) The UUT must be free from all rust, nicks and burrs that would affect the results of the measurements and operation of the UUT.

4) Linear measurements are affected by temperature and all measurements must be conducted in a temperature controlled environment. The preferred environment is 68°F with no greater than  $\pm 1^\circ$  per hour deviation from nominal. The temperature must have been stable and within the preferred range for a minimum of 8 hours prior to beginning the calibration soak time.

**Length Calibration Process.**—*Preferred Method:* 1) Install the shortest extension rod available for the UUT set being calibrated. If the UUT has end caps (Type II Class 3 Style A) install just the end caps. This section will calibrate the micrometer head accuracy.

*Note:* If the TI being calibrated is equipped with two end caps that can be removed and interchanged (Type II Class 3 Style A), the end caps must be checked for wear and must be the same length (nominal 0.250 inch). If the end caps differ in length by more than  $\pm 0.00025$  inch (as measured on the *Supermicrometer* or *Standard Measuring Machine*, both TI end caps must be replaced.

2) Select a gage block of a length close to the nominal length of the UUT when set to zero on the micrometer head and the extension rod or end cap for minimum length indication is installed.

3) For UUT with greater than 0.0001 inch (0.001 mm) resolution, gage block stacks that are wrung together to achieve the nominal setting dimension over 8 inches, must soak for one hour before establishing the setting dimension. This does not apply to single gage blocks used as setting standards.

4) Set the *Reference* of the supermicrometer or standard measuring machine to zero.

5) With the UUT set to zero, place into the measuring plane of the supermicrometer or standard measuring machine and measure the UUT. Assure that the UUT is supported on either a flattened round or adequate support to allow it to maintain alignment with the axis of measurement of the standard.

6) Verify that the measurement is within the tolerance limits for the UUT. Refer to the tolerance tables for the Type II Class 2 (Table 4), Type II Class 3 Style A (Table 5), and Type II Class 3 Style B (Table 6) for applicable tolerance limits.

7) Remove the UUT from the standard and set to the next test point as defined in Table 12 for the 1 inch (25 mm) micrometer head.

8) Repeat Items 5) and 6) for all remaining test points.

*Alternate Method:* 1) Install the shortest extension rod or end caps and set UUT to zero on the micrometer head. Wring together appropriate size gage blocks to measure the zero indication assembly.

2) Wring or attach the *Caliper Jaw End Blocks* from the gage block accessories and assure the setup is square and true. If using the connecting rods, minimal force is required to secure the end blocks to the gage block stack.

*Note:* For UUT with greater than 0.0001 inch resolution, gage block assemblies longer than 8.00 in (200 mm) will require 1 hour stabilization time before taking measurement.

3) Use the UUT to measure the gage block stack. Care must be taken to assure that the measurement is taken at the shortest distance between the caliper end block faces.

Fig. 27. Inside Micrometer Gage Block Stack Measurement

4) Repeat Items to 3) for each remaining test point. Measure each gage block setup and assure that the indication is within the tolerance limits as defined in the Table 4, Table 5, and Table 6 for the Type II Class 2, Type II Class 3 Style A, and Type II Class 3 Style B inside micrometers.

**Extension Rod Calibration.**—*Preferred Method:* 1) Remove the shortest extension rod or one end cap used in the linearity calibration and replace with the next UUT extension rod in the set.

2) Ensure the *Standard Measuring Machine* has retained its reference. Verify the zero setting if necessary. The *Supermicrometer* will require re-mastering every 1 inch and can only be used up to 10 inches (generally). The standard measuring machine uses a continuous measurement path but must be re-mastered every 8 inches.

3) For UUT with 0.0001 inch (0.001 mm) resolution, allow for 1 hour stabilization time for gage block stacks that are wrung to achieve nominal length over 8 inches (200 mm).

4) Using a flattened round or appropriate supporting device, mount the UUT into the standard. Assure the alignment of the measuring path and measure the UUT.

5) Confirm that the indication is within the tolerance limits as listed in the Table 4, Table 5, and Table 6 for the Type II Class 2, Type II Class 3 Style A, and Type II Class 3 Style B inside micrometer.

6) Repeat **Items to 5)** for all remaining extension rods, sleeves and end caps in the set.

*Alternate Method:* 1) Remove the shortest extension rod or one end cap used in the linearity calibration, and replace with the next UUT extension rod in the set.

2) Wring together a gage block stack to achieve the nominal desired length of the micrometer head at zero indication and the included extension rod.

3) Wring, or attach using the accessory attachment rods, the outside caliper jaws to the gage block stack. Assure stack is square and true. Minimal force is required to secure the outside caliper jaws to the gage block stack.

4) For UUT with 0.0001 inch (0.001 mm) resolution, allow for 1 hour stabilization time for gage block stacks that are wrung to achieve nominal length over 8 inches (200 mm).

5) Use the UUT to measure the gage block stack.

6) Confirm that the measured value is within the tolerance limits as listed in the **Table 4, Table 5, and Table 6** for the Type II Class 2, Type II Class 3 Style A, and Type II Class 3 Style B inside micrometer.

7) Repeat **Items to 6)** for all remaining extension rods, sleeves and end caps in the set.

### Calibration of Vernier, Dial and Digital Calipers

**Preliminary Operations.**—1) Review and become familiar with the entire calibration procedure before beginning calibration process. Ensure familiarity with setup and operation of all standards involved in the procedure.

2) Always observe safe handling methods for all standards and exercise caution in the handling of all precision standards.

3) Ensure the work area is clean, well illuminated, and free from excessive drafts and humidity.

4) Ensure measuring surfaces are clean and free of nicks and burrs that could affect the accuracy of the measurements. Observe the Outside Measuring Jaws and Inside Measuring Jaws for any possible damage and observe the unit for wear or deformation or any condition that may affect the parallelism of the measuring surfaces. Close the measuring jaws completely and tighten the lock screw. Hold the UUT in front of a strong light source and verify that there are no burrs on the OD or ID measuring jaws. If any condition of concern is observed in regards to nicks or burrs along the beam, light stoning with a hard Arkansas stone can be used with care to remove these incursions.

5) Observe the condition of the rack along the full length of a dial caliper to assure there is no damage to the rack gear tooth or embedded chips or dirt that will affect or damage the movement. Look for bent or damaged gearing. Open and close the slide slowly and listen and feel for evidence or broken or damaged drive pinion gear.

6) Assure that the movement along the length of the beam does not bind or indicate the presence of any nicks or burrs along the beam. Assure the movement is not too loose. Observe the position of the gib slide screws that they have not been removed or loosened.

7) Bring the UUT (Unit Under Test) into the controlled environment a minimum of 4 hours prior to beginning the calibration process. Allow all standards and UUT to stabilize to common temperature before proceeding.

**Table 19. Equipment Requirements and Minimum Accuracy Specifications of Required Standards**

Noun	Minimum Use Specifications	Recommended Measurement Standards	Alternative
Gage Block Set	Range: 0.050 to 4.000 inch 2.0 to 450 mm	Starrett Webber SC 81.A1 Starrett Webber S2C 88.MA1	Mitutoyo 516-401-16 Mitutoyo 516-442-10
Gage Block Set (Long Block)	5 to 84 inch 125 to 500 mm	Starrett Webber SS 8.A1X Starrett Webber SS 8.MA1X	Mitutoyo 516-762-16 Mitutoyo 516-753-10

**Table 19. (Continued) Equipment Requirements and Minimum Accuracy Specifications of Required Standards**

Noun	Minimum Use Specifications	Recommended Measurement Standards	Alternative
Precision Micrometer	Range: 0–1.0000 inch 0–25 mm	Mitutoyo Series 293	Starrett No.3732
Precision Pin or Ball	0.500 inch / 12 mm	Van Keuren Class XX	Precision Ground Pin or Ball ±40 in / 0.001 mm
Surface Plate	Range: 24 x 36 Accuracy: Grade A	Starrett Crystal Pink EDP 80655	Mitutoyo 517-808

*Note:* Standards listed are recommended and are determined to meet the necessary accuracy requirements of the calibration process. Substitute or alternative standards may be used as long as they have a current in tolerance calibration status and have been determined to meet or exceed the minimum accuracy specifications as listed in Table 19.

*Note:* Special care should be taken to clean and apply protective coating when handling gage blocks or other precision standards with bare hands. The use of clean cotton or vinyl gloves is recommended to prevent corrosive oils from damaging precision surfaces.

**Vernier, Dial and Digital Caliper Calibration Process.**—The temperature of the calibration environment must be maintained at approximately 23° C with a fluctuation in temperature of no more than ±0.1° per hour.

**Table 20. Range and Tolerance Limits**

Feature	Range (inch)	Accuracy (inch)	Method
Scale Zero	Set at Zero	±0.0005	Determined by observation of scale
Jaw Parallelism	0.00–0.250	±0.001 inch	Measured with Precision cylindrical plug gage
ID Jaws (Nibs) Set at Scale Zero	0 to 6.000–0.250 0 to 9.000–0.300 0 to 12.000–0.300 0 to 24.000–0.300 0 to 36.000–0.500 0 to 48.000–0.500	(inch) +0.000 –0.005	Measured with precision micrometer
Outside (OD) Jaws	0–6.00 inch 6–24 inch 24–48 inch	±0.0010 inch ±0.0020 inch ±0.0030 inch	Determined at 4 equal points along the main scale by direct comparison with gage blocks
ID Jaws (Knife Edge)	0–6.00 inch 6–24 inch 24–48 inch	±0.0010 inch ±0.0020 inch ±0.0030 inch	Measured with gage blocks
Depth Rod	0.000–6.000 inch	±0.001 inch	Measured with gage blocks

*Note:* Metric equivalents apply to all tolerance limits stated in Table 20. All tolerances based on AFMETCAL, NAVAIR and GGG-C-11 guidelines and specifications. Default to manufacturers specifications if different from those represented here.

**Nib Calibration, Inside Measurement, Type 1.**—*Class 1, 2, and 3:* The Total Nib Width (measured to the fourth place) shall be measured over both nibs with the jaws fully closed as shown in Fig. 28. The offset value shall be marked on the *Inside Measurement* side of the sliding jaw or main beam and on both sides of the main beam of the Type 1, Class 3.

- a) Alternately the vernier scale can be adjusted to directly compensate for and deviation from nominal dimension of the nib. This can be accomplished by adjusting the inside measurement vernier scale to zero on a known standard. Measurement of the nib nominal dimension must still be performed as excessive wear to the nib will result in adjustment in excess of the available range of the vernier scale.
- b) Assemble a 1.000 inch gage block with accessory end blocks as shown in Fig. 30 of the *Calibration of Inside Dimension Jaws (Nibs)* section.
- c) Measure the gage block stack and adjust the vernier scale to zero at this known point.
- d) This method is applied to the Type 1 style caliper only.

Fig. 28. Nib Dimension Measurement Location

**Calibration of Jaw Parallelism.**—1) Slide jaws together and tighten the sliding jaw lock screw. Hold the UUT in front of a strong light source. Observe that no light is visible between the jaw measuring surfaces. Look carefully for evidence of burrs, damage to the measuring surfaces, excessive wear or bowing.

- a) If any burrs or damage appears gently stone the jaws with a white hard Arkansas stone. Only use a super fine grain stone for this operation.
- 2) Loosen the sliding jaw lock screw and open the jaws. Place the precision cylindrical plug gage or ball in between the jaws as close as possible to the beam and measure the standard. Observe the scale, dial, or digital reading.
  - 3) Move the plug gage or ball to the opposite end of the measuring jaws (tip) and remeasure. The difference between the two readings must be within tolerance stated in [Table 20. Range and Tolerance Limits](#) for “Outside Jaws”.
  - 4) If the readings are within tolerance, proceed to Calibration of Outside Jaws. If adjustment is needed, go to [Items 5](#)) through 7), in *Adjustment of Gib Slide Set Screws*.

**Adjustment of Gib Slide Set Screws.**—5) Using a small precision screwdriver loosen the gib slide set screws then retighten evenly with a slight pressure.

- a) It is important that both set screws are tightened evenly and a slight resistance is felt in the sliding jaw full range movement.
- 6) Operate the UUT several times over its full range to ensure that the sliding jaw can be moved smoothly over the full length of the beam.

7) Repeat steps 1 through 3 to verify the Jaw Parallelism in within tolerance as stated in Table 2 for Outside Jaws.

8) If the readings are within tolerance, proceed to *Calibration of Outside Jaws*. If readings are not within tolerance, record all readings as "As Found" and consult the end user to determine the course of action that they desire. Excessive damage or wear to the Jaws, Nibs or ID measuring contacts can result in a high degree of uncertainty in all measurements taken with the instrument and is cause for concern. Consideration of these facts should be addressed before proceeding.

**Calibration of Outside Jaws.**—1) Slide the UUT jaws together and tighten the sliding jaw set screw.

- 2) Set zero for this calibration measurement.
  - a) For vernier calipers close the jaws and observe the alignment of the zero indication on the main scale and vernier scale.
  - b) For dial calipers, adjust the bezel for proper zero indication.
  - c) For digital calipers, press the ZERO set button on the face of the UUT. Verify the digital indication is between  $-0.0005$  and  $+0.0005$ .
- 3) Loosen the sliding jaw lock screw. Open and close the sliding jaw to verify repeatability of the zero setting.
  - a) For digital calipers, loosen the jaw set screw and open the calipers to a mid-point location. Lock the jaw set screw then press the zero set switch on the front of the instrument. Verify the digital indication is between  $-0.0005$  and  $+0.0005$ . Close the slide jaw and zero the instrument.
- 4) Select the gage blocks needed to check the caliper at the test points listed below:
  - a) For dial calipers, select the proper gage blocks to check the caliper at the 3 o'clock, 6 o'clock, 9 o'clock and 12 o'clock positions of the dial face in the first inch. (0.125, 0.550, 0.675, 1.000)
  - b) For digital and vernier calipers, select gage blocks equal to 25, 50, 75, 100 percent of the first inch (0.250, 0.500, 0.750 and 1.000 inches).
- 5) Select the gage blocks needed to check the UUT at 25, 50, 75, and 100 percent of full scale. Place the UUT and all gage blocks on the surface plate for a minimum of 15 minutes to stabilize. The gage blocks should have both working surfaces exposed, as in Fig. 29.

Fig. 29. Gage Blocks and End Blocks Staged for Calibration of 6-inch Dial Caliper

6) Open the outside jaws and measure the gage block that equates to the first test point defined in step 4. Ensure that the jaws are squarely placed with a slight pressure against the gage block measuring surfaces. Use the thumb wheel or fine adjust to apply gentle but steady pressure against the gage block. Rock the caliper gently to ensure that the OD measuring faces are seated squarely. Seek the smallest reading obtainable with gentle pressure. Record the value.

7) Repeat **Item 6)** for remaining test points defined in **Item 4)**, parts a) and b), and **Item 5)**.

8) If the outside jaws are within tolerance, proceed to the next section: *Calibration of Inside Dimension Jaws (Nibs)*. If the outside jaws are found Out of Tolerance, continue through each calibration section and record all data as "As Found" prior to any further adjustments. Upon completion of procedure, report any out of tolerance conditions that may have been discovered. *Any out of tolerance conditions must be addressed before returning the UUT to service.*

**Calibration of Inside Dimension Jaws (Nibs).**—1) Select the gage block needed to check the UUT at the first test point as defined above in **Item 4)** of *Calibration of Outside Jaws*. Clean the surface of the gage block and end blocks with lint free wipe and alcohol and assemble the Accessory End Blocks and assure they are secured in position snugly.

2) Close the caliper jaws and assure the dial or digital indication or vernier scale indicate zero.

3) Measure the dimension of the gage block as illustrated in **Fig. 30**. Use a gentle rocking motion to assure that the jaws are seated squarely. Seek the lowest reading as this is the true distance between the parallel faces of the end blocks.

*Note:* Excessive force must be avoided as this can cause deformation of the UUT jaws and result in erroneous readings. A gentle consistent feel must be used to provide an accurate reading. If too much force is applied or the ID measuring jaws are not in line and perpendicular to the parallel planes of the end blocks, a larger and unrepeatable reading will result. Repeat all measurements several times to assure that you have a true reading.

Fig. 30. Inside Dimension Measurement of Gage Blocks using Accessory End Blocks

4) Repeat the set up and readings at the 3 o'clock, 6 o'clock, 9 o'clock and 12 o'clock positions of the dial face in the first inch. For vernier and digital calipers measure at 0.250, 0.500, 0.750 and 1.000 inches. Record all readings.

5) Measure the remainder of the length of the UUT at 25, 50, 75, and 100 percent of full scale. Select the appropriate gage blocks and assemble as illustrated in Fig. 30. Measure each test point and record all readings.

**Calibration of Depth Rod.**—1) Select a 1.000 inch gage block and position it on the surface plate with the measuring surface against the plate.

2) Close the caliper jaws completely and place the end of the main beam flat on the surface plate in a vertical position. Apply slight downward pressure bringing the depth rod in contact with the surface plate. Zero the dial or display at this point.

- a) Type 1 Class 1 calipers do not have depth measurement capability.
- b) Type 1 Class 2 have a depth rod that is directly tied to the Vernier Scale. If the Zero Reading is OOT (out of tolerance) at this point the depth rod will require service or replacement.

Fig. 31. Caliper Depth Rod Extended through Center Relief Hole of Gage Block.

3) Place the caliper depth rod through the center relief hole of the gage block and extend the rod to make contact with the surface plate as shown in Fig. 31. Assure that the end of the main beam is seated squarely on the surface of the gage block. Apply gently downward pressure with the thumb wheel until contact on the surface plate is felt. Using the thumb wheel, lift the depth rod and re-apply contact to repeat the measurement. Confirm the measurement repeats before accepting.

- a) Alternately, the depth rod can be extended down the outside of the gage block while in direct contact with the outer surface. The end of the main beam is squarely in contact with the surface of the gage block. This method can be used with a rectangular gage block that has no center relief hole or to assure a square contact between the end of the main beam and the depth rod.
- 4) If the depth rod is determined to be within tolerance, proceed to the next section, *Calibration of Step Height*. If the depth rod is found out of tolerance, continue through

each calibration section and record all data as "As Found" prior to any further action. Upon completion of procedure, report any out of tolerance conditions that may have been discovered. *Any out of tolerance conditions must be addressed before returning the UUT to service.*

**Calibration of Step Height.**—1) Close the caliper jaws completely and set zero on the dial or display.

2) Place the caliper head downward on the surface plate as shown in Fig. 32.

Fig. 32. Step Height Measurement with Gage Block in Position behind Main Beam Engaging Step Height Measurement Surface

3) Open the caliper jaws to accommodate the measurement of a 1.000 inch gage block by the Step Height measuring surface on the back side of the moveable jaw.

4) Bring the *Step Height* measuring surface into contact with the surface of the gage block. Assure the back of the main beam is in direct contact with the outside of the gage block to establish a good perpendicular condition.

5) Apply gently downward pressure with the thumb wheel.

6) Repeat the measurement several times to confirm repeatability before accepting the measurement.

7) Record the measurement. There is no adjustment for this feature.

8) If the Step Height is determined to be within tolerance, remove and store all standards in their appropriate containers and apply any corrosion protection methods as required. If the step height is found Out of Tolerance, record all data as "As Found" prior to any further action. Upon completion of procedure, report any out of tolerance conditions that may have been discovered. *Any out of tolerance conditions must be addressed before returning the UUT to service.*

Note: Indicated Measurement Error tolerances for UUT with 0.001 inch graduations (no vernier scale) are set to  $\pm 0.001$  inch up to 30 inch, and  $\pm 0.002$  inch from 31 to 36 inch. Tolerances of UUT over 36 inch are subject to manufacturer's specification. Tolerance for UUT with a resolution of 50  $\mu$ m shall be  $\pm 50 \mu$ m for 0-1 inch;  $\pm 0.0001$  inch for 1 through 4 inches;  $\pm 0.0002$  inch for 4 three 9 inches;  $\pm 0.0003$  inch for 9 three 12 inches;  $\pm 0.0004$  inch for 12 to 18 inches;  $\pm 0.0005$  for 18 to 24 inches;  $\pm 0.0006$  for 24 to 30 inches; and  $\pm 0.0007$  for 30 to 36 inches. All metric equivalents shall apply to UUT of this resolution. Metric Scale UUT with 0.01 mm graduations are set at  $\pm 0.01$  mm for up to 300 mm. Tolerances above 300 mm are subject to manufacturers specifications.

## SURFACE TEXTURE

**American National Standard Surface Texture  
(Surface Roughness, Waviness, and Lay)**

American National Standard ANSI/ASME B46.1-2009 is concerned with the geometric irregularities of surfaces of solid materials, physical specimens for gaging roughness, and the characteristics of stylus instrumentation for measuring roughness. The standard defines surface texture and its constituents: roughness, waviness, lay, and flaws. A set of symbols for drawings, specifications, and reports is established. To ensure a uniform basis for measurements, the standard also provides specifications for Precision Reference Specimens, and Roughness Comparison Specimens, and establishes requirements for stylus-type instruments. The standard is not concerned with luster, appearance, color, corrosion resistance, wear resistance, hardness, subsurface microstructure, surface integrity, or many other characteristics that may govern considerations in specific applications.

The standard is expressed in SI metric units, but US customary units may be used without prejudice. The standard does not define the degrees of surface roughness and waviness or type of lay suitable for specific purposes, nor does it specify the means by which any degree of such irregularities may be obtained or produced. However, criteria for selection of surface qualities and information on instrument techniques and methods of producing, controlling and inspecting surfaces are included in Appendixes attached to the standard. The Appendix sections are not considered a part of the standard: they are included for clarification or information purposes only.

Surfaces, in general, are very complex in character. The standard deals only with the height, width, and direction of surface irregularities because these characteristics are of practical importance in specific applications. Surface texture designations as delineated in this standard may not be a sufficient index to performance. Other part characteristics such as dimensional and geometrical relationships, material, metallurgy, and stress must also be controlled.

**Definitions of Terms Relating to the Surfaces of Solid Materials.**—The terms and ratings in the standard relate to surfaces produced by such means as abrading, casting, coating, cutting, etching, plastic deformation, sintering, wear, and erosion.

*Error of form* is considered to be that deviation from the nominal surface caused by errors in machine tool ways, guides, insecure clamping or incorrect alignment of the workpiece or wear, none of which are included in surface texture. Out-of-roundness and out-of-flatness are examples of errors of form. See ANSI/ASME B89.3.1-1972 (R2003) for measurement of out-of-roundness.

*Flaws* are unintentional, unexpected, and unwanted interruptions in the topography typical of a part surface and are defined as such only when agreed upon by buyer and seller. If flaws are defined, the surface should be inspected specifically to determine whether flaws are present, and rejected or accepted prior to performing final surface roughness measurements. If defined flaws are not present, or if flaws are not defined, then interruptions in the part surface may be included in roughness measurements.

*Lay* is the direction of the predominant surface pattern, ordinarily determined by the production method used.

*Roughness* consists of the finer irregularities of the surface texture, usually including those irregularities that result from the inherent action of the production process. These irregularities are considered to include traverse feed marks and other irregularities within the limits of the roughness sampling length.

*Surface* is the boundary of an object that separates that object from another object, substance or space.

*Surface, measured* is the real surface obtained by instrumental or other means.

Fig. 1. Pictorial Display of Surface Characteristics

*Surface, nominal* is the intended surface contour (exclusive of any intended surface roughness), the shape and extent of which is usually shown and dimensioned on a drawing or descriptive specification.

*Surface, real* is the actual boundary of the object. Manufacturing processes determine its deviation from the nominal surface.

*Surface texture* is repetitive or random deviations from the real surface that forms the three-dimensional topography of the surface. Surface texture includes roughness, waviness, lay and flaws. Fig. 1 is an example of a unidirectional lay surface. Roughness and waviness parallel to the lay are not represented in the expanded views.

*Waviness* is the more widely spaced component of surface texture. Unless otherwise noted, waviness includes all irregularities whose spacing is greater than the roughness sampling length and less than the waviness sampling length. Waviness may result from

such factors as machine or work deflections, vibration, chatter, heat treatment, or warping strains. Roughness may be considered as being superposed on a 'wavy' surface.

**Definitions of Terms Relating to the Measurement of Surface Texture.**—Terms regarding surface texture pertain to the geometric irregularities of surfaces and include roughness, waviness and lay.

*Profile* is the contour of the surface in a plane measured normal, or perpendicular, to the surface, unless another angle is specified.

*Graphical centerline.* See Mean Line.

*Height ( $z$ )* is considered to be those measurements of the profile in a direction normal, or perpendicular, to the nominal profile. For digital instruments, the profile  $Z(x)$  is approximated by a set of digitized values. Height parameters are expressed in micrometers ( $\mu\text{m}$ ).

*Height range ( $z$ )* is the maximum peak-to-valley surface height that can be detected accurately with the instrument. It is measurement normal, or perpendicular, to the nominal profile and is another key specification.

*Mean line ( $M$ )* is the line about which deviations are measured and is parallel to the general direction of the profile within the limits of the sampling length. See Fig. 2. The mean line may be determined in one of two ways. The filtered mean line is the centerline established by the selected cutoff and its associated circuitry in an electronic roughness average measuring instrument. The least squares mean line is formed by the nominal profile, but by dividing into selected lengths the sum of the squares of the deviations minimizes the deviation from the nominal form. The form of the nominal profile could be a curve or a straight line.

*Peak* is the point of maximum height on that portion of a profile that lies above the mean line and between two intersections of the profile with the mean line.

*Profile measured* is a representation of the real profile obtained by instrumental or other means. When the measured profile is a graphical representation, it will usually be distorted through the use of different vertical and horizontal magnifications but shall otherwise be as faithful to the profile as technically possible.

*Profile, modified* is the measured profile where filter mechanisms (including the instrument datum) are used to minimize certain surface texture characteristics and emphasize others. Instrument users apply profile modifications typically to differentiate surface roughness from surface waviness.

*Profile, nominal* is the profile of the nominal surface; it is the intended profile (exclusive of any intended roughness profile). Profile is usually drawn in an  $x$ - $z$  coordinate system. See Fig. 2.

Fig. 2. Nominal and Measured Profiles

*Profile, real* is the profile of the real surface.

*Profile, total* is the measured profile where the heights and spacing may be amplified differently, but otherwise no filtering takes place.

*Roughness profile* is obtained by filtering out the longer wavelengths characteristic of waviness.

*Roughness spacing* is the average spacing between adjacent peaks of the measured profile within the roughness sampling length.

*Roughness topography* is the modified topography obtained by filtering out the longer wavelengths of waviness and form error.

*Sampling length* is the nominal spacing within which a surface characteristic is determined. The range of sampling lengths is a key specification of a measuring instrument.

*Spacing* is the distance between specified points on the profile measured parallel to the nominal profile.

*Spatial ( $x$ ) resolution* is the smallest wavelength that can be resolved to 50 percent of the actual amplitude. This also is a key specification of a measuring instrument.

*System height resolution* is the minimum height that can be distinguished from background noise of the measurement instrument. Background noise values can be determined by measuring approximate rms roughness of a sample surface where actual roughness is significantly less than the background noise of the measuring instrument. It is a key instrumentation specification.

*Topography* is the three-dimensional representation of geometric surface irregularities.

*Topography, measured* is the three-dimensional representation of geometric surface irregularities obtained by measurement.

*Topography, modified* is the three-dimensional representation of geometric surface irregularities obtained by measurement but filtered to minimize certain surface characteristics and accentuate others.

*Valley* is the point of maximum depth on that portion of a profile that lies below the mean line and between two intersections of the profile with the mean line.

*Waviness, evaluation length ( $L$ )*, is the length within which waviness parameters are determined.

*Waviness, long-wavelength cutoff ( $lcw$ )* is the spatial wavelength above which the undulations of waviness profile are removed to identify form parameters. A digital Gaussian filter can be used to separate form error from waviness, but its use must be specified.

*Waviness profile* is obtained by filtering out the shorter roughness wavelengths characteristic of roughness and the longer wavelengths associated with the part form parameters.

*Waviness sampling length* is a concept no longer used. See waviness long-wavelength cutoff and waviness evaluation length.

*Waviness short-wavelength cutoff ( $lsw$ )* is the spatial wavelength below which roughness parameters are removed by electrical or digital filters.

*Waviness topography* is the modified topography obtained by filtering out the shorter wavelengths of roughness and the longer wavelengths associated with form error.

*Waviness spacing* is the average spacing between adjacent peaks of the measured profile within the waviness sampling length.

**Sampling Lengths.**—Sampling length is the normal interval for a single value of a surface parameter. Generally it is the longest spatial wavelength to be included in the profile measurement. Range of sampling lengths is an important specification for a measuring instrument.

Fig. 3. Traverse Length

*Roughness sampling length ( $l$ )* is the sampling length within which the roughness average is determined. This length is chosen to separate the profile irregularities designated as roughness from those irregularities designated as waviness. It is different from evaluation length ( $L$ ) and the traversing length. See Fig. 3.

*Evaluation length ( $L$ )* is the length the surface characteristics are evaluated. The evaluation length is a key specification of a measuring instrument.

*Traversing length* is the profile length traversed to establish a representative evaluation length. It is always longer than the evaluation length. See Section 4.4.4 of ANSI/ASME B46.1-2009 for values that should be used for different types of measurements.

*Cutoff* is the electrical response characteristic of the measuring instrument which is selected to limit the spacing of the surface irregularities to be included in the assessment of surface texture. Cutoff is rated in millimeters. In most electrical averaging instruments, the cutoff can be user-selected and is a characteristic of the instrument rather than of the surface being measured. In specifying the cutoff, care must be taken to choose a value that will include all the surface irregularities to be assessed.

*Waviness sampling length ( $l$ )* is a concept no longer used. See waviness long-wavelength cutoff and waviness evaluation length.

**Roughness Parameters.**—Roughness refers to the fine irregularities of the surface texture resulting from the production process or material condition.

*Roughness average ( $R_a$  or  $R_a$ )*, also known as arithmetic average (AA), is the arithmetic average of the absolute values of the measured profile height deviations divided by the evaluation length,  $L$ . This is shown as the shaded area of Fig. 4 and generally includes sampling lengths or cutoffs. For graphical determinations of roughness average, the height deviations are measured normal, or perpendicular, to the chart center line.

Fig. 4.

Roughness average is expressed in micrometers ( $\mu\text{m}$ ). A micrometer is one millionth of a meter (0.000001 meter). A microinch ( $\mu\text{in}$ ) is one millionth of an inch (0.000001 inch). One microinch equals 0.0254 micrometer ( $1 \mu\text{in.} = 0.0254 \mu\text{m}$ ).

*Roughness average ( $R_a$ ) value from continuously averaging meter reading* may be made of readings from stylus-type instruments of the continuously averaging type. To ensure uniform interpretation, it should be understood that the reading that is considered significant is the mean reading around which the needle tends to dwell or fluctuate with a small amplitude.

Roughness is also indicated by the root-mean-square (rms) average, which is the square root of the average value squared, within the evaluation length and measured from the mean line shown in Fig. 4, expressed in micrometers. A roughness-measuring instrument calibrated for rms average usually reads about 11 percent higher than an instrument calibrated for arithmetical average. Such instruments usually can be recalibrated to read arithmetical average. Some manufacturers consider the difference between rms and AA to be small enough that rms on a drawing may be read as AA for many purposes.

*Roughness evaluation length* ( $L$ ), for statistical purposes should, whenever possible, consist of five sampling lengths ( $l$ ). Use of other than five sampling lengths must be clearly indicated.

**Waviness Parameters.**—Waviness is the more widely spaced component of surface texture. Roughness may be thought of as superimposed on waviness.

*Waviness height* ( $Wt$ ) is the peak-to-valley height of the modified profile with roughness and part form errors removed by filtering, smoothing or other means. This value is typically three or more times the roughness average. The measurement is taken normal, or perpendicular, to the nominal profile within the limits of the waviness sampling length.

*Waviness evaluation length* ( $L_w$ ) is the evaluation length required to determine waviness parameters. For waviness, the sampling length concept is no longer used. Rather, only waviness evaluation length ( $L_w$ ) and waviness long-wavelength cutoff ( $l_w$ ) are defined. For better statistics, the waviness evaluation length should be several times the waviness long-wavelength cutoff.

**Relation of Surface Roughness to Tolerances.**—Because the measurement of surface roughness involves the determination of the average linear deviation of the measured surface from the nominal surface, there is a direct relationship between the dimensional tolerance on a part and the permissible surface roughness. It is evident that a requirement for the accurate measurement of a dimension is that the variations introduced by surface roughness should not exceed the dimensional tolerances. If this is not the case, the measurement of the dimension will be subject to an uncertainty greater than the required tolerance, as illustrated in Fig. 5.

Fig. 5.

The standard method of measuring surface roughness involves the determination of the average deviation from the mean surface. On most surfaces the total profile height of the surface roughness (peak-to-valley height) will be approximately four times ( $4\times$ ) the measured average surface roughness. This factor will vary somewhat with the character of the surface under consideration, but the value of four may be used to establish approximate profile heights.

From these considerations it follows that if the arithmetical average value of surface roughness specified on a part exceeds one eighth of the dimensional tolerance, the whole tolerance will be taken up by the roughness height. In most cases, a smaller roughness specification than this will be found; but, on parts where very small dimensional tolerances are given, it is necessary to specify a suitably small surface roughness so useful dimensional measurements can be made. The tables on pages 648 and 674 show the relations between machining processes and working tolerances.

Values for surface roughness produced by common processing methods are shown in Table 1. The ability of a processing operation to produce a specific surface roughness depends on many factors. For example, in surface grinding, the final surface depends on the peripheral speed of the wheel, the speed of the traverse, the rate of feed, the grit size, bonding material and state of dress of the wheel, the amount and type of lubrication at the

point of cutting, and the mechanical properties of the piece being ground. A small change in any of the above factors can have a marked effect on the surface produced.

**Table 1. Surface Roughness Produced by Common Production Methods**

Process	Roughness Average, Ra - Micrometers $\mu\text{m}$ (Microinches $\mu\text{in}$ )												
	50 (2000)	25 (1000)	12.5 (500)	6.3 (250)	3.2 (125)	1.6 (63)	0.80 (32)	0.40 (16)	0.20 (8)	0.10 (4)	0.05 (2)	0.025 (1)	0.012 (0.5)

**Instrumentation for Surface Texture Measurement.**—Instrumentation used for measurement of surface texture, including roughness and waviness generally falls into six types. These include:

*Type I, Profiling Contact Skidless Instruments:* Used for very smooth to very rough surfaces. Used for roughness and may measure waviness. Can generate filtered or unfiltered profiles and may have a selection of filters and parameters for data analysis. Examples include: 1) skidless stylus-type with LVDT (linear variable differential transformer) vertical transducers; 2) skidless-type using an interferometric transducer; 3) skidless stylus-type using capacitance transducer.

*Type II, Profiling Non-contact Instruments:* Capable of full profiling or topographical analysis. Non-contact operation may be advantageous for softness but may vary with sample type and reflectivity. Can generate filtered or unfiltered profiles but may have difficulty with steeply inclined surfaces. Examples include: 1) interferometric microscope; 2) optical focus sensing; 3) Nomarski differential profiling; 4) laser triangulation; 5) scanning electron microscope (SEM) stereoscopy; 6) confocal optical microscope.

*Type III, Scanned Probe Microscope:* Features high spatial resolution (at or near the atomic scale) but area of measurement may be limited. Examples include: 1) scanning tunneling microscope (STM) and 2) atomic force microscope (AFM).

*Type IV, Profiling Contact Skidded Instruments:* Uses a skid as a datum to eliminate longer wavelengths; thus cannot be used for waviness or errors of form. May have a selection of filters and parameters and generates an output recording of filtered and skid-modified profiles. Examples include: 1) skidded, stylus-type with LVDT vertical measuring transducer and 2) fringe-field capacitance (FFC) transducer.

*Type V, Skidded Instruments with Parameters Only:* Uses a skid as a datum to eliminate longer wavelengths; thus cannot be used for waviness or errors of form. Does not generate a profile. Filters are typically 2RC type and generate Ra, but other parameters may be available. Examples include: 1) skidded, stylus-type with piezoelectric measuring transducer and 2) skidded, stylus-type with moving coil measuring transducer.

*Type VI, Area Averaging Methods:* Used to measure averaged parameters over defined areas, but do not generate profiles. Examples include: 1) parallel plate capacitance (PPC) method; 2) total integrated scatter (TIS); 3) angle resolved scatter (ARS)/bi-directional reflectance distribution function (BRDF).

**Selecting Cutoff for Roughness Measurements.**—In general, surfaces will contain irregularities with a large range of widths. Surface texture instruments are designed to respond only to irregularity spacings less than a given value, called cutoff. In some cases, such as surfaces in which actual contact area with a mating surface is important, the largest convenient cutoff will be used. In other cases, such as surfaces subject to fatigue failure, only the irregularities of small width will be important, and more significant values will be obtained when a short cutoff is used. In still other cases, such as identifying chatter marks on machined surfaces, information is needed on only the widely spaced irregularities. For such measurements, a large cutoff value and a larger radius stylus should be used.

The effect of variation in cutoff can be understood better by reference to Fig. 6. The profile at the top is the true movement of a stylus on a surface having a roughness spacing of about 1 mm and the profiles below are interpretations of the same surface with cutoff value settings of 0.8 mm, 0.25 mm and 0.08 mm, respectively. It can be seen that the trace based on 0.8 mm cutoff includes most of the coarse irregularities and all of the fine irregularities of the surface. The trace based on 0.25 mm excludes the coarser irregularities but includes the fine and medium fine. The trace based on 0.08 mm cutoff includes only the very fine irregularities. In this example, the effect of reducing the cutoff has been to reduce the roughness average indication. However, had the surface been made up only of irregularities as fine as those of the bottom trace, the roughness average values would have been the same for all three cutoff settings.

In other words, all irregularities having a spacing less than the value of the cutoff used are included in a measurement. Obviously, if the cutoff value is too small to include coarser irregularities of a surface, the measurements will not agree with those taken with a larger cutoff. For this reason, care must be taken to choose a cutoff value which will include all of the surface irregularities it is desired to assess.

To become proficient in the use of continuously averaging stylus-type instruments, the inspector or machine operator must realize that for uniform interpretation the reading considered significant is the mean reading around which the needle tends to dwell or fluctuate under small amplitude.

**Drawing Practices for Surface Texture Symbols.**—American National Standard ANSI/ASME Y14.36-2018 establishes the method to designate symbolic controls for surface texture of solid materials. It includes methods for controlling roughness, waviness, and lay, and provides a set of symbols for use on drawings, specifications, or other documents. The standard is expressed in SI metric units, but US customary units may be used without prejudice. Units used (metric or non-metric) should be consistent with the other units used on the drawing or documents. Approximate non-metric equivalents are shown for reference.

Fig. 6. Effects of Various Cutoff Values

**Surface Texture Symbol.**—The symbol used to designate control of surface irregularities is shown in Fig. 7b and Fig. 7d. Where surface texture values other than roughness average are specified, the symbol must be drawn with the horizontal extension as shown in Fig. 7f.

*Use of Surface Texture Symbols:* When required from a functional standpoint, the desired surface characteristics should be specified. Where no surface texture control is specified, the surface produced by normal manufacturing methods is satisfactory provided it is within the limits of size (and form) specified in accordance with ASME Y14.5-2018, Dimensioning and Tolerancing. It is considered good practice to always specify some maximum value, either specifically or by default (for example, in the manner of the note shown in Fig. 8 on page 818).

*Material Removal Required or Prohibited:* The surface texture symbol is modified when necessary to require or prohibit removal of material. When it is necessary to indicate that a surface must be produced by removal of material by machining, specify the symbol shown in Fig. 7b. When required, the amount of material to be removed is specified, as shown in Fig. 7c, in millimeters for metric drawings and in inches for non-metric drawings. Tolerance for material removal may be added to the basic value shown or specified in a general note. When it is necessary to indicate that a surface must be produced without material removal, specify the machining prohibited symbol as shown in Fig. 7d.

*Proportions of Surface Texture Symbols:* The recommended proportions for drawing the surface texture symbol are shown in Fig. 7f. The letter height and line width should be the same as those for dimensions and dimension lines.

## Surface Texture Symbols and Construction

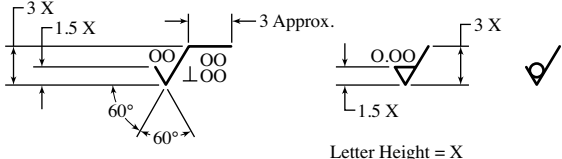

Symbol	Meaning
 Fig. 7a.	Basic Surface Texture Symbol. Surface may be produced by any method except when the bar or circle (Fig. 7b or Fig. 7d) is specified.
 Fig. 7b.	Material Removal By Machining Is Required. The horizontal bar indicates that material removal by machining is required to produce the surface and that material must be provided for that purpose.
 Fig. 7c.	Material Removal Allowance. The number indicates the amount of stock to be removed by machining in millimeters (or inches). Tolerances may be added to the basic value shown or in general note.
 Fig. 7d.	Material Removal Prohibited. The circle in the V-shape indicates that the surface must be produced by processes such as casting, forging, hot finishing, cold finishing, die casting, powder metallurgy or injection molding without subsequent removal of material.
 Fig. 7e.	Surface Texture Symbol. To be used when any surface characteristics are specified above the horizontal line or the right of the symbol. Surface may be produced by any method except when the bar or circle (Fig. 7b and Fig. 7d) is specified.
 Letter Height = X	

Fig. 7f.

**Applying Surface Texture Symbols.**—The point of the symbol should be on a line representing the surface, an extension line of the surface, or a leader line directed to the surface, or to an extension line. The symbol may be specified following a diameter dimension. Although ASME Y14.5-2018, “Dimensioning and Tolerancing,” specifies that normally all textual dimensions and notes should be read from the bottom of the drawing, the surface texture symbol itself with its textual values may be rotated as required. Regardless, the long leg (and extension) must be to the right as the symbol is read. For parts requiring extensive and uniform surface roughness control, a general note may be added to the drawing that applies to each surface texture symbol specified without values as shown in Fig. 8.

When the symbol is used with a dimension, it affects the entire surface defined by the dimension. Areas of transition, such as chamfers and fillets, shall conform with the rough-text adjacent finished area unless otherwise indicated.

Surface texture values, unless otherwise specified, apply to the complete surface. Drawings or specifications for plated or coated parts shall indicate whether the surface texture values apply before plating, after plating, or both before and after plating.

Only those values required to specify and verify the required texture characteristics should be included in the symbol. Values should be in metric units for metric drawing and non-metric units for non-metric drawings. Minority units on dual dimensioned drawings are enclosed in brackets.

Fig. 8. Application of Surface Texture Symbols

Roughness and waviness measurements, unless otherwise specified, apply in a direction which gives the maximum reading, generally across the lay.

*Cutoff or Roughness Sampling Length, (l):* Standard values are listed in Table 2. When no value is specified, the value 0.8 mm (0.030 in.) applies.

**Table 2. Standard Roughness Sampling Length (Cutoff) Values**

mm	in.	mm	in.
0.08	0.003	2.5	0.1
0.25	0.010	8.0	0.3
0.80	0.030	25.0	1.0

*Roughness Average (Ra or  $R_a$ ):* The preferred series of specified roughness average values is given in Table 3.

**Table 3. Preferred Series Roughness Average (Ra) Values**

$\mu\text{m}$	$\mu\text{in}$	$\mu\text{m}$	$\mu\text{in}$	$\mu\text{m}$	$\mu\text{in}$
0.012	0.5	0.40 <sup>a</sup>	16 <sup>a</sup>	4.0	160

0.005	0.0002	0.08	0.003	0.80	0.030

**Lay:** Symbols for designating the direction of lay are shown and interpreted in Table 5.

**Example Designations.**—Table 6 illustrates examples of designations of roughness, waviness, and lay by insertion of values in appropriate positions relative to the symbol.

Where surface roughness control of several operations is required within a given area or on a given surface, surface qualities may be designated, as in Fig. 9a. If a surface must be produced by one particular process or a series of processes, they should be specified as shown in Fig. 9b. Where special requirements are needed on a designated surface, a note should be added at the symbol giving the requirements and the area involved. An example is illustrated in Fig. 9c.

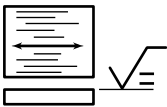

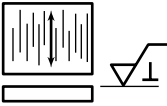

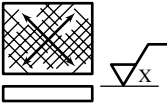

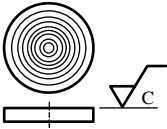

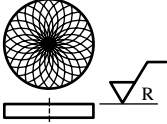

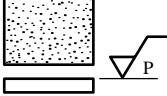

**Surface Texture of Castings.**—Surface characteristics should not be controlled on a drawing or specification unless such control is essential to functional performance or appearance of the product. Imposition of such restrictions when unnecessary may increase production costs and in any event will serve to lessen the emphasis on the control specified for important surfaces. Surface characteristics of castings should never be considered on the same basis as machined surfaces. Castings are characterized by random distribution of nondirectional deviations from the nominal surface.

Surfaces of castings rarely need control beyond that provided by the production method necessary to meet dimensional requirements. Comparison specimens are frequently used for evaluating surfaces having specific functional requirements. Surface texture control should not be specified unless required for appearance or function of the surface. Specification of such requirements may increase cost to the user.

Engineers should recognize that different areas of the same castings may have different surface textures. It is recommended that specifications of the surface be limited to defined areas of the casting. Practicality of and methods of determining that a casting's surface texture meets the specification shall be coordinated with the producer. The Society of Automotive Engineers standard J435 "Automotive Steel Castings" describes methods of evaluating steel casting surface texture used in the automotive and related industries.

**Metric Dimensions on Drawings.**—The length units of the metric system most generally used in connection with any work relating to mechanical engineering are the meter (39.37 inches) and the millimeter (0.03937 inch). One meter equals 1000 millimeters. On mechanical drawings, all dimensions are generally given in millimeters, no matter how large the dimensions may be. In fact, dimensions of such machines as locomotives and large electrical apparatus are given exclusively in millimeters. This practice is adopted to avoid mistakes due to misplacing decimal points, or misreading dimensions as when other units are used as well. When dimensions are given in millimeters, many of them can be given without resorting to decimal points, as a millimeter is only a little more than  $\frac{1}{25}$  inch. Only dimensions of precision need be given in decimals of a millimeter; such dimensions are generally given in hundredths of a millimeter—for example, 0.02 millimeter, which is equal to 0.0008 inch. As 0.01 millimeter is equal to 0.0004 inch, dimensions are seldom given with greater accuracy than to hundredths of a millimeter.

**Table 5. Lay Symbols**

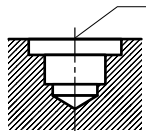

Lay Symbol	Meaning	Example Showing Direction of Tool Marks
<b>=</b>	Lay approximately parallel to the line representing the surface to which the symbol is applied.	
<b>⊥</b>	Lay approximately perpendicular to the line representing the surface to which the symbol is applied.	
<b>X</b>	Lay angular in both directions to line representing the surface to which the symbol is applied.	
<b>M</b>	Lay multidirectional.	
<b>C</b>	Lay approximately circular relative to the center of the surface to which the symbol is applied.	
<b>R</b>	Lay approximately radial relative to the center of the surface to which the symbol is applied.	
<b>P</b>	Lay particulate, nondirectional, or protuberant.	

*Scales of Metric Drawings:* Drawings made to the metric system are not made to scales of  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ , etc., as with drawings made to the English system. If the object cannot be drawn full size, it may be drawn  $\frac{1}{2}$ ,  $\frac{1}{5}$ ,  $\frac{1}{10}$ ,  $\frac{1}{20}$ ,  $\frac{1}{50}$ ,  $\frac{1}{100}$ ,  $\frac{1}{200}$ ,  $\frac{1}{500}$ , or  $\frac{1}{1000}$  size. If the object is too small and has to be drawn larger, it is drawn 2, 5, or 10 times its actual size.

**Table 6. Application of Surface Texture Values to Symbol ANSI B46.1-1978**

	Roughness average rating is placed at the left of the long leg. The specification of only one rating shall indicate the maximum value, and any lesser value shall be acceptable. Specify in micrometers (microinch).
	Material removal by machining is required to produce the surface. The basic amount of stock provided for material removal is specified at the left of the short leg of the symbol. Specify in millimeters (inch).
	The specification of maximum and minimum roughness average values indicates permissible range of roughness. Specify in micrometers (microinch).
	Removal of material is prohibited.
	Maximum waviness height rating is the first rating place above the horizontal extension. Any lesser rating shall be acceptable. Specify in millimeters (inch). Maximum waviness spacing rating is the second rating placed above the horizontal extension and to the right of the waviness height rating. Any lesser rating shall be acceptable. Specify in millimeters (inch).
	Lay designation is indicated by the lay symbol placed at the right of the long leg.
	Roughness sampling length or cutoff rating is placed below the horizontal extension. When no value is shown, 0.80 mm (0.030 inch) applies. Specify in millimeters (inch).
	Where required, maximum roughness spacing shall be placed at the right of the lay symbol. Any lesser rating shall be acceptable. Specify in millimeters (inch).

## ISO Surface Finish Standards

ISO surface finish standards are comprised of numerous individual standards that, taken as a whole, form a set of standards roughly comparable in scope to American National Standard ANSI/ASME Y14.36.

**ISO Surface Finish (ISO 1302).**—The primary standard dealing with surface finish, ISO 1302:2002 is concerned with the methods of specifying surface texture symbology and additional indications on engineering drawings. The parameters in ISO surface finish standards relate to surfaces produced by abrading, casting, coating, cutting, etching, plastic deformation, sintering, wear, erosion, and some other methods.

ISO 1302 defines how surface texture and its constituents, roughness, waviness, and lay, are specified on the symbology. Surface defects are specifically excluded from consideration during inspection of surface texture, but definitions of flaws and imperfections are discussed in ISO 8785.

<p>✓ Basic symbol for surface under consideration or to a specification explained elsewhere in a note. The textual indication is APA (any process allowed)</p> <p>✓ Basic symbol for material removal is required, for example machining. The textual indication is MRR (material removal required)</p> <p>✓ Basic symbol where material removal is not permitted. The textual indication is NMR (no material removed)</p> <p>○ Basic symbol with all round circle added to indicate the specification applies to all surfaces in the view shown in profile (outline)</p>	<p>Position of complementary requirements: all values in millimeters</p>
Text height $h$ (ISO 3098-2)	2.5 3.5 5 7 10 14 20
Line width for symbols $d$ and $d'$	0.25 0.35 0.5 0.7 1 1.2 2
Height for segment $x$	3.5 5 7 10 14 20 28
Height for symbol segment $x'$	7.5 10.5 15 21 30 42 60

Fig. 1. ISO Surface Finish Symbols

*Differences Between ISO and ANSI/ASME Surface Finish Symbology:* ISO 1302, like ANSI/ASME Y14.36-2018, is not concerned with luster, appearance, color, corrosion resistance, wear resistance, hardness, sub-surface microstructure, surface integrity, or many other characteristics that may govern considerations in specific applications. Visually, ISO 1302 surface finish symbols are similar to the ANSI/ASME symbols; however, with the release of the 2002 edition, the indication of some of the parameters has changed when compared to ANSI/ASME Y14.36. The proportions of the symbol in

relationship to text height differs in each as well. There is now less harmonization between ANSI/ASME Y14.36 and ISO 1302 than has been the case previously.

**Table 1. Other ISO Standards Related to Surface Finish**

ISO 3274:1996	“Geometrical Product Specifications (GPS) — Surface texture: Profile method; Nominal characteristics of contact (stylus) instruments.”
ISO 4287:1997	“Geometrical Product Specifications (GPS) — Surface texture: Profile method; Terms, definitions and surface texture parameters.”
ISO 4288:1996	“Geometrical Product Specifications (GPS) — Surface texture: Profile method; Rules and procedures for the assessment of surface texture.”
ISO 8785:1998	“Geometrical Product Specifications (GPS) — Surface imperfections — Terms, definitions and parameters.”
ISO 12085:1996	“Geometrical Product Specifications (GPS) — Surface texture: Profile method — Motif parameters.”
ISO 13565-1:1996	“Geometrical Product Specifications (GPS) — Surface texture: Profile method; Surfaces having stratified functional properties Part 1: Filtering and general measurement conditions.” Part 2: Height characterization using the linear material ratio curve.” Part 3: Height characterization using the material probability curve.”
ISO 13565-2:1996	
ISO 13565-3:1998	

**Table 2. ISO Surface Parameter Symbols (ISO 4287:1997)**

$R_p$ = max height profile	$R\delta c$ = profile section height difference
$R_v$ = max profile valley depth	$l_p$ = sampling length - primary profile
$Rz^*$ = max height of the profile	$l_w$ = sampling length - waviness profile
$R_c$ = mean height of the profile	$l_r$ = sampling length - roughness profile
$R_t$ = total height of the profile	$l_n$ = evaluation length
$R_a$ = arithmetic mean deviation of the profile	$Z(x)$ = ordinate value
$R_q$ = root mean square deviation of the profile	$dZ/dX$ = local slope
$Rsk$ = skewness of the profile	$Z_p$ = profile peak height
$Rku$ = kurtosis of the profile	$Z_v$ = profile valley depth
$RSm$ = mean width of the profile	$Z_t$ = profile element height
$R\Delta q$ = root mean square slope of the profile	$X_s$ = profile element width
$Rmr$ = material ration of the profile	$MI$ = material length of the profile

**Graphic Symbology Textural Descriptions.**—New to this version of ISO 1302:2002 is the ability to add textual descriptions of the graphic symbology used on drawing. This gives specifications writers a consistent means to describe surface texture specification from within a body of text without having to add illustrations. See Fig. 1 for textual application definitions, then Fig. 2- Fig. 6 for applications of this concept.

ISO 1302:2002 does not define the degrees of surface roughness and waviness or type of lay for specific purposes, nor does it specify the means by which any degree of such irregularities may be obtained or produced. Also, errors of form such as out-of-roundness and out-of-flatness are not addressed in the ISO surface finish standards. This edition does better illustrate how surface texture indications can be used on castings to reflect machining allowances (Fig. 2) and how symbology can be attached to geometric dimensioning and tolerancing symbology (See Fig. 3).

Fig. 4. Indication of Bilateral Surface Specification Shown Textually and as Indicated on a Drawing

Fig. 5a. Indication of Manufacturing Processes or Related Information

Fig. 5b. Indication of Manufacturing Processes or Related Information

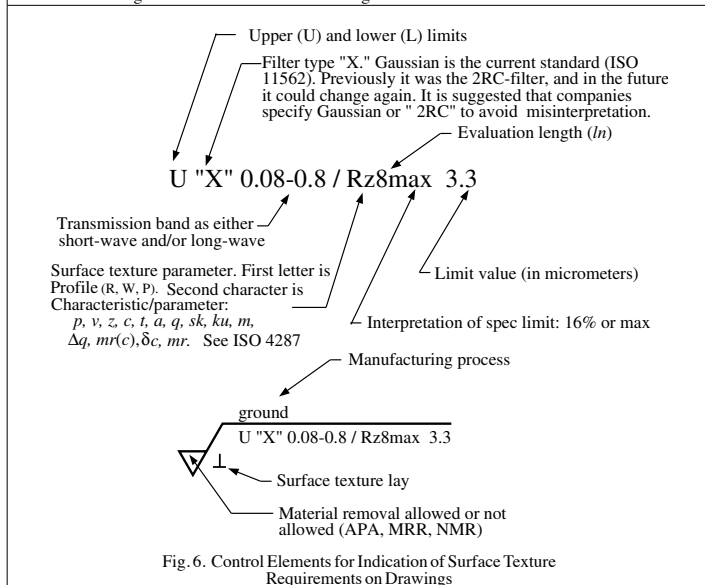

Fig. 6. Control Elements for Indication of Surface Texture Requirements on Drawings

**ISO Profiles.**—Profile parameters may be one of three types (ISO 4287). These include:

*R-profile:* Defined as the evaluation length. The ISO default length  $l_n$  consists of five sampling lengths  $l_r$ , thus  $l_n = 5 \times l_r$ .

*W-profile:* This parameter indicates waviness. There is no default length.

*P-profile:* Indicates the structure parameters. The default evaluation length is defined in ISO 4288: 1996.

**Rules for Comparing Measured Values to Specified Limits.**—

*Max Rule:* When a maximum requirement is specified for a surface finish parameter on a drawing (e.g.  $Rz1.5\max$ ), none of the inspected values may extend beyond the upper limit over the entire surface. The term “max” must be added to the parametric symbol in the surface finish symbology on the drawing.

*16%-Rule:* When upper and lower limits are specified, no more than 16% of all measured values of the selected parameter within the evaluation length may exceed the upper limit. No more than 16% of all measured values of the selected parameter within the evaluation length may be less than the lower limit.

*Exceptions to the 16%-Rule:* Where the measured values of roughness profiles being inspected follow a normal distribution, the 16%-rule may be overridden. This is allowed when greater than 16% of the measured values exceeds the upper limit, but the total roughness profile conforms with the sum of the arithmetic mean and standard deviation ( $\mu + \sigma$ ). Effectively, this means that the greater the value of  $\sigma$ , the further  $\mu$  must be from the upper limit (see Fig. 7).

Fig. 7. Roughness Parameter Value Curves Showing Mean and Standard Deviation

*Indications of Transmission Band and Sampling Length in Textual Format:* With the “16%-rule” transmission band as default it is shown textually and in drawings as:

MRR Ra 0.7; Rz1 3.3

If the “max-rule” transmission band is applied, it is shown textually and in drawings as:

MRR 0.0025-0.8 / Rz 3.0

Transmission band and sampling length are specified when there is no default value. The transmission band is indicated with the cut-off value of the filters in millimeters separated by a hyphen (-) with the short-wave filter first and the long-wave filter second. Again, in textual format and on drawings:

MRR 0.0025-0.8 / Rz 3.0

A specification may indicate one or both of the two transmission band filters. If only one is indicated, the hyphen is maintained to indicate whether the indication is the short-wave or the long-wave filter.

0.008- (short-wave filter indication) or -0.25 (long-wave filter indication)

**Determining Cut-off Wavelength:** When the sampling length is specified on the drawing or in documentation, the cut-off wavelength  $\lambda_c$  is equal to the sample length. When no sampling length is specified, the cut-off wavelength is estimated using Table 3.

**Measurement of Roughness Parameters:** For non-periodic roughness, the parameter  $Ra, Rz, Rz1_{max}$  or  $RSm$  is first estimated using visual inspection, comparison to specimens, graphic analysis, etc. The sampling length is then selected from Table 3, based on the use of  $Ra, Rz, Rz1_{max}$  or  $RSm$ . Then, with instrumentation, a representative sample is taken using the sampling length chosen above.

The measured values are then compared to the ranges of values in Table 3 for the particular parameter. If the value is outside the range of values for the estimated sampling length, the measuring instrument is adjusted for the next higher or lower sampling length and the measurement repeated. If the final setting corresponds to Table 3, then both the sampling length setting and  $Ra, Rz, Rz1_{max}$  or  $RSm$  values are correct and a representative measurement of the parameter can be taken.

For periodic roughness, the parameter  $RSm$  is estimated graphically and the recommended cut-off values selected using Table 3. If the value is outside the range of values for the estimated sampling length, the measuring instrument is adjusted for the next higher or lower sampling length and the measurement repeated. If the final setting corresponds to Table 3, then both the sampling length setting and  $RSm$  values are correct and a representative measurement of the parameter can be taken.

**Table 3. Sampling Lengths**

Curves for Non-periodic Profiles such as Ground Surfaces		Curves for Periodic and Non-periodic Profiles	Sampling length, $l_r$ (mm)	Evaluation length, $l_n$ (mm)
For $Ra, Rq, Rsk, Rku, R\Delta q$	For $Rz, Rz, Rv, Rp, Rc, Rt$	For $R$ -parameters and $RSm$		
$Ra, \mu m$	$Rz, Rz1_{max}, \mu m$	$RSm, \mu m$		
$(0.006) < Ra \leq 0.02$	$(0.025) < Rz, Rz1_{max} \leq 0.1$	$0.013 < RSm \leq 0.04$	0.08	0.4
$0.02 < Ra \leq 0.1$	$0.1 < Rz, Rz1_{max} \leq 0.5$	$0.04 < RSm \leq 0.13$	0.25	1.25
$0.1 < Ra \leq 2$	$0.5 < Rz, Rz1_{max} \leq 10$	$0.13 < RSm \leq 0.4$	0.8	4
$2 < Ra \leq 10$	$10 < Rz, Rz1_{max} \leq 50$	$0.4 < RSm \leq 1.3$	2.5	12.5
$10 < Ra \leq 80$	$50 < Rz, Rz1_{max} \leq 200$	$1.3 < RSm \leq 4$	8	40

**Table 4. Preferred Roughness Values and Roughness Grades**

Roughness values, $Ra$		Previous Grade Number from ISO 1302	Roughness values, $Ra$		Previous Grade Number from ISO 1302
$\mu m$	$\mu in$		$\mu m$	$\mu in$	
50	2000	N12	0.8	32	N6
25	1000	N11	0.4	16	N5
12.5	500	N10	0.2	8	N4
6.3	250	N9	0.1	4	N3
3.2	125	N8	0.05	2	N2
1.6	63	N7	0.025	1	N1

## Examples of ISO Applications of Surface Texture Symbology

*Example 1:* Surface roughness in Fig. 8 is produced by milling with a bilateral tolerance between an upper limit of  $Ra = 55 \mu\text{m}$  and a lower limit of  $Ra = 6.2 \mu\text{m}$ . Both apply the "16%-rule" default (ISO 4288). Both transmission bands are 0.008 - 4 mm, using default evaluation length ( $5 \times 4 \text{ mm} = 20 \text{ mm}$ ) (ISO 4288). The surface lay is circular about the center.  $U$  and  $L$  are omitted because it is obvious one is upper and one lower. Material removal is allowed.

Fig. 8.

Fig. 9.

*Example 2:* Surface roughness in Fig. 9 is produced by grinding to two upper limit specifications:  $Ra = 1.5 \mu\text{m}$  and limited to  $Rz = 6.7 \mu\text{m}$  max. The default "16%-rule," default transmission band and default evaluation length apply to the  $Ra$ , while the "max-rule", a  $-2.5 \text{ mm}$  transmission band and default evaluation length, apply to the  $Rz$ . The surface lay is perpendicular relative to the plane of projection, and material removal is allowed.

*Example 3:* Fig. 10 indicates a simplified representation where surface roughness of  $Rz = 6.1 \mu\text{m}$  is the default for all surfaces as indicated by the  $Rz = 6.1$  specification, plus basic symbol within parentheses. The default "16%-rule" applies to both as does the default transmission band (ISO 4288 and ISO 3274). Any deviating specification is called out with local notes such as the  $Ra = 0.7 \mu\text{m}$  specification. There is no lay requirement, and material removal is allowed.

Fig. 10.

Fig. 11.

Fig. 12.

*Example 4:* Surface treatment without any material removal allowed is indicated in Fig. 11, and to a single unilateral upper limit specification of  $Rz = 1 \mu\text{m}$ . The default "16%-rule," default transmission band and default evaluation length apply. The surface treatment is nickel-chrome plated to all surfaces shown in profile (outline) in the view where the symbol is applied. There is no lay requirement.

*Example 5:* In Fig. 12, surface roughness is produced by any material removal process to one unilateral upper limit and one bilateral specification: the unilateral  $Ra = 3.1$  is to the default "16%-rule," a transmission band of  $-0.8 \text{ mm}$  and the default evaluation length ( $5 \times 0.8 = 4 \text{ mm}$ ). The bilateral  $Rz$  has an upper limit of  $Rz = 18 \mu\text{m}$  and a lower limit of  $Rz = 6.5 \mu\text{m}$ . Both limits are to a transmission band of  $-2.5 \text{ mm}$  with both to the default  $5 \times 2.5 = 12.5 \text{ mm}$ . The symbols  $U$  and  $L$  may be indicated even if it is obvious. Surface treatment is nickel/chromium plating. There is no lay requirement.

*Example 6:* Surface texture symbology may be combined with dimension leaders and witness (extension) lines, as in Fig. 13. Surface roughness for the side surfaces of the keyway is produced by any material removal process to one unilateral upper limit specification,  $Ra = 6.5 \mu\text{m}$ . It is to the default "16%-rule," default transmission band and default evaluation length ( $5 \times \lambda c$ ) (ISO 3274). There is no lay requirement.

Surface roughness for the chamfer is produced by any material removal process to one unilateral upper limit specification,  $Ra = 2.5 \mu\text{m}$ . It is to the default "16%-rule," default transmission band and default evaluation length ( $5 \times \lambda c$ ) (ISO 3274). There is no lay requirement.

Fig. 13.

Fig. 14.

*Example 7:* Surface texture symbology may be applied to extended extension lines or extended projection lines, Fig. 14. All feature surface roughness specifications shown are obtainable by any material removal process and are single unilateral upper limit specifications, respectively:  $Ra = 1.5 \mu\text{m}$ ,  $Ra = 6.2 \mu\text{m}$  and  $Rz = 50 \mu\text{m}$ . All are to "16%-rule" default, default transmission band and default evaluation length ( $5 \times \lambda c$ ). There is no lay requirement for any of the three.

*Example 8:* Surface texture symbology and dimensions may be combined on leader lines, as in Fig. 15. The feature surface roughness specifications shown are obtainable by any material removal process and are single unilateral upper limit specifications, respectively:  $Rz = 1 \mu\text{m}$ , to the default "16%-rule," default transmission band and default evaluation length ( $5 \times \lambda c$ ). There is no lay requirement.

Fig. 15.

Fig. 16.

*Example 9:* Symbology can be used for *dimensional information* and *surface treatment*. Fig. 16 illustrates three successive steps of a manufacturing process.

The first step is a single unilateral upper limit  $Rz = 1.7 \mu\text{m}$  to the default "16%-rule," default evaluation length ( $5 \times \lambda c$ ) and default transmission band. It is obtainable by any material removal process, with no lay characteristics specified. Step two, indicated with a phantom line over the whole length of the cylinder, has no surface texture requirement other than chromium plating.

The third step is a single unilateral upper limit of  $Rz = 6.5 \mu\text{m}$  applied only to the first 14 mm of the cylinder surface. The default "16%-rule" applies as does default evaluation length ( $5 \times \lambda c$ ) and default transmission band. Material removal is to be by grinding, with no lay characteristics specified.

## CUTTING TOOLS

## Terms and Definitions

**Tool Contour.**—Tools for turning, planing, etc., are made in straight, bent, offset, and other forms to place the cutting edges in convenient positions for operating on differently located surfaces. The contour or shape of the cutting edge may also be varied to suit different classes of work. Tool shapes, however, are not only related to the kind of operation, but, in roughing tools particularly, the contour may have a decided effect upon the cutting efficiency of the tool. To illustrate, an increase in the side cutting-edge angle of a roughing tool, or in the nose radius, tends to permit higher cutting speeds because the chip will be thinner for a given feed rate. Such changes, however, may result in chattering or vibrations unless the work and the machine are rigid; hence, the most desirable contour may be a compromise between the ideal form and one that is needed to meet practical requirements.

**Terms and Definitions.**—The terms and definitions relating to single-point tools vary somewhat in different plants, but the following are in general use.

Fig. 1. Terms Applied to Single-Point Turning Tools

**Single-Point Tool:** This term is applied to tools for turning, planing, boring, etc., which have a cutting edge at one end. This cutting edge may be formed on one end of a solid piece of steel, or the cutting part of the tool may consist of an insert or tip which is held to the body of the tool by brazing, welding, or mechanical means.

**Shank:** The shank is the main body of the tool. If the tool is an inserted cutter type, the shank supports the cutter or bit. (See diagram, Fig. 1.)

**Nose:** A general term sometimes used to designate the cutting end but usually relating more particularly to the rounded tip of the cutting end.

**Face:** The surface against which the chips bear, as they are severed in turning or planing operations, is called the face.

**Flank:** The flank is that end surface adjacent to the cutting edge and below it when the tool is in a horizontal position as for turning.

**Base:** The base is the surface of the tool shank that bears against the supporting tool-holder or block.

**Side Cutting Edge:** The side cutting edge is the cutting edge on the side of the tool. Tools such as that shown in Fig. 1 do the bulk of the cutting with this cutting edge and are, therefore, sometimes called side cutting edge tools.

**End Cutting Edge:** The end cutting edge is the cutting edge at the end of the tool.

On side cutting edge tools, the end cutting edge can be used for light plunging and facing cuts. Cutoff tools and similar tools have only one cutting edge located on the end. These

tools and other tools that are intended to cut primarily with the end cutting edge are sometimes called end cutting edge tools.

**Rake:** A metal-cutting tool is said to have rake when the tool face or surface against which the chips bear as they are being severed is inclined for the purpose of either increasing or diminishing the keenness or bluntness of the edge. The magnitude of the rake is most conveniently measured by two angles called the back rake angle and the side rake angle. The tool shown in Fig. 1 has rake. If the face of the tool did not incline but was parallel to the base, there would be no rake; the rake angles would be zero.

**Positive Rake:** If the inclination of the tool face is such as to make the cutting edge keener or more acute than when the rake angle is zero, the rake angle is defined as positive.

**Negative Rake:** If the inclination of the tool face makes the cutting edge less keen or more blunt than when the rake angle is zero, the rake is defined as negative.

**Back Rake:** The back rake is the inclination of the face toward or away from the end or the end cutting edge of the tool. When the inclination is away from the end cutting edge, as shown in Fig. 1, the back rake is positive. If the inclination is downward toward the end cutting edge, the back rake is negative.

**Side Rake:** The side rake is the inclination of the face toward or away from the side cutting edge. When the inclination is away from the side cutting edge, as shown in Fig. 1, the side rake is positive. If the inclination is toward the side cutting edge the side rake is negative.

**Relief:** The flanks below the side cutting edge and the end cutting edge must be relieved to allow these cutting edges to penetrate into the workpiece when taking a cut. If the flanks are not provided with relief, the cutting edges will rub against the workpiece and be unable to penetrate in order to form the chip. Relief is also provided below the nose of the tool to allow it to penetrate into the workpiece. The relief at the nose is usually a blend of the side relief and the end relief.

**End Relief Angle:** The end relief angle is a measure of the relief below the end cutting edge.

**Side Relief Angle:** The side relief angle is a measure of the relief below the side cutting edge.

**Back Rake Angle:** The back rake angle is a measure of the back rake. It is measured in a plane that passes through the side cutting edge and is perpendicular to the base. Thus, the back rake angle can be defined by measuring the inclination of the side cutting edge with respect to a line or plane that is parallel to the base. The back rake angle may be positive, negative, or zero depending upon the magnitude and direction of the back rake.

**Side Rake Angle:** The side rake angle is a measure of the side rake. This angle is always measured in a plane that is perpendicular to the side cutting edge and perpendicular to the base. Thus, the side rake angle is the angle of inclination of the face perpendicular to the side cutting edge with reference to a line or a plane that is parallel to the base.

**End Cutting Edge Angle:** The end cutting edge angle is the angle made by the end cutting edge with respect to a plane perpendicular to the axis of the tool shank. It is provided to allow the end cutting edge to clear the finish machined surface on the workpiece.

**Side Cutting Edge Angle:** The side cutting edge angle is the angle made by the side cutting edge and a plane that is parallel to the side of the shank.

**Nose Radius:** The nose radius is the radius of the nose of the tool. The performance of the tool, in part, is influenced by nose radius so that it must be carefully controlled.

**Lead Angle:** The lead angle, shown in Fig. 2, is not ground on the tool. It is a tool setting angle which has a great influence on the performance of the tool. The lead angle is bounded by the side cutting edge and a plane perpendicular to the workpiece surface when the tool is in position to cut; or, more exactly, the lead angle is the angle between the side cutting edge and a plane perpendicular to the direction of the feed travel.

Fig. 2. Lead Angle on Single-Point Turning Tool

**Solid Tool:** A solid tool is a cutting tool made from one piece of tool material.

**Brazed Tool:** A brazed tool is a cutting tool having a blank of cutting-tool material permanently brazed to a steel shank.

**Blank:** A blank is an unground piece of cutting-tool material from which a brazed tool is made.

**Tool Bit:** A tool bit is a relatively small cutting tool that is clamped in a holder in such a way that it can readily be removed and replaced. It is intended primarily to be reground when dull and not indexed.

**Tool-Bit Blank:** The tool-bit blank is an unground piece of cutting-tool material from which a tool bit can be made by grinding. It is available in standard sizes and shapes.

**Tool-Bit Holder:** Usually made from forged steel, the tool-bit holder is used to hold the tool bit, to act as an extended shank for the tool bit, and to provide a means for clamping in the tool post.

**Straight-Shank Tool-Bit Holder:** A straight-shank tool-bit holder has a straight shank when viewed from the top. The axis of the tool bit is held parallel to the axis of the shank.

**Offset-Shank Tool-Bit Holder:** An offset-shank tool-bit holder has the shank bent to the right or left, as seen in Fig. 3. The axis of the tool bit is held at an angle with respect to the axis of the shank.

**Side Cutting Tool:** A side cutting tool has its major cutting edge on the side of the cutting part of the tool. The major cutting edge may be parallel or at an angle with respect to the axis of the tool.

**Indexable Inserts:** An indexable insert is a relatively small piece of cutting-tool material that is geometrically shaped to have two or several cutting edges that are used until dull. The insert is then indexed on the holder to apply a sharp cutting edge. When all the cutting edges have been dulled, the insert is discarded. The insert is held in a pocket or against other locating surfaces on an indexable insert holder by means of a mechanical clamping device that can be tightened or loosened easily.

**Indexable Insert Holder:** Made of steel, an indexable insert holder is used to hold indexable inserts. It is equipped with a mechanical clamping device that holds the inserts firmly in a pocket or against other seating surfaces.

**Straight-Shank Indexable Insert Holder:** A straight-shank indexable insert tool-holder is essentially straight when viewed from the top, although the cutting edge of the insert may be oriented parallel, or at an angle to, the axis of the holder.

**Offset-Shank Indexable Insert Holder:** An offset-shank indexable insert holder has the head end, or the end containing the insert pocket, offset to the right or left, as shown in Fig. 3.

Fig. 3. Top: Right-Hand Offset-Shank, Indexable Insert Holder  
Bottom: Right-Hand Offset-Shank Tool-Bit Holder

**End Cutting Tool:** An end cutting tool has its major cutting edge on the end of the cutting part of the tool. The major cutting edge may be perpendicular or at an angle, with respect to the axis of the tool.

**Curved Cutting-Edge Tool:** A curved cutting-edge tool has a continuously variable side cutting edge angle. The cutting edge is usually in the form of a smooth, continuous curve along its entire length, or along a large portion of its length.

**Right-Hand Tool:** A right-hand tool has the major, or working, cutting edge on the right-hand side when viewed from the cutting end with the face up. As used in a lathe, such a tool is usually fed into the work from right to left, when viewed from the shank end.

**Left-Hand Tool:** A left-hand tool has the major or working cutting edge on the left-hand side when viewed from the cutting end with the face up. As used in a lathe, the tool is usually fed into the work from left to right, when viewed from the shank end.

**Neutral-Hand Tool:** A neutral-hand tool is a tool to cut either left to right or right to left; or the cut may be parallel to the axis of the shank as when plunge cutting.

**Chipbreaker:** A groove formed in or on a shoulder on the face of a turning tool back of the cutting edge to break up the chips and prevent the formation of long, continuous chips that would be dangerous to the operator and also bulky and cumbersome to handle. A chipbreaker of the shoulder type may be formed directly on the tool face, or it may consist of a separate piece that is held either by brazing or by clamping.

**Relief Angles.**—The end relief angle and the side relief angle on single-point cutting tools are usually, though not invariably, made equal to each other. The relief angle under the nose of the tool is a blend of the side and end relief angles.

The size of the relief angles has a pronounced effect on the performance of the cutting tool. If the relief angles are too large, the cutting edge will be weakened and in danger of breaking when a heavy cutting load is placed on it by a hard and tough material. On finish cuts, rapid wear of the cutting edge may cause problems with size control on the part. Relief angles that are too small will cause the rate of wear on the flank of the tool below the cutting edge to increase, thereby significantly reducing the tool life. In general, when cutting hard and tough materials, the relief angles should be 6 to 8 degrees for high-speed steel tools and 5 to 7 degrees for carbide tools. For medium steels, mild steels, cast iron, and other average work the recommended values of the relief angles are 8 to 12 degrees for high-speed steel tools and 5 to 10 degrees for carbides. Ductile materials having a relatively low modulus of elasticity should be cut using larger relief angles. For example, the relief angles recommended for turning copper, brass, bronze, aluminum,

ferritic malleable iron, and similar metals are 12 to 16 degrees for high-speed steel tools and 8 to 14 degrees for carbides.

Larger relief angles generally tend to produce a better finish on the finish machined surface because less surface of the worn flank of the tool rubs against the workpiece. For this reason, single-point thread-cutting tools should be provided with relief angles that are as large as circumstances will permit. Problems encountered when machining stainless steel may be overcome by increasing the size of the relief angle. The relief angles used should never be smaller than necessary.

**Rake Angles.**—Machinability tests have confirmed that when the rake angle along which the chip slides, called the true rake angle, is made larger in the positive direction, the cutting force and the cutting temperature will decrease. Also, the tool life for a given cutting speed will increase with increases in the true rake angle up to an optimum value, after which it will decrease again. For turning tools that cut primarily with the side cutting edge, the true rake angle corresponds rather closely with the side rake angle except when taking shallow cuts. Increasing the side rake angle in the positive direction lowers the cutting force and the cutting temperature, while at the same time it results in a longer tool life or a higher permissible cutting speed up to an optimum value of the side rake angle. After the optimum value is exceeded, the cutting force and the cutting temperature will continue to drop; however, the tool life and the permissible cutting speed will decrease.

As an approximation, the magnitude of the cutting force will decrease about one percent per degree increase in the side rake angle. While not exact, this rule of thumb does correspond approximately to test results and can be used to make rough estimates. Of course, the cutting force also increases about one percent per degree decrease in the side rake angle. The limiting value of the side rake angle for optimum tool life or cutting speed depends upon the work material and the cutting tool material. In general, lower values can be used for hard and tough work materials. Cemented carbides are harder and more brittle than high-speed steel; therefore, the rake angles usually used for cemented carbides are less positive than for high-speed steel.

Negative rake angles cause the face of the tool to slope in the opposite direction from positive rake angles and, as might be expected, they have an opposite effect. For side cutting edge tools, increasing the side rake angle in a negative direction will result in an increase in the cutting force and an increase in the cutting temperature of approximately one percent per degree change in rake angle. For example, if the side rake angle is changed from 5 degrees positive to 5 degrees negative, the cutting force will be about 10 percent larger. Usually the tool life will also decrease when negative side rake angles are used, although the tool life will sometimes increase when the negative rake angle is not too large and when a fast cutting speed is used.

Negative side rake angles are usually used in combination with negative back rake angles on single-point cutting tools. The negative rake angles strengthen the cutting edges, enabling them to sustain heavier cutting loads and shock loads. They are recommended for turning very hard materials and for heavy interrupted cuts. There is also an economic advantage in favor of using negative rake indexable inserts and tool holders inasmuch as the cutting edges provided on both the top and bottom of the insert can be used.

On turning tools that cut primarily with the side cutting edge, the effect of the back rake angle alone is much less than the effect of the side rake angle, although the direction of the change in cutting force, cutting temperature, and tool life is the same. The effect that the back rake angle has can be ignored unless, of course, extremely large changes in this angle are made. A positive back rake angle does improve the performance of the nose of the tool somewhat and is helpful in taking light finishing cuts. A negative back rake angle strengthens the nose of the tool and is helpful when interrupted cuts are taken. The back rake angle has a very significant effect on the performance of end cutting edge tools, such as cut-off tools. For these tools, the effect of the back rake angle is very similar to the effect of the side rake angle on side cutting edge tools.

**Side Cutting Edge and Lead Angles.**—These angles are considered together because the side cutting edge angle is usually designed to provide the desired lead angle when the tool is being used. The side cutting edge angle and the lead angle will be equal when the shank of the cutting tool is positioned perpendicular to the workpiece, or, more correctly, perpendicular to the direction of the feed. When the shank is not perpendicular, the lead angle is determined by the side cutting edge and an imaginary line perpendicular to the feed direction.

The flow of the chips over the face of the tool is approximately perpendicular to the side cutting edge except when shallow cuts are taken. The thickness of the undeformed chip is measured perpendicular to the side cutting edge. As the lead angle is increased, the length of chip in contact with the side cutting edge is increased, and the chip will become longer and thinner. This effect is the same as increasing the depth of cut and decreasing the feed, although the actual depth of cut and feed remain the same and the same amount of metal is removed. The effect of lengthening and thinning the chip by increasing the lead angle is very beneficial as it increases the tool life for a given cutting speed or that speed can be increased. Increasing the cutting speed while the feed and the tool life remain the same leads to faster production.

However, an adverse effect must be considered. Chatter can be caused by a cutting edge that is oriented at a high lead angle when turning, and sometimes, when turning long and slender shafts, even a small lead angle can cause chatter. In fact, an unsuitable lead angle of the side cutting edge is one of the principal causes of chatter. When chatter occurs, often simply reducing the lead angle will cure it. Sometimes, very long and slender shafts can be turned successfully with a tool having a zero degree lead angle (and having a small nose radius). Boring bars, being usually somewhat long and slender, are also susceptible to chatter if a large lead angle is used. The lead angle for boring bars should be kept small, and for very long and slender boring bars a zero-degree lead angle is recommended. It is impossible to provide a rule that will determine when chatter caused by a lead angle will occur and when it will not. The first consideration is the length to diameter ratio of the part to be turned, or of the boring bar. Then the method of holding the workpiece must be considered — a part that is firmly held is less apt to chatter. Finally, the overall condition and rigidity of the machine must be considered because they may be the real cause of chatter.

Although chatter can be a problem, the advantages gained from high lead angles are such that the lead angle should be as large as possible at all times.

**End Cutting Edge Angle.**—The size of the end cutting edge angle is important when tool wear by cratering occurs. Frequently, the crater will enlarge until it breaks through the end cutting edge just behind the nose, and tool failure follows shortly. Reducing the size of the end cutting edge angle tends to delay the time of crater breakthrough. When cratering takes place, the recommended end cutting edge angle is 8 to 15 degrees. If there is no cratering, the angle can be made larger. Larger end cutting edge angles may be required to enable profile turning tools to plunge into the work without interference from the end cutting edge.

**Nose Radius.**—The tool nose is a very critical part of the cutting edge since it cuts the finished surface on the workpiece. If the nose is made to a sharp point, the finish machined surface will usually be unacceptable and the life of the tool will be short. Thus, a nose radius is required to obtain an acceptable surface finish and tool life. The surface finish obtained is determined by the feed rate and by the nose radius if other factors such as the work material, the cutting speed, and cutting fluids are not considered. A large nose radius will give a better surface finish and will permit a faster feed rate to be used.

Machinability tests have demonstrated that increasing the nose radius will also improve the tool life or allow a faster cutting speed to be used. For example, high-speed steel tools were used to turn an alloy steel in one series of tests where complete or catastrophic tool failure was used as a criterion for the end of tool life. The cutting speed for a 60-minute

tool life was found to be 125 fpm (0.635 m/s) when the nose radius was  $\frac{1}{16}$  inch (1.59 mm) and 160 fpm (0.8.13 m/s) when the nose radius was  $\frac{1}{4}$  inch (6.35 mm).

A very large nose radius can often be used but a limit is sometimes imposed because the tendency for chatter to occur is increased as the nose radius is made larger. A nose radius that is too large can cause chatter, and, when it does, a smaller nose radius must be used on the tool. It is always good practice to make the nose radius as large as is compatible with the operation being performed.

**Chipbreakers.**—Many steel turning tools are equipped with chipbreaking devices to prevent the formation of long continuous chips in connection with the turning of steel at the high speeds made possible by high-speed steel and especially cemented carbide tools. Long steel chips are dangerous to the operator and cumbersome to handle, and they may twist around the tool and cause damage. Broken chips not only occupy less space, but permit a better flow of coolant to the cutting edge. Several different forms of chipbreakers are illustrated in Fig. 4.

*Angular Shoulder Type:* The angular shoulder type shown at A is one of the commonly used forms. As the enlarged sectional view shows, the chipbreaking shoulder is located back of the cutting edge. The angle  $a$  between the shoulder and cutting edge may vary from 6 to 15 degrees or more, 8 degrees being a fair average. The ideal angle, width  $W$  and depth  $G$ , depend upon the speed and feed, the depth of cut, and the material. As a general rule, width  $W$ , at the end of the tool, varies from  $\frac{3}{32}$  to  $\frac{7}{32}$  inch (2.4–5.6 mm), and the depth  $G$  may range from  $\frac{1}{64}$  to  $\frac{1}{16}$  inch (0.4–1.6 mm). The shoulder radius equals depth  $G$ . If the tool has a large nose radius, the corner of the shoulder at the nose end may be beveled off, as illustrated at B, to prevent it from coming into contact with the work. The width  $K$  for type B should equal approximately 1.5 times the nose radius.

*Parallel Shoulder Type:* Diagram C shows a design with a chipbreaking shoulder that is parallel with the cutting edge. With this form, the chips are likely to come off in short curled sections. The parallel form may also be applied to straight tools that do not have a side cutting-edge angle. The tendency with this parallel shoulder form is to force the chips against the work and damage it.

Fig. 4. Different Forms of Chipbreakers for Turning Tools

*Groove Type:* This type (diagram D) has a groove in the face of the tool produced by grinding. Between the groove and the cutting edge, there is a land  $L$ . Under ideal conditions, this width  $L$ , the groove width  $W$ , and the groove depth  $G$ , would be varied to suit the feed, depth of cut and material. For average use,  $L$  and  $G$  are about  $\frac{1}{32}$  inch (0.79 mm), and  $W$   $\frac{1}{16}$  inch (1.59 mm). There are differences of opinion concerning the relative merits of the groove type and the shoulder type. Both types have proved satisfactory when properly proportioned for a given class of work.

*Chipbreaker for Light Cuts:* Diagram E illustrates a form of chipbreaker that is sometimes used on tools for finishing cuts having a maximum depth of about  $\frac{1}{32}$  inch (0.79 mm). This chipbreaker is a shoulder type, having an angle of 45 degrees and a maximum width of about  $\frac{1}{16}$  inch (1.59 mm). It is important in grinding all chipbreakers to give the chip-bearing surfaces a fine finish, such as would be obtained by honing. This finish greatly increases the life of the tool.

**Planing Tools.**—Many of the principles governing the shape of turning tools also apply in the grinding of tools for planing. The amount of rake depends upon the hardness of the material, and the direction of the rake should be away from the *working part* of the cutting edge. The angle of clearance should be about 4 or 5 degrees for planer tools, which is less than for lathe tools. This small clearance is allowable because a planer tool is held about square with the platen, whereas a lathe tool, the height and inclination of which can be varied, may not always be clamped in the same position.

**Carbide Tools:** Carbide tools for planing usually have negative rake. Round-nose and square-nose end-cutting tools should have a “negative back rake” (or front rake) of 2 or 3 degrees. Side cutting tools may have a negative back rake of 10 degrees, a negative side rake of 5 degrees, and a side cutting-edge angle of 8 degrees.

### Indexable Inserts

**Introduction.**—A large proportion of cemented carbide, single-point cutting tools are indexable inserts and indexable insert tool holders. Dimensional specifications for solid sintered carbide indexable inserts are given in ANSI B212.12-1991 (R2002). Samples of the many insert shapes are shown in [Table 3b](#). Most modern, cemented carbide, face milling cutters are of the indexable insert type. Larger size end milling cutters, side milling or slotting cutters, boring tools, and a wide variety of special tools are made to use indexable inserts. These inserts are primarily made from cemented carbide, although most of the cemented oxide cutting tools are also indexable inserts.

The objective of this type of tooling is to provide an insert with several cutting edges. When an edge is worn, the insert is indexed in the tool holder until all the cutting edges are used up, after which it is discarded. The insert is not intended to be reground. The advantages are that the cutting edges on the tool can be rapidly changed without removing the tool holder from the machine, tool-grinding costs are eliminated, and the cost of the insert is less than the cost of a similar, brazed carbide tool. Of course, the cost of the tool holder must be added to the cost of the insert; however, one tool holder will usually last for a long time before it, too, must be replaced.

Indexable inserts and tool holders are made with a negative or positive rake. Negative rake inserts have the advantage of having twice as many cutting edges available as comparable positive rake inserts, because the cutting edges on both the top and bottom of negative rake inserts can be used, while only the top cutting edges can be used on positive rake inserts. Positive rake inserts have a distinct advantage when machining long and slender parts, thin-walled parts, or other parts that are subject to bending or chatter when the cutting load is applied to them, because the cutting force is significantly lower as compared to that for negative rake inserts. Indexable inserts can be obtained in the following forms: utility ground, or ground on top and bottom only; precision ground, or ground on all surfaces; preformed to produce a slight rounding of the cutting edge; and precision molded, which are unground. Positive-negative rake inserts also are available. These inserts are held on a negative-rake tool holder and have a chipbreaker groove that is formed to produce an effective positive-rake angle while cutting. Cutting edges may be available on the top surface only, or on both top and bottom surfaces. The positive-rake chipbreaker surface may be ground or precision molded on the insert.

Many materials, such as gray cast iron, form a discontinuous chip. For these materials an insert that has plain faces without chipbreaker grooves should always be used. Steels and

other ductile materials form a continuous chip that must be broken into small segments when machined on lathes and planers having single-point, cemented carbide and cemented-oxide cutting tools; otherwise, the chips can cause injury to the operator. In this case a chipbreaker must be used. Some inserts are made with chipbreaker grooves molded or ground directly on the insert. When inserts with plain faces are used, a cemented-carbide plate-type chipbreaker is clamped on top of the insert.

**Identification System for Indexable Inserts.**—The size of indexable inserts is determined by the diameter of an inscribed circle (I.C.), except for rectangular and parallelogram inserts where the length and width are used. To describe an insert in its entirety, a standard ANSI B212.4-2002 identification system is used where each position number designates a feature of the insert. The ANSI Standard includes items now commonly used and facilitates identification of items not in common use. Identification consists of up to ten positions; each position defines a characteristic of the insert as shown below:

1	2	3	4	5	6	7	8 <sup>a</sup>	9 <sup>a</sup>	10 <sup>a</sup>
<b>T</b>	<b>N</b>	<b>M</b>	<b>G</b>	<b>5</b>	<b>4</b>	<b>3</b>			<b>A</b>

<sup>a</sup> Eighth, Ninth, and Tenth Positions are used only when required.

1) *Shape*: The shape of an insert is designated by a letter: **R** for round; **S**, square; **T**, triangle; **A**, 85° parallelogram; **B**, 82° parallelogram; **C**, 80° diamond; **D**, 55° diamond; **E**, 75° diamond; **H**, hexagon; **K**, 55° parallelogram; **L**, rectangle; **M**, 86° diamond; **O**, octagon; **P**, pentagon; **V**, 35° diamond; and **W**, 80° trigon.

2) *Relief Angle (Clearances)*: The second position is a letter denoting the relief angles: **N** for 0°; **A**, 3°; **B**, 5°; **C**, 7°; **P**, 11°; **D**, 15°; **E**, 20°; **F**, 25°; **G**, 30°; **H**, 0° & 11°; **J**, 0° & 14°; **K**, 0° & 17°; **L**, 0° & 20°; **M**, 11° & 14°; **R**, 11° & 17°; **S**, 11° & 20°. When mounted on a holder, the actual relief angle may be different from that on the insert.

3) *Tolerances*: The third position is a letter and indicates the tolerances controlling the indexability of the insert. Tolerances specified do not imply the method of manufacture.

Symbol	Tolerance (± from nominal)		Symbol	Tolerance (± from nominal)	
	Inscribed Circle, Inch	Thickness, Inch		Inscribed Circle, Inch	Thickness, Inch
A	0.001	0.001	H	0.0005	0.001
B	0.001	0.005	J	0.002–0.005	0.001
C	0.001	0.001	K	0.002–0.005	0.001
D	0.001	0.005	L	0.002–0.005	0.001
E	0.001	0.001	M	0.002–0.004 <sup>a</sup>	0.005
F	0.0005	0.001	U	0.005–0.010 <sup>a</sup>	0.005
G	0.001	0.005	N	0.002–0.004 <sup>a</sup>	0.001

<sup>a</sup> Exact tolerance is determined by size of insert. See ANSI B212.12.

4) *Type*: The type of insert is designated by a letter: **A**, with hole; **B**, with hole and countersink; **C**, with hole and two countersinks; **F**, chip grooves both surfaces, no hole; **G**, same as **F** but with hole; **H**, with hole, one countersink, and chip groove on one rake surface; **J**, with hole, two countersinks and chip grooves on two rake surfaces; **M**, with hole and chip groove on one rake surface; **N**, without hole; **Q**, with hole and two countersinks; **R**, without hole but with chip groove on one rake surface; **T**, with hole, one countersink, and chip groove on one rake face; **U**, with hole, two countersinks, and chip grooves on two rake faces; and **W**, with hole and one countersink. *Note*: a dash may be used after

\* Second angle is secondary facet angle, which may vary by ± 1°.

position 4 to separate the shape-describing portion from the following dimensional description of the insert and is not to be considered a position in the standard description.

5) *Size*: The size of the insert is designated by a one- or two-digit number. For regular polygons and diamonds, insert size is the number of eighths of an inch in the nominal size of the inscribed circle, and will be a one- or two-digit number when the number of eighths is a whole number. It will be a two-digit number, including one decimal place, when it is not a whole number. Rectangular and parallelogram inserts require two digits: the first digit indicates the number of eighths of an inch width and the second digit the number of quarters of an inch length.

6) *Thickness*: The thickness is designated by a one- or two-digit number, which indicates the number of sixteenths of an inch in the thickness of the insert. Thickness is a one-digit number when the number of sixteenths is a whole number; it is a two-digit number carried to one decimal place when the number of sixteenths of an inch is not a whole number.

7) *Cutting Point Configuration*: The cutting point, or nose radius, is designated by a number representing  $\frac{1}{64}$ ths of an inch; a flat at the cutting point or nose, is designated by a letter: **0** for sharp corner, 0.002 inch max. radius; **0.2** for 0.004 radius; **0.3** for **0.008** radius; **1**,  $\frac{1}{64}$  inch radius; **2**,  $\frac{1}{32}$  inch radius; **3**,  $\frac{3}{64}$  inch radius; **4**,  $\frac{1}{16}$  inch radius; **5**,  $\frac{5}{64}$  inch radius; **6**,  $\frac{3}{32}$  inch radius; **7**,  $\frac{7}{64}$  inch radius; **8**,  $\frac{1}{8}$  inch radius; **X**, any other radius; **A**, square insert with 45° chamfer; **D**, square insert with 30° chamfer; **E**, square insert with 15° chamfer; **F**, square insert with 3° chamfer; **K**, square insert with 30° double chamfer; **L**, square insert with 15° double chamfer; **M**, square insert with 3° double chamfer; **N**, truncated triangle insert; and **P**, flattened corner triangle insert.

8) *Special Cutting Point Definition*: The eighth position, if it follows a letter in the 7th position, is a number indicating the number of  $\frac{1}{64}$ ths of an inch in the primary facet length measured parallel to the edge of the facet.

9) *Hand*: **R**, right; **L**, left; to be used when required in ninth position.

10) *Other Conditions*: Position ten defines special conditions (such as edge treatment, surface finish): **A**, honed, 0.0005 to less than 0.003 inch (0.0127 to 0.0762 mm); **B**, honed, 0.003 to less than 0.005 inch (0.0762 to 0.127 mm); **C**, honed, 0.005 to less than 0.007 inch (0.127 to 0.178 mm); **J**, polished, 4  $\mu$ inch (0.1016  $\mu$ m) arithmetic average (AA) on rake surfaces only; **T**, chamfered, manufacturer's standard negative land, rake face only.

**Indexable Insert Tool Holders.**—Indexable insert tool holders are made from a good grade of steel which is heat treated to a hardness of 44 to 48 RC (Rockwell C scale) for most normal applications. Accurate pockets that serve to locate the insert in position and to provide surfaces against which the insert can be clamped are machined in the ends of tool holders. A cemented carbide seat usually is provided and is held in the bottom of the pocket by a screw or by the clamping pin, if one is used. The seat is necessary to provide a flat bearing surface upon which the insert can rest and, in so doing, it adds materially to the ability of the insert to withstand the cutting load. The seating surface of the holder may provide a positive-, negative-, or a neutral-rake orientation to the insert when it is in position on the holder. Holders, therefore, are classified as positive, negative, or neutral rake.

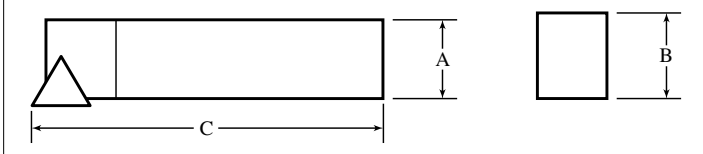

Four basic methods are used to clamp the insert on the holder: 1) Clamping, usually top clamping; 2) Pin-lock clamping; 3) Multiple clamping using a clamp, usually a top clamp, and a pin lock; and 4) Clamping the insert with a machine screw.

All top clamps are actuated by a screw that forces the clamp directly against the insert. When required, a cemented carbide, plate-type chipbreaker is placed between the clamp and the insert. Pin-lock clamps require an insert having a hole: the pin acts against the walls of the hole to clamp the insert firmly against the seating surfaces of the holder. Multiple or combination clamping, simultaneously using both a pin-lock and a top clamp, is recommended when taking heavier or interrupted cuts. Holders are available on which all the above-mentioned methods of clamping may be used. Other holders are made with only a top clamp or a pin lock. Screw-on type holders use a machine screw to hold the

insert in the pocket. Most standard indexable insert holders are either straight-shank or offset-shank, although special holders are made having a wide variety of configurations.

The common shank sizes of indexable insert tool holders are shown in Table 1. Not all styles are available in every shank size. Positive- and negative-rake tools are also not available in every style or shank size. Some manufacturers provide additional shank sizes for certain tool holder styles. For more complete details, the manufacturers' catalogs must be consulted.

**Table 1. Standard Shank Sizes for Indexable Insert Holders**

Basic Shank Size	Shank Dimensions for Indexable Insert Holders					
	A		B		C <sup>a</sup>	
	inch	mm	inch	mm	inch	mm
1/2 x 1/2 x 4 1/2	0.500	12.70	0.500	12.70	4.500	114.30
3/8 x 3/8 x 4 1/2	0.625	15.87	0.625	15.87	4.500	114.30
5/8 x 1 1/4 x 6	0.625	15.87	1.250	31.75	6.000	152.40
3/4 x 3/4 x 4 1/2	0.750	19.05	0.750	19.05	4.500	114.30
3/4 x 1 x 6	0.750	19.05	1.000	25.40	6.000	152.40
3/4 x 1 1/4 x 6	0.750	19.05	1.250	31.75	6.000	152.40

<sup>a</sup> Holder length; may vary by manufacturer. Actual shank length depends on holder style.

**Identification System for Indexable Insert Holders.**—The following identification system conforms to the American National Standard, ANSI B212.5-2002, Metric Holders for Indexable Inserts.

Each position in the system designates a feature of the holder in the following sequence:

1 2 3 4 5 — 6 — 7 — 8<sup>a</sup> — 9 — 10<sup>a</sup>  
**C T N A R — 85 — 25 — D — 16 — Q**

1) *Method of Holding Horizontally Mounted Insert:* The method of holding or clamping is designated by a letter: **C**, top clamping, insert without hole; **M**, top and hole clamping, insert with hole; **P**, hole clamping, insert with hole; **S**, screw clamping through hole, insert with hole; **W**, wedge clamping.

2) *Insert Shape:* The insert shape is identified by a letter: **H**, hexagonal; **O**, octagonal; **P**, pentagonal; **S**, square; **T**, triangular; **C**, rhombic, 80° included angle; **D**, rhombic, 55° included angle; **E**, rhombic, 75° included angle; **M**, rhombic, 86° included angle; **V**, rhombic, 35° included angle; **W**, hexagonal, 80° included angle; **L**, rectangular; **A**, parallelogram, 85° included angle; **B**, parallelogram, 82° included angle; **K**, parallelogram, 55° included angle; **R**, round. The included angle is always the smaller angle.

3) *Holder Style:* The holder style designates the shank style and the side cutting edge angle, or end cutting edge angle, or the purpose for which the holder is used. It is designated

by a letter: **A** for straight shank with  $0^\circ$  side cutting edge angle; **B**, straight shank with  $15^\circ$  side cutting edge angle; **C**, straight-shank end cutting tool with  $0^\circ$  end cutting edge angle; **D**, straight shank with  $45^\circ$  side cutting edge angle; **E**, straight shank with  $30^\circ$  side cutting edge angle; **F**, offset shank with  $0^\circ$  end cutting edge angle; **G**, offset shank with  $0^\circ$  side cutting edge angle; **J**, offset shank with negative  $3^\circ$  side cutting edge angle; **K**, offset shank with  $15^\circ$  end cutting edge angle; **L**, offset shank with negative  $5^\circ$  side cutting edge angle and  $5^\circ$  end cutting edge angle; **M**, straight shank with  $40^\circ$  side cutting edge angle; **N**, straight shank with  $27^\circ$  side cutting edge angle; **R**, offset shank with  $15^\circ$  side cutting edge angle; **S**, offset shank with  $45^\circ$  side cutting edge angle; **T**, offset shank with  $30^\circ$  side cutting edge angle; **U**, offset shank with negative  $3^\circ$  end cutting edge angle; **V**, straight shank with  $17\frac{1}{2}^\circ$  side cutting edge angle; **W**, offset shank with  $30^\circ$  end cutting edge angle; **Y**, offset shank with  $5^\circ$  end cutting edge angle.

4) *Normal Clearances*: The normal clearances of inserts are identified by letters: **A**,  $3^\circ$ ; **B**,  $5^\circ$ ; **C**,  $7^\circ$ ; **D**,  $15^\circ$ ; **E**,  $20^\circ$ ; **F**,  $25^\circ$ ; **G**,  $30^\circ$ ; **N**,  $0^\circ$ ; **P**,  $11^\circ$ .

5) *Hand of tool*: The hand of the tool is designated by a letter: **R** for right-hand; **L**, left-hand; and **N**, neutral, or either hand.

6) *Tool Height for Rectangular Shank Cross Sections*: The tool height for tool holders with a rectangular shank cross section and the height of cutting edge equal to shank height are given as two-digit numbers representing these values in millimeters. For example, a height of 32 mm would be encoded as 32; 8 mm would be encoded as 08, where the one-digit value is preceded by a zero.

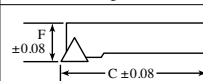

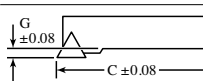

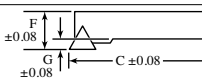

7) *Tool Width for Rectangular Shank Cross Sections*: The tool width for tool holders with a rectangular shank cross section is given as a two-digit number representing this value in millimeters. For example, a width of 25 mm would be encoded as 25; 8 mm would be encoded as 08, where the one-digit value is preceded by a zero.

8) *Tool Length*: The tool length is designated by a letter: **A**, 32 mm; **B**, 40 mm; **C**, 50 mm; **D**, 60 mm; **E**, 70 mm; **F**, 80 mm; **G**, 90 mm; **H**, 100 mm; **J**, 110 mm; **K**, 125 mm; **L**, 140 mm; **M**, 150 mm; **N**, 160 mm; **P**, 170 mm; **Q**, 180 mm; **R**, 200 mm; **S**, 250 mm; **T**, 300 mm; **U**, 350 mm; **V**, 400 mm; **W**, 450 mm; **X**, special length to be specified; **Y**, 500 mm.

9) *Indexable Insert Size*: The size of indexable inserts is encoded as follows: For insert shapes **C, D, E, H, M, O, P, R, S, T, V**, the side length (the diameter for **R** inserts) in millimeters is used as a two-digit number, with decimals being disregarded. For example, the symbol for a side length of 16.5 mm is 16. For insert shapes **A, B, K, L**, the length of the main cutting edge or of the longer cutting edge in millimeters is encoded as a two-digit number, disregarding decimals. If the symbol obtained has only one digit, then it should be preceded by a zero. For example, the symbol for a main cutting edge of 19.5 mm is 19; for an edge of 9.5 mm, the symbol is 09.

10) *Special Tolerances*: Special tolerances are indicated by a letter: **Q**, back and end qualified tool; **F**, front and end qualified tool; **B**, back, front, and end qualified tool. A qualified tool is one that has tolerances of  $\pm 0.08$  mm for dimensions *F*, *G*, and *C*. (See Table 2.)

**Selecting Indexable Insert Holders.**—A guide for selecting indexable insert holders is provided by [Table 3b](#). Some operations such as deep grooving, cut-off, and threading are not given in this table. However, tool holders designed specifically for these operations are available. The boring operations listed in [Table 3b](#) refer primarily to larger holes into which the holders will fit. Smaller holes are bored using boring bars. An examination of this table shows that several tool-holder styles can be and frequently are used for each operation. Selection of the best holder for a given job depends largely on the job, and there are certain basic facts that should be considered in making the selection.

**Rake Angle:** A negative-rake insert has twice as many cutting edges available as a comparable positive-rake insert. Sometimes the tool life obtained when using the second face may be less than that obtained on the first face because the tool wear on the cutting edges of the first face may reduce the insert strength. Nevertheless, the advantage of negative-rake inserts and holders is such that they should be considered first in making any choice. Positive-rake holders should be used where lower cutting forces are required, as when machining slender or small-diameter parts, when chatter may occur, and for machining some materials, such as aluminum, copper, and certain grades of stainless steel, when positive-negative rake inserts can sometimes be used to advantage. These inserts are held on negative-rake holders that have their rake surfaces ground or molded to form a positive-rake angle.

**Insert Shape:** The configuration of the workpiece, the operation to be performed, and the lead angle required often determine the insert shape. When these factors need not be considered, the insert shape should be selected on the basis of insert strength and the maximum number of cutting edges available. Thus, a round insert is the strongest and has a maximum number of available cutting edges. It can be used with heavier feeds while producing a good surface finish. Round inserts are limited by their tendency to cause chatter, which may preclude their use. The square insert is the next most effective shape, providing good corner strength and more cutting edges than all other inserts except the round insert. The only limitation of this insert shape is that it must be used with a lead angle. Therefore, the square insert cannot be used for turning square shoulders or for back-facing. Triangle inserts are the most versatile and can be used to perform more operations than any other insert shape. The 80-degree diamond insert is designed primarily for heavy turning and facing operations using the 100-degree corners, and, for turning and back-facing square shoulders, using the 80-degree corners. The 55- and 35-degree diamond inserts are intended primarily for tracing.

**Lead Angle:** Tool holders should be selected to provide the largest possible lead angle, although limitations are sometimes imposed by the nature of the job. For example, when tuning and back-facing a shoulder, a negative lead angle must be used. Slender or small-diameter parts may deflect, causing difficulties in holding size, or chatter when the lead angle is too large.

**End Cutting Edge Angle:** When tracing or contour turning, the plunge angle is determined by the end cutting edge angle. A 2-deg minimum clearance angle should be provided between the workpiece surface and the end cutting edge of the insert. [Table 3a](#) provides the maximum plunge angle for holders commonly used to plunge when tracing where insert shape identifiers are *S* = square, *T* = triangle, *D* = 55-deg diamond, *V* = 35-deg diamond. When severe cratering cannot be avoided, an insert having a small, end cutting edge angle is desirable to delay the crater breakthrough behind the nose. For very heavy cuts, a small, end cutting edge angle will strengthen the corner of the tool. Tool holders for numerical control machines are discussed beginning page [856](#).

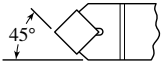

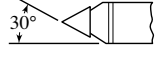

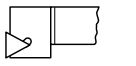

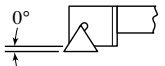

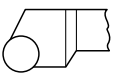

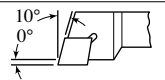

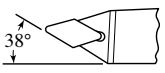

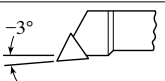

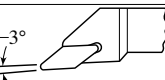

**Table 3a. Maximum Plunge Angle for Tracing or Contour Turning**

Tool Holder Style	Insert Shape	Maximum Plunge Angle	Tool Holder Style	Insert Shape	Maximum Plunge Angle

**Sintered Carbide Blanks and Cutting Tools**

**Sintered Carbide Blanks.**—As shown in Table 4, American National Standard ANSI B212.1-2002 provides standard sizes and designations for eight styles of sintered carbide blanks. These blanks are the unground solid carbide from which either solid or tipped cutting tools are made. Tipped cutting tools are made by brazing a blank onto a shank to produce the cutting tool; these tools differ from carbide *insert* cutting tools which consist of a carbide insert held mechanically in a tool holder. A typical single-point carbide-tipped cutting tool is shown in Fig. 1 on page 849.

**Single-Point, Sintered Carbide-Tipped Tools.**—American National Standard ANSI B212.1-2002 covers eight different styles of single-point, carbide-tipped general purpose tools. These styles are designated by the letters A to G inclusive. Styles A, B, F, G, and E with offset point are either right- or left-hand cutting as indicated by the letters R or L. Dimensions of tips and shanks are given in Table 5 to Table 12. For dimensions and tolerances not shown, and for the identification system, dimensions, and tolerances of sintered carbide boring tools, see the Standard.

A number follows the letters of the tool style and hand designation, and, for square shank tools, represents the number of sixteenths of an inch of width, *W*, and height, *H*. With rectangular shanks, the first digit of the number indicates the number of eighths of an inch in the shank width, *W*, and the second digit the number of quarters of an inch in the shank height, *H*. One exception is the 1½ × 2-inch size, which has been arbitrarily assigned the number 90.

<sup>a</sup> All dimensions are in inches.<sup>b</sup> See Fig. 1 on page 849 for a description of styles.

A typical single-point carbide-tipped cutting tool is shown in Fig. 2. The side rake, side relief, and the clearance angles are normal to the side-cutting edge, rather than the shank, to facilitate its being ground on a tilting-table grinder. The end-relief and clearance angles are *normal* to the end-cutting edge. The back-rake angle is parallel to the side-cutting edge.

Fig. 1. Eight styles of Sintered Carbide Blanks (see Table 4)

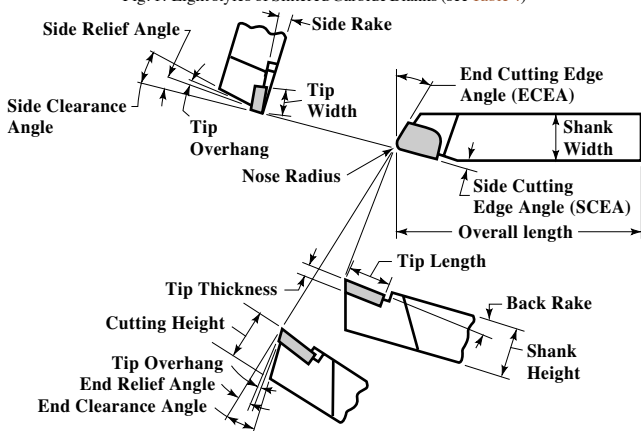

Fig. 2. A Typical Single-Point Carbide-Tipped Cutting Tool

The tip of the brazed carbide blank overhangs the shank of the tool by either  $\frac{1}{32}$  or  $\frac{1}{16}$  inch, depending on the size of the tool. For tools in Table 5, Table 6, Table 7, Table 8, Table 11 and Table 12, the maximum overhang is  $\frac{1}{32}$  inch for shank sizes 4, 5, 6, 7, 8, 10, 12 and 44; for other shank sizes in these tables, the maximum overhang is  $\frac{1}{16}$  inch. In Table 9 and Table 10, all tools have maximum overhang of  $\frac{1}{32}$  inch.

*Single-point Tool Nose Radii:* The tool nose radii recommended in the American National Standard are as follows: For square-shank tools up to and including  $\frac{3}{8}$ -inch

square tools,  $\frac{1}{64}$  inch; for those over  $\frac{3}{8}$ -inch square through  $1\frac{1}{4}$ -inches square,  $\frac{1}{32}$  inch; and for those above  $1\frac{1}{4}$ -inches square,  $\frac{1}{16}$  inch. For rectangular-shank tools with shank sections of  $\frac{1}{2} \times 1$  inch through  $1 \times 1\frac{1}{2}$  inches, the nose radii are  $\frac{1}{32}$  inch, and for  $1 \times 2$ - and  $1\frac{1}{2} \times 2$ -inch shanks, the nose radius is  $\frac{1}{16}$  inch.

**Single-point Tool Angle Tolerances:** The tool angles shown on the diagrams in Table 5 through Table 12 are general recommendations. Tolerances applicable to these angles are  $\pm 1$  degree on all angles except end and side clearance angles; for these the tolerance is  $\pm 2$  degrees.

**Brazing Carbide Tips to Steel Shanks.**—Sintered carbide tips or blanks are attached to steel shanks by brazing. Shanks usually are made of low-alloy steels having carbon contents ranging from 0.40 to 0.60 percent. Shank Preparation: The carbide tip usually is inserted into a milled recess or seat. When a recess is used, the bottom should be flat to provide a firm even support for the tip. The corner radius of the seat should be somewhat smaller than the radius on the tip to avoid contact and insure support along each side of the recess. Cleaning: All surfaces to be brazed must be absolutely clean. Surfaces of the tip may be cleaned by grinding lightly or by sand-blasting. Brazing Materials and Equipment: The brazing metal may be copper, naval brass such as Tobin bronze, or silver solder. A flux such as borax is used to protect the clean surfaces and prevent oxidation. Heating may be done in a furnace or by oxy-acetylene torch or an oxy-hydrogen torch. Copper brazing usually is done in a furnace, although an oxy-hydrogen torch with excess hydrogen is sometimes used. Brazing Procedure: One method using a torch is to place a thin sheet material, such as copper foil, around and beneath the carbide tip, the top of which is covered with flux. The flame is applied to the underside of the tool shank, and, when the materials melt, the tip is pressed firmly into its seat with tongs or with the end of a rod. Brazing material in the form of wire or rod may be used to coat or tin the surfaces of the recess after the flux

melts and runs freely. The tip is then inserted, flux is applied to the top, and heating is continued until the coatings melt and run freely. The tip, after coating with flux, is placed in the recess and the shank end is heated. Then a small piece of silver solder, having a melting point of 1325°F (718°C), is placed on top of the tip. When this solder melts, it runs over the nickel-coated surfaces while the tip is held firmly into its seat. The brazed tool should be cooled slowly to avoid cracking due to unequal contraction between the steel and carbide.

**Carbide Tools.**—Cemented or sintered carbides are used in the machine-building and various other industries, chiefly for cutting tools but also for certain other tools or parts subject to considerable abrasion or wear. Carbide cutting tools, when properly selected to obtain the right combination of strength and hardness, are very effective in machining all classes of iron and steel, nonferrous alloys, non-metallic materials, hard rubber, synthetic resins, slate, marble, and other materials which would quickly dull steel tools either because of hardness or abrasive action. Carbide cutting tools are not only durable, but capable of exceptionally high cutting speeds. See *CEMENTED CARBIDES* starting on page 860 for more on these materials.

*Tungsten carbide* is used extensively in cutting cast iron, nonferrous metals that form short chips in cutting, plastics and various other non-metallic materials. A grade having

All dimensions are in inches. Where a pair of tip numbers is shown, the upper number applies to GR tools, the lower to GL tools.

a hardness of 87.5 RA on the Rockwell A scale might be used where a strong grade is required, as for roughing cuts, whereas for light high-speed finishing or other cuts, a hardness of about 92 RA might be preferable. When tungsten carbide is applied to steel, craters or chip cavities are formed back of the cutting edge; hence other carbides have been developed that offer greater resistance to abrasion.

*Tungsten-titanium carbide* (often called "titanium carbide") is adapted to cutting either heat-treated or non-heat-treated steels, cast steel, or any tough material that might form chip cavities. It is also applicable to bronzes, monel metal, aluminum alloys, etc.

*Tungsten-tantalum carbide* or "tantalum carbide" cutting tools are also applicable to steels, bronzes or other tough materials. A hardness of 86.8 RA is recommended by one manufacturer for roughing steel, whereas a grade for finishing might have a hardness ranging from 88.8 to 91.5 RA.

**Chipbreaker.**—The term “chipbreaker” indicates a method of forming or grinding turning tools which will cause the chips to break up into short pieces, thus preventing the formation of long or continuous chips that would occupy considerable space and be difficult to handle. The chipbreaking form of cutting end is especially useful in turning with carbide-tipped steel turning tools because the cutting speeds are high and the chip formation rapid. The chipbreaker consists of a shoulder back of the cutting edge. As the chip encounters this shoulder it is bent and broken repeatedly into small pieces. Some tools have attached or “mechanical” chipbreakers, which serve the same purpose as the shoulder.

**Chipless Machining.**—Chipless machining is the term applied to methods of cold forming metals to the required finished part shape (or nearly finished shape) without the production of chips (or with a minimum of subsequent machining required). Cold forming of steel has long been performed in such operations as wire-, bar-, and tube-drawing; cold-heading; coining; and conventional stamping and drawing. However, newer methods of plastic deformation with greatly increased degrees of metal displacement have been developed. Among these processes are the rolling of serrations, splines, and gears; power spinning; internal swaging; radial forging; the cold forming of multiple-diameter shafts; cold extrusion; and high-energy-rate forming, which includes explosive forming. The processes of cold heading, thread rolling and rotary swaging are also considered chipless machining processes.

**Indexable Insert Holders for NC.**—Indexable insert holders for numerical control lathes are usually made to more precise standards than ordinary holders. Where applicable, reference should be made to American National Standard B212.3-2002, Precision Holders for Indexable Inserts. This standard covers the dimensional specifications, styles, and designations of precision holders for indexable inserts, which are defined as tool holders that locate the gage insert (a combination of shim and insert thicknesses) from the back or front and end surfaces to a specified dimension with a  $\pm 0.003$  inch ( $\pm 0.08$  mm) tolerance. In NC programming, the programmed path is that followed by the center of the tool tip, which is the center of the point, or nose radius, of the insert. The surfaces produced are the result of the path of the nose and the major cutting edge, so it is necessary to compensate for the nose or point radius and the lead angle when writing the program. Table 1, from B212.3, gives the compensating dimensions for different holder styles. The reference point is determined by the intersection of extensions from the major and minor cutting edges, which would be the location of the point of a sharp pointed tool. The distances from this point to the nose radius are  $L1$  and  $D1$ ;  $L2$  and  $D2$  are the distances from the sharp point to the center of the nose radius. Threading tools have sharp corners and do not require a radius compensation. Other dimensions of importance in programming threading tools are also given in Table 2; the data were developed by Kennametal, Inc.

The  $C$  and  $F$  characters are tool holder dimensions other than the shank size. In all instances, the  $C$  dimension is parallel to the length of the shank and the  $F$  dimension is parallel to the side dimension; actual dimensions must be obtained from the manufacturer. For all  $K$  style holders, the  $C$  dimension is the distance from the end of the shank to the tangent point of the nose radius and the end cutting edge of the insert. For all other holders, the  $C$  dimension is from the end of the shank to a tangent to the nose radius of the insert. The  $F$  dimension on all B, D, E, M, P, and V style holders is measured from the back side of the shank to the tangent point of the nose radius and the side cutting edge of the insert. For all A, F, G, J, K, and L style holders, the  $F$  dimension is the distance from the back side of the shank to the tangent of the nose radius of the insert. In all these designs, the nose radius is the standard radius corresponding to those given in the paragraph *Cutting Point Configuration* on page 841.

## CEMENTED CARBIDES

### Cemented Carbides and Other Hard Materials

**Carbides and Carbonitrides.**—Though high-speed steel retains its importance for such applications as drilling and broaching, most metal cutting is carried out with carbide tools. For materials that are very difficult to machine, carbide is now being replaced by carbonitrides, ceramics, and superhard materials. Cemented (or sintered) carbides and carbonitrides, known collectively in most parts of the world as hard metals, are a range of very hard, refractory, wear-resistant alloys made by powder metallurgy techniques. The minute carbide or nitride particles are “cemented” by a binder metal that is liquid at the sintering temperature. Compositions and properties of individual hardmetals can be as different as those of brass and high-speed steel.

All hardmetals are *cermets*, combining *ceramic* particles with a *metallic* binder. It is unfortunate that (owing to a mistranslation) the term *cermet* has come to mean either all hardmetals with a titanium carbide (TiC) base or simply cemented titanium carbonitrides. Although no single element other than carbon is present in all hardmetals, it is no accident that the generic term is “tungsten carbide.” The earliest successful grades were based on carbon, as are the majority of those made today, as listed in [Table 1](#).

The outstanding machining capabilities of high-speed steel are due to the presence of very hard carbide particles, notably tungsten carbide, in the iron-rich matrix. Modern methods of making cutting tools from pure tungsten carbide were based on this knowledge. Early pieces of cemented carbide were much too brittle for industrial use, but it was soon found that mixing tungsten carbide powder with up to 10 percent of metals such as iron, nickel, or cobalt, allowed pressed compacts to be sintered at about 1500°C to give a product with low porosity, very high hardness, and considerable strength. This combination of properties made the materials ideally suitable for use as tools for cutting metal.

Cemented carbides for cutting tools were introduced commercially in 1927, and, although the key discoveries were made in Germany, many of the later developments have taken place in the United States, Austria, Sweden, and other countries. Recent years have seen two “revolutions” in carbide cutting tools, one led by the United States and the other by Europe. These were the change from brazed to clamped carbide inserts and the rapid development of coating technology.

When indexable tips were first introduced, it was found that so little carbide was worn away before they were discarded that a minor industry began to develop, regrinding the so-called “throwaway” tips and selling them for reuse in adapted toolholders. Hardmetal consumption, which had grown dramatically when indexable inserts were introduced, leveled off and began to decline. This situation was changed by the advent and rapid acceptance of carbide, nitride, and oxide coatings. Application of an even harder, more wear-resistant surface to a tougher, more shock-resistant substrate allowed production of new generations of longer-lasting inserts. Regrinding destroyed the enhanced properties of the coatings and was, therefore, abandoned for coated tooling.

Brazed tools have the advantage that they can be reground over and over again, until almost no carbide is left, but the tools must always be reset after grinding to maintain machining accuracy. However, all brazed tools suffer to some extent from the stresses left by the brazing process, which in unskilled hands or with poor design can shatter the carbide even before it has been used to cut metal. In present conditions, it is cheaper to use indexable inserts, which are tool tips of precise size, clamped in similarly precise holders, needing no time-consuming and costly resetting but usable only until each cutting edge or corner has lost its initial sharpness (see [Introduction](#) and related topics starting on page 839 and [Indexable Insert Holders for NC](#) on page 856). The absence of brazing stresses and the “one-use” concept also means that harder, longer-lasting grades can be used.

**Table 1. Typical Properties of Tungsten Carbide-Based Cutting Tool Hard Metals**

ISO Application Code	Composition (%)				Density (g/cm <sup>3</sup> )	Hardness (Vickers)	Transverse Rupture Strength (N/mm <sup>2</sup> )

K20	94			6	14.8	1650	1950
K30	91			9	14.4	1400	2250
K40	89			11	14.1	1320	2500

A complementary development was the introduction of ever more complex chipbreakers derived from computer-aided design and pressed and sintered to precise shapes and dimensions. Another advance was the application of hot isostatic pressing (HIP), which has moved hardmetals into applications that were formerly uneconomical. This method allows virtually all residual porosity to be squeezed out of the carbide by means of inert gas at high pressure applied at about the sintering temperature. Toughness, rupture strength, and shock resistance can be doubled or tripled by this method, and the reject rates of very large sintered components are reduced to a fraction of their previous levels.

Further research has produced a substantial number of excellent cutting-tool materials based on titanium carbonitride. Generally called "cermets," as noted previously, carbonitride-based cutting inserts offer excellent performance and considerable prospects for the future.

*Compositions and Structures:* Properties of hardmetals are profoundly influenced by microstructure. The microstructure, in turn, depends on many factors, including basic chemical composition of the carbide and matrix phases; size, shape, and distribution of carbide particles; relative proportions of carbide and matrix phases; degree of intersolubility of carbides; excess or deficiency of carbon; variations in composition and structure caused by diffusion or segregation; production methods generally, but especially milling, carburizing, and sintering methods, and the types of raw materials; post sintering treatments such as hot isostatic pressing; and coatings or diffusion layers applied after initial sintering.

*Tungsten Carbide/Cobalt (WC/Co):* The first commercially available cemented carbides consisted of fine angular particles of tungsten carbide bonded with metallic cobalt. Intended initially for wire-drawing dies, this composition type is still considered to have the greatest resistance to simple abrasive wear and, therefore, to have many applications in machining.

For maximum hardness to be obtained from closeness of packing, the tungsten carbide grains should be as small as possible, preferably below 1  $\mu\text{m}$  (0.00004 inch) and considerably less for special purposes. Hardness and abrasion resistance increase as the cobalt content is lowered, provided that a minimum of cobalt is present (2 percent can be enough,

although 3 percent is the realistic minimum) to ensure complete sintering. In general, as carbide grain size or cobalt content or both are increased—frequently in unison—tougher and less hard grades are obtained. No porosity should be visible, even under the highest optical magnification.

WC/Co compositions used for cutting tools range from about 2 to 13 percent cobalt, and from less than 0.5 to more than 5  $\mu\text{m}$  (0.00002–0.0002 in.) in grain size. For stamping tools, swaying dies, and other wear applications for parts subjected to moderate or severe shock, cobalt content can be as much as 30 percent, and grain size a maximum of about 10  $\mu\text{m}$  (0.0004 in.). In recent years, “micrograin” carbides, combining submicron (less than 0.00004 in.) carbide grains with relatively high cobalt content have found increasing use for machining at low speeds and high feed rates. An early use was in high-speed wood-working cutters such as are used for planing.

For optimum properties, porosity should be at a minimum, carbide grain size as regular as possible, and carbon content of the tungsten carbide phase close to the theoretical (stoichiometric) value. Many tungsten carbide/cobalt compositions are modified by small but important additions—from 0.5 to perhaps 3 percent of tantalum, niobium, chromium, vanadium, titanium, hafnium, or other carbides. The basic purpose of these additions is generally inhibition of grain growth so that a consistently fine structure is maintained.

*Tungsten-Titanium Carbide/Cobalt (WC/TiC/Co):* These grades are used for tools to cut steels and other ferrous alloys, the purpose of the TiC content being to resist the high-temperature diffusive attack that causes chemical breakdown and cratering. Tungsten carbide diffuses readily into the chip surface, but titanium carbide is extremely resistant to such diffusion. A solid solution or “mixed crystal” of WC in TiC retains the anticratering property to a great extent.

Unfortunately, titanium carbide and TiC-based solid solutions are considerably more brittle and less abrasion resistant than tungsten carbide. TiC content, therefore, is kept as low as possible, only sufficient TiC being provided to avoid severe cratering wear. Even 2 or 3 percent of titanium carbide has a noticeable effect, and, as the relative content is substantially increased, the cratering tendency becomes more severe.

In the limiting formulation, the carbide is tungsten-free and based entirely on TiC, but, generally, TiC content extends to no more than about 18 percent. Above this figure, the carbide becomes excessively brittle and is very difficult to braze, although this drawback is not a problem with throwaway inserts.

WC/TiC/Co grades generally have two distinct carbide phases, angular crystals of almost pure WC and rounded TiC/WC mixed crystals. Among progressive manufacturers, although WC/TiC/Co hardmetals are very widely used, in certain important respects they are obsolescent, having been superseded by the WC/TiC/Ta(Nb)C/Co series in the many applications where higher strength combined with crater resistance is an advantage. TiC, TiN, and other coatings on tough substrates have also diminished the attractions of high-TiC grades for high-speed machining of steels and ferrous alloys.

*Tungsten-Titanium-Tantalum (-Niobium) Carbide/Cobalt:* Except for coated carbides, tungsten-titanium-tantalum (-niobium) grades could be the most popular class of hardmetals. Used mainly for cutting steel, they combine and improve upon most of the best features of the longer-established WC/TiC/Co compositions. These carbides compete directly with carbonitrides and silicon nitride ceramics, and the best cemented carbides of this class can undertake very heavy cuts at high speeds on all types of steels, including austenitic stainless varieties. These tools also operate well on ductile cast irons and nickel-base superalloys, where great heat and high pressures are generated at the cutting edge. However, they do not have the resistance to abrasive wear possessed by micrograin straight tungsten carbide grades nor the good resistance to cratering of coated grades and titanium carbide-based cermets.

*Titanium Carbide/Molybdenum/Nickel (TiC/Mo/Ni):* The extreme indentation hardness and crater resistance of titanium carbide, allied to the cheapness and availability of its

main raw material (titanium dioxide,  $\text{TiO}_2$ ), provide a strong inducement to use grades based on this carbide alone. Although developed early in the history of hardmetals, these carbides were difficult to braze satisfactorily and consequently were little used until the advent of clamped, throwaway inserts. Moreover, the carbides were notoriously brittle and could take only fine cuts in minimal-shock conditions.

Titanium carbide-based grades again came into prominence about 1960, when nickel-molybdenum began to be used as a binder instead of nickel. The new grades were able to perform a wider range of tasks, including interrupted cutting and cutting under shock conditions.

The very high indentation hardness values recorded for titanium carbide grades are not accompanied by correspondingly greater resistance to abrasive wear, the apparently less hard tungsten carbide being considerably superior in this property. Moreover, carbonitrides, advanced tantalum-containing multicarbides, and coated variants generally provide better all-around cutting performances.

*Titanium-Base Carbonitrides:* Development of titanium-carbonitride-based cutting-tool materials predates the use of coatings of this type on more conventional hardmetals by many years. Appreciable, though uncontrolled, amounts of carbonitride were often present, if only by accident, when cracked ammonia was used as a less expensive substitute for hydrogen in some stages of the production process in the 1950s and perhaps for two decades earlier.

Much of the recent, more scientific development of this class of materials has taken place in the United States, particularly by Teledyne Firth Sterling with its  $\text{SD}_3$  grade and in Japan by several companies. Many of the compositions currently in use are extremely complex, and their structures—even with apparently similar compositions—can vary enormously. For instance, Mitsubishi characterizes its Himet NX series of cermets as  $\text{TiC}/\text{WC}/\text{Ta}(\text{Nb})\text{C}/\text{Mo}_2\text{C}/\text{TiN}/\text{Ni}/\text{Co}/\text{Al}$ , with a structure comprised of both large and medium-size carbide particles (mainly  $\text{TiC}$  according to the quoted density) in a superalloy-type matrix containing an aluminum-bearing intermetallic compound.

*Steel- and Alloy-Bonded Titanium Carbide:* The class of material exemplified by Ferro-Tic, as it is known, consists primarily of titanium carbide bonded with heat-treatable steel, but some grades also contain tungsten carbide or are bonded with nickel- or copper-base alloys. These cemented carbides are characterized by high binder contents (typically 50–60 percent by volume) and lower hardnesses, compared with the more usual hardmetals, and by the great variation in properties obtained by heat treatment.

In the annealed condition, steel-bonded carbides have a relatively soft matrix and can be machined with little difficulty, especially by CBN (superhard cubic boron nitride) tools. After heat treatment, the degree of hardness and wear resistance achieved is considerably greater than that of normal tool steels, although understandably much less than that of traditional sintered carbides. Microstructures are extremely varied, being composed of 40–50 percent  $\text{TiC}$  by volume and a matrix appropriate to the alloy composition and the stage of heat treatment. Applications include stamping, blanking and drawing dies, machine components, and similar items where the ability to machine before hardening reduces production costs substantially.

*Coating:* As a final stage in carbide manufacture, coatings of various kinds are applied mainly to cutting tools, where for cutting steel in particular it is advantageous to give the flank and clearance surfaces characteristics that are quite different from those of the body of the insert. Coatings of titanium carbide, nitride, or carbonitride; of aluminum oxide; and of other refractory compounds are applied to a variety of hardmetal substrates by chemical or physical vapor deposition (CVD or PVD) or by newer plasma methods.

The most recent types of coatings include hafnium, tantalum, and zirconium carbides and nitrides; alumina/titanium oxide; and multiple carbide/carbonitride/nitride/oxide, oxynitride or oxycarbonitride combinations. Greatly improved properties have been

claimed for variants with as many as 13 distinct CVD coatings. A markedly sharper cutting edge compared with other CVD-coated hardmetals is claimed, permitting finer cuts and the successful machining of soft but abrasive alloys.

The keenest edges on coated carbides are achieved by the techniques of physical vapor deposition. In this process, ions are deposited directionally from the electrodes, rather than evenly on all surfaces, so the sharpness of cutting edges is maintained and may even be enhanced. PVD coatings currently available include titanium nitride and carbonitride, their distinctive gold color having become familiar throughout the world on high-speed steel tooling. The high temperatures required for normal CVD tend to soften heat-treated high-speed steel. PVD-coated hardmetals have been produced commercially for several years, especially for precision milling inserts.

Recent developments in extremely hard coatings, generally involving exotic techniques, include boron carbide, cubic boron nitride, and pure diamond. Almost the ultimate in wear resistance, the commercial applications of thin plasma-generated diamond surfaces at present are mainly in the manufacture of semiconductors, where other special properties are important.

For cutting tools, the substrate is of equal importance to the coating in many respects, its critical properties including fracture toughness (resistance to crack propagation), elastic modulus, resistance to heat and abrasion, and expansion coefficient. Some manufacturers are now producing inserts with graded composition so that structures and properties are optimized at both surface and interior, and coatings are less likely to crack or break away.

*Specifications:* Compared with other standardized materials, the world of sintered hardmetals is peculiar. For instance, an engineer who seeks a carbide grade for the finish-machining of a steel component may be told to use *ISO Standard Grade P10* or *Industry Code C7*. If the composition and nominal properties of the designated tool material are then requested, the surprising answer is that, in basic composition alone, the tungsten carbide content of P10 (or of the now superseded C7) can vary from zero to about 75, titanium carbide from 8 to 80, cobalt 0 to 10, and nickel 0 to 15 percent. There are other possible constituents, also, in this so-called standard alloy, and many basic properties can vary as much as the composition. All that these dissimilar materials have in common, and all that the so-called standards mean, is that their suppliers—and sometimes their suppliers alone—consider them suitable for one particular and ill-defined machining application (which for P10 or C7 is the finish machining of steel).

This peculiar situation arose because the production of cemented carbides in occupied Europe during World War II was controlled by the German Hartmetallzentrale, and no factory other than Krupp was permitted to produce more than one grade. By the end of the war, all German-controlled producers were equipped to make the G, S, H, and F series to German standards. In the postwar years, this series of carbides formed the basis of unofficial European standardization. With the advent of the newer multicarbides, the previous identities of grades were gradually lost. The applications relating to the old grades were retained, however, as a new German DIN standard, eventually being adopted, in somewhat modified form, by the International Standards Organization (ISO) and by ANSI in the United States.

The American cemented carbides industry developed under diverse ownership and solid competition. The major companies actively and independently developed new varieties of hardmetals, and there was little or no standardization, although there were many attempts to compile equivalent charts as a substitute for true standardization. Around 1942, the Buick division of GMC produced a simple classification code that arranged nearly 100 grades derived from 10 manufacturers under only 14 symbols (TC-1 to TC-14). In spite of serious deficiencies, this system remained in use for many years as an American industry standard; that is, Buick TC-1 was equivalent to industry code C1. Buick itself went much further, using the tremendous influence, research facilities, and purchasing potential of its parent company to standardize the

products of each carbide manufacturer by properties that could be tested, rather than by the indeterminate recommended applications. Many large-scale carbide users have developed similar systems in attempts to exert some degree of in-house standardization and quality control. Small and medium-sized users, however, still suffer from so-called industry standards, which only provide a starting point for grade selection.

ISO standard 513, summarized in Table 2, divides all machining grades into three color-coded groups: straight tungsten carbide grades (letter K, color red) for cutting gray cast iron, nonferrous metals, and nonmetallics; highly alloyed grades (letter P, color blue) for machining steel; and less alloyed grades (letter M, color yellow, generally with less TiC than the corresponding P series), which are multipurpose and may be used on steels, nickel-base superalloys, ductile cast irons, and so on. Each grade within a group is also given a number to represent its position in a range from maximum hardness to maximum toughness (shock resistance). Typical applications are described for grades at more or less regular numerical intervals. Although coated grades scarcely existed when the ISO standard was prepared, it is easy to classify coated as uncoated carbides—or carbonitrides, ceramics, and superhard materials—according to this system.

In this situation, it is easy to see how one plant will prefer one manufacturer's carbide and a second plant will prefer that of another. Each has found the carbide most nearly ideal for the particular conditions involved. In these circumstances it pays each manufacturer to make grades that differ in hardness, toughness, and crater resistance, so that they can provide a product that is near the optimum for a specific customer's application.

Although not classified as a hard metal, new particle or powder metallurgical methods of manufacture, coupled with new coating technology, have led in recent years to something of an upsurge in the use of high-speed steel. Lower cost is a big factor, and the development of such coatings as titanium nitride, cubic boron nitride, and pure diamond, has enabled some high-speed steel tools to rival tools made from tungsten and other carbides in their ability to maintain cutting accuracy and prolong tool life. Multiple layers may be used to produce optimum properties in the coating, with adhesive strength where there is contact with the substrate, combined with hardness at the cutting surface to resist abrasion. Total thickness of such coating, even with multiple layers, is seldom more than 15 microns (0.00060 in.).

*Importance of Correct Grades:* A great diversity of hardmetal types is required to cope with all possible combinations of metals and alloys, machining operations, and working conditions. Tough, shock-resistant grades are needed for slow speeds and interrupted cutting, harder grades for high-speed finishing, heat-resisting alloyed grades for machining superalloys, and crater-resistant compositions, including most of the many coated varieties, for machining steels and ductile iron.

**Ceramics.**—Moving up the hardness scale, ceramics provide increasing competition for cemented carbides, both in performance and in cost-effectiveness, though not yet in reliability. Hardmetals themselves consist of ceramics—nonmetallic refractory compounds, usually carbides or carbonitrides—with a metallic binder of much lower melting point. In such systems, densification generally takes place by liquid-phase sintering. Pure ceramics have no metallic binder, but may contain lower-melting-point compounds or ceramic mixtures that permit liquid-phase sintering to take place. Where this condition is not possible, hot pressing or hot isostatic pressing can often be used to make a strong, relatively pore-free component or cutting insert. This section is restricted to those ceramics that compete directly with hardmetals, mainly in the cutting-tool category as shown in Table 3.

Ceramics are hard, completely nonmetallic substances that resist heat and abrasive wear. Increasingly used as clamped indexable tool inserts, ceramics differ significantly from tool steels, which are completely metallic. Ceramics also differ from cermets such as cemented carbides and carbonitrides, which comprise minute ceramic particles held together by metallic binders.

**Table 2. ISO Classifications of Hardmetals (Cemented Carbides and Carbonitrides) by Application**

Main Types of Chip Removal		Groups of Applications			Direction of Decrease in Characteristic	
Symbol and Color	Broad Categories of Materials to be Machined	Designation (Grade)	Specific Material to be Machined	Use and Working Conditions	of cut	of carbide
P Blue	Ferrous with long chips	P01	Steel, steel castings	Finish turning and boring; high cutting speeds, small chip sections, accurate dimensions, fine finish, vibration-free operations	↑ speed ↑ wear resistance	
		P10	Steel, steel castings	Turning, copying, threading, milling; high cutting speeds; small or medium chip sections		
		P20	Steel, steel castings, ductile cast iron with long chips	Turning, copying, milling; medium cutting speeds and chip sections, planing with small chip sections		
		P30	Steel, steel castings, ductile cast iron with long chips	Turning, milling, planing; medium or large chip sections, unfavorable machining conditions		
		P40	Steel, steel castings with sand inclusions and cavities	Turning, planing, slotting; low cutting speeds, large chip sections, with possible large cutting angles, unfavorable cutting conditions, and work on automatic machines		
		P50	Steel, steel castings of medium- or low-tensile strength, with sand inclusions and cavities	Operations demanding very tough carbides; turning, planing, slotting; low cutting speeds, large chip sections, with possible large cutting angles, unfavorable conditions and work on automatic machines		
M Yellow	Ferrous metals with long or short chips, and nonferrous metals	M10	Steel, steel castings, manganese steel, gray cast iron, alloy cast iron	Turning; medium or high cutting speeds, small or medium chip sections		
		M20	Steel, steel castings, austenitic or manganese steel, gray cast iron	Turning, milling; medium cutting speeds and chip sections		
		M30	Steel, steel castings, austenitic steel, gray cast iron, high-temperature-resistant alloys	Turning, milling, planing; medium cutting speeds, medium or large chip sections		
		M40	Mild, free-cutting steel, low-tensile steel, nonferrous metals and light alloys	Turning, parting off; particularly on automatic machines		
K Red	Ferrous metals with short chips, nonferrous metals and non-metallic materials	K01	Very hard gray cast iron, chilled castings over 85 Shore, high-silicon aluminum alloys, hardened steel, highly abrasive plastics, hard cardboard, ceramics	Turning, finish turning, boring, milling, scraping		
		K10	Gray cast iron over 220 BHN (Brinell), malleable cast iron with short chips, hardened steel, silicon-aluminum and copper alloys, plastics, glass, hard rubber, hard cardboard, porcelain, stone	Turning, milling, drilling, boring, broaching, scraping		
		K20	Gray cast iron up to 220 BHN, nonferrous metals, copper, brass, aluminum	Turning, milling, planing, boring, broaching, demanding very tough carbide		
		K30	Low-hardness gray cast iron, low-tensile steel, compressed wood	Turning, milling, planing, slotting, unfavorable conditions, and possibility of large cutting angles		
		K40	Softwood or hardwood, nonferrous metals	Turning, milling, planing, slotting, unfavorable conditions, and possibility of large cutting angles		
					↓ feed ↓ toughness	

**Table 3. Typical Properties of Cutting Tool Ceramics**

Group	Alumina	Alumina/TiC	Silicon Nitride	PCD	PCBN
Typical composition types	Al <sub>2</sub> O <sub>3</sub> or Al <sub>2</sub> O <sub>3</sub> /ZrO <sub>2</sub>	70/30 Al <sub>2</sub> O <sub>3</sub> /TiC	Si <sub>3</sub> N <sub>4</sub> /Y <sub>2</sub> O <sub>3</sub> plus		
Density (g/cm <sup>3</sup> )	4.0	4.25	3.27	3.4	3.1
Transverse rupture strength (N/mm <sup>2</sup> )	700	750	800		800
Compressive strength (kN/mm <sup>2</sup> )	4.0	4.5	4.0	4.7	3.8
Hardness (HV)	1750	1800	1600		
Hardness HK (kN/mm <sup>2</sup> )				50	28
Young's modulus (kN/mm <sup>2</sup> )	380	370	300	925	680

Fracture toughness (K <sub>1c</sub> MN/m <sup>3/2</sup> )	2.3	3.3	5.0	7.9	10

Alumina-based ceramics were introduced as cutting inserts during World War II and were for many years considered too brittle for regular machine-shop use. Improved machine tools and finer-grain, tougher compositions incorporating zirconia or silicon carbide “whiskers” now permit their use in a wide range of applications. Silicon nitride, often combined with alumina (aluminum oxide), yttria (yttrium oxide), and other oxides and nitrides, is used for much of the high-speed machining of superalloys, and newer grades have been formulated specifically for cast iron—potentially a far larger market.

In addition to improvements in toolholders, great advances have been made in machine tools, many of which now feature the higher powers and speeds required for the efficient use of ceramic tooling. Brittleness at the cutting edge is no longer a disadvantage, with the improvements made to the ceramics themselves, mainly in toughness, but also in other critical properties.

Although very large numbers of useful ceramic materials are now available, only a few combinations have been found to combine such properties as minimum porosity, hardness, wear resistance, chemical stability, and resistance to shock to the extent necessary for cutting-tool inserts. Most ceramics used for machining are still based on high-purity, fine-grained alumina (aluminum oxide) but embody property-enhancing additions of other ceramics such as zirconia (zirconium oxide), titania (titanium oxide), titanium carbide, tungsten carbide, and titanium nitride. For commercial purposes, those more commonly used are often termed “white” (alumina with or without zirconia) or “black” (roughly 70 ± 30 alumina/titanium carbide). More recent developments are the distinctively green alumina ceramics strengthened with silicon carbide whiskers and the brown-tinged silicon nitride types.

Ceramics benefit from hot isostatic pressing to remove the last vestiges of porosity and raise substantially the material's shock resistance, even more than carbide-based hard-metals. Significant improvements are derived by even small parts such as tool inserts, although, in principle, they should not need such treatment if raw materials and manufacturing methods are properly controlled.

*Oxide Ceramics:* Alumina cutting tips have extreme hardness—more than HV 2000 or HRA 94—and give excellent service in their limited but important range of uses such as the machining of chilled iron rolls and brake drums. A substantial family of alumina-based materials has been developed, and fine-grained alumina-based composites now have sufficient strength for milling cast iron at speeds up to 2500 ft/min (800 m/min). Resistance to cratering when machining steel is exceptional.

*Oxide/Carbide Ceramics:* A second important class of alumina-based cutting ceramics combines aluminum oxide or alumina-zirconia with a refractory carbide or carbides,

nearly always 30 percent TiC. The compound is black and normally hot pressed or hot isostatically pressed (HIPed). As shown in Table 3, the physical and mechanical properties of this material are generally similar to those of the pure alumina ceramics, but strength and shock resistance are generally higher, being comparable with those of higher-toughness simple alumina-zirconia grades. Current commercial grades are even more complex, combining alumina, zirconia, and titanium carbide with the further addition of titanium nitride.

**Silicon Nitride Base:** One of the most effective ceramic cutting-tool materials developed in the United Kingdom is Syalon (from SiAlON or silicon-aluminum-oxynitride) though it incorporates a substantial amount of yttria for efficient liquid-phase sintering). The material combines high strength with hot hardness, shock resistance, and other vital properties. Syalon cutting inserts are made by Kennametal and Sandvik and sold as Kyon 2000 and CC680, respectively. The brown Kyon 200 is suitable for machining high-nickel alloys and cast iron, but a later development, Kyon 3000, has good potential for machining cast iron.

Resistance to thermal stress and thermal shock of Kyon 2000 are comparable to those of sintered carbides. Toughness is substantially less than that of carbides, but roughly twice that of oxide-based cutting-tool materials at temperatures up to 850°C. Syon 200 can cut at high edge temperatures and is harder than carbide and some other ceramics at over 700°C, although softer than most at room temperature.

**Whisker-Reinforced Ceramics:** To improve toughness, Greenleaf Corporation has reinforced alumina ceramics with silicon carbide single-crystal “whiskers” that impart a distinctive green color to the material, marketed as WG300. Typically as thin as human hairs, the immensely strong whiskers improve tool life under arduous conditions. Whisker-reinforced ceramics and perhaps hardmetals are likely to become increasingly important as cutting and wear-resistant materials. Their only drawback seems to be the carcinogenic nature of the included fibers, which requires stringent precautions during manufacture.

**Superhard Materials.**—Polycrystalline synthetic diamond (PCD) and cubic boron nitride (PCBN), in the two columns at the right in Table 3, are almost the only cutting-insert materials in the “superhard” category. Both PCD and PCBN are usually made with the highest practicable concentration of the hard constituent, although ceramic or metallic binders can be almost equally important in providing overall strength and optimizing other properties. Variations in grain size are another critical factor in determining cutting characteristics and edge stability. Some manufacturers treat CBN in similar fashion to tungsten carbide, varying the composition and amount of binder within exceptionally wide limits to influence the physical and mechanical properties of the sintered compact.

In comparing these materials, users should note that some inserts comprise solid polycrystalline diamond or CBN and are double-sized to provide twice the number of cutting edges. Others consist of a layer, from 0.020- to 0.040-inch (0.5- to 1-mm) thick, on a tough carbide backing. A third type is produced with a solid superhard material almost surrounded by sintered carbide. A fourth type, used mainly for cutting inserts, is comprised of solid hard metal with a tiny superhard insert at one or more (usually only one) cutting corners or edges. Superhard cutting inserts are expensive—up to 30 times the cost of equivalent shapes or sizes in ceramic or cemented carbide—but their outstanding properties, exceptional performance and extremely long life can make them by far the most cost-effective for certain applications.

**Diamond:** Diamond is the hardest material found or made. As harder, more abrasive ceramics and other materials came into widespread use, diamond began to be used for grinding wheel grits. Cemented carbide tools virtually demanded diamond grinding wheels for fine edge finishing. Solid single-crystal diamond tools were and are used to a small extent for special purposes, such as microtomes, for machining of hard materials, and for exceptionally fine finishes. These diamonds are made from comparatively large,

high-quality gem-type diamonds, have isotropic properties, and are very expensive. By comparison, diamond abrasive grits cost only a few dollars a carat.

Synthetic diamonds are produced from graphite using high temperatures and extremely high pressures. The fine diamond particles produced are sintered together in the presence of a metal "catalyst" to produce high-efficiency anisotropic cutting-tool inserts. These tools comprise either a solid diamond compact or a layer of sintered diamond on a carbide backing, and are made under conditions similar to, though less severe than, those used in diamond synthesis. Both natural and synthetic diamond can be sintered in this way, although the latter method is the most frequently used.

Polycrystalline diamond (PCD) compacts are immensely hard and can be used to machine many substances, from highly abrasive hardwoods and glass fiber to nonferrous metals, hardmetals, and tough ceramics. Important classes of tools that are also available with cubic boron nitride inserts include brazed-tip drills, single-point turning tools, and face-milling cutters.

*Boron Nitride:* Polycrystalline diamond has one big limitation: it cannot be used to machine steel or any other ferrous material without rapid chemical breakdown. Boron nitride does not have this limitation. Normally soft and slippery like graphite, the soft hexagonal crystals (HBN) become cubic boron nitride (CBN) when subjected to ultrahigh pressures and temperatures, with a structure similar to and hardness second only to diamond. As a solid insert of polycrystalline cubic boron nitride (PCBN), the compound machines even the hardest steel with relative immunity from chemical breakdown or cratering.

Backed by sintered carbide, inserts of PCBN can readily be brazed, increasing the usefulness of the material and the range of tooling in which it can be used. With great hardness and abrasion resistance, coupled with extreme chemical stability when in contact with ferrous alloys at high temperatures, PCBN has the ability to machine both steels and cast irons at high speeds for long operating cycles. Only its currently high cost in relation to hardmetals prevents its wider use in mass-production machining.

Similar in general properties to PCBN, the recently developed "Wurbon" consists of a mixture of ultrafine (0.02  $\mu\text{m}$  grain size) hexagonal and cubic boron nitride with a "wurtzite" structure, and is produced from soft hexagonal boron nitride in a microsecond by an explosive shockwave.

*Basic Machining Data:* Most mass-production metal-cutting operations are carried out with carbide-tipped tools, but their correct application is not simple. Even apparently similar batches of the same material vary greatly in their machining characteristics and may require different tool settings to attain optimum performance. Depth of cut, feed, surface speed, cutting rate, desired surface finish, and target tool life often need to be modified to suit the requirements of a particular component.

For the same downtime, the life of an insert between indexings can be less than that of an equivalent brazed tool between regrinds, so a much higher rate of metal removal is possible with the indexable or throwaway insert. It is commonplace for the claims for a new coating to include increases in surface-speed rates of 200–300 percent, and for a new insert design to offer similar improvements. Many operations are run at metal removal rates that are far from optimum for tool life because the rates used maximize productivity and cost-effectiveness.

Thus any recommendations for cutting speeds and feeds must be oversimplified or extremely complex, and must be hedged with many provisos, dependent on the technical and economic conditions in the manufacturing plant concerned. A preliminary grade selection should be made from the ISO-based tables and manufacturers' literature consulted for recommendations on the chosen grades and tool designs. If tool life is much greater than that desired under the suggested conditions, speeds, feeds, or depths of cut may be increased. If tools fail by edge breakage, a tougher (more shock-resistant) grade should be selected, with a numerically higher ISO code.

Alternatively, increasing the surface speed and decreasing the feed may be tried. If tools fail prematurely from what appears to be abrasive wear, a harder grade with numerically lower ISO designation should be tried. If cratering is severe, use a grade with higher titanium carbide content; that is, switch from an ISO K to M or M to P grade, use a P grade with lower numerical value, change to a coated grade, or use a coated grade with a (claimed) more-resistant surface layer.

*Built-Up Edge and Cratering:* The big problem in cutting steel with carbide tools is associated with the built-up edge and the familiar phenomenon called cratering. Research has shown that the built-up edge is continuous with the chip itself during normal cutting. Additions of titanium, tantalum, and niobium to the basic carbide mixture have a remarkable effect on the nature and degree of cratering, which is related to adhesion between the tool and the chip.

**Hardmetal Tooling for Wood and Nonmetallics.**—Carbide-tipped circular saws are now conventional for cutting wood, wood products such as chipboard, and plastics, and tipped bandsaws of large size are also gaining in popularity. Tipped handsaws and mechanical equivalents are seldom needed for wood, but they are extremely useful for cutting abrasive building boards, glass-reinforced plastics, and similar material. Like the hardmetal tips used on most other woodworking tools, saw tips generally make use of straight (unalloyed) tungsten carbide/cobalt grades. However, where excessive heat is generated as with the cutting of high-silica hardwoods and particularly abrasive chipboards, the very hard but tough tungsten-titanium-tantalum-niobium carbide solid-solution grades, normally reserved for steel finishing, may be preferred. Saw tips are usually brazed and reground a number of times during service, so coated grades appear to have little immediate potential in this field.

*Cutting Blades and Plane Irons:* These tools comprise long, thin, comparatively wide slabs of carbide on a minimal-thickness steel backing. Compositions are straight tungsten carbide, preferably micrograin (to maintain a keen cutting edge with an included angle of 30° or less), but with relatively high amounts of cobalt, 11–13 percent, for toughness. Considerable expertise is necessary to braze and grind these cutters without inducing or failing to relieve the excessive stresses that cause distortion or cracking.

*Other Woodworking Cutters:* Routers and other cutters are generally similar to those used on metals and include many indexable-insert designs. The main difference with wood is that rotational and surface speeds can be the maximum available on the machine. High-speed routing of aluminum and magnesium alloys was developed largely from machines and techniques originally designed for work on wood.

*Cutting Other Materials:* The machining of plastics, fiber-reinforced plastics, graphite, asbestos, and other hard and abrasive constructional materials mainly requires abrasion resistance. Cutting pressures and power requirements are generally low. With thermoplastics and some other materials, particular attention must be given to cooling because of softening or degradation of the work material that might be caused by the heat generated in cutting. An important application of cemented carbides is the drilling and routing of printed circuit boards. Solid tungsten carbide drills of extremely small sizes are used for this work.

## MILLING CUTTERS

## Selection of Milling Cutters

The most suitable type of milling cutter for a particular milling operation depends on such factors as the kind of cut to be made, the material to be cut, the number of parts to be machined, and the type of milling machine available. Solid cutters of small size will usually cost less, initially, than inserted blade types; for long-run production, inserted-blade cutters will probably have a lower overall cost. Depending on either the material to be cut or the amount of production involved, the use of carbide-tipped cutters in preference to high-speed steel or other cutting tool materials may be justified.

Rake angles depend on both the cutter material and the work material. Carbide and cast alloy cutting tool materials generally have smaller rake angles than high-speed steel tool materials because of their lower edge strength and greater abrasion resistance. Soft work materials permit higher radial rake angles than hard materials; thin cutters permit zero or practically zero axial rake angles; and wide cutters operate more smoothly with high axial rake angles. See *Rake Angles for Milling Cutters* on page 901.

Cutting edge relief or clearance angles are usually from 3 to 6 degrees for hard or tough materials, 4 to 7 degrees for average materials, and 6 to 12 degrees for easily machined materials. See *Clearance Angles for Milling Cutter Teeth* on page 900.

The number of teeth in the milling cutter is also a factor that should be given consideration, as explained in the next paragraph.

**Number of Teeth in Milling Cutters.**—In determining the number of teeth a milling cutter should have for optimum performance, there is no universal rule.

There are, however, two factors that should be considered in making a choice: 1) The number of teeth should never be so great as to reduce the chip space between the teeth to a point where a free flow of chips is prevented; and 2) The chip space should be smooth and without sharp corners that would cause clogging of the chips in the space.

For milling ductile materials that produce a continuous and curled chip, a cutter with large chip spaces is preferable. Such coarse tooth cutters permit an easier flow of the chips through the chip space than would be obtained with fine tooth cutters and help to eliminate cutter “chatter.” For cutting operations in thin materials, fine tooth cutters reduce cutter and workpiece vibration and the tendency for the cutter teeth to “straddle” the workpiece and dig in. For slitting copper and other soft nonferrous materials, teeth that are either chamfered or alternately flat and V-shaped are best.

As a general rule, to give satisfactory performance the number of teeth in milling cutters should be such that no more than two teeth at a time are engaged in the cut. Based on this rule, the following formulas (valid in both SI and English system of units) are recommended:

For face milling cutters,

$$T = \frac{6.3D}{W} \quad (1)$$

For peripheral milling cutters,

$$T = \frac{12.6D \cos A}{D + 4d} \quad (2)$$

where  $T$  = number of teeth in cutter;  $D$  = cutter diameter in inches (mm);  $W$  = width of cut in inches (mm);  $d$  = depth of cut in inches (mm); and  $A$  = helix angle of cutter.

To find the number of teeth that a cutter should have when other than two teeth are in the cut at the same time, Formulas (1) and (2) should be divided by 2 and the result multiplied by the number of teeth desired in the cut.

*Example:* Determine the required number of teeth in a face mill where  $D = 6$  inches and  $W = 4$  inches. Using [Formula \(1\)](#),

$$T = \frac{6.3 \times 6}{4} = 10 \text{ teeth, approximately}$$

*Example:* Determine the required number of teeth in a plain milling cutter where  $D = 4$  inches and  $d = \frac{1}{4}$  inch. Using [Formula \(2\)](#),

$$T = \frac{12.6 \times 4 \times \cos 0^\circ}{4 + \left(4 \times \frac{1}{4}\right)} = 10 \text{ teeth, approximately}$$

In *high-speed milling* with sintered carbide, high-speed steel, and cast nonferrous cutting tool materials, a formula that permits full use of the power available at the cutter but prevents overloading of the motor driving the milling machine is:

$$T = \frac{K \times H}{F \times N \times d \times W} \quad (3)$$

where  $T$  = number of cutter teeth;  $H$  = horsepower (kilowatts) available at the cutter;  $F$  = feed per tooth in inches (mm);  $N$  = revolutions per minute of cutter;  $d$  = depth of cut in inches (mm);  $W$  = width of cut in inches (mm); and  $K$  = a constant that may be taken as 0.65 for average steel, 1.5 for cast iron, and 2.5 for aluminum. **For metric units,  $K = 14278$  for average steel, 32949 for cast iron, and 54915 for aluminum.** These values are conservative and take into account dulling of the cutter in service.

*Example:* Determine the required number of teeth in a sintered carbide-tipped face mill for high-speed milling of 200 BHN (Brinell Hardness Number) alloy steel if  $H = 7.5$  kilowatt;  $F = 0.2032$  mm;  $N = 272$  rpm;  $d = 3.2$  mm;  $W = 152.4$  mm; and  $K$  for alloy steel is 14278. Using [Formula \(3\)](#),

$$T = \frac{14278 \times 7.5}{0.2032 \times 272 \times 3.2 \times 152.4} = 4 \text{ teeth, approximately}$$

**American National Standard Milling Cutters.**—According to American National Standard ANSI/ASME B94.19-1997 (R2019), milling cutters may be classified in two general ways, given as follows:

*By Type of Relief on Cutting Edges:* Milling cutters may be described on the basis of one of two methods of providing relief for the cutting edges. *Profile sharpened* cutters are those on which relief is obtained and which are resharpened by grinding a narrow land back of the cutting edges. Profile sharpened cutters may produce flat, curved, or irregular surfaces. *Form relieved* cutters are those which are so relieved that by grinding only the faces of the teeth the original form is maintained throughout the life of the cutters. Form relieved cutters may produce flat, curved or irregular surfaces.

*By Method of Mounting:* Milling cutters may be described by one of two methods used to mount the cutter. *Arbor type* cutters are those which have a hole for mounting on an arbor and usually have a keyway to receive a driving key. These are sometimes called *Shell type*. *Shank type* cutters are those which have a straight or tapered shank to fit the machine tool spindle or adapter.

**Explanation of the “Hand” of Milling Cutters.**—In the ANSI/ASME Standard, the terms “right hand” and “left hand” are used to describe hand of rotation, hand of cutter and hand of flute helix.

*Hand of Rotation or Hand of Cut* is described as either “right hand” if the cutter revolves counterclockwise as it cuts when viewed from a position in front of a horizontal milling machine and facing the spindle, or “left hand” if the cutter revolves clockwise as it cuts when viewed from the same position.

**American National Standard Plain Milling Cutters**  
ANSI/ASME B94.19-1997 (R2019)

Cutter Diameter			Range of Face Widths, Nom. <sup>a</sup>	Hole Diameter		
Nom.	Max.	Min.		Nom.	Max.	Min.
<b>Light-duty Cutters<sup>b</sup></b>

3	3.015	2.985	¾, ¼, ⅝, ⅜, ⅝, ¾, and 1½	1	1.00075	1.0000
3	3.015	2.985	½, ⅝, ¾, 1, 1¼, 1½, 2 and 3	1¼	1.2510	1.2500
4	4.015	3.985	¼, ⅝ and ⅜ ⅜, ½, ⅜, ¾,	1	1.00075	1.0000
4	4.015	3.985	1, 1½, 2, 3 and 4	1¼	1.2510	1.2500
<b>Heavy-duty Cutters<sup>c</sup></b>						
2½	2.515	2.485	2	1	1.00075	1.0000
2½	2.515	2.485	4	1	1.0010	1.0000
3	3.015	2.985	2, 2½, 3, 4 and 6	1¼	1.2510	1.2500
4	4.015	3.985	2, 3, 4 and 6	1½	1.5010	1.5000
<b>High-helix Cutters<sup>d</sup></b>						
3	3.015	2.985	4 and 6	1¼	1.2510	1.2500
4	4.015	3.985	8	1½	1.5010	1.5000

<sup>a</sup> *Tolerances on Face Widths:* Up to 1 inch, inclusive, ± 0.001 inch; over 1 to 2 inches, inclusive, +0.010, -0.000 inch; over 2 inches, +0.020, -0.000 inch.

<sup>b</sup> Light-duty plain milling cutters with face widths under ¾ inch have straight teeth. Cutters with ¾-inch face and wider have helix angles of not less than 15 degrees nor greater than 25 degrees.

<sup>c</sup> Heavy-duty plain milling cutters have a helix angle of not less than 25 degrees nor greater than 45 degrees.

<sup>d</sup> High-helix plain milling cutters have a helix angle of not less than 45 degrees nor greater than 52 degrees.

All dimensions are in inches. All cutters are high-speed steel. Plain milling cutters are of cylindrical shape, having teeth on the peripheral surface only.

**Hand of Cutter:** Some types of cutters require special consideration when referring to their hand. These are principally cutters with unsymmetrical forms, face-type cutters, or cutters with threaded holes. *Symmetrical* cutters may be reversed on the arbor in the same axial position and rotated in the cutting direction without altering the contour produced on the work-piece, and may be considered as either right or left hand. *Unsymmetrical* cutters reverse the contour produced on the work-piece when reversed on the arbor in the same axial position and rotated in the cutting direction. A *single-angle* cutter is considered to be a right-hand cutter if it revolves counterclockwise, or a left-hand cutter if it revolves clockwise, when cutting as viewed from the side of the larger diameter. The *hand of rotation* of a single angle milling cutter need not necessarily be the same as its *hand of cutter*. A *single corner rounding* cutter is considered to be a right-hand cutter if it revolves counterclockwise, or a left-hand cutter if it revolves clockwise, when cutting as viewed from the side of the smaller diameter.

6	6.015	5.985	$\frac{3}{4}$	$1\frac{1}{4}$	1.2510	1.2500

<sup>a</sup> *Tolerances on Face Widths:* For side cutters, +0.002, -0.001 inch; for staggered-tooth side cutters up to  $\frac{3}{4}$ -inch face width, inclusive, +0.000 -0.0005 inch, and over  $\frac{3}{4}$  to 1 inch, inclusive, +0.000 -0.0010 inch; and for half side cutters, +0.015, -0.000 inch.

<sup>b</sup> Side milling cutters have straight peripheral teeth and side teeth on both sides.

<sup>c</sup> Staggered-tooth side milling cutters have peripheral teeth of alternate right- and left-hand helix and alternate side teeth.

<sup>d</sup> Half side milling cutters have side teeth on one side only. The peripheral teeth are helical of the same hand as the cut. Made either with right-hand or left-hand cut.

All dimensions are in inches. All cutters are high-speed steel. Side milling cutters are of cylindrical shape, having teeth on the periphery and on one or both sides.

**Hand of Flute Helix:** Milling cutters may have *straight flutes*, which means that their cutting edges are in planes parallel to the cutter axis. Milling cutters with flute helix in one direction only are described as having a right-hand helix if the flutes twist away from the observer in a clockwise direction when viewed from either end of the cutter or as having a left-hand helix if the flutes twist away from the observer in a counterclockwise direction when viewed from either end of the cutter. *Staggered tooth cutters* are milling cutters with every other flute of opposite (right- and left-hand) helix.

An illustration describing the various milling cutter elements of both a profile cutter and a form-relieved cutter is given on page 876.

12	12.015	11.985	⅞, ⅙	1½	1.5010	1.5000

<sup>a</sup> Tolerances on face widths are plus or minus 0.001 inch.

<sup>b</sup> Plain metal slitting saws are relatively thin plain milling cutters having peripheral teeth only. They are furnished with or without hub, and their sides are concaved to the arbor hole or hub.

<sup>c</sup> Metal slitting saws with side teeth are relatively thin side milling cutters having both peripheral and side teeth.

<sup>d</sup> Metal slitting saws with staggered peripheral and side teeth are relatively thin staggered-tooth milling cutters having peripheral teeth of alternate right- and left-hand helix and alternate side teeth.

All dimensions are in inches. All saws are high-speed steel. Metal slitting saws are similar to plain or side milling cutters but are relatively thin.

**Milling Cutter Terms**

**Milling Cutter Terms (Continued)**

**American National Standard Single- and Double-Angle Milling Cutters ANSI/ASME B94.19-1997 (R2019)**

Cutter Diameter			Nominal Face Width <sup>a</sup>	Hole Diameter		
Nom.	Max.	Min.		Nom.	Max.	Min.
Single-Angle Cutters <sup>b</sup>						
1¼	1.265	1.235	⅞	¾-24 UNF-2B RH ¾-24 UNF-2B LH		
1⅝	1.640	1.610	⅞	½-20 UNF-2B RH		
2¾	2.765	2.735	½	1	1.00075	1.0000
3	3.015	2.985	½	¼	1.2510	1.2500
Double-Angle Cutters <sup>d</sup>						
2¾	2.765	2.735	½	1	1.00075	1.0000

<sup>a</sup> Face width tolerances are plus or minus 0.015 inch.

<sup>b</sup> Single-angle milling cutters have peripheral teeth, one cutting edge of which lies in a conical surface and the other in the plane perpendicular to the cutter axis. There are two types; one has a plain keywayed hole and has an included tooth angle of either 45 or 60 degrees ±10 minutes; the other has a threaded hole and an included tooth angle of 60 degrees ±10 minutes. Cutters with a right-hand threaded hole have a right-hand hand of rotation and a right-hand hand of cutter. Cutters with a left-hand threaded hole have a left-hand hand of rotation and a left-hand hand of cutter. Cutters with plain keywayed holes are standard as either right-hand or left-hand cutters.

<sup>c</sup> These cutters have threaded holes, the sizes of which are given under "Hole Diameter."

<sup>d</sup> Double-angle milling cutters have symmetrical peripheral teeth, both sides of which lie in conical surfaces. They are designated by the included angle, which may be 45, 60 or 90 degrees. Tolerances are ±10 minutes for the half angle on each side of the center.

All dimensions are in inches. All cutters are high-speed steel.

<sup>a</sup> *N* = Number of flutes.

<sup>b</sup> In this size of regular mill, a left-hand cutter with left-hand helix is also standard.

All dimensions are in inches. All cutters are high-speed steel. Helix angle is greater than 19 degrees but not more than 39 degrees. Right-hand cutters with right-hand helix are standard.

Tolerances: On *D*, +0.003 inch; on *S*, -0.0001 to -0.0005 inch; on *W*, ±1/32 inch; on *L*, ±1/16 inch.

**ANSI Two-Flute, High Helix, Regular-, Long-, and Extra-Long-Length, Single-End End Mills with Weldon Shanks ANSI/ASME B94.19-1997 (R2019)**

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 39 degrees.

Tolerances: On D, +0.003 inch; on S, -0.0001 to -0.0005 inch; on W, ±1/32 inch; and on L, ±1/16 inch.

**Combination Shanks for End Mills ANSI/ASME B94.19-1997 (R2019)**

<sup>a</sup> Length of shank.

All dimensions are in inches.

Modified for use as Weldon or Pin Drive shank.

**ANSI Roughing, Single-End End Mills with Weldon Shanks,  
High-Speed Steel ANSI/ASME B94.19-1997 (R2019)**

1	1	2	4 1/2	2	1 1/4	4	6 1/2		

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

Tolerances: On *D*, +0.003 inch; on *S*, -0.0001 to -0.0005 inch; on *W*, ±1/32 inch; and on *L*, ±1/16 inch.

The following center-cutting, single-end end mills are available in premium high-speed steel: regular-length, multiple flute, with *D* ranging from 1/8 to 1 1/2 inches; long length, multiple flute, with *D* ranging from 3/8 to 1 1/4 inches; and extra-long-length, multiple flute, with *D* ranging from 3/8 to 1 1/4 inches.

All dimensions are in inches. All cutters are high-speed steel. Right-hand cutters with right-hand helix are standard. Helix angle is greater than 19 degrees but not more than 39 degrees.

Tolerances: On C and D, +0.005 inch for 2, 3, 4 and 6 flutes: on W,  $\pm 1/16$  inch; and on L,  $\pm 1/16$  inch.

**Dimensions of American National Standard Weldon Shanks  
ANSI/ASME B94.19-1997 (R2019)**

Shank		Flat		Shank		Flat	
Dia.	Length	X <sup>a</sup>	Length <sup>b</sup>	Dia.	Length	X <sup>a</sup>	Length <sup>b</sup>
¾	1 <sup>5</sup> / <sub>16</sub>	0.325	0.280	1	2 <sup>9</sup> / <sub>32</sub>	0.925	0.515
½	1 <sup>25</sup> / <sub>32</sub>	0.440	0.330	1¼	2 <sup>9</sup> / <sub>32</sub>	1.156	0.515
¾	1 <sup>29</sup> / <sub>32</sub>	0.560	0.400	1½	2 <sup>11</sup> / <sub>16</sub>	1.406	0.515
¾	2 <sup>1</sup> / <sub>32</sub>	0.675	0.455	2	3¼	1.900	0.700
¾	2 <sup>1</sup> / <sub>32</sub>	0.810	0.455	2½	3½	2.400	0.700

<sup>a</sup> X is distance from bottom of flat to opposite side of shank.

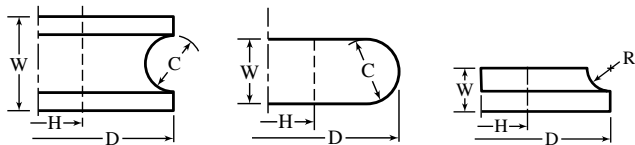

<sup>b</sup> Minimum.

All dimensions are in inches.

Centerline of flat is at half-length of shank except for 1½-, 2- and 2½-inch shanks where it is 1<sup>3</sup>/<sub>16</sub>, 1<sup>27</sup>/<sub>32</sub> and 1<sup>13</sup>/<sub>16</sub> from shank end, respectively.

Tolerance on shank diameter, -0.0001 to -0.0005 inch.

<sup>a</sup> Tolerances on cutter diameter are  $+1/16, -1/16$  inch for all sizes.

<sup>b</sup> Tolerance does not apply to convex cutters.

<sup>c</sup> Size of cutter is designated by specifying diameter *C* of circular form.

<sup>d</sup> Size of cutter is designated by specifying radius *R* of circular form.

All dimensions in inches. All cutters are high-speed steel and are form relieved.

Right-hand corner rounding cutters are standard, but left-hand cutter for 1/4-inch size is also standard.

For key and keyway dimensions for these cutters, see page 894.

5	3¾	1¼	12	2¾	1
5	3¾	1	12	2¼	¾
6	4¼	1¾	14	2½	1

All dimensions are in inches.

All gear milling cutters are high-speed steel and are form relieved.

For keyway dimensions see page 894.

**Tolerances:** On outside diameter, +  $\frac{1}{16}$ , -  $\frac{1}{16}$  inch; on hole diameter, through 1-inch hole diameter, +0.00075 inch, over 1-inch and through 2-inch hole diameter, +0.0010 inch.

For cutter number relative to numbers of gear teeth, see page 2227. Roughing cutters are made with No. 1 cutter form only.

**American National Standard Gear Milling Cutters for Mitre and Bevel Gears with  $14\frac{1}{2}$ -Degree Pressure Angles ANSI/ASME B94.19-1997 (R2019)**

Diametral Pitch	Diameter of Cutter, <i>D</i>	Diameter of Hole, <i>H</i>	Diametral Pitch	Diameter of Cutter, <i>D</i>	Diameter of Hole, <i>H</i>
3	4	1¼	10	2¾	¾
4	3½	1¼	12	2¼	¾
5	3¾	1¼	14	2½	¾
6	3¼	1	16	2½	¾
7	2¾	1	20	2	¾
8	2¾	1	24	1¾	¾

All dimensions are in inches.

All cutters are high-speed steel and are form relieved.

For keyway dimensions see page 894. For cutter selection see page 2266.

**Tolerances:** On outside diameter,  $+1/16, -1/16$  inch; on hole diameter, through 1-inch hole diameter,  $+0.00075$  inch, for  $1\frac{1}{4}$ -inch hole diameter,  $+0.0010$  inch.

To select the cutter number for bevel gears with the axis at any angle, double the back cone radius and multiply the result by the diametral pitch. This procedure gives the number of equivalent spur gear teeth and is the basis for selecting the cutter number from the table on page 2229.

All dimensions are in inches.

All cutters are high-speed steel and are form relieved.

For keyway dimensions see page 894.

**Tolerances:** Outside diameter,  $+1/16$ ,  $-1/16$  inch; hole diameter, through 1-inch diameter,  $+0.00075$  inch, above 1-inch diameter and through 2-inch diameter,  $+0.0010$  inch.

For tooth form, see ANSI/ASME sprocket tooth form table on page 2633.

822	2¾	¼	1	1228	3½	⅝	1	...	...	...	...

All dimensions are given in inches. All cutters are high-speed steel.

Shank type cutters are standard with right-hand cut and straight teeth. All sizes have ½-inch diameter straight shank.

Arbor type cutters have staggered teeth.

For Woodruff key and key-slot dimensions, see pages 2557 through 2559.

**Tolerances:** Face with *W* for shank-type cutters: ¼- to ⅝-inch face, +0.0000, -0.0005; ⅝ to ⅞, -0.0002, -0.0007; ¼, -0.0003, -0.0008; ⅜, -0.0004, -0.0009; ⅝, -0.0005, -0.0010 inch. Face width *W* for arbor-type cutters; ⅜ inch face, -0.0002, -0.0007; ¼, -0.0003, -0.0008; ⅝, -0.0004, -0.0009; ⅝ and over, -0.0005, -0.0010 inch. Hole size *H*: +0.00075, -0.0000 inch. Diameter *D* for shank type cutters: ¼- through ¾-inch diameter, +0.010, +0.015, ⅞ through 1½, +0.012, +0.017; 1¼ through 1½, +0.015, +0.020 inch. These tolerances include an allowance for sharpening. For arbor-type cutters, diameter *D* is furnished ⅝ inch larger than listed, and a tolerance of ±0.002 inch applies to the oversize diameter.

**Setting Angles for Milling Straight Teeth of Uniform Land Width in End Mills, Angular Cutters, and Taper Reamers.**—The accompanying tables give setting angles for the dividing head when straight teeth, having a land of uniform width throughout their length, are to be milled using single-angle fluting cutters. These setting angles depend upon three factors: the number of teeth to be cut; the angle of the blank in which the teeth are to be cut; and the angle of the fluting cutter. Setting angles for various combinations of these three factors are given in the tables. For example, assume that 12 teeth are to be cut on the end of an end mill using a 60-degree cutter. By following the horizontal line from 12 teeth, read in the column under 60 degrees that the dividing head should be set to an angle of 70 degrees and 32 minutes.

The following formulas, which were used to compile these tables, may be used to calculate the setting-angles for combinations of number of teeth, blank angle, and cutter angle not covered by the tables. In these formulas,  $A$  = setting-angle for dividing head,  $B$  = angle of blank in which teeth are to be cut,  $C$  = angle of fluting cutter,  $N$  = number of teeth to be cut, and  $D$  and  $E$  are angles not shown on the accompanying diagram that are used only to simplify calculations.

$$\tan D = \cos(360^\circ/N) \times \cot C \quad (1)$$

$$\sin E = \tan(360^\circ/N) \times \cot C \times \sin D \quad (2)$$

$$\text{Setting-angle } A = D - E \quad (3)$$

*Example:* Suppose 9 teeth are to be cut in a 35-degree blank using a 55-degree single-angle fluting cutter. Then,  $N = 9$ ,  $B = 35^\circ$ , and  $C = 55^\circ$ .

$$\tan D = \cos(360^\circ/9) \times \cot 55^\circ = 0.76604 \times 1.4281 = 1.0940; \text{ and } D = 47^\circ 34'$$

$$\sin E = \tan(360^\circ/9) \times \cot 55^\circ \times \sin 47^\circ 34' = 0.83910 \times 0.70021 \times 0.73806 \\ = 0.43365; \text{ and } E = 25^\circ 42'$$

$$\text{Setting angle } A = 47^\circ 34' - 25^\circ 42' = 21^\circ 52'$$

For end mills and side mills, the angle of the blank  $B$  is 0 degrees, and the following simplified formula may be used to find the setting angle  $A$ :

$$\cos A = \tan\left(\frac{360^\circ}{N}\right) \times \cot C \quad (4)$$

*Example:* If in the previous example the blank angle was 0 degrees,

$$\cos A = \tan(360^\circ/9) \times \cot 55^\circ = 0.83910 \times 0.70021 = 0.58755$$

and setting-angle  $A = 54^\circ 1'$ .

**Angles of Elevation for Milling Straight Teeth in 0-, 5-, 10-, 15-, 20-, 25-, 30-, and 35-degree Blanks Using Single-Angle Fluting Cutters**

**Spline-Shaft Milling Cutter.**—The most efficient method of forming splines on shafts is by hobbing, but special milling cutters may also be used. Since the cutter forms the space between adjacent splines, it must be made to suit the number of splines and the root diameter of the shaft. The cutter angle  $B$  equals 360 degrees divided by the number of splines. The following formulas are for determining the chordal width  $C$  at the root of the splines or the chordal width across the concave edge of the cutter. In these formulas,  $A$  = angle between center line of spline and a radial line passing through the intersection of the root circle and one side of the spline;  $W$  = width of spline;  $d$  = root diameter of splined shaft;  $C$  = chordal width at root circle between adjacent splines;  $N$  = number of splines.

$$\sin A = \frac{W}{d} \quad C = d \times \sin \left( \frac{180}{N} - A \right)$$

Splines of involute form are often used in preference to the straight-sided type. Dimensions of the American Standard involute splines and hobs are given in the section on splines.

### Cutter Grinding

**Wheels for Sharpening Milling Cutters.**—Milling cutters may be sharpened by using either the periphery of a disk wheel or the face of a cup wheel. The latter grinds the lands of the teeth flat, whereas the periphery of a disk wheel leaves the teeth slightly concave back of the cutting edges. The concavity produced by disk wheels reduces the effective clearance angle on the teeth, the effect being more pronounced for wheels of small diameter than for wheels of large diameter. For this reason, large diameter wheels are preferred when sharpening milling cutters with disk type wheels. Irrespective of what type of wheel is used to sharpen a milling cutter, any burrs resulting from grinding should be carefully removed by a hand stoning operation. Stoning also helps to reduce the roughness

of grinding marks and improves the quality of the finish produced on the surface being machined. Unless done very carefully, hand stoning may dull the cutting edge. Stoning may be avoided and a sharper cutting edge produced if the wheel rotates toward the cutting edge, which requires that the operator maintain contact between the tool and the rest while the wheel rotation is trying to move the tool away from the rest. Though slightly more difficult, this method will eliminate the burr.

### Specifications of Grinding Wheels for Sharpening Milling Cutters

Cutter Material	Operation	Grinding Wheel			
		Abrasive Material	Grain Size	Grade	Bond
Carbon Tool Steel	Roughing Finishing	Aluminum Oxide	46-60 100	K H	Vitrified Vitrified
High-Speed Steel:					
18-4-1 {	Roughing Finishing	Aluminum Oxide	60	K,H	Vitrified
18-4-2 {	Roughing Finishing		100	H	Vitrified
			80	F,G,H	Vitrified
			100	H	Vitrified
Cast Nonferrous Tool Material	Roughing Finishing	Aluminum Oxide	46 100-120	H,K,L,N H	Vitrified Vitrified
Sintered Carbide	Roughing after Brazing	Silicon Carbide	60	G	Vitrified
	Roughing Finishing	Diamond	100	a	Resinoid
		Diamond	Up to 500	a	Resinoid
Carbon Tool Steel and High-Speed Steel <sup>b</sup>	Roughing Finishing	Cubic Boron Nitride	80-100 100-120	R,P S,T	Resinoid Resinoid

<sup>a</sup> Not indicated in diamond wheel markings.

<sup>b</sup> For hardnesses above 56 RC on the Rockwell C scale.

**Wheel Speeds and Feeds for Sharpening Milling Cutters.**—Relatively low cutting speeds should be used when sharpening milling cutters to avoid tempering and heat checking. Dry grinding is recommended in all cases except when diamond wheels are employed. The surface speed of grinding wheels should be in the range of 4500–6500 ft/min (22.8 to 33 m/s) for grinding milling cutters of high-speed steel or cast nonferrous tool material. For sintered carbide cutters, 5000–5500 ft/min (25.4 to 27.9 m/s) should be used.

The maximum stock removed per pass of the grinding wheel should not exceed about 0.0004 inch (0.010 mm) for sintered carbide cutters; 0.003 inch (0.076 mm) for large high-speed steel and cast nonferrous tool material cutters; and 0.0015 inch (0.038 mm) for narrow saws and slotting cutters of high-speed steel or cast nonferrous tool material. The stock removed per pass of the wheel may be increased for backing-off operations such as the grinding of secondary clearance behind the teeth since there is usually a sufficient body of metal to carry off the heat.

**Clearance Angles for Milling Cutter Teeth.**—The clearance angle provided on the cutting edges of milling cutters has an important bearing on cutter performance, cutting efficiency, and cutter life between sharpenings. It is desirable in all cases to use a clearance angle as small as possible so as to leave more metal back of the cutting edges for better heat dissipation and to provide maximum support. Excessive clearance angles not only weaken the cutting edges, but also increase the likelihood of “chatter,” which will result in poor finish on the machined surface and reduce the life of the cutter. According to The Cincinnati Milling Machine Co., milling cutters used for general purpose work and having diameters from 1/8 to 3 inches (3.18–76.2 mm) should have clearance angles from 13 to 5 degrees, respectively, decreasing proportionately as the diameter increases. General

purpose cutters over 3 inches (76.2 mm) in diameter should be provided with a clearance angle of 4 to 5 degrees. The land width is usually  $\frac{1}{64}$ ,  $\frac{1}{32}$ , and  $\frac{1}{16}$  inch (0.4, 0.8, and 1.6 mm), respectively, for small, medium, and large cutters.

The primary clearance or relief angle for best results varies according to the material being milled, as follows: low-carbon, high-carbon, and alloy steels, 3 to 5 degrees; cast iron and medium and hard bronze, 4 to 7 degrees; brass, soft bronze, aluminum, magnesium, plastics, etc., 10 to 12 degrees. When milling cutters are resharpened, it is customary to grind a secondary clearance angle of 3 to 5 degrees behind the primary clearance angle to reduce the land width to its original value and thus avoid interference with the surface to be milled. The following is a general formula for plain milling cutters, face mills, and form relieved cutters, which gives the clearance angle  $C$ , in degrees, necessitated by the feed per revolution  $F$ , in inches; the width of land  $L$ , in inches; the depth of cut  $d$ , in inches (mm); the cutter diameter  $D$ , in inches; and the Brinell Hardness Number  $B$  of the work being cut:

$$C = \frac{45860}{DB} \left( 1.5L + \frac{F}{\pi D} \sqrt{d(D-d)} \right)$$

**Rake Angles for Milling Cutters.**—In peripheral milling cutters, the rake angle is generally defined as the angle in degrees that the tooth face deviates from a radial line to the cutting edge. In face milling cutters, the teeth are inclined with respect to both the radial and axial lines. These angles are called *radial* and *axial* rake, respectively. The radial and axial rake angles may be positive, zero, or negative.

Positive rake angles should be used whenever possible for all types of high-speed steel milling cutters. For sintered carbide-tipped cutters, zero and negative rake angles are frequently employed to provide more material back of the cutting edge to resist shock loads.

**Rake Angles for High-Speed Steel Cutters:** Positive rake angles of 10 to 15 degrees are satisfactory for milling steels of various compositions with plain milling cutters. For softer materials, such as magnesium and aluminum alloys, the rake angle may be 25 degrees or more. Metal slitting saws for cutting alloy steel usually have rake angles from 5 to 10 degrees, whereas zero and sometimes negative rake angles are used for saws to cut copper and other soft nonferrous metals to reduce the tendency to “hog in.” Form relieved cutters usually have rake angles of 0, 5, or 10 degrees. Commercial face milling cutters usually have 10 degrees positive radial and axial rake angles for general use in milling cast iron, forged and alloy steel, brass, and bronze. For milling castings and forgings of magnesium and free-cutting aluminum and their alloys, the rake angles may be increased to 25 degrees positive or more, depending on the operating conditions; a smaller rake angle is used for abrasive or difficult to machine aluminum alloys.

**Cast Nonferrous Tool Material Milling Cutters:** Positive rake angles are generally provided on milling cutters using cast nonferrous tool materials, although negative rake angles may be used advantageously for some operations such as those where shock loads are encountered or where it is necessary to eliminate vibration when milling thin sections.

**Sintered Carbide Milling Cutters:** Peripheral milling cutters, such as slab mills, slotting cutters, saws, etc., tipped with sintered carbide, generally have negative radial rake angles of 5 degrees for soft low-carbon steel and 10 degrees or more for alloy steels. Positive axial rake angles of 5 and 10 degrees, respectively, may be provided, and for slotting saws and cutters, 0 degree axial rake may be used. On soft materials, such as free-cutting aluminum alloys, positive rake angles of 10 to so degrees are used. For milling abrasive or difficult to machine aluminum alloys, small positive or even negative rake angles are used.

**Eccentric-Type Radial Relief.**—When the radial relief angles on peripheral teeth of milling cutters are ground with a disc-type grinding wheel in the conventional manner, the ground surfaces on the lands are slightly concave, conforming approximately to the radius of the wheel. A flat land is produced when the radial relief angle is ground with a cup wheel. Another entirely different method of grinding the radial angle is by the eccentric method, which produces a slightly convex surface on the land. If the radial relief angle at

the cutting edge is equal for all of the three types of land mentioned, it will be found that the land with the eccentric relief will drop away from the cutting edge a somewhat greater distance for a given distance around the land than will the others. This is evident from a study of *Table 1, Indicator Drops for Checking the Radial Relief Angle on Peripheral Teeth*. This feature is an advantage of the eccentric-type relief, which also produces an excellent finish.

**Table 1. Indicator Drops for Checking the Radial Relief Angle on Peripheral Teeth**

Cutter Diameter, Inch	Rec. Range of Radial Relief Angles, Degrees	Checking Distance, Inch	Indicator Drops, Inches				Rec. Max. Primary Land Width, Inch
			For Flat and Concave Relief		For Eccentric Relief

The setup for grinding an eccentric relief is shown in Fig. 1. In this setup, the point of contact between the cutter and the tooth rest must be in the same plane as the centers, or axes, of the grinding wheel and the cutter. A wide face is used on the grinding wheel, which is trued and dressed at an angle with respect to the axis of the cutter. An alternate method is to tilt the wheel at this angle. Then as the cutter is traversed and rotated past the grinding wheel while in contact with the tooth rest, an eccentric relief will be generated by the angular face of the wheel. This type of relief can only be ground on the peripheral teeth on milling cutters having helical flutes because the combination of the angular wheel face and the twisting motion of the cutter is required to generate the eccentric relief. Therefore, an eccentric relief cannot be ground on the peripheral teeth of straight-fluted cutters.

Table 2 is a table of wheel angles for grinding an eccentric relief for different combinations of relief angles and helix angles. When angles are required that cannot be found in this table, the wheel angle,  $W$ , can be calculated by using the following formula, in which  $R$  is the radial relief angle and  $H$  is the helix angle of the flutes on the cutter.

$$\tan W = \tan R \times \tan H$$

**Table 2. Grinding Wheel Angles for Grinding Eccentric-Type Radial Relief Angle**

Radial Relief Angle, $R$ , Degrees	Helix Angle of Cutter Flutes, $H$ , Degrees							
	12	18	20	30	40	45	50	52

**Indicator Drop Method of Checking Relief and Rake Angles.**—The most convenient and inexpensive method of checking the relief and rake angles on milling cutters is by the indicator drop method. Three tables, Table 1, Table 3 and Table 4, of indicator drops are provided in this section for checking radial relief angles on the peripheral teeth, relief angles on side and end teeth, and rake angles on the tooth faces.

Fig. 1. Setup for Grinding Eccentric-Type Radial Relief Angle

**Table 3. Indicator Drops for Checking Relief Angles on Side Teeth and End Teeth**

Checking Distance, Inch	Given Relief Angle								
	1°	2°	3°	4°	5°	6°	7°	8°	9°
	Indicator Drop, inch

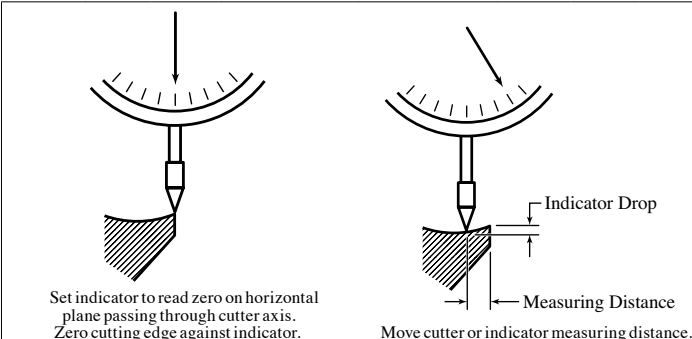

Fig. 2. Setup for Checking the Radial Relief Angle by Indicator Drop Method

The setup for checking the radial relief angle is illustrated in Fig. 2. Two dial test indicators are required, one of which should have a sharp-pointed contact point. This indicator is positioned so that the axis of its spindle is vertical, passing through the axis of the cutter. The cutter may be held by its shank in the spindle of a tool and cutter grinder workhead, or

between centers while mounted on a mandrel. The cutter is rotated to the position where the vertical indicator contacts a cutting edge. The second indicator is positioned with its spindle axis horizontal and with the contact point touching the tool face just below the cutting edge. With both indicators adjusted to read zero, the cutter is rotated a distance equal to the checking distance, as determined by the reading on the second indicator. Then the indicator drop is read on the vertical indicator and checked against the values in the tables. The indicator drops for radial relief angles ground by a disc-type grinding wheel and those ground with a cup wheel are so nearly equal that the values are listed together; values for the eccentric-type relief are listed separately, since they are larger. A similar procedure is used to check the relief angles on the side and end teeth of milling cutters; however, only one indicator is used. Also, instead of rotating the cutter, the indicator or the cutter must be moved a distance equal to the checking distance in a straight line.

**Table 4. Indicator Drops for Checking Rake Angles on Milling Cutter Face**

Set indicator to read zero on horizontal plane passing through cutter axis. Zero cutting edge against indicator.

Move cutter or indicator measuring distance.

Rate Angle, Deg.	Measuring Distance, inch				Rate Angle, Deg.	Measuring Distance, inch

**Relieving Attachments.**—A relieving attachment is a device applied to lathes (especially those used in tool-rooms) for imparting a reciprocating motion to the tool-slide and tool, in order to provide relief or clearance for the cutting edges of milling cutters, taps, hobs, etc. For example, in making a milling cutter of the formed type, such as is used for cutting gears, it is essential to provide clearance for the teeth and so form them that they may be ground repeatedly without changing the contour or shape of the cutting edge. This may be accomplished by using a relieving attachment. The tool for “backing off” or giving clearance to the teeth corresponds to the shape required, and it is given a certain amount of reciprocating movement, so that it forms a surface back of each cutting edge, which is of uniform cross section on a radial plane but eccentric to the axis of the cutter sufficiently to provide the necessary clearance for the cutting edges.

## Various Set-ups Used in Grinding the Clearance Angle on Milling Cutter Teeth

## Distance to Set Center of Wheel Above the Cutter Center (Disk Wheel)

Dia. of Wheel, Inches	Desired Clearance Angle, Degrees											
	1	2	3	4	5	6	7	8	9	10	11	12
	*Distance to Offset Wheel Center Above Cutter Center, Inches											
3	.026	.052	.079	.105	.131	.157	.183	.209	.235	.260	.286	.312
4	.035	.070	.105	.140	.174	.209	.244	.278	.313	.347	.382	.416
5	.044	.087	.131	.174	.218	.261	.305	.348	.391	.434	.477	.520
6	.052	.105	.157	.209	.261	.314	.366	.417	.469	.521	.572	.624
7	.061	.122	.183	.244	.305	.366	.427	.487	.547	.608	.668	.728
8	.070	.140	.209	.279	.349	.418	.488	.557	.626	.695	.763	.832
9	.079	.157	.236	.314	.392	.470	.548	.626	.704	.781	.859	.936
10	.087	.175	.262	.349	.436	.523	.609	.696	.782	.868	.954	1.040

\* Calculated from the formula: Offset = Wheel Diameter  $\times \frac{1}{2} \times$  Sine of Clearance Angle.

## Distance to Set Center of Wheel Below the Cutter Center (Disk Wheel)

Dia. of Cutter, Inches	Desired Clearance Angle, Degrees											
	1	2	3	4	5	6	7	8	9	10	11	12
	*Distance to Offset Wheel Center Below Cutter Center, Inches											
2	.017	.035	.052	.070	.087	.105	.122	.139	.156	.174	.191	.208
3	.026	.052	.079	.105	.131	.157	.183	.209	.235	.260	.286	.312
4	.035	.070	.105	.140	.174	.209	.244	.278	.313	.347	.382	.416
5	.044	.087	.131	.174	.218	.261	.305	.348	.391	.434	.477	.520
6	.052	.105	.157	.209	.261	.314	.366	.417	.469	.521	.572	.624
7	.061	.122	.183	.244	.305	.366	.427	.487	.547	.608	.668	.728
8	.070	.140	.209	.279	.349	.418	.488	.557	.626	.695	.763	.832
9	.079	.157	.236	.314	.392	.470	.548	.626	.704	.781	.859	.936
10	.087	.175	.262	.349	.436	.523	.609	.696	.782	.868	.954	1.040

\* Calculated from the formula: Offset = Cutter Diameter  $\times \frac{1}{2} \times$  Sine of Clearance Angle.

**Distance to Set Tooth Rest Below Center Line of Wheel and Cutter.**—When the clearance angle is ground with a disc-type wheel by keeping the center line of the wheel in line with the center line of the cutter, the tooth rest should be lowered by an amount given by the following formula:

$$\text{Offset} = \frac{\text{Wheel Diam.} \times \text{Cutter Diam.} \times \text{Sine of One-half the Clearance Angle}}{\text{Wheel Diam.} + \text{Cutter Diam.}}$$

**Distance to Set Tooth Rest Below Cutter Center When Cup Wheel is Used.**—When the clearance is ground with a cup wheel, the tooth rest is set below the center of the cutter the same amount as given in the table for *Distance to Set Center of Wheel Below the Cutter Center (Disk Wheel)*.

**Counter Milling.**—Changing the direction of a linear milling operation by a specific angle requires a linear offset before changing the angle of cut. This compensates for the radius of the milling cutters, as illustrated in Fig. 1a and Fig. 1b.

Fig. 1a. Inside Milling

Fig. 1b. Outside Milling

For inside cuts the offset is subtracted from the point at which the cutting direction changes (Fig. 1a), and for outside cuts the offset is added to the point at which the cutting direction changes (Fig. 1b). The formula for the offset is

$$x = rM$$

where  $x$  = offset distance;  $r$  = radius of the milling cutter; and,  $M$  = the multiplication factor ( $M = \tan^2 \frac{\theta}{2}$ ). The value of  $M$  for certain angles can be found in Table 5.

Table 5. Offset Multiplication Factors

Deg°	$M$	Deg°	$M$	Deg°	$M$	Deg°	$M$	Deg°	$M$

Multiply factor  $M$  by the tool radius  $r$  to determine the offset dimension

## REAMERS

**Hand Reamers.**—Hand reamers are made with both straight and helical flutes. Helical flutes provide a shearing cut and are especially useful in reaming holes having keyways or grooves, as these are bridged over by the helical flutes, thus preventing binding or chattering. Hand reamers are made in both solid and expansion forms. The American standard dimensions for solid forms are given in the accompanying table. The expansion type is useful whenever, in connection with repair or other work, it is necessary to enlarge a reamed hole by a few thousandths of an inch. The expansion form is split through the fluted section and a slight amount of expansion is obtained by screwing in a tapering plug. The diameter increase may vary from 0.005 to 0.008 inch (0.127–0.2 mm) for reamers up to about 1 inch (25.4 mm) diameter and from 0.010 to 0.012 inch (0.25–0.3 mm) for diameters between 1 and 2 inches (25.4 and 50.8 mm). Hand reamers are tapered slightly on the end to facilitate starting them properly. The actual diameter of the shanks of commercial reamers may be from 0.002 to 0.005 inch (0.05–0.13 mm) under the reamer size. That part of the shank that is squared should be turned smaller in diameter than the shank itself, so that, when applying a wrench, no burr may be raised that may mar the reamed hole if the reamer is passed clear through it.

When fluting reamers, the cutter is so set with relation to the center of the reamer blank that the tooth gets a slight negative rake; that is, the cutter should be set *ahead* of the center, as shown in the illustration accompanying the table giving the amount to set the cutter ahead of the radial line. The amount is so selected that a tangent to the circumference of the reamer at the cutting point makes an angle of approximately 95 degrees with the front face of the cutting edge.

Amount to Set Cutter Ahead of Radial Line to Obtain Negative Front Rake

Size of Reamer	<i>a</i> , Inches	Size of Reamer	<i>a</i> , Inches	Size of Reamer	<i>a</i> , Inches
¼	0.011	⅞	0.038	2	0.087
⅜	0.016	1	0.044	2¼	0.098
½	0.022	1¼	0.055	2½	0.109
⅝	0.027	1½	0.066	2¾	0.120
¾	0.033	1¾	0.076	3	0.131

When fluting reamers, it is necessary to “break up the flutes,” that is, to space the cutting edges unevenly around the reamer. The difference in spacing should be very slight and need not exceed two degrees one way or the other. The manner in which the breaking up of the flutes is usually done is to move the index head to which the reamer is fixed a certain amount more or less than it would be moved if the spacing were regular. A table is given showing the amount of this additional movement of the index crank for reamers with different numbers of flutes. When a reamer is provided with helical flutes, the angle of spiral should be such that the cutting edges make an angle of about 10 or at most 15 degrees with the axis of the reamer.

The relief of the cutting edges should be comparatively slight. An eccentric relief, that is, one where the land back of the cutting edge is convex, rather than flat, is used by one or two manufacturers and is preferable for finishing reamers, as the reamer will hold its size longer. When hand reamers are used merely for removing stock, or simply for enlarging holes, the flat relief is better because the reamer has a keener cutting edge. The width of the land of the cutting edges should be about  $\frac{1}{32}$  inch (0.79 mm) for a  $\frac{1}{4}$ -inch (6.35 mm),  $\frac{1}{16}$  inch (1.59 mm) for a 1-inch (25.4 mm), and  $\frac{3}{32}$  inch (2.38 mm) for a 3-inch (76.2 mm) reamer.

## Irregular Spacing of Teeth in Reamers

Number of Flutes in Reamer	4	6	8	10	12	14	16

16th flute	...	...	...	...	...	...	2 less

**Threaded-End Hand Reamers.**—Hand reamers are sometimes provided with a thread at the extreme point in order to give them a uniform feed when reaming. The diameter on the top of this thread at the point of the reamer is slightly smaller than the reamer itself, and the thread tapers upward until it reaches a dimension of from 0.003 to 0.008 inch (0.076–0.2 mm), according to size, below the size of the reamer; at this point, the thread stops and a short neck about  $\frac{1}{16}$ -inch (1.59 mm) wide separates the threaded portion from the actual reamer, which is provided with a short taper from  $\frac{3}{16}$  to  $\frac{7}{16}$  inch (4.76–11.1 mm) long up to where the standard diameter is reached. The length of the threaded portion and the number of threads per inch for reamers of this kind are given in the accompanying table. The thread employed is a sharp V-thread.

## Dimensions for Threaded-End Hand Reamers

Sizes of Reamers	Length of Threaded Part	No. of Threads per Inch	Dia. of Thread at Point of Reamer	Sizes of Reamers	Length of Threaded Part	No. of Threads per Inch	Dia. of Thread at Point of Reamer
			Full diameter				Full diameter
$\frac{1}{8}$ - $\frac{5}{16}$	$\frac{3}{8}$	32	-0.006	$1\frac{1}{2}$ - $1\frac{1}{2}$	$\frac{9}{16}$	18	-0.010
$1\frac{1}{32}$ - $\frac{1}{2}$	$\frac{7}{16}$	28	-0.006	$1\frac{17}{32}$ -2	$\frac{9}{16}$	18	-0.012
$1\frac{17}{32}$ - $\frac{3}{4}$	$\frac{1}{2}$	24	-0.008	$2\frac{1}{2}$ - $2\frac{1}{2}$	$\frac{9}{16}$	18	-0.015
$2\frac{25}{32}$ -1	$\frac{9}{16}$	18	-0.008	$2\frac{17}{32}$ -3	$\frac{9}{16}$	18	-0.020

**Fluted Chucking Reamers.**—Reamers of this type are used in turret lathes, screw machines, etc., for enlarging holes and finishing them smooth and to the required size. The best results are obtained with a floating type of holder that permits a reamer to align itself with the hole being reamed. These reamers are intended for removing a small amount of metal, 0.005 to 0.010 inch (0.127–0.25 mm) being common allowances. Fluted chucking reamers are provided either with a straight shank or a standard taper shank. (See table on page 910 for standard dimensions.)

## Fluting Cutters for Reamers

<sup>a</sup> Sharp corner, no radius

**Rose Chucking Reamers.**—The rose type of reamer is used for enlarging cored or other holes. The cutting edges at the end are ground to a 45-degree bevel. This type of reamer will remove considerable metal in one cut. The cylindrical part of the reamer has no cutting edges but merely grooves cut for the full length of the reamer body, providing a way for the chips to escape and a channel for lubricant to reach the cutting edges. There is no relief on the cylindrical surface of the body part, but it is slightly back-tapered so that the diameter at the point with the beveled cutting edges is slightly larger than the diameter farther back. The back-taper should not exceed 0.001 inch per inch (or mm/mm). This form of reamer usually produces holes slightly larger than its size; it is, therefore, always made from 0.005 to 0.010 inch (0.127-0.25 mm) smaller than its nominal size, so that it may be followed by a fluted reamer for finishing. The grooves on the cylindrical portion are cut by a convex cutter having a width equal to from one-fifth to one-fourth the diameter of the rose reamer itself. The depth of the groove should be from one-eighth to one-sixth the diameter of the reamer. The teeth at the end of the reamer are milled with a 75-degree angular cutter; the width of the land of the cutting edge should be about one-fifth the distance from tooth to tooth. If an angular cutter is preferred to a convex cutter for milling the grooves on the cylindrical portion because of the higher cutting speed possible when milling, an 80-degree angular cutter slightly rounded at the point may be used.

**Cutters for Fluting Rose Chucking Reamers.**—The cutters used for fluting rose chucking reamers on the end are 80-degree angular cutters for 1/4- and 5/16-inch diameter reamers; 75-degree angular cutters for 3/8- and 7/16-inch reamers; and 70-degree angular cutters for all larger sizes. The grooves on the cylindrical portion are milled with convex cutters of approximately the following sizes for given diameters of reamers: 5/32-inch convex cutter for 1/2-inch reamers; 5/16-inch cutter for 1-inch reamers; 3/8-inch cutter for 1 1/2-inch reamers; 13/32-inch cutters for 2-inch reamers; and 15/32-inch cutters for 2 1/2-inch reamers.

Dimensions of Formed Reamer Fluting Cutters

The making and maintenance of cutters of the formed type involve greater expense than the use of angular cutters, dimensions of which are given on the previous page; but the form of flute produced by the formed type of cutter is preferred by many reamer users. The claims made for the formed type of flute are that the chips can be more readily removed from the reamer and that the reamer has greater strength and is less likely to crack or spring out of shape in hardening.

Reamer Size	No. of Teeth in Reamer	Cutter Dia. D	Cutter Width A	Hole Dia. B	Bearing Width C	Bevel Length E	Radius F	Radius F	Tooth Depth H	No. of Cutter Teeth
1/8-3/16	6	13/4	3/16	7/8	...	0.125	0.016	7/32	0.21	14
1/4-5/16	6	13/4	1/4	7/8	...	0.152	0.022	9/32	0.25	13
3/8-7/16	6	17/8	3/8	7/8	1/8	0.178	0.029	1/2	0.28	12
1/2-11/16	6-8	2	7/16	7/8	1/8	0.205	0.036	9/16	0.30	12
3/4-1	8	2 1/8	1/2	7/8	5/32	0.232	0.042	11/16	0.32	12
1 1/16-1 1/2	10	2 1/4	9/16	7/8	3/32	0.258	0.049	3/4	0.38	11
1 1/16-2 1/8	12	2 3/8	5/8	7/8	3/16	0.285	0.056	27/32	0.40	11
2 1/4-3	14	2 5/8	11/16	7/8	3/16	0.312	0.062	7/8	0.44	10

The smaller sizes of reamers, from 1/4 to 3/8 inch in diameter, are often milled, with regular double-angle reamer fluting cutters having a radius of 1/64 inch for 1/4-inch reamer, and 1/32 inch for 5/16-inch and 3/8-inch sizes.

**Reamer Terms and Definitions.**—*Reamer*: A rotary cutting tool with one or more cutting elements used for enlarging to size and contour a previously formed hole. Its principal support during the cutting action is obtained from the workpiece. (See Fig. 1.)

*Actual Size*: The actual measured diameter of a reamer, usually slightly larger than the nominal size to allow for wear.

*Angle of Taper*: The included angle of taper on a taper tool or taper shank.

*Arbor Hole*: The central mounting hole in a shell reamer.

*Axis*: The imaginary straight line that forms the longitudinal centerline of a reamer, usually established by rotating the reamer between centers.

*Back Taper*: A slight decrease in diameter, from front to back, in the flute length of reamers.

*Bevel*: An unrelieved angular surface of revolution (not to be confused with chamfer).

*Body*: The fluted full-diameter portion of a reamer, inclusive of the chamfer, starting taper, and bevel.

*Chamfer*: The angular cutting portion at the entering end of a reamer (see also *Secondary Chamfer*).

**Chamfer Angle:** The angle between the axis and the cutting edge of the chamfer measured in an axial plane at the cutting edge.

**Chamfer Length:** The length of the chamfer measured parallel to the axis at the cutting edge.

**Chamfer Relief Angle:** See under *Relief*.

**Chamfer Relief:** See under *Relief*.

**Chipbreakers:** Notches or grooves in the cutting edges of some taper reamers designed to break the continuity of the chips.

**Circular Land:** See preferred term *Margin*.

**Clearance:** The space created by the relief behind the cutting edge or margin of a reamer.

## Illustration of Terms Applying to Reamers

Hand Reamer

Machine Reamer

Straight Flutes

Chucking Reamer, Straight and Taper Shank

**Core:** The central portion of a reamer that joins the lands below the flutes.

**Core Diameter:** The diameter at a given point along the axis of the largest circle which does not project into the flutes.

**Cutter Sweep:** The section removed by the milling cutter or grinding wheel in entering or leaving a flute.

**Cutting Edge:** The leading edge of the relieved land in the direction of rotation for cutting.

**Cutting Face:** The leading side of the relieved land in the direction of rotation for cutting on which the chip impinges.

**External Center:** The pointed end of a reamer. The included angle varies with manufacturing practice.

**Flutes:** Longitudinal channels formed in the body of the reamer to provide cutting edges, permit passage of chips, and allow cutting fluid to reach the cutting edges.

**Angular Flute:** A flute that forms a cutting face lying in a plane intersecting the reamer axis at an angle. It is unlike a helical flute in that it forms a cutting face that lies in a single plane.

**Helical Flute:** Sometimes called a spiral flute, a flute formed in a helical path around the axis of a reamer.

**Spiral flute:** 1) On a taper reamer, a flute of constant lead; or 2) in reference to a straight reamer, see preferred term *Helical Flute*.

**Straight Flute:** A flute that forms a cutting edge lying in an axial plane.

**Flute Length:** The length of the flutes, not including the cutter sweep.

**Guide:** A cylindrical portion following the flutes of a reamer to maintain alignment.

**Heel:** The trailing edge of the land in the direction of rotation for cutting.

**Helix Angle:** The angle which a helical cutting edge at a given point makes with an axial plane through the same point.

**Hook:** A concave condition of a cutting face. The rake of a hooked cutting face must be determined at a given point.

**Internal Center:** A 60-degree countersink with clearance at the bottom, in one or both ends of a tool, which establishes the tool axis.

**Irregular Spacing:** A deliberate variation from uniform spacing of the reamer cutting edges.

**Land:** The section of the reamer between adjacent flutes.

**Land Width:** The distance between the leading edge of the land and the heel, measured at a right angle to the leading edge.

**Lead of Flute:** The axial advance of a helical or spiral cutting edge in one turn around the reamer axis.

**Length:** The dimension of any reamer element measured parallel to the reamer axis.

**Limits:** The maximum and minimum values designated for a specific element.

**Margin:** The unrelieved part of the periphery of the land adjacent to the cutting edge.

**Margin Width:** The distance between the cutting edge and the primary relief measured at a right angle to the cutting edge.

**Neck:** The section of reduced diameter connecting shank to body, or connecting other portions of the reamer.

**Nominal Size:** The designated basic size of a reamer overall length—the extreme length of the complete reamer from end to end, but not including external centers or expansion screws.

**Periphery:** The outside circumference of a reamer.

**Pilot:** A cylindrical portion preceding the entering end of the reamer body to maintain alignment.

**Rake:** The angular relationship between the cutting face, or a tangent to the cutting face at a given point and a given reference plane or line.

**Axial Rake:** Applies to angular (not helical or spiral) cutting faces. It is the angle between a plane containing the cutting face, or tangent to the cutting face at a given point, and the reamer axis.

**Helical Rake:** Applies only to helical and spiral cutting faces (not angular). It is the angle between a plane, tangent to the cutting face at a given point on the cutting edge, and the reamer axis.

**Negative Rake:** Describes a cutting face in rotation whose cutting edge lags the surface of the cutting face.

**Positive Rake:** Describes a cutting face in rotation whose cutting edge leads the surface of the cutting face.

**Radial Rake Angle:** The angle in a transverse plane between a straight cutting face and a radial line passing through the cutting edge.

**Relief:** The result of the removal of tool material behind or adjacent to the cutting edge to provide clearance and prevent rubbing (heel drag).

**Axial Relief:** The relief measured in the axial direction between a plane perpendicular to the axis and the relieved surface. It can be measured by the amount of indicator drop at a given radius in a given amount of angular rotation.

**Cam Relief:** The relief from the cutting edge to the heel of the land produced by a cam action.

**Chamfer Relief Angle:** The axial relief angle at the outer corner of the chamfer. It is measured by projection into a plane tangent to the periphery at the outer corner of the chamfer.

**Chamfer Relief:** The axial relief on the chamfer of the reamer.

**Eccentric Relief:** A convex relieved surface behind the cutting edge.

**Flat Relief:** A relieved surface behind the cutting edge which is essentially flat.

**Radial Relief:** Relief in a radial direction measured in the plane of rotation. It can be measured by the amount of indicator drop at a given radius in a given amount of angular rotation.

**Primary Relief:** The relief immediately behind the cutting edge or margin. Properly called relief.

**Secondary Relief:** An additional relief behind the primary relief.

**Relief Angle:** The angle, measured in a transverse plane, between the relieved surface and a plane tangent to the periphery at the cutting edge.

**Secondary Chamfer:** A slight relieved chamfer adjacent to and following the initial chamfer on a reamer.

**Shank:** The portion of the reamer by which it is held and driven.

**Squared Shank:** A cylindrical shank having a driving square on the back end.

**Starting Radius:** A relieved radius at the entering end of a reamer in place of a chamfer.

**Starting Taper:** A slight relieved taper on the front end of a reamer.

**Straight Shank:** A cylindrical shank.

**Tang:** The flattened end of a taper shank which fits a slot in the socket.

**Taper per Foot:** The difference in diameter between two points 12 in. apart measured along the axis.

**Taper Shank:** A shank made to fit a specific (conical) taper socket.

**Direction of Rotation and Helix.**—The terms “right hand” and “left hand” are used to describe both direction of rotation and direction of flute helix or reamers.

**Hand of Rotation (or Hand of Cut): Right-hand Rotation (or Right-hand Cut):** When viewed from the cutting end, the reamer must revolve counterclockwise to cut

**Left-hand Rotation (or Left-hand Cut):** When viewed from the cutting end, the reamer must revolve clockwise to cut

**Hand of Flute Helix: Right-hand Helix:** When the flutes twist away from the observer in a clockwise direction when viewed from either end of the reamer.

**Left-hand Helix:** When the flutes twist away from the observer in a counterclockwise direction when viewed from either end of the reamer. The standard reamers on the tables that follow are all right-hand rotation.

## Straight-Shank Center Reamers and Machine Countersinks

ANSI/ASME B94.2-1995 (R2015)

Center Reamers (Short Countersinks)				Machine Countersinks			
Dia. of Cut	Approx. Length Overall, A	Length of Shank, S	Dia. of Shank, D	Dia. of Cut	Approx. Length Overall, A	Length of Shank, S	Dia. of Shank, D
1/4	1 1/2	3/4	3/16	1/2	3 3/8	2 1/4	1/2
3/8	1 3/4	7/8	1/4	5/8	4	2 1/4	1/2
1/2	2	1	3/8	3/4	4 1/8	2 1/4	1/2
5/8	2 1/4	1	3/8	7/8	4 1/4	2 1/4	1/2
3/4	2 3/8	1 1/4	1/2	1	4 3/8	2 1/4	1/2

All dimensions are given in inches. Material is high-speed steel. Reamers and countersinks have 3 or 4 flutes. Center reamers are standard with 60, 82, 90, or 100 degrees included angle. Machine countersinks are standard with either 60 or 82 degrees included angle.

**Tolerances:** On overall length A, the tolerance is  $\pm 1/8$  inch for center reamers in a size range of from 1/4 to 3/8 inch, incl., and machine countersinks in a size range of from 1/2 to 3/8 inch, incl.;  $\pm 3/16$  inch for center reamers, 1/2 to 3/4 inch, incl.; and machine countersinks, 3/4 to 1 inch, incl. On shank diameter D, the tolerance is -0.0005 to -0.002 inch. On shank length S, the tolerance is  $\pm 1/16$  inch.

**Calculating Countersink and Spot Drill Depths.**—The following formulas are for countersinks and spot drills that have been sharpened to a point, allowances on tool depth will have to be made if the countersink or spot drill is not sharpened to a point.

Fig. 1. For Countersinks and Spot Drills that have been Sharpened to a Point

$\alpha$  = countersink angle

D = countersink diameter

Z = depth of tool travel required from surface of part

To find the tool travel "Z" required for any sharp-point countersink or spot drill angle, use either of the following formulas:

$$Z = \frac{D}{2} \cdot \frac{1}{\tan \frac{\alpha}{2}} \quad \text{or} \quad Z = \frac{D}{2} \cdot \cot \frac{\alpha}{2}$$

To find the tool travel "Z-a" required for any truncated countersink or spot drill angle, use either of the following formulas:

$$Z - a = \frac{D - T}{2} \cdot \frac{1}{\tan \frac{\alpha}{2}} \quad \text{or} \quad Z - a = \frac{D - T}{2} \cdot \cot \frac{\alpha}{2}$$

Fig. 2. For Countersinks and Spot Drills that are a Truncated Cone

$\alpha$  = allowance for truncated countersink tool

$d$  = diameter of hole

$T$  = diameter of small end of truncated tool

The table below is a quick reference for some predefined angles on countersinks and spot drills that have been sharpened to a point. To calculate the tool travel "Z", multiply the factor by the countersink diameter.

Countersink Angle $\alpha$ , degrees	Factor (Imperial or Metric Units)	Countersink Angle $\alpha$ , degrees	Factor (Imperial or Metric Units)
60	0.8660	118	0.3004
82	0.5752	120	0.2887
90	0.5000	135	0.2071
100	0.4195	142	0.1722

**Reamer Difficulties.**—Certain frequently occurring problems in reaming require remedial measures. These difficulties include the production of oversize holes, bellmouth holes, and holes with a poor finish. The following is taken from suggestions for correction of these difficulties by the National Twist Drill and Tool Co. and Winter Brothers Co.\*

**Oversize Holes:** The cutting of a hole oversize from the start of the reaming operations usually indicates a mechanical defect in the setup or reamer. Thus, the wrong reamer for the workpiece material may have been used or there may be inadequate workpiece support; inadequate or worn guide bushings; misalignment of the spindles, bushings, or workpiece; or runout of the spindle or reamer holder. The reamer itself may be defective due to chamfer runout or runout of the cutting end due to a bent or nonconcentric shank.

When reamers gradually start to cut oversize, it is due to pickup or galling, principally on the reamer margins. This condition is partly due to the workpiece material. Mild steels, certain cast irons, and some aluminum alloys are particularly troublesome in this respect.

Corrective measures include reducing the reamer margin widths to about 0.005 to 0.010 inch (0.127-0.25 mm), use of hard case surface treatments on high-speed steel reamers, either alone or in combination with black oxide treatments, and the use of a high-grade finish on the reamer faces, margins, and chamfer relief surfaces.

**Bellmouth Holes:** The cutting of a hole that becomes oversize at the entry end with the oversize decreasing gradually along its length always reflects misalignment of the cutting portion of the reamer with respect to the hole. The obvious solution is to provide improved guiding of the reamer by the use of accurate bushings and pilot surfaces. If this solution is not feasible and the reamer is cutting in a vertical position, a flexible element may be employed to hold the reamer in such a way that it has both radial and axial float, with the hope that the reamer will follow the original hole and prevent the bellmouth condition.

In horizontal setups where the reamer is held fixed and the workpiece rotated, any misalignment exerts a sideways force on the reamer as it is fed to depth, resulting in the formation of a tapered hole. This type of bellmouthing can frequently be reduced by shortening

\*"Some Aspects of Reamer Design and Operation," *Metal Cuttings*, April 1963.

the bearing length of the cutting portion of the reamer. One way to do this is to reduce the reamer diameter by 0.010 to 0.030 inch (0.25–0.76 mm), depending on size and length, behind a short full-diameter section,  $\frac{1}{8}$  to  $\frac{1}{2}$  inch (3.18 to 12.7 mm) long according to length and size, following the chamfer. The second method is to grind a high back taper, 0.008 to 0.015 inch per inch (or mm/mm), behind the short full-diameter section. These modifications reduce the length of the reamer tooth that can cause the bellmouth condition.

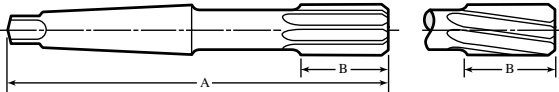

**Poor Finish:** The most obvious step toward producing a good finish is to reduce the reamer feed per revolution. Feeds as low as 0.0002 to 0.0005 inch (0.005 to 0.013 mm) per tooth have been used successfully. However, better reamer life results if the maximum feasible feed is used.

The minimum practical amount of reaming stock allowance will often improve finish by reducing the volume of chips and the resulting heat generated on the cutting portion of the chamfer. Too little reamer stock, however, can be troublesome in that the reamer teeth may not cut freely but will deflect or push the work material out of the way. When this happens, excessive heat, poor finish, and rapid reamer wear can occur.

Because of superior abrasion resistance, carbide reamers are often used when fine finishes are required. When properly conditioned, carbide reamers can produce a large number of good-quality holes. Careful honing of the carbide reamer edges is very important.

### Types and Sizes of Reamers

<sup>a</sup> Straight shank only.

<sup>b</sup> Taper shank only.

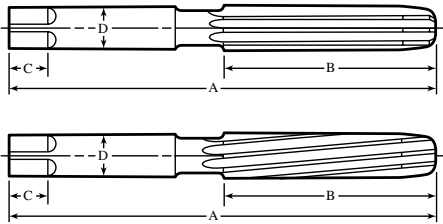

All dimensions in inches. Material is high-speed steel. The number of flutes is as follows: 3/8- to 15/32-inch sizes, 4 to 6; 1/2- to 31/32-inch sizes, 6 to 8; 1- to 11/16-inch sizes, 8 to 10; 1 1/4- to 1 15/16-inch sizes, 8 to 12; 2- to 2 1/4-inch sizes, 10 to 12; 2 3/8- and 2 1/2-inch sizes, 10 to 14. The expansion feature of these reamers provides a means of adjustment that is important in reaming holes to close tolerances. When worn undersize, they may be expanded and reground to the original size.

**Tolerances:** On reamer diameter, 3/8- to 1-inch sizes, incl., +0.0001 to +0.0005 inch; over 1-inch size, +0.0002 to +0.0006 inch. On length A and flute length B, 3/8- to 1-inch sizes, incl., ±1/16 inch; 1 1/2- to 2-inch sizes, incl., ±3/32 inch; over 2-inch sizes, ±1/8 inch.

**Taper is Morse taper:** No. 1 for sizes 3/8 to 19/32 inch, incl.; No. 2 for sizes 5/8 to 29/32 incl.; No. 3 for sizes 15/16 to 1 1/32, incl.; No. 4 for sizes 1 1/4 to 1 3/8, incl.; and No. 5 for sizes 1 3/4 to 2 1/2, incl. For amount of taper, see Table on page 1013.

All dimensions are given in inches. Material is carbon steel. Reamers with helical flutes that are left hand are standard. Expansion hand reamers are primarily designed for work where it is necessary to enlarge reamed holes by a few thousandths. The pilots and guides on these reamers are ground undersize for clearance. The maximum expansion on these reamers is as follows: .006 inch for the 1/4- to 7/16-inch sizes, .010 inch for the 1/2- to 7/8-inch sizes and .012 inch for the 1- to 1 1/4-inch sizes.

**Tolerances:** On length overall A and flute length B,  $\pm 1/16$  inch for 1/4- to 1-inch sizes,  $\pm 3/32$  inch for 1 1/8- to 1 1/4-inch sizes; on length of square C,  $\pm 1/32$  inch for 1/4- to 1-inch sizes,  $\pm 1/16$  inch for 1 1/8- to 1 1/4-inch sizes; on shank diameter D—-.001 to —.005 inch for 1/4- to 1-inch sizes, —.0015 to —.006 inch for 1 1/8- to 1 1/4-inch sizes; on size of square, —.004 inch for 1/4- to 1/2-inch sizes, —.006 inch for 3/16- to 1-inch sizes, and —.008 inch for 1 1/8- to 1 1/4-inch sizes.

<sup>a</sup> American National Standard self-holding tapers (Table 7a on page 1020.)

All dimensions in inches. Material is high-speed steel.

**Tolerances:** On reamer diameter, 1/4-inch size, +.0001 to +.0004 inch; over 1/4- to 1-inch size, incl., +.0001 to +.0005 inch; over 1-inch size, +.0002 to +.0006 inch. On overall length A and length of flute B, 1/4- to 1-inch size, incl., ±1/16 inch; and 1 1/16- to 1 1/2-inch size, incl., ±3/32 inch.

**American National Standard Driving Slots and Lugs for Shell Reamers or Shell Reamer Arbors ANSI/ASME B94.2-1995 (R2015)**

Arbor Size No.	Fitting Reamer Sizes	Driving Slot		Lug on Arbor		Reamer Hole Dia. at Large End
		Width W	Depth J	Width L	Depth M	
4	3/4	5/32	3/16	9/64	5/32	0.375
5	13/16 to 1	3/16	1/4	11/64	7/32	0.500
6	1 1/16 to 1 1/4	3/16	1/4	11/64	7/32	0.625
7	1 5/16 to 1 3/8	1/4	5/16	15/64	9/32	0.750
8	1 11/16 to 2	1/4	5/16	15/64	9/32	1.000
9	2 1/16 to 2 1/2	5/16	3/8	19/64	11/32	1.250

All dimension are given in inches. The hole in shell reamers has a taper of 1/8 inch per foot, with arbors tapered to correspond. Shell reamer arbor tapers are made to permit a driving fit with the reamer.

<sup>a</sup> Reamer with straight flutes is standard only.<sup>b</sup> Reamer with helical flutes is standard only.

All dimensions are given in inches. Material is high-speed steel. Chucking reamers are end cutting on the chamfer and the relief for the outside diameter is ground in back of the margin for the full length of land. Lands of rose chucking reamers are not relieved on the periphery but have a relatively large amount of back taper.

**Tolerances:** On reamer diameter, up to  $\frac{1}{4}$ -inch size, incl., + .0001 to + .0004 inch; over  $\frac{1}{4}$ - to 1-inch size, incl., + .0001 to + .0005 inch; over 1-inch size, + .0002 to + .0006 inch. On length overall  $A$  and flute length  $B$ , up to 1-inch size, incl.,  $\pm \frac{1}{16}$  inch;  $\frac{1}{16}$ - to  $1\frac{1}{2}$ -inch size, incl.,  $\pm \frac{3}{32}$  inch.

Helical flutes are right- or left-hand helix, right-hand cut, except sizes  $1\frac{1}{16}$  through  $1\frac{1}{2}$  inches, which are right-hand helix only.

$2\frac{1}{2}$ <sup>a</sup>	$3\frac{3}{4}$	$2\frac{3}{4}$	1.250	9	14 to 16

<sup>a</sup> Helical flutes only.

All dimensions are given in inches. Material is high-speed steel. Helical flute shell reamers with left-hand helical flutes are standard. Shell reamers are designed as a sizing or finishing reamer and are held on an arbor provided with driving lugs. The holes in these reamers are ground with a taper of  $\frac{1}{8}$  inch per foot.

**Tolerances:** On diameter of reamer,  $\frac{3}{4}$ - to 1-inch size, incl., + .0001 to + .0005 inch; over 1-inch size, + .0002 to + .0006 inch. On length overall  $A$  and flute length  $B$ ,  $\frac{3}{4}$ - to 1-inch size, incl.,  $\pm \frac{1}{16}$  inch;  $1\frac{1}{16}$ - to 2-inch size, incl.,  $\pm \frac{3}{32}$  inch;  $2\frac{1}{16}$ - to  $2\frac{1}{2}$ -inch size, incl.,  $\pm \frac{1}{8}$  inch.

<sup>a</sup> Morse. For amount of taper see Table on page 1013.

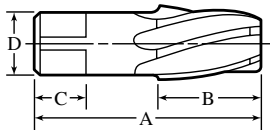

All dimension are given in inches. Material is high-speed steel. The chamfer on the cutting end of the reamer is optional. Squared shank reamers are standard with straight flutes. Tapered shank reamers are standard with straight or spiral flutes. Spiral flute reamers are standard with left-hand spiral flutes.

**Tolerances:** On overall length A and flute length B, in taper numbers 0 to 3, incl.,  $\pm 1/16$  inch, in taper numbers 4 and 5,  $\pm 3/32$  inch. On length of square C, in taper numbers 0 to 3, incl.,  $\pm 1/32$  inch; in taper numbers 4 and 5,  $\pm 1/16$  inch. On shank diameter D,  $-0.005$  to  $-0.002$  inch. On size of square, in taper numbers 0 and 1,  $-0.004$  inch; in taper numbers 2 and 3,  $-0.006$  inch; in taper numbers 4 and 5,  $-0.008$  inch.

**Center Reamers.**—A “center reamer” is a reamer the teeth of which meet in a point. By their use, small conical holes may be reamed in the ends of parts to be machined as on lathe centers. When large holes—usually cored—must be center-reamed, a large reamer is ordinarily used in which the teeth do not meet in a point, the reamer forming the frustum of a cone. Center reamers for such work are called “bull” or “pipe” center reamers.

**Bull Center Reamer:** A conical reamer used for reaming the ends of large holes—usually cored—so that they will fit on a lathe center. The cutting part of the reamer is generally in the shape of a frustum of a cone. It is also known as a pipe center reamer.

<sup>a</sup> For taper per foot, see Table 10 on page 1023.

These reamers are no longer ANSI/ASME Standard.

All dimensions are given in inches. Material is high-speed steel. The chamfer on the cutting end of the reamer is optional. All reamers are finishing reamers. Spiral flute reamers are standard with left-hand spiral flutes. (Tapered reamers, especially those with left-hand spirals, should not have circular lands because cutting must take place on the outer diameter of the tool.) B & S taper reamers are designed for use in reaming out Brown & Sharpe standard taper sockets.

**Tolerances:** On length overall A and flute length B, taper nos. 1 to 7, incl., ±1/16 inch; taper nos. 8 to 10, incl., ±1/32 inch. On length of square C, taper nos. 1 to 9, incl., ±1/32 inch; taper no. 10, ±1/16 inch. On shank diameter D, - .0005 to - .002 inch. On size of square, taper nos. 1 to 3, incl., - .004 inch; taper nos. 4 to 9, incl., - .006 inch; taper no. 10, - .008 inch.

<sup>a</sup> Not applicable to high-spiral flute reamers.

<sup>b</sup> Not applicable to straight and left-hand spiral-fluted, squared-shank reamers.

All dimensions in inches. Reamers have a taper of ¼ inch per foot and are made of high-speed steel. Straight flute reamers of carbon steel are also standard. The number of flutes is as follows; 3 or 4, for 7/0 to 4/0 sizes; 4 to 6, for 3/0 to 0 sizes; 5 or 6, for 1 to 5 sizes; 6 to 8, for 6 to 9 sizes; 7 or 8, for the 10 size in the case of straight- and spiral-flute reamers; and 2 or 3, for 8/0 to 8 sizes; 2 to 4, for the 9 and 10 sizes in the case of high-spiral flute reamers.

Tolerances: On length overall A and flute length B,  $\pm 1/16$  inch. On length of square C,  $\pm 1/32$  inch. On shank diameter D,  $-0.001$  to  $-0.005$  inch for straight- and spiral-flute reamers and  $-0.0005$  to  $-0.002$  inch for high-spiral flute reamers. On size of square,  $-0.004$  inch for 7/0 to 7 sizes and  $-0.006$  inch for 8 to 10 sizes.

**TWIST DRILLS AND COUNTERBORES**

Twist drills are rotary end-cutting tools having one or more cutting lips and one or more straight or helical flutes for the passage of chips and cutting fluids. Twist drills are made with straight or tapered shanks, but most have straight shanks. All but the smaller sizes are ground with "back taper," reducing the diameter from the point toward the shank, to prevent binding in the hole when the drill is worn.

*Straight-Shank Drills:* Straight-shank drills have cylindrical shanks that may be of the same or of a different diameter than the body diameter of the drill and may be made with or without driving flats, tang, or grooves.

*Taper-Shank Drills:* Taper-shank drills are preferable to the straight-shank type for drilling medium- and large-size holes. The taper on the shank conforms to one of the tapers in the American Standard (Morse) Series.

**American National Standard.**—American National Standard B94.11M-1993 covers nomenclature, definitions, sizes and tolerances for High-Speed Steel Straight- and Taper-Shank Drills and Combined Drills and Countersinks, Plain and Bell types. It covers both inch and metric sizes. Dimensional tables from the Standard will be found on the following pages.

**Definitions of Twist Drill Terms.**—The following definitions are included in the Standard.

*Axis:* The imaginary straight line that forms the longitudinal center of the drill.

*Back Taper:* A slight decrease in diameter from point to back in the body of the drill.

*Body:* The portion of the drill extending from the shank or neck to the outer corners of the cutting lips.

*Body Diameter Clearance:* That portion of the land that has been cut away so it will not rub against the wall of the hole.

*Chisel Edge:* The edge at the ends of the web that connects the cutting lips.

*Chisel Edge Angle:* The angle included between the chisel edge and the cutting lip as viewed from the end of the drill.

*Clearance Diameter:* The diameter over the cutaway portion of the drill lands.

*Drill Diameter:* The diameter over the margins of the drill measured at the point.

*Flutes:* Helical or straight grooves cut or formed in the body of the drill to provide cutting lips, to permit removal of chips, and to allow cutting fluid to reach the cutting lips.

*Helix Angle:* The angle made by the leading edge of the land with a plane containing the axis of the drill.

*Land:* The peripheral portion of the drill body between adjacent flutes.

*Land Width:* The distance between the leading edge and the heel of the land measured at a right angle to the leading edge.

*Lips—Two-Flute Drill:* The cutting edges extending from the chisel edge to the periphery.

*Lips—Three- or Four-Flute Drill (Core Drill):* The cutting edges extending from the bottom of the chamfer to the periphery.

*Lip Relief:* The axial relief on the drill point.

*Lip Relief Angle:* The axial relief angle at the outer corner of the lip. It is measured by projection into a plane tangent to the periphery at the outer corner of the lip. (Lip relief angle is usually measured across the margin of the twist drill.)

*Margin:* The cylindrical portion of the land that is not cut away to provide clearance.

*Neck:* The section of reduced diameter between the body and the shank of a drill.

*Overall Length:* The length from the extreme end of the shank to the outer corners of the cutting lips. It does not include the conical-shank end often used on straight-shank drills, nor does it include the conical cutting point used on both straight- and taper-shank drills. (For core drills with an external center on the cutting end, the overall length is the same as for two-flute drills. For core drills with an internal center on the cutting end, the overall length is to the extreme ends of the tool.)

**Point:** The cutting end of a drill made up of the ends of the lands, the web, and the lips. In form, it resembles a cone but departs from a true cone to furnish clearance behind the cutting lips.

**Point Angle:** The angle included between the lips projected upon a plane parallel to the drill axis and parallel to the cutting lips.

**Shank:** The part of the drill by which it is held and driven.

**Tang:** The flattened end of a taper shank, intended to fit into a driving slot in the socket.

**Tang Drive:** Two opposite parallel driving flats on the end of a straight shank.

**Web:** The central portion of the body that joins the end of the lands. The end of the web forms the chisel edge on a two-flute drill.

**Web Thickness:** The thickness of the web at the point unless another specific location is indicated.

**Web Thinning:** The operation of reducing the web thickness at the point to reduce drilling thrust.

ANSI Standard Twist Drill Nomenclature

**Types of Drills.**—Drills may be classified based on the type of shank, number of flutes or hand of cut.

**Straight-Shank Drills:** Those having cylindrical shanks that may be the same or a different diameter than the body of the drill. The shank may be with or without driving flats, tang, grooves, or threads.

**Taper-Shank Drills:** Those having conical shanks suitable for direct fitting into tapered holes in machine spindles, driving sleeves, or sockets. Tapered shanks generally have a driving tang.

**Two-Flute Drills:** The conventional type of drill used for originating holes.

**Three-Flute Drills (Core Drills):** Drills commonly used for enlarging and finishing drilled, cast or punched holes. They will not produce original holes.

**Four-Flute Drills (Core Drills):** Used interchangeably with three-flute drills. They are of similar construction except for the number of flutes.

**Right-Hand Cut:** When viewed from the cutting point, the counterclockwise rotation of a drill in order to cut.

**Left-Hand Cut:** When viewed from the cutting point, the clockwise rotation of a drill in order to cut.

**Teat Drill:** The cutting edges of a teat drill are at right angles to the axis, and in the center there is a small teat of pyramid shape which leads the drill and holds it in position. This form is used for squaring the bottoms of holes made by ordinary twist drills or for drilling the entire hole, especially if it is not very deep and a square bottom is required. For instance, when drilling holes to form clearance spaces at the end of a keyseat, preparatory to cutting it out by planing or chipping, the teat drill is commonly used.

**Table 1. ANSI Straight-Shank Twist Drills — Jobbers Length through 17.5 mm, Taper Length through 12.7 mm, and Screw Machine Length through 25.4 mm Diameter ANSI/ASME B94.11M-1993**

**Table 8. American National Standard Drill Drivers — Split-Sleeve, Collet-Type ANSI/ASME B94.35-1972 (R2015)**

Taper Number	<i>G</i> Overall Length	<i>H</i> Diameter at Gage Line	<i>J</i> Taper per Foot <sup>a</sup>	<i>K</i> Length to Gage Line	<i>L</i> Driver Projection
0 <sup>b</sup>	2.38	0.356	0.62460	2.22	0.16
1	2.62	0.475	0.59858	2.44	0.19
2	3.19	0.700	0.59941	2.94	0.25

<sup>a</sup> Taper rate in accordance with ANSI/ASME B5.10-1994 (R2013), Machine Tapers.

<sup>b</sup> Size 0 is not an American National Standard but is included here to meet special needs.

All dimensions are in inches.

**British Standard Combined Drills and Countersinks (Center Drills).**—BS 328: Part 2: 1972 (1990) provides dimensions of combined drills and countersinks for center holes. Three types of drill and countersink combinations are shown in this standard but are not given here. These three types will produce center holes without protecting chamfers, with protecting chamfers, and with protecting chamfers of radius form.

**Drill Drivers—Split-Sleeve, Collet-Type.**—American National Standard ANSI/ASME B94.35-1972 (R2015) covers split-sleeve, collet-type drivers for driving straight shank drills, reamers, and similar tools, without tangs from 0.0390-inch through 0.1220-inch diameter, and with tangs from 0.1250-inch through 0.7500-inch diameter, including metric sizes.

For sizes 0.0390 through 0.0595 inch, the standard taper number is 1, and the optional taper number is 0. For sizes 0.0610 through 0.1875 inch, the standard taper number is 1, first optional taper number is 0, and second optional taper number is 2. For sizes 0.1890 through 0.2520 inch, the standard taper number is 1, first optional taper number is 2, and second optional taper number is 0. For sizes 0.2570 through 0.3750 inch, the standard taper number is 1 and the optional taper number is 2. For sizes 0.3860 through 0.5625 inch, the standard taper number is 2 and the optional taper number is 3. For sizes 0.5781 through 0.7500 inch, the standard taper number is 3 and the optional taper number is 4.

The depth  $B$  that the drill enters the driver is 0.44 inch for sizes 0.0390 through 0.0781 inch; 0.50 inch for sizes 0.0785 through 0.0938 inch; 0.56 inch for sizes 0.0960 through 0.1094 inch; 0.62 inch for sizes 0.1100 through 0.1220 inch; 0.75 inch for sizes 0.1250 through 0.1875 inch; 0.88 inch for sizes 0.1890 through 0.2500 inch; 1.00 inch for sizes 0.2520 through 0.3125 inch; 1.12 inches for sizes 0.3160 through 0.3750 inch; 1.25 inches for sizes 0.3860 through 0.4688 inch; 1.31 inches for sizes 0.4844 through 0.5625 inch; 1.47 inches for sizes 0.5781 through 0.6562 inch; and 1.62 inches for sizes 0.6719 through 0.7500 inch.

**British Standard Metric Twist Drills.**—BS 328: Part 1:1959 (incorporating amendments issued March 1960 and March 1964) covers twist drills made to inch and metric dimensions that are intended for general engineering purposes. ISO recommendations are taken into account. The accompanying tables give the standard metric sizes of Morse taper-shank twist drills and core drills, parallel-shank jobbing and long-series drills, and stub drills.

All drills are right-hand cutting unless otherwise specified, and normal, slow, or quick helix angles may be provided. A “back-taper” is ground on the diameter from point to shank to provide longitudinal clearance. Core drills may have three or four flutes and are intended for opening up cast holes or enlarging machined holes, for example. The parallel-shank jobber, long-series drills, and stub drills are made without driving tenons.

Morse taper shank drills with oversize dimensions are also listed, and Table 11 shows metric drill sizes superseding gage and letter-size drills, which are now obsolete in Britain. To meet special requirements, the Standard lists nonstandard sizes for the various types of drills.

The limits of tolerance on cutting diameters, as measured across the lands at the outer corners of a drill, shall be  $h8$ , in accordance with BS 1916, Limits and Fits for Engineering (Part I, Limits and Tolerances); Table 14 shows the values common to the different types of drills mentioned before.

The drills shall be permanently and legibly marked whenever possible, preferably by rolling, showing the size, and the manufacturer's name or trademark. If they are made from high-speed steel, they shall be marked with the letters H.S. where practicable.

*Drill Elements:* The following definitions of drill elements are given.

*Axis:* The longitudinal center line.

*Body:* That portion of the drill extending from the extreme cutting end to the commencement of the shank.

*Shank:* That portion of the drill by which it is held and driven.

*Flutes:* The grooves in the body of the drill that provide lips, permit the removal of chips and allow cutting fluid to reach the lips.

*Web (Core):* The central portion of the drill situated between the roots of the flutes and extending from the point end toward the shank; the point end of the web or core forms the chisel edge.

*Lands:* The cylindrical-ground surfaces on the leading edges of the drill flutes. The width of the land is measured at right angles to the flute helix.

*Body Clearance:* The portion of the body surface that is reduced in diameter to provide diametral clearance.

*Heel:* The edge formed by the intersection of the flute surface and the body clearance.

*Point:* The sharpened end of the drill, consisting of all that part of the drill that is shaped to produce lips, faces, flanks, and chisel edge.

*Face:* That portion of the flute surface adjacent to the lip on which the chip impinges as it is cut from the work.

*Flank:* The surface on a drill point that extends behind the lip to the following flute.

*Lip (Cutting Edge):* The edge formed by the intersection of the flank and face.

*Relative Lip Height:* The relative position of the lips measured at the outer corners in a direction parallel to the drill axis.

*Outer Corner:* The corner formed by the intersection of the lip and the leading edge of the land.

*Chisel Edge:* The edge formed by the intersection of the flanks.

*Chisel Edge Corner:* The corner formed by the intersection of a lip and the chisel edge.

Gauge and letter-size drills are now obsolete in the United Kingdom and should not be used in the production of new designs. The table is given to assist users in changing over to the recommended standard sizes.

72.00			87.00					
73.00			88.00					
74.00			89.00					
75.00			90.00					

All dimensions are in millimeters. Tolerances on diameters are given in the table below.

Table 13 shows twist drills that may be supplied with the shank and length oversize, but they should be regarded as nonpreferred.

The Morse taper shanks of these twist and core drills are as follows: 3.00 to 14.00 mm diameter, M.T. No. 1; 14.25 to 23.00 mm diameter, M.T. No. 2; 23.25 to 31.50 mm diameter, M.T. No. 3; 31.75 to 50.50 mm diameter, M.T. No. 4; 51.00 to 76.00 mm diameter, M.T. No. 5; 77.00 to 100.00 mm diameter, M.T. No. 6.

**Table 13. British Standard Morse Taper-Shank Twist Drills — Metric Oversize Shank and Length Series BS 328: Part 1:1959**

Dia. Range	Overall Length	M. T. No.	Dia. Range	Overall Length	M. T. No.	Dia. Range	Overall Length	M. T. No.
12.00 to 13.20	199	2	22.50 to 23.00	276	3	45.50 to 47.50	402	5
13.50 to 14.00	206	2	26.75 to 28.00	319	4	48.00 to 50.00	407	5
18.25 to 19.00	256	3	29.00 to 30.00	324	4	50.50	412	5
19.25 to 20.00	251	3	30.25 to 31.50	329	4	64.00 to 67.00	499	6
20.25 to 21.00	266	3	40.50 to 42.50	392	5	68.00 to 71.00	504	6
21.25 to 22.25	271	3	43.00 to 45.00	397	5	72.00 to 75.00	509	6

Diameters and lengths are given in millimeters. For the individual sizes within the diameter ranges given, see Table 12.

This series of drills should be regarded as non-preferred.

**Table 14. British Standard Limits of Tolerance on Diameter for Twist Drills and Core Drills — Metric Series BS 328: Part 1:1959**

Drill Size (Diameter measured across lands at outer corners)	Tolerance (h8)
0 to 1 inclusive	Plus 0.000 to Minus 0.014
Over 1 to 3 inclusive	Plus 0.000 to Minus 0.014
Over 3 to 6 inclusive	Plus 0.000 to Minus 0.018
Over 6 to 10 inclusive	Plus 0.000 to Minus 0.022
Over 10 to 18 inclusive	Plus 0.000 to Minus 0.027
Over 18 to 30 inclusive	Plus 0.000 to Minus 0.033
Over 30 to 50 inclusive	Plus 0.000 to Minus 0.039
Over 50 to 80 inclusive	Plus 0.000 to Minus 0.046
Over 80 to 120 inclusive	Plus 0.000 to Minus 0.054

All dimensions are given in millimeters.

**Table 15. British Standard Parallel Shank Jobber Series Twist Drills – Standard Metric Sizes BS 328: Part 1:1959**

4.80	26	62	9.20			13.80	54	107	25.00	75	151

All dimensions are given in millimeters. Tolerances on diameters are given in Table 14.

**Steels for Twist Drills.**—Twist drill steels need good toughness, abrasion resistance, and ability to resist softening due to heat generated by cutting. The amount of heat generated indicates the type of steel that should be used.

*Carbon Tool Steel* may be used where little heat is generated during drilling.

*High-Speed Steel* is preferred because of its combination of red hardness and wear resistance, which permits higher operating speeds and increased productivity. Optimum properties can be obtained by selection of alloy analysis and heat treatment.

*Cobalt High-Speed Steel* alloys have higher red hardness than standard high-speed steels, permitting drilling of materials such as heat-resistant alloys and materials with hardness greater than 38 RC (Rockwell C scale). These high-speed drills can withstand cutting speeds beyond the range of conventional high-speed steel drills and have superior resistance to abrasion but are not equal to tungsten carbide-tipped tools.

**Accuracy of Drilled Holes.**—Normally, the diameter of drilled holes is not given a tolerance; the size of the hole is expected to be as close to the drill size as can be obtained.

The accuracy of holes drilled with a two-fluted twist drill is influenced by many factors, including accuracy of the drill point; size of the drill; length and shape of the chisel edge; whether or not a bushing is used to guide the drill; work material; length of the drill; runout of the spindle and the chuck; rigidity of the machine tool, workpiece, and the setup; and cutting fluid used, if any.

The diameter of the drilled holes will be oversize in most materials. The table *Oversize Diameters in Drilling* on page 962 provides the results of tests reported by The United States Cutting Tool Institute in which the diameters of over 2800 holes drilled in steel and cast iron were measured. The values in this table indicate what might be expected under average shop conditions; however, when the drill point is accurately ground and the other machining conditions are correct, the resulting hole size is more likely to be between the mean and average minimum values given in this table. If the drill is ground and used incorrectly, holes that are even larger than the average maximum values can result.

## Oversize Diameters in Drilling

Drill Dia., Inch	Amount Oversize, Inch			Drill Dia., Inch	Amount Oversize, Inch		
	Average Max.	Mean	Average Min.		Average Max.	Mean	Average Min.
1/16	0.002	0.0015	0.001	1/2	0.008	0.005	0.003
1/8	0.0045	0.003	0.001	3/4	0.008	0.005	0.003
1/4	0.0065	0.004	0.0025	1	0.009	0.007	0.004

Courtesy of The United States Cutting Tool Institute

Some conditions will cause the drilled hole to be undersize. For example, holes drilled in light metals and in other materials having a high coefficient of thermal expansion such as plastics may contract to a size that is smaller than the diameter of the drill as the material surrounding the hole is cooled after having been heated by the drilling. The elastic action of the material surrounding the hole may also cause the drilled hole to be undersize when drilling high-strength materials with a drill that is dull at its outer corner.

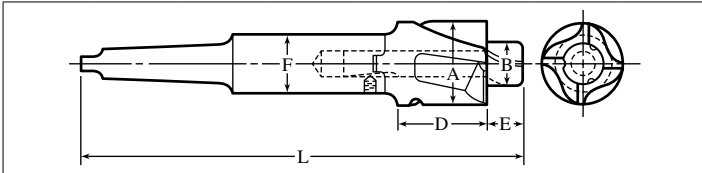

The accuracy of the drill point has a great effect on the accuracy of the drilled hole. An inaccurately ground twist drill will produce holes that are excessively oversize. The drill point must be symmetrical; i.e., the point angles must be equal, as well as the lip lengths and the axial height of the lips. Any alterations to the lips or to the chisel edge, such as thinning the web, must be done carefully to preserve the symmetry of the drill point. Adequate relief should be provided behind the chisel edge to prevent heel drag. On conventionally ground drill points, this relief can be estimated by the chisel edge angle.

When drilling a hole, as the drill point starts to enter the workpiece, the drill will be unstable and will tend to wander. Then, as the body of the drill enters the hole, the drill will tend to stabilize. The result of this action is a tendency to drill a bellmouth shape in the hole at the entrance and perhaps beyond. Factors contributing to bellmouthing are: an unsymmetrically ground drill point; a large chisel edge length; inadequate relief behind the chisel edge; runout of the spindle and the chuck; using a slender drill that will bend easily; and lack of rigidity of the machine tool, workpiece, or the setup. Correcting these conditions as required will reduce the tendency for bellmouthing to occur and improve the accuracy of the hole diameter and its straightness. Starting the hole with a short stiff drill, such as a center drill, will quickly stabilize the drill that follows and reduce or eliminate bellmouthing; this procedure should always be used when drilling in a lathe, where the work is rotating. Bellmouthing can also be eliminated almost entirely and the accuracy of the hole improved by using a close-fitting drill jig bushing placed close to the workpiece. Although specific recommendations cannot be made, many cutting fluids will help to increase the accuracy of the diameters of drilled holes. Double-margin twist drills, available in the smaller sizes, will drill a more accurate hole than conventional twist drills having only a single margin at the leading edge of the land. The second land, located on the trailing edge of each land, provides greater stability in the drill bushing and in the hole. These drills are especially useful in drilling intersecting off-center holes. Single and double-margin step drills, also available in the smaller sizes, will produce very accurate drilled holes, which are usually less than 0.002 inch (0.051 mm) larger than the drill size.

**Counterboring.**—Counterboring (called spot-facing if the depth is shallow) is the enlargement of a previously formed hole. Counterbores for screw holes are generally made in sets. Each set contains three counterbores: one with the body of the size of the screw head and the pilot the size of the hole to admit the body of the screw; one with the body the size of the head of the screw and the pilot the size of the tap drill; and the third with the body the size of the body of the screw and the pilot the size of the tap drill. Counterbores are usually provided with helical flutes to provide positive effective rake on the cutting edges. The four flutes are so positioned that the end teeth cut ahead of center to provide a shearing action and eliminate chatter in the cut. Three designs are most common: solid, two-piece, and three-piece. Solid designs have the body, cutter, and pilot all in one piece. Two-piece designs have an integral shank and counterbore cutter, with an interchangeable pilot, and provide true concentricity of the cutter diameter with the shank while

allowing use of various pilot diameters. Three-piece counterbores have separate holder, counterbore cutter, and pilot, so that a holder will take any size of counterbore cutter. Each counterbore cutter, in turn, can be fitted with any suitable size diameter of pilot. Counterbores for brass are fluted straight.

### Counterbores with Interchangeable Cutters and Guides

No. of Holder	No. of Morse Taper Shank	Range of Cutter Diameters, A	Range of Pilot Diameters, B	Total Length, C	Length of Cutter Body, D	Length of Pilot, E	Dia. of Shank, F
1	1 or 2	$\frac{3}{4}$ - $1\frac{1}{16}$	$\frac{1}{2}$ - $\frac{3}{4}$	$7\frac{1}{4}$	1	$\frac{5}{8}$	$\frac{3}{4}$
2	2 or 3	$1\frac{1}{8}$ - $1\frac{9}{16}$	$1\frac{1}{16}$ - $1\frac{1}{8}$	$9\frac{1}{2}$	$1\frac{3}{8}$	$\frac{7}{8}$	$1\frac{1}{8}$
3	3 or 4	$1\frac{3}{8}$ - $2\frac{1}{16}$	$\frac{7}{8}$ - $1\frac{3}{8}$	$12\frac{1}{2}$	$1\frac{3}{4}$	$1\frac{1}{8}$	$1\frac{3}{8}$
4	4 or 5	$2\frac{1}{8}$ - $3\frac{1}{2}$	$1$ - $2\frac{1}{8}$	15	$2\frac{1}{4}$	$1\frac{3}{8}$	$2\frac{1}{8}$

Small counterbores are often made with three flutes, but should then have the size plainly stamped on them before fluting, as they cannot afterwards be conveniently measured. The flutes should be deep enough to come below the surface of the pilot. The counterbore should be relieved on the end of the body only, and not on the cylindrical surface. To facilitate the relieving process, a small neck is turned between the guide and the body for clearance. The amount of clearance on the cutting edges is, for general work, from 4 to 5 degrees. The accompanying table gives dimensions for straight shank counterbores.

### Solid Counterbores with Integral Pilot

Counterbore Diameters	Pilot Diameters			Straight Shank Diameter	Overall Length	
	Nominal	$+\frac{1}{64}$	$+\frac{1}{32}$		Short	Long
0.110	0.060	0.076	...	$\frac{7}{64}$	$2\frac{1}{2}$	...
0.133	0.073	0.089	...	$\frac{1}{8}$	$2\frac{1}{2}$	...
0.155	0.086	0.102	...	$\frac{5}{32}$	$2\frac{1}{2}$	...

0.241	0.138	0.154	...	$\frac{7}{32}$	$2\frac{1}{2}$	...
0.285	0.164	0.180	...	$\frac{1}{4}$	$2\frac{1}{2}$	...
0.327	0.190	0.206	...	$\frac{9}{32}$	$2\frac{3}{4}$	...
0.372	0.216	0.232	...	$\frac{5}{16}$	$2\frac{3}{4}$	...
$\frac{13}{32}$	$\frac{1}{4}$	$\frac{17}{64}$	$\frac{9}{32}$	$\frac{3}{8}$	$3\frac{1}{2}$	$5\frac{1}{2}$
$\frac{1}{2}$	$\frac{5}{16}$	$\frac{21}{64}$	$\frac{11}{32}$	$\frac{3}{8}$	$3\frac{1}{2}$	$5\frac{1}{2}$
$\frac{19}{32}$	$\frac{3}{8}$	$\frac{25}{64}$	$\frac{13}{32}$	$\frac{1}{2}$	4	6
$\frac{11}{16}$	$\frac{7}{16}$	$\frac{29}{64}$	$\frac{15}{32}$	$\frac{1}{2}$	4	6
$\frac{25}{32}$	$\frac{1}{2}$	$\frac{33}{64}$	$\frac{17}{32}$	$\frac{1}{2}$	5	7

All dimensions are in inches.

**Three-Piece Counterbores.**—Data shown for the first two styles of counterbores are for straight-shank designs. These tools are also available with taper shanks in most sizes. Sizes of taper shanks for cutter diameters of  $\frac{1}{4}$  to  $\frac{9}{16}$  in. are No. 1; for  $\frac{19}{32}$  to  $\frac{7}{8}$  in., No. 2; for  $\frac{15}{16}$  to  $1\frac{3}{8}$  in., No. 3; for  $1\frac{1}{2}$  to 2 in., No. 4; and for  $2\frac{1}{8}$  to  $2\frac{1}{2}$  in., No. 5.

**Counterbore Sizes for Hex-Head Bolts and Nuts.**—Table 3a, page 1689, shows the maximum socket wrench dimensions for standard  $\frac{1}{4}$ -,  $\frac{1}{2}$ - and  $\frac{3}{4}$ -inch drive socket sets. For a given socket size (nominal size equals the maximum width across the flats of nut or bolt head), the dimension *K* given in the table is the minimum counterbore diameter required to provide socket wrench clearance for access to the bolt or nut.

**Sintered Carbide Boring Tools.**—Industrial experience has shown that the shapes of tools used for boring operations need to be different from those of single-point tools ordinarily used for general applications such as lathe work. Accordingly, Section 5 of American National Standard ANSI B212.1-2002 gives standard sizes, styles and designations for four basic types of sintered carbide boring tools, namely: solid carbide square; carbide-tipped square; solid carbide round; and carbide-tipped round boring tools. In addition to these ready-to-use standard boring tools, solid carbide round and square unsharpened boring tool bits are provided.

*Style Designations for Carbide Boring Tools:* Table 1 shows designations used to specify the styles of American Standard sintered carbide boring tools. The first letter denotes solid (S) or tipped (T). The second letter denotes square (S) or round (R). The side cutting edge angle is denoted by a third letter (A through H) to complete the style designation. Solid square and round bits with the mounting surfaces ground but the cutting edges unsharpened (Table 3) are designated using the same system except that the third letter indicating the side cutting edge angle is omitted.

**Table 1. American National Standard Sintered Carbide Boring Tools — Style Designations ANSI B212.1-2002 (R2007)**

Side Cutting Edge Angle <i>E</i>		Boring Tool Styles			
Degrees	Designation	Solid Square (SS)	Tipped Square (TS)	Solid Round (SR)	Tipped Round (TR)
0	A		TSA		
10	B		TSB		
30	C	SSC	TSC	SRC	TRC
40	D		TSD		
45	E	SSE	TSE	SRE	TRE
55	F		TSF		
90 (0° Rake)	G				TRG
90 (10° Rake)	H				TRH

*Size Designation of Carbide Boring Tools:* Specific sizes of boring tools are identified by the addition of numbers after the style designation. The first number denotes the diameter or square size in number of  $\frac{1}{32}$ nds for types SS and SR and in number of  $\frac{1}{16}$ ths for types TS and TR. The second number denotes length in number of  $\frac{1}{8}$ ths for types SS and SR. For styles TRG and TRH, a letter "U" after the number denotes a semi-finished tool (cutting edges unsharpened). Complete designations for the various standard sizes of carbide boring tools are given in Table 2 through Table 7. In the diagrams in the tables, angles shown without tolerance are  $\pm 1^\circ$ .

*Examples of Tool Designation:* The designation TSC-8 indicates a carbide-tipped tool (T); square cross section (S); 30-degree side cutting edge angle (C); and  $\frac{8}{16}$  or  $\frac{1}{2}$  inch square size (8).

The designation SRE-66 indicates a solid carbide tool (S); round cross section (R); 45-degree side cutting edge angle (E);  $\frac{6}{32}$  or  $\frac{3}{16}$  inch diameter (6); and  $\frac{6}{8}$  or  $\frac{3}{4}$  inch long (6).

The designation SS-610 indicates a solid carbide tool (S); square cross section (S);  $\frac{6}{32}$  or  $\frac{3}{16}$  inch square size (6);  $\frac{10}{8}$  or  $1\frac{1}{4}$  inches long (10).

It should be noted in this last example that the absence of a third letter (from A to H) indicates that the tool has its mounting surfaces ground but that the cutting edges are unsharpened.

**Boring Machines, Origin.**—The first boring machine was built by John Wilkinson in 1775. John Smeaton had built one in 1769 which had a large rotary head, with inserted cutters, carried on the end of a light, overhanging shaft. The cylinder to be bored was fed forward against the cutter on a rude carriage, running on a track laid in the floor. The cutter head followed the inaccuracies of the bore, doing little more than smooth out local roughness of the surface. Watt's first steam cylinders were bored on this machine and he complained that one, 18 inches in diameter, was 3/8 inch out of true. Wilkinson thought of the expedient, which had escaped both Smeaton and Watt, of extending the boring-bar completely through the cylinder and giving it an out-board bearing, at the same time making it much larger and stiffer. With this machine, cylinders 57 inches in diameter were bored which were within 1/16 inch of true. Its importance can hardly be overestimated as it insured the commercial success of Watt's steam engine, which, up to that time, had not passed the experimental stage.

## TAPS

A tap is a mechanical device applied to make a standard thread on a hole. A range of tap pitch diameter (PD) limits, from which the user may select to suit local conditions, is available. Taps included in the ANSI/ASME B94.9 standard are categorized according to type, style, size and chamfer, and blank design. General dimensions and tap markings are given in the standard ANSI/ASME B94.9 Taps: *Ground Thread With Cut Thread Appendix (Inch and Metric Sizes)* for straight-fluted taps, spiral-pointed taps, spiral-pointed-only taps, spiral-fluted taps, fast spiral-fluted taps, thread-forming taps, pulley taps, nut taps, and pipe taps. The standard also gives the thread limits for taps with cut threads and ground threads. The tap thread limits and tolerances are given in Table 2 to Table 4, tap dimensions for cut thread and ground thread are given in Table 5a through Table 10. Pulley tap dimensions and tolerances are given in Table 12, straight and taper pipe thread tap dimensions and tolerances are given on Table 13a and Table 13b, and thread limits for cut thread and ground thread taps are given in Table 15 through Table 26a.

## Thread Form, Styles, and Types

**Thread Form.**—The basic angle of thread between the flanks of thread measured in an axial plane is 60 degrees. The line bisecting this 60° angle is perpendicular to the axis of the screw thread. The symmetrical height of the thread form,  $h$ , is found as follows:

$$h = 0.64951905P = \frac{0.64951905}{n} \quad (1)$$

The basic pitch diameter (PD) is obtained by subtracting the symmetrical single thread height,  $h$ , from the basic major diameter as follows:

$$\text{Basic Pitch Diameter} = D_{bsc} - h \quad (2)$$

$D_{bsc}$  = basic major diameter

$P$  = pitch of thread

$h$  = symmetrical height of thread

$n$  = number of threads per inch

**Types and Styles of Taps.**—Tap *type* is based on general dimensions such as standard straight thread, taper and straight pipe, pulley, etc., or is based on purpose, such as thread forming and screw thread inserts (STI).

Tap *style* is based on flute construction for cutting taps, such as straight, spiral, or spiral point, and on lobe style and construction for forming taps, such as straight or spiral.

*Straight-Flute Taps:* These taps have straight flutes of a number specified as either standard or optional, and are for general purpose applications. This standard applies to machine screw, fractional, metric, and STI sizes in high-speed steel ground thread, and to machine screw and fractional sizes in high speed and carbon steel cut thread, with taper, plug, semibottom, and bottom chamfer.

BLANK Design 1

BLANK Design 3

BLANK Design 2

*Spiral-Pointed Taps:* These taps have straight flutes, and the cutting face of the first few threads is ground at an angle to force the chips ahead and prevent clogging in the flutes. This standard applies to machine screw, fractional, metric, and STI sizes in high-speed

steel ground thread, and to cut thread in machine screw and fractional sizes with plug, semibottom, and bottom chamfer.

*Spiral-Pointed-Only Taps:* These taps are made with the spiral point feature only, without longitudinal flutes. These taps are especially suitable for tapping thin materials. This standard applies to machine screw and fractional sizes in high-speed steel, ground thread, with plug chamfer.

*Spiral-Fluted Taps:* These taps have right-hand helical flutes with a helix angle of 25 to 35 degrees. These features are designed to help draw chips from the hole or to bridge a keyway. This standard applies to machine screw, fractional, metric, and STI sizes in high-speed steel and to ground thread with plug, semibottom, and bottom chamfer.

*Fast Spiral-Fluted Taps:* These taps are similar to spiral-fluted taps, except the helix angle is from 45 to 60 degrees. This standard applies to machine screw, fractional, metric, and STI sizes in high-speed steel with plug, semibottom, and bottom chamfer.

*Thread-Forming Taps:* These taps are fluteless except as optionally designed with one or more lubricating grooves. The thread form on the tap is lobed, so that there are a finite number of points contacting the work thread form. The tap does not cut, but forms the thread by extrusion. This standard applies to machine screw, fractional, and metric sizes, in high-speed steel, ground thread form, with plug, semibottom, and bottom entry taper.

Blank Design 1

Blank Design 2

Blank Design 3

**Pulley Taps:** These taps were originally designed for tapping line-shaft pulleys by hand. Today, these taps have shanks that are extended in length by a standard amount for use where added reach is required. The shank is the same nominal diameter as the thread. This standard applies to fractional size and ground thread with plug and bottom chamfer.

**Pipe Taps:** These taps are used to produce standard straight or tapered pipe threads. This standard applies to fractional size in high-speed steel, ground thread, to high-speed steel and carbon steel in cut thread, and to straight pipe taps having plug chamfers and taper pipe taps.

**Standard System of Tap Marking.**—Ground thread taps specified in the US customary system are marked with the nominal size, number of threads per inch, the proper symbol to identify the thread form, “HS” for high-speed steel, “G” for ground thread, and designators for tap pitch diameter and special features, such as left-hand and multi-start threads.

Cut thread taps specified in the US customary system are marked with the nominal size, number of threads per inch, and the proper symbol to identify the thread form. High-speed steel taps are marked “HS,” but carbon steel taps need not be marked.

Ground thread taps made with metric screw threads (M profile) are marked with “M,” followed by the nominal size and pitch in millimeters, separated by “X.” Marking also includes “HS” for high-speed steel, “G” for ground thread, designators for tap pitch diameter and special features, such as left-hand and multi-start threads.

Thread symbol designators are listed in the accompanying table. Tap pitch diameter designators, systems of limits, special features, and examples for ground threads are given in the following section.

**Standard System of Tap Thread Limits and Identification for Unified Inch Screw Threads, Ground Thread.**—*H or L Limits:* For Unified inch screw threads, when the maximum tap pitch diameter is over basic pitch diameter by an even multiple of 0.0005 inches, or the minimum tap pitch diameter limit is under basic pitch diameter by an even multiple of 0.0005 inches, the taps are marked “H” or “L,” respectively, followed by a limit number, determined as follows:

$$\text{H Limit number} = \frac{\text{Tap PD} - \text{Basic PD}}{0.0005}$$

$$\text{L Limit number} = \frac{\text{Basic PD} - \text{Tap PD}}{0.0005}$$

The tap PD tolerances for ground threads are given in Table 2, column D; PD tolerances for cut threads are given in Table 3, column D. For standard taps, the PD limits for various H limit numbers are given in Table 20. The minimum tap PD equals the basic PD minus the

number of half-thousandths (0.0005 in.) represented by the limit number. The maximum tap PD equals the minimum PD plus the PD tolerance given in [Table 20](#).

*Tap Marking with H or L Limit Numbers*

*Example 1:*  $\frac{3}{8}$ -16 NC HS H1

$$\begin{aligned}\text{Maximum tap PD} &= \text{Basic PD} + 0.0005 \\ &= \frac{3}{8} - \left(0.64951904 \times \frac{1}{16}\right) + 0.0005 \\ &= 0.3344 + 0.0005 \\ &= 0.3349\end{aligned}$$

$$\begin{aligned}\text{Minimum tap PD} &= \text{Maximum tap PD} - 0.0005 \\ &= 0.3349 - 0.0005 \\ &= 0.3344\end{aligned}$$

*Example 2:*  $\frac{3}{8}$ -16 NC HS G L2

$$\begin{aligned}\text{Minimum tap PD} &= \text{Basic PD} - 0.0010 \\ &= \frac{3}{8} - \left(0.64951904 \times \frac{1}{16}\right) - 0.0010 \\ &= 0.3344 - 0.0010 \\ &= 0.3334\end{aligned}$$

$$\begin{aligned}\text{Maximum tap PD} &= \text{Minimum tap PD} + 0.0005 \\ &= 0.3334 + 0.0005 \\ &= 0.3339\end{aligned}$$

*Oversize or Undersize:* When the maximum tap PD over basic PD or the minimum tap PD under basic PD is not an even multiple of 0.0005, the tap PD is usually designated as an amount oversize or undersize. The amount oversize is added to the basic PD to establish the *minimum* tap PD. The amount undersize is subtracted from the basic PD to establish the *minimum* tap PD. The PD tolerance from [Table 2](#) is added to the minimum tap PD to establish the maximum tap PD for both.

*Example:*  $\frac{7}{16}$ -14 NC plus 0.0017 HS G

$$\text{Min. tap PD} = \text{Basic PD} + 0.0017 \text{ in.}$$

$$\text{Max. tap PD} = \text{Min. tap PD} + 0.0005 \text{ in.}$$

Whenever possible for oversize or other special tap PD requirements, the maximum and minimum tap PD requirements should be specified.

*Special Tap Pitch Diameter:* Taps not made to H or L limit numbers, to the specifications in, or to the formula for oversize or undersize taps may be marked with the letter "S" enclosed by a circle or by some other special identifier. Example:  $\frac{1}{2}$ -16 NC HS G.

*Left-Hand Taps:* Taps with left-hand threads are marked "LEFT HAND" or "LH."

*Example:*  $\frac{3}{8}$ -16 NC LH HS G H3.

Dimensions are given in inches.

The tables and formulas are used in determining the limits and tolerances for ground thread taps having a thread lead angle not in excess of 5°, unless otherwise specified.

The tap major diameter must be determined from a specified tap pitch diameter: the minimum major diameter equals the maximum specified tap pitch diameter minus constant C, plus 0.64951904P plus constant A.

$$\text{Minimum Major Diameter} = \text{Tap Pitch Diameter} - C + 0.64951904P + A$$

For intermediate pitches, use value of next coarser pitch; for C and D use formulas for A and B.

Lead Tolerance: ± 0.0005 inch within any two threads not farther apart than 1 inch.

Angle Tolerance: ± 20' in half angle for 4 to 5 1/2 pitch; ± 25' in half angle for 6 to 9 pitch; and ± 30' in half angle for 10 to 80 pitch.

**Table 3. Tap Thread Limits and Tolerances ANSI/ASME B94.9-2008 (R2018)  
Formulas for Unified Inch Screw Threads (Cut Thread)**

Min. Major Diameter = Basic Diameter + $B + C$		Min. Pitch Diameter = Basic Diameter + $B$			
Max. Major Diameter = Min. Maj. Dia. + $A$		Max. Pitch Diameter = Min. Pitch Dia. + $D$			
$A$ = Major diameter tolerance					
$B$ = Amount over basic for minimum pitch diameter					
$C$ = A constant to add for major diameter: 20% of theoretical truncation for 2 to 5.5 threads per inch and 25% for 6 to 80 threads per inch					
$D$ = Pitch diameter tolerance

## Angle Tolerance

Threads per Inch	Deviation in Half angle	Deviation in Half angle	Threads per Inch	Deviation in Half angle	Deviation in Half angle
4 and coarser	$\pm 30'$	$\pm 45'$	10 to 28	$\pm 45'$	$\pm 68'$
$4\frac{1}{2}$ to $5\frac{1}{2}$	$\pm 35'$	$\pm 53'$	30 and finer	$\pm 60'$	$\pm 90'$
6 to 9	$\pm 40'$	$\pm 60'$			

Dimensions are given in inches.

The tables and formulas are used in determining the limits and tolerances for cut thread metric taps having special diameter, special pitch, or both.

For intermediate pitches, use value of next coarser pitch.

**Lead Tolerance:**  $\pm 0.003$  inch within any two threads not farther apart than 1 inch.

Taps over  $1\frac{1}{2}$  in. with 10 or more threads per inch have tolerances for N.F. and finer.

**Standard System of Ground Thread Tap Limits and Identification for Metric Screw Threads, M Profile.**—All calculations for metric taps use millimeter values. When US customary values are needed, they are translated from the three-place millimeter tap diameters only after the calculations are completed.

**Table 4. Tap Thread Limits and Tolerances ANSI/ASME B94.9-2008 (R2018)  
Formulas for Metric Thread (Ground Thread)**

Min. major diameter = Basic diameter + W		Max. pitch diameter = Basic diameter + Y

6.00	0.480	0.100	...	...	0.143	0.156	...	...	0.064	0.064

Dimensions are given in millimeters.

The tables and formulas are used in determining the limits and tolerances for ground thread metric taps having a thread lead angle not in excess of 5°, unless otherwise specified. They apply only to metric thread having a 60° form with a P/8 flat at the major diameter of the basic thread form. All calculations for metric taps are done using millimeter values as shown. When inch values are needed, they are translated from the three-place millimeter tap diameters only after calculations are performed.

The tap major diameter must be determined from a specified tap pitch diameter: the minimum major diameter equals the maximum specified tap pitch diameter minus constant Y, plus 0.64951905P plus constant W.

Minimum major diameter = Max. tap pitch diameter - Y + 0.64951904P + W

For intermediate pitches, use value of next coarser pitch.

Lead Tolerance: ±0.013 mm within any two threads not farther apart than 25 mm.

Angle Tolerance: ±30' in half angle for 0.25 to 2.5 pitch; ±25' in half angle for 2.5 to 4 pitch; and ±20' in half angle for 4 to 6 pitch.

**D or DU Limits:** When the maximum tap pitch diameter is over basic pitch diameter by an even multiple of 0.013 mm (0.000512 in. reference), or the minimum tap pitch diameter limit is under basic pitch diameter by an even multiple of 0.013 mm, the taps are marked

with the letters "D" or "DU," respectively, followed by a limit number. The limit number is determined as follows:

$$\text{D Limit number} = \frac{\text{Tap PD} - \text{Basic PD}}{0.0013}$$

$$\text{DU Limit number} = \frac{\text{Basic PD} - \text{Tap PD}}{0.0013}$$

*Example:* M1.6×0.35 HS G D3

$$\begin{aligned} \text{Maximum tap PD} &= \text{Basic PD} + 0.0039 \\ &= 1.6 - (0.64951904 \times 0.35) + 0.0039 \\ &= 1.3727 + 0.039 \\ &= 1.412 \end{aligned}$$

$$\begin{aligned} \text{Minimum tap PD} &= \text{Maximum tap PD} - 0.015 \\ &= 1.412 - 0.015 \\ &= 1.397 \end{aligned}$$

M6×1 HS G DU4

$$\begin{aligned} \text{Minimum tap PD} &= \text{Basic PD} - 0.052 \\ &= 6 - (0.64951904 \times 1.0) - 0.052 \\ &= 5.350 - 0.052 \\ &= 5.298 \end{aligned}$$

$$\begin{aligned} \text{Maximum tap PD} &= \text{Minimum tap PD} + 0.025 \\ &= 5.298 + 0.025 \\ &= 5.323 \end{aligned}$$

**Definitions of Tap Terms.**—The definitions that follow are taken from ANSI/ASME B94.9 but include only the more important terms. Some tap terms are the same as screw thread terms; therefore, see *Definitions of Screw Threads* starting on page 1942.

*Actual size:* The measured size of an element on an individual part.

*Allowance:* A prescribed difference between the maximum material limits of mating parts. It is the minimum clearance or maximum interference between such parts.

*Basic Size:* The size from which the limits are derived by application of allowance and tolerance.

*Bottom Top:* A tap having a chamfer length of 1 to 2 pitches.

*Chamfer:* Tapering of the threads at the front end of each land or chaser of a tap by cutting away and relieving the crest of the first few teeth to distribute the cutting action over several teeth.

*Chamfer Angle:* Angle formed between the chamfer and the axis of the tap measured in an axial plane at the cutting edge.

*Chamfer Relief:* The gradual degrees in land height from cutting edge to heel on the chamfered portion of the land to provide radial clearance for the cutting edge.

*Chamfer Relief Angle:* Complement of the angle formed between a tangent to the relieved surface at the cutting edge and a radial line to the same point on the cutting edge.

*Classes of Thread:* Designation of the class that determines the specification of the size, allowance, and tolerance to which a given threaded product is to be manufactured. It is not applicable to the tools used for threading.

*Concentric:* Having a common center.

*Crest:* The surface of the thread that joins the flanks of the thread and is farthest from the cylinder or cone from which the thread projects.

*Cutter Sweep:* The section removed by the milling cutter or the grinding wheel in entering or leaving a flute.

*Cutting Edge:* The intersection of cutting edge and the major diameter in the direction of rotation for cutting, which does the actual cutting.

*Core Diameter:* The diameter of a circle that is tangent to the bottom of the flutes at a given point on the axis.

*Diameter, Major:* The major cylinder on a straight thread.

*Diameter, Minor:* The minor cylinder on a straight thread.

*Dryseal:* A thread system used for both external and internal pipe threads applications designed for use where the assembled product must withstand high fluid or gas pressure without the use of sealing compound.

*Eccentric:* Not having a common center.

*Eccentricity:* One half of the total indicator variation (TIV) with respect to the tool axis.

*Entry Taper:* The portion of the thread forming, where the thread forming is tapered toward the front to allow entry into the hole to be tapped.

*External Center:* The pointed end on a tap. On bottom-chamfered taps, the point on the front end may be removed.

*Flank:* The flank of a thread is the surface connecting the crest with the root.

*Flank Angle:* Angle between the individual flank and the perpendicular to the axis of the thread, measured in an axial plane. A flank angle of a symmetrical thread is commonly termed the "half angle of thread."

*Flank, Leading:* 1) Flank of a thread facing toward the chamfered end of a threading tool; and 2) The leading flank of a thread is the one which, when the thread is about to be assembled with a mating thread, faces the mating thread.

*Flank, Trailing:* The trailing flank of a thread is the one opposite the leading flank.

*Flutes:* Longitudinal channels formed in a tap to create cutting edges on the thread profile and to provide chip spaces and cutting fluid passages. On a parallel or straight-thread tap, they may be straight, angular or helical; on a taper-thread tap, they may be straight, angular or spiral.

*Flute Lead Angle:* Angle at which a helical- or spiral-cutting edge at a given point makes with an axial plane through the same point.

*Flute, Spiral:* A flute with uniform axial lead in a spiral path around the axis of a conical tap.

*Flute, Straight:* A flute that forms a cutting edge lying in an axial plane.

*Flute, Tapered:* A flute lying in a plane intersecting the tool axis at an angle.

*Full Indicator Movement (FIM):* The total movement of an indicator where appropriately applied to a surface to measure its surface.

*Functional Size:* The functional diameter of an external or internal thread is the PD of the enveloping thread of perfect pitch, lead, and flank angles, having full depth of engagement but clear at crests and roots, and of a specified length of engagement.

*Heel:* Edge of the land opposite the cutting edge.

*Height of Thread:* The height of a thread is the distance, measured radially, between the major and minor cylinders or cones, respectively.

*Holes, Blind:* A hole that does not pass through the work piece and is not threaded to its full depth.

*Holes, Bottom:* A blind hole that is threaded close to the bottom.

*Hook Angle:* Inclination of a concave cutting face, usually specified either as Chordal Hook or Tangential Hook.

*Hook, Chordal Angle:* Angle between the chord passing through the root and crest of a thread form at the cutting face, and a radial line through the crest at the cutting edge.

*Hook, Tangential Angle:* Angle between a line tangent to a hook cutting face at the cutting edge and a radial line to the same point.

*Internal Center:* A countersink with clearance at the bottom, in one or both ends of a tool, which establishes the tool axis.

**Interrupted Thread Tap:** A tap having an odd number of lands with alternate teeth in the thread helix removed. In some designs, alternate teeth are removed only for a portion of the thread length.

**Land:** One of the threaded sections between the flutes of a tap.

**Lead:** Distance a screw thread advances axially in one complete turn.

**Lead Error:** Deviation from prescribed limits.

**Lead Deviation:** Deviation from the basic nominal lead.

**Progressive Lead Deviation:** (1) On a straight thread, the deviation from a true helix where the thread helix advances uniformly. (2) On a taper thread, the deviation from a true spiral where the thread spiral advances uniformly.

Fig. 3. Tap Terms

**Left Hand Cut:** Rotation in a clockwise direction from cutting when viewed from the chamfered end of a tap.

**Length of Engagement:** The length of engagement of two mating threads is the axial distance over which two mating threads are designed to contact.

**Length of Thread:** The length of the thread of the tap includes the chamfered threads and the full threads, but does not include an external center. It is indicated by the letter "B" in the illustrations at the heads of the tables.

**Limits:** The limits of size are the applicable maximum and minimum sizes.

**Major Diameter:** On a straight thread, the major diameter is that of the major cylinder. On a taper thread, the major diameter at a given position on the thread axis is that of the major cone at that position.

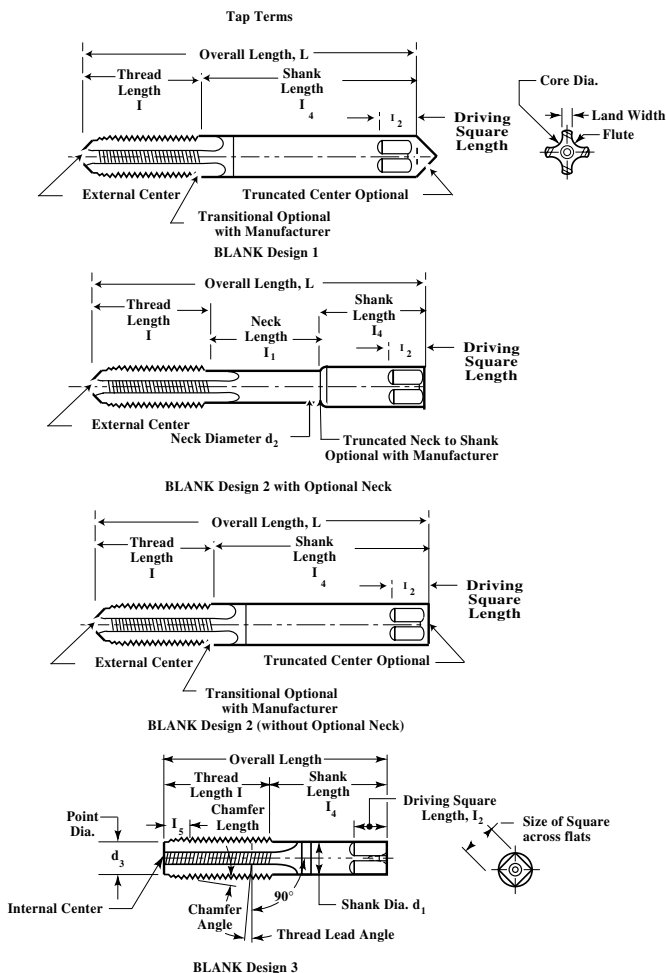

Fig. 4. Taps Terms

**Minor Diameter:** On a straight thread, the minor diameter is that of the minor cylinder. On a taper thread, the minor diameter at a given position on the thread axis is that of the minor cone at that position.

**Neck:** A section of reduced diameter between two adjacent portions of a tool.

**Pitch:** The distance from any point on a screw thread to a corresponding point in the next thread, measured parallel to the axis and on the same side of the axis.

*Pitch Diameter (Simple Effective Diameter):* On a straight thread, the pitch diameter is the diameter of the imaginary coaxial cylinder, the surface of which would pass through the thread profiles at such points as to make the width of the groove equal to one-half the basic pitch. On a perfect thread, this coincidence occurs at the point where the widths of the thread and groove are equal. On a taper thread, the pitch diameter at a given position on the thread axis is the diameter of the pitch cone at that position.

*Point Diameter:* Diameter at the cutting edge of the leading end of the chamfered section.

*Plug Tap:* A tap having a chamfer length of 3 to 5 pitches.

*Rake:* Angular relationship of the straight cutting face of a tooth with respect to a radial line through the crest of the tooth at the cutting edge. Positive rake means that the crest of the cutting face is angularly ahead of the balance of the cutting face of the tooth. Negative rake means that the crest of the cutting face is angularly behind the balance of the cutting face of the tooth. Zero rake means that the cutting face is directly on a radial line.

*Relief:* Removal of metal behind the cutting edge to provide clearance between the part being threaded and the threaded land.

*Relief, Center:* Clearance produced on a portion of the tap land by reducing the diameter of the entire thread form between cutting edge and heel.

*Relief, Chamfer:* Gradual decrease in land height from cutting edge to heel on the chamfered portion of the land on a tap to provide radial clearance for the cutting edge.

*Relief, Con-Eccentric Thread:* Radial relief in the thread form starting back of a concentric margin.

*Relief, Double Eccentric Thread:* Combination of a slight radial relief in the thread form starting at the cutting edge and continuing for a portion of the land width, and a greater radial relief for the balance of the land.

*Relief, Eccentric Thread:* Radial relief in the thread form starting at the cutting edge and continuing to the heel.

*Relief, Flatted Land:* Clearance produced on a portion of the tap land by truncating the thread between cutting edge and heel.

*Relief, Grooved Land:* Clearance produced on a tap land by forming a longitudinal groove in the center of the land.

*Relief, Radial:* Clearance produced by removal of metal from behind the cutting edge. Taps should have the chamfer relieved and should have back taper, but may or may not have relief in the angle and on the major diameter of the threads. When the thread angle is relieved, starting at the cutting edge and continuing to the heel, the tap is said to have "eccentric" relief. If the thread angle is relieved back of a concentric margin (usually one-third of land width), the tap is said to have "con-eccentric" relief.

*Right Hand Cut:* Rotation in clockwise direction for cutting when viewed from the chamfered end of a tap or die.

*Roots:* The surface of the thread that joins the flanks of adjacent thread forms and is identical to cone from which the thread projects.

*Screw Thread:* A uniform section produced by forming a groove in the form of helix on the external or the internal surface of a cylinder.

*Screw Thread Inserts (STI):* Screw thread bushing coiled from diamond-shape cross-section wire. They are screwed into oversized tapped holes to size nominal-size internal threads.

*Screw Thread Insert (STI) Taps:* These taps are over the nominal size to the extent that the internal thread they produce will accommodate a helical coil screw insert, which at final assembly will accept a screw thread of the nominal size and pitch.

**Shank:** The portion of the tool body by which it is held and driven.

**Shaving:** The excessive removal of material from the product thread profile by the tool thread flanks caused by an axial advance per revolution less than or more than the actual lead in the tool.

**Size, Actual:** Measured size of an element on an individual part.

**Size, Basic:** That size from which the limits of size are derived by the application of allowances and tolerances.

**Size, Functional:** The functional diameter of an external or internal thread is the pitch diameter of the enveloping thread of perfect pitch, lead and flank angles, having full depth of engagement but clear at crests and roots, and of a specified length of engagement. It may be derived by adding to the pitch diameter in an external thread, or subtracting from the pitch diameter in an internal thread, the cumulative effects of deviations from specified profile, including variations in lead and flank angle over a specified length of engagement. The effects of taper, out-of-roundness, and surface defects may be positive or negative on either external or internal threads.

**Size, Nominal:** Designation used for the purpose of general identification.

**Spiral Flute:** See *Flutes*.

**Spiral Point:** Angular fluting in the cutting face of the land at the chamfered end. It is formed at an angle with respect to the tap axis of opposite hand to that of rotation. Its length is usually greater than the chamfer length and its angle with respect to the tap axis is usually made great enough to direct the chips ahead of the tap. The tap may or may not have longitudinal flutes.

**Taper, Back:** A gradual decrease in the diameter of the thread form on a tap from the chamfered end of the land towards the back, which creates a slight radial relief in the threads.

**Taper per Inch:** The difference in diameter in one inch measured parallel to the axis.

**Taper Tap:** A tap having a chamfer length of 7 to 10 pitches.

**Taper Thread Tap:** A tap with tapered threads for producing a tapered internal thread.

**Thread, Angle of:** The angle between the flanks of the thread measured in an axial plane.

**Thread Lead Angle:** On a straight thread, the lead angle is the angle made by the helix of the thread at the pitch line with a plane perpendicular to the axis. On a taper thread, the lead angle at a given axial position is the angle made by the conical spiral of the thread, with the plane perpendicular to the axis, at the pitch line.

**Thread per Inch:** The number of thread pitches in one inch of thread length.

**Tolerance:** The total permissible variation of size or difference between limits of size.

**Total Indicator Variation (TIV):** The difference between maximum and minimum indicator readings during a checking cycle.

Special taps greater than 1.010 inch to 1.510 inch in diameter inclusive, having 14 or more threads per inch or 1.75- mm pitch and finer, and sizes over 1.510 inch in diameter with 10 or more threads per inch or 2.5- mm pitch and finer are made to general dimensions shown in [Table 10](#).

For standard ground thread tap limits see [Table 20](#), and [Table 21](#) for inch and [Table 16](#) for metric.

For cut thread tap limits see [Table 22](#) and [Table 23](#).

Special ground thread tap limits are determined by using the formulas shown in [Table 2](#) for unified inch screw threads and [Table 4](#) for metric M profile screw threads.

Tap sizes 0.395 inch and smaller have an external center on the thread end (may be removed on bottom taps). Sizes 0.223 inch and smaller have an external center on the shank end. Sizes 0.224 inch through 0.395 inch have truncated partial cone centers on the shank end (of diameter of shank). Sizes greater than 0.395 inch have internal centers on both the thread and shank ends.

For standard thread limits and tolerances see [Table 17](#) for unified inch screw threads and [Table 19](#) for metric threads.

For runout tolerances of tap elements see [Table 14](#).

For number of flutes see [Table 11](#).

**Table 5b. Standard Tap Dimensions Tolerances**  
**(Ground and Cut Thread) ANSI/ASME B94.9-2008 (R2018)**

	0.5100	1.0100	—	0.0060	0.0060
	1.0100	2.0000	—	0.0080	0.0080

**Entry Taper Length.**—Entry taper length is measured on the full diameter of the thread-forming lobes and is the axial distance from the entry diameter position to the theoretical intersection of tap major diameter and entry taper angle. Beveled end threads provided on taps having internal center or incomplete threads retained when external center is removed. Whenever entry taper length is specified in terms of number of threads, this length is measured in number of pitches,  $P$ .

$$\text{Bottom length} = 1 \sim 2\frac{1}{2} \text{ pitches}$$

$$\text{Plug length} = 3 \sim 5 \text{ pitches}$$

Entry diameter measured at the thread crest nearest the front of the tap is an appropriate amount smaller than the diameter of the hole drilled for tapping.

Optional Neck and Optional Shortened Thread Length,  
 Ground and Cut Thread (Table 6)

Thread length,  $I$ , is based on a length of 12 pitches of the UNC thread series.

Thread length,  $I$ , is a minimum value and has no tolerance.

When thread length,  $I$ , is added to neck length,  $I_1$ , the total shall be no less than the minimum thread length,  $I$ .

Unless otherwise specified, all tolerances are in accordance with [Table 5b](#).

For runout tolerances, see [Table 14](#).

For number of flutes see [Table 11](#).

These threads are larger than nominal size to the extent that the internal thread they produce will accommodate a helical coil screw insert, which at final assembly will accept a screw thread of the nominal size and pitch.

For optional necks, refer to [Table 6](#) using dimensions for equivalent blank sizes.

**Ground Thread Taps:** STI sizes  $5/16$  inch and smaller have external center on thread end (may be removed on bottom taps); sizes 10 through  $5/16$  inch will have an external partial cone center on shank end, with the length of the cone center approximately  $1/4$  of the diameter of shank; sizes larger than  $5/16$  inch may have internal centers on both the thread and shank ends.

For runout tolerances of tap elements, refer to [Table 14](#) using dimensions for equivalent blank sizes.

For number of flutes, refer to [Table 11](#) using dimensions for equivalent blank sizes.

For general dimension tolerances, refer to [Table 5b](#) using [Table 5a](#) equivalent blank size.

These taps are larger than nominal size to the extent that the internal thread they produce will accommodate a helical coil screw insert, which at final assembly will accept a screw thread of the nominal size and pitch. For optional necks, use Table 6 and dimensions for equivalent blank sizes.

*Ground Thread Taps:* STI sizes M8 and smaller have external center on thread end (may be removed on bottom taps); STI sizes M5 through M10 will have an external partial cone center on shank end, with the length of the cone center approximately ¼ of the diameter of shank; STI sizes larger than M10 inch may have internal centers on both the thread and shank ends.

For runout tolerances of tap elements, refer to Table 14 using dimensions for equivalent blank sizes. For number of flutes, refer to Table 11 using dimensions for equivalent blank sizes. For general dimension tolerances, refer to Table 5b using Table 5a equivalent blank sizes.

Tolerances			
For shank diameter, $d_1$ for $I_4$ length			
Fractional, Inch	Machine Screw	Pipe, Inch	Tolerances
¼ to ⅝ incl.	0 to 14 incl.	⅛ to ½ incl.	-0.003
1⅛ to 1½ incl.	...	¼ to 1 incl.	-0.004
1⅝ to 4 incl.	...	1¼ to 4 incl.	-0.006

Unless otherwise specified, special extension taps will be furnished with dimensions and tolerances as shown for machine screw and fractional taps in Table 5a, Table 5b, and Table 6, and for pipe taps in Table 13a. Exceptions are as follows: Types of centers are optional with manufacturer. Tolerances on shank diameter  $d_1$  and  $I_4$  length as shown on the above Table 9. Shank runout tolerance applies only to the  $I_4$  length shown on the above Table 9.

Unless otherwise specified, special taps 1.010 inches to 1.510 inches in diameter, inclusive, have 14 or more threads per inch or 1.75 mm pitch and finer. Sizes greater than 1.510 inch in diameter with 10 or more threads per inch or 2.5 mm pitch and finer will be made to the general dimensions shown above.

For tolerances, see [Table 5b](#). For runout tolerances of tap elements, see [Table 14](#).

Tolerances for General Dimensions

Element	Diameter Range	Tolerance	Element	Diameter Range	Tolerance
Overall length, $L$	$\frac{1}{4}$ to $\frac{3}{4}$	$\pm 0.06$	Shank Diameter, $d_1^a$	$\frac{1}{4}$ to $\frac{1}{2}$	-0.005
Thread length, $I$	$\frac{1}{4}$ to $\frac{3}{4}$	$\pm 0.06$	Size of Square, $a^b$	$\frac{1}{4}$ to $\frac{1}{2}$	-0.004
Square length, $I_2$	$\frac{1}{4}$ to $\frac{3}{4}$	$\pm 0.03$		$\frac{5}{8}$ to $\frac{3}{4}$	-0.006
Neck length, $I_1$	$\frac{1}{4}$ to $\frac{3}{4}$	c	Length of close tolerance shank, $I_4$	$\frac{1}{4}$ to $\frac{3}{4}$	d

<sup>a</sup> Shank diameter,  $d_1$ , is approximately the same as the maximum major diameter for that size.

<sup>b</sup> Size of square,  $a$ , is equal to  $0.75d_1$  to the nearest 0.001 in.

<sup>c</sup> Neck length,  $I_1$ , is optional with manufacturer.

<sup>d</sup> Length of close tolerance shank,  $I_4$ , is a min. length that is held to runout tolerances per Table 14.

These taps are standard with plug chamfer in H3 limit only. All dimensions are given in inches. These taps have an internal center in thread end. For standard thread limits, see Table 20. For runout tolerances of tap elements, see Table 14.

Straight and Taper Pipe Tap Dimensions, Ground and Cut Thread (Table 13a and Table 13b)

**Table 13a. Straight and Taper Pipe Tap Dimensions (Ground and Cut Thread) ANSI/ASME B94.9-2008 (R2018)**

<sup>a</sup> Pipe taps 1/8 inch are furnished with large-size shanks unless the small shank is specified.

<sup>b</sup> High-speed ground thread 1/16 to 2 inches including noninterrupted (NPT, NPTF, and ANPT).

<sup>c</sup> High-speed ground thread 1/8 to 1 1/4 inch including interrupted (NPT, NPTF, and ANPT).

<sup>d</sup> High-speed ground thread 1/8 to 1 inch including noninterrupted (NPSC and NPSM).

<sup>e</sup> High-speed cut thread 1/8 to 1 inch including noninterrupted (NPSC and NPSM).

<sup>f</sup> High-speed cut thread 1/8 to 1 inch including noninterrupted (NPT).

<sup>g</sup> High-speed cut thread 1/8 to 1 1/4 inch including interrupted (NPT).

<sup>h</sup> Carbon cut thread 1/8 to 1 1/4 inch including interrupted (NPT).

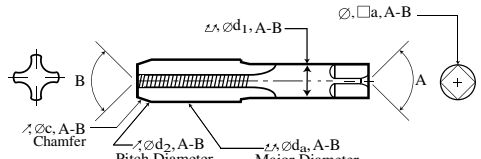

<sup>i</sup> High-speed ground thread 1 1/2 to 2 inches including interrupted (NPT).

**Table 13b. Straight and Taper Pipe Taps Tolerances (Ground and Cut Thread) ANSI/ASME B94.9-2008 (R2018)**

Ground Thread				Cut Thread			
Element	Nominal Diameter Range, inch		Tolerances, inch	Element	Nominal Diameter Range, inch		Tolerances, inch

Diameter of shank, $d_1$	$\frac{1}{16}$ $\frac{1}{4}$	$\frac{1}{8}$ 1	-0.002 -0.002	Diameter of shank, $d_1$	$\frac{1}{8}$ $\frac{3}{4}$	$\frac{1}{2}$ 3	-0.007 -0.009
	$1\frac{1}{4}$	2	-0.002		$\frac{1}{8}$ 1	... 3	-0.004 -0.006 -0.008
Size of square, $a$	$\frac{1}{16}$ $\frac{1}{4}$	$\frac{1}{8}$ $\frac{3}{4}$	-0.004 -0.006	Size of square, $a$	$\frac{1}{4}$ 1	$\frac{3}{4}$ 3	-0.006 -0.008
	1	2	-0.008				

All dimensions are given in inches.

The first few threads on interrupted thread pipe taps are left full. These taps have internal centers. For runout tolerances of tap elements, see Table 14. Taps marked NPS are suitable for NPSC and NPSM. These taps have 2 to  $3\frac{1}{2}$  threads chamfer, see Table 5a. Optional neck is for manufacturing use only. For taper pipe thread limit, see Table 24a. For straight pipe thread limits, see Table 23a, Table 23b, and Table 23d.

**Table 14. Runout and Locational Tolerance of Tap Elements ANSI/ASME B94.9-2008 (R2018)**

	Range Sizes (Inclusive)			Total Runout FIM, Inch		Location, Inch
	Machine Screw	Metric	Pipe, Inch	Cut Thread	Ground Thread	
Shank, $d_1$	#0 to $\frac{5}{16}$ $1\frac{1}{32}$ to 4	M1.6 to M8 M10 to M100	$\frac{1}{16}$ $\frac{1}{8}$ to 4	0.0060 0.0080	0.0010 0.0016	... ...
Major diameter, $d_a$	#0 to $\frac{5}{16}$ $1\frac{1}{32}$ to 4	M1.6 to M8 M10 to M100	$\frac{1}{16}$ $\frac{1}{8}$ to 4	0.0050 0.0080	0.0010 0.0016	... ...
Pitch Diameter, $d_2$	#0 to $\frac{5}{16}$ $1\frac{1}{32}$ to 4	M1.6 to M8 M10 to M100	$\frac{1}{16}$ $\frac{1}{8}$ to 4	0.0050 0.0080	0.0010 0.0016	... ...
Chamfer <sup>a</sup> , $c$	#0 to $\frac{1}{2}$	M1.6 to M12	$\frac{1}{16}$ to $\frac{1}{8}$	0.0040	0.0020	...
	$1\frac{1}{32}$ to 4	M14 to M100	$\frac{1}{8}$ to 4	0.0060	0.0030	...
Square, $a$	#0 to $\frac{1}{2}$	M1.6 to M12	$\frac{1}{16}$ to $\frac{1}{8}$	...	...	0.0060
	$1\frac{1}{32}$ to 4	M14 to M100	$\frac{1}{8}$ to 4	...	...	0.0080

<sup>a</sup> Chamfer should preferably be inspected by light projection to avoid errors due to indicator contact points dropping into the thread groove.

<sup>a</sup> Minimum and maximum major diameters are 0.00102 larger than shown.

<sup>b</sup> Standard D limit for thread-forming taps.

<sup>c</sup> Minimum and maximum major diameters are 0.00154 larger than shown.

<sup>d</sup> Minimum and maximum major diameters are 0.00205 larger than shown.

<sup>e</sup> Minimum and maximum major diameters are 0.00256 larger than shown.

<sup>f</sup> These sizes are intended for spark plug applications; use tolerances from Table 2, column D.

All dimensions are given in inches. Not all styles of taps are available with all limits listed. For calculation of limits other than those listed, see formulas in Table 4.

**Table 16. Tap Thread Limits: Metric Sizes, Ground Thread

36	4	D9	33.402	33.702	1.31504	1.32685

The above recommended taps normally produce the class of thread indicated in average materials when used with reasonable care. However, if the tap specified does not give a satisfactory gage fit in the work, a choice of some other limit tap will be necessary.

**Table 18. Standard Chamfers for Thread Cutting Taps ANSI/ASME B94.9-2008 (R2018)**

Type of tap	Chamfer length		Type of tap	Chamfer length	
	Min.	Max.		Min.	Max.
Straight threads taps	Bottom	1P	2P	Taper pipe taps	2P
	Semibottom	2P	3P		
	Plug	3P	5P		
	Taper	7P	10P		
					3½P

P = pitch.

The chamfered length is measured at the cutting edge and is the axial length from the point diameter to the theoretical intersection of the major diameter and the chamfer angle. Whenever chamfer length is specified in terms of threads, this length is measured in number of pitches as shown. The point diameter is approximately equal to the basic thread minor diameter.

<sup>a</sup> Recommended taps are for cutting threads only and are not for roll-form threads.

<sup>b</sup> Cut-thread taps in sizes #3 to 1½ in. NC and NF, inclusive, may be used under all normal conditions and in average materials for producing Class 2B tapped holes.

<sup>c</sup> Taps suited for class 3B are satisfactory for class 2B threads.

All dimensions are given in inches.

The above recommended taps normally produce the class of thread indicated in average materials when used with reasonable care. However, if the tap specified does not give a satisfactory gage fit in the work, a choice of some other limit tap will be necessary.

**Table 20. Tap Thread Limits: Machine Screw Sizes, Ground Thread ANSI/ASME B94.9-2008 (R2018)

<sup>a</sup> Minimum and maximum major diameters are 0.0010 larger than shown.

<sup>b</sup> Minimum and maximum major diameters are 0.0020 larger than shown.

<sup>c</sup> Minimum and maximum major diameters are 0.0035 larger than shown.

<sup>d</sup> Minimum and maximum major diameters are 0.0015 larger than shown.

General notes:

Limits listed in above table are the most commonly used in the industry.

Not all styles of taps are available with all limits listed.

For calculation of limits other than those listed, see formulas and Table 2.

<sup>a</sup> Minimum and maximum major diameters are 0.0010 larger than shown.<sup>b</sup> Minimum and maximum major diameters are 0.0035 larger than shown.<sup>c</sup> Minimum and maximum major diameters are 0.0020 larger than shown.<sup>d</sup> Minimum and maximum major diameters are 0.0015 larger than shown.

General notes:

Limits listed in Table 21 are the most commonly used in the industry.

Not all styles of taps are available with all limits listed.

For calculation of limits other than those listed, see formulas and Table 2.

**Table 22. Tap Thread Limits: Machine Screw Sizes, Cut Thread**  
*ANSI/ASME B94.9-2008 (R2018) Unified and American National Thread Forms,*

Threads per Inch	Half Angle	Full Angle
4 1/2 to 5 1/2	±0° 35'	±0° 53'
6 to 9	±0° 40'	±0° 60'
10 to 28	±0° 45'	±0° 68'
30 to 64	±0° 60'	±0° 90'

A maximum lead error of ±0.003 inch in 1 inch of thread is permitted.

All dimensions are given in inches.

Thread limits are computed from Table 3.

**Table 23a. Straight Pipe Thread Limits: NPS, Ground Thread**  
**ANSI Straight Pipe Thread Form (NPSC, NPSM) ANSI/ASME B94.9-2008 (R2018)**

Nominal Size, Inches	Threads per Inch, NPS, NPSC, NPSM	Major Diameter			Pitch Diameter		
		Plug at Gaging Notch	Min. <i>G</i>	Max. <i>H</i>	Plug at Gaging Notch <i>E</i>	Min. <i>K</i>	Max. <i>L</i>
1/8	27	0.3983	0.4022	0.4032	0.3736	0.3746	0.3751
1/4	18	0.5286	0.5347	0.5357	0.4916	0.4933	0.4938
3/8	18	0.6640	0.6701	0.6711	0.6270	0.6287	0.6292
1/2	14	0.8260	0.8347	0.8357	0.7784	0.7806	0.7811
3/4	14	1.0364	1.0447	1.0457	0.9889	0.9906	0.9916
1	11 1/2	1.2966	1.3062	1.3077	1.2386	1.2402	1.2412

Formulas for NPS Ground Thread Taps <sup>a</sup>						
Nominal Size	Major Diameter		Minor Dia.	Threads per Inch	<i>A</i>	<i>B</i>
	Min. <i>G</i>	Max. <i>H</i>	Max.			
1/8	$H - 0.0010$	$(K + A) - 0.0010$	$M - B$	27	0.0296	0.0257
1/4 to 3/4	$H - 0.0010$	$(K + A) - 0.0020$	$M - B$	18	0.0444	0.0401
1	$H - 0.0015$	$(K + A) - 0.0021$	$M - B$	14	0.0571	0.0525
				11 1/2	0.0696	0.0647

<sup>a</sup> In the formulas, *M* equals the actual measured pitch diameter.

All dimensions are given in inches.

*Maximum pitch diameter* of tap is based upon an allowance deducted from the maximum product pitch diameter of NPSC or NPSM, whichever is smaller.

*Minimum pitch diameter* of tap is derived by subtracting the ground thread pitch diameter tolerance for actual equivalent size.

*Lead tolerance*: A maximum lead deviation of  $\pm 0.0005$  inch within any two threads not farther apart than one inch.

*Angle Tolerance*: 11 1/2 to 27 threads per inch, plus or minus 30 min. in half angle.

Taps made to the specifications in Table 23a are to be marked NPS and used for NPSC and NPSM.

**Table 23b. Straight Pipe Thread Limits: NPSF Ground Thread**  
**ANSI Standard Straight Pipe Thread Form (NPSF) ANSI/ASME B94.9-2008 (R2018)**

Nominal Size, Inches	Threads per Inch	Major Diameter		Pitch Diameter			Minor <sup>a</sup> Dia. Flat, Max.

$\frac{3}{4}$	$H - 0.0010$	$K + Q - 0.0005$	$L - 0.0005$	$E - F$	$M - Q$

Values to Use in Formulas				
Threads per Inch	<i>E</i>	<i>F</i>	<i>M</i>	<i>Q</i>
27	Pitch diameter of plug at gaging notch	0.0035	Actual measured pitch diameter	0.0251
18		0.0052		0.0395
14		0.0067		0.0533

All dimensions are given in inches.

*Lead Tolerance:* A maximum lead deviation of  $\pm 0.0005$  inch within any two threads not farther apart than one inch.

*Angle Tolerance:* Plus or minus 30 min. in half angle for 14 to 27 threads per inch, inclusive.

**Table 23d. ANSI Standard Straight Pipe Tap Limits: (NPS) Cut Thread  
ANSI Standard Pipe Thread Form (NPS) ANSI/ASME B94.9-2008 (R2018)**

Nominal Size	Threads per Inch, NPS, NPSC	Size at Gaging Notch	Pitch Diameter		Values to Use in Formulas		
			Min.	Max.	<i>A</i>	<i>B</i>	<i>C</i>
$\frac{1}{8}$	27	0.3736	0.3721	0.3751	0.0267	0.0296	0.0257
$\frac{1}{4}$	18	0.4916	0.4908	0.4938	0.0408	0.0444	0.0401
$\frac{3}{8}$	18	0.6270	0.6257	0.6292			
$\frac{1}{2}$	14	0.7784	0.7776	0.7811	0.0535	0.0571	0.0525
$\frac{3}{4}$	14	0.9889	0.9876	0.9916			
1	11½	1.2386	1.2372	1.2412	0.0658	0.0696	0.0647

The following are approximate formulas, in which *M* = measured pitch diameter in inches:

$$\text{Major dia., min.} = M + A$$

$$\text{Major dia., max.} = M + B$$

$$\text{Minor dia., max.} = M - C$$

*Maximum pitch diameter* of tap is based on an allowance deducted from the maximum product pitch diameter of NPSC.

*Minimum pitch diameter* of tap equals maximum pitch diameter minus the tolerance.

All dimensions are given in inches.

*Lead Tolerance:*  $\pm 0.003$  inch per inch of thread.

*Angle Tolerance:* For all pitches, tolerance will be  $\pm 45^\circ$  for half angle and  $\pm 68^\circ$  for full angle.

Taps made to these specifications are to be marked NPS and used for NPSC thread form.

Taps made to the specifications in Table 23a are to be marked NPS and used for NPSF.

As the American National Standard straight pipe thread form is to be maintained, the major and minor diameters vary with the pitch diameter. Either a flat or rounded form is allowable at both the crest and the root.

**Table 24a. Taper Pipe Thread Limits (Ground and Cut Thread: Ground Thread For NPS, NPTF, and ANPT; Cut Thread for NPT only) ANSI/ASME B94.9-2008 (R2018)**

<sup>a</sup> Taper is 0.0625 inch per 1.000 inch on diameter (1:16) (3/4 inch per 12 inches).

<sup>b</sup> Distance, small end of tap projects through L<sub>1</sub> taper ring gage.

<sup>c</sup> Dimension, L<sub>1</sub>, thickness on thin ring gage; see ANSI/ASME B1.20.1 and B1.20.5.

<sup>d</sup> Given sizes permit direct tapping without reaming the hole, but only give full threads for approximate L<sub>1</sub> distance.

All dimensions are given in inches.

*Lead Tolerance:* ±0.003 inch per inch on cut thread, and ±0.0005 inch per inch on ground thread.

*Angle Tolerance:* ±40 min. in half angle and 60 min. in full angle for 8 cut threads per inch; ±45 min. in half angle and 68 min. in full angle for 11 1/2 to 27 cut threads per inch; ±25 min. in half angle for 8 ground threads per inch; and ±30 min. in half angle for 11 1/2 to 27 ground threads per inch.

**Table 24b. Taper Pipe Thread — Widths of Flats at Tap Crests and Roots for Cut Thread NPT and Ground Thread NPT, ANPT, and NPTF ANSI/ASME B94.9-2008 (R2018)**

Threads per Inch	Tap Flat Width at	Column I		Column II	
		NPT—Cut and Ground Thread <sup>a</sup> ANPT—Ground Thread <sup>a</sup>		NPTF	Ground Thread <sup>a</sup>
		Min. <sup>b</sup>	Max.		
27	Major diameter	0.0014	0.0041	0.0040	0.0055
	Minor diameter	...	0.0041	...	0.0040
18	Major diameter	0.0021	0.0057	0.0050	0.0065
	Minor diameter	...	0.0057	...	0.0050
14	Major diameter	0.0027	0.0064	0.0050	0.0065
	Minor diameter	...	0.0064	...	0.0050
11 1/2	Major diameter	0.0033	0.0073	0.0060	0.0083
	Minor diameter	...	0.0073	...	0.0060
8	Major diameter	0.0048	0.0090	0.0080	0.0103
	Minor diameter	...	0.0090	...	0.0080

<sup>a</sup> Cut thread taps made to Column I are marked NPT but are not recommended for ANPT applications. Ground thread taps made to Column I are marked NPT and may be used for NPT and ANPT applications. Ground thread taps made to Column II are marked NPTF and used for dryseal application.

<sup>b</sup> Minimum minor diameter flats are not specified and may be as sharp as practicable.

All dimensions are given in inches.

**Table 25. Tap Thread Limits for Screw Thread Inserts (STI), Ground Thread, Machine Screw, and Fractional Size ANSI/ASME B94.9-2008 (R2018)**

These taps are over the nominal size to the extent that the internal thread they produce will accommodate a helical coil screw insert, which at final assembly will accept a screw thread of the normal size and pitch.

STI basic thread dimensions are determined by adding twice the single thread height ( $2 \times 0.64952P$ ) to the basic dimensions of the nominal thread size.

Formulas for major and pitch diameters are presented in MIL-T-21309E.

	4	44.615	44.516	6	41.674	41.648	8	41.699	41.674

These taps are over the nominal size to the extent that the internal thread they produce will accommodate a helical coil screw insert, which at final assembly will accept a screw thread of the normal size and pitch.

STI basic thread dimensions are determined by adding twice the single thread height ( $2 \times 0.64952P$ ) to the basic dimensions of the nominal thread size.

Formulas for major and pitch diameters are presented in MIL-T-21309E.

### Acme and Square-Threaded Taps

These taps are usually made in sets, three taps in a set being the most common. For very fine pitches, two taps in a set will be found sufficient, whereas as many as five taps in a set are used for coarse pitches. The table on the next page gives dimensions for proportioning both Acme and square-threaded taps when made in sets. In cutting the threads of square-threaded taps, one leading tap maker uses the following rules: The width of the groove between two threads is made equal to one-half the pitch of the thread, less 0.004 inch (0.102 mm), making the width of the thread itself equal to one-half of the pitch, plus 0.004 inch (0.102 mm). The depth of the thread is made equal to 0.45 times the pitch, plus 0.0025 inch (0.064 mm). This latter rule produces a thread that for all the ordinarily used pitches for square-threaded taps has a depth less than the generally accepted standard depth, this latter depth being equal to one-half the pitch. The object of this shallow thread is to ensure that if the hole to be threaded by the tap is not bored out so as to provide clearance at the bottom of the thread, the tap will cut its own clearance. The hole should, however, always be drilled out large enough so that the cutting of the clearance is not required of the tap.

The table, *Dimensions of Acme Threads Taps in Sets of Three Taps*, may also be used for the length dimensions for Acme taps. The dimensions in this table apply to single-threaded taps. For multiple-threaded taps or taps with very coarse pitch relative to the diameter, the length of the chamfered part of the thread may be increased. Square-threaded taps are made to the same table as Acme taps, with the exception of the figures in column *K*, which for square-threaded taps should be equal to the nominal diameter of the tap, no oversize allowance being customary in these taps. The first tap in a set of Acme taps (not square-threaded taps) should be turned to a taper at the bottom of the thread for a distance of about one-quarter of the length of the threaded part. The taper should be so selected that the root diameter is about  $\frac{1}{32}$  inch (0.794 mm) smaller at the point than the proper root diameter of the tap. The first tap should preferably be provided with a short pilot at the point. For very coarse pitches, the first tap may be provided with spiral flutes at right angles to the angle of the thread. Acme and square-threaded taps should be relieved or backed off on the top of the thread of the chamfered portion on all the taps in the set. When the taps are used as machine taps, rather than as hand taps, they should be relieved in the angle of the thread, as well as on the top, for the whole length of the chamfered portion. Acme taps should also always be relieved on the front side of the thread to within  $\frac{1}{32}$  inch (0.794 mm) of the cutting edge.

**Adjustable Taps.**—Many adjustable taps are now used, especially for accurate work. Some taps of this class are made of a solid piece of tool steel that is split and provided with means of expanding sufficiently to compensate for wear. Most of the larger adjustable taps have inserted blades or chasers that are held rigidly but are capable of radial adjustment. The use of taps of this general class enables standard sizes to be maintained readily.

**Drill Hole Sizes for Acme Threads.**—Many tap and die manufacturers and vendors make available to their customers computer programs designed to calculate drill hole sizes for all the Acme threads in their ranges from the basic dimensions. The large variety and combination of dimensions for such tools prevent inclusion of a complete set of tables of tap drills for Acme taps in this Handbook. The following formulas (dimensions in inches) for calculating drill hole sizes for Acme threads are derived from the American National Standard, ANSI/ASME B1.5-1997 (R2014), Acme Screw Threads.

To select a tap drill size for an Acme thread, first calculate the maximum and minimum internal product minor diameters for the thread to be produced. (Dimensions for general purpose, centralizing, and stub Acme screw threads are given in the Threads and Threading section, starting on page 2054.) Then select a drill that will yield a finished hole somewhere between the established maximum and minimum product minor diameters. To reduce the amount of material to be removed when cutting the thread, consider staying close to the maximum product limit in selecting the hole size. If there is no standard drill size that matches the hole diameter selected, it may be necessary to drill and ream, or bore, the hole to size, to achieve the required hole diameter.

**Table 27. Dimensions of Acme Threads Taps in Sets of Three Taps**

Nominal Dia.	A	B	C	D	E	F	G	H	I	K
1/2	4 1/4	1 7/8	2 3/8	1/2	1 7/8	5/8	1 3/4	7/8	1 1/2	0.520

*Diameters of General-Purpose Acme Screw Threads of Classes 2G, 3G, and 4G may be calculated from pitch = 1/number of threads per inch, and:*

minimum diameter = basic major diameter – pitch

maximum diameter = minimum minor diameter + 0.05 × pitch

**Table 28. Proportions of Acme and Square-Threaded Taps Made in Sets**

$R =$  root diameter of thread  
 $T =$  double depth of full thread  
 $D =$  full diameter of tap

Types of Tap	No. of Taps in Set	Order of Tap in Set	A	B	C
Acme Thread Taps	2	1st	$R + 0.65T$	$R + 0.010$	$\frac{1}{8}L$ to $\frac{1}{6}L$
		2d	$D$	A on 1st tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
	3	1st	$R + 0.45T$	$R + 0.010$	$\frac{1}{8}L$ to $\frac{1}{6}L$
		2d	$R + 0.80T$	A on 1st tap - 0.005	$\frac{1}{6}L$ to $\frac{1}{4}L$
		3d	$D$	A on 2d tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
	4	1st	$R + 0.40T$	$R + 0.010$	$\frac{1}{8}L$
		2d	$R + 0.70T$	A on 1st tap - 0.005	$\frac{1}{6}L$
		3d	$R + 0.90T$	A on 2d tap - 0.005	$\frac{1}{5}L$
		4th	$D$	A on 3d tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
	5	1st	$R + 0.37T$	$R + 0.010$	$\frac{1}{8}L$
		2d	$R + 0.63T$	A on 1st tap - 0.005	$\frac{1}{6}L$
		3d	$R + 0.82T$	A on 2d tap - 0.005	$\frac{1}{5}L$
		4th	$R + 0.94T$	A on 3d tap - 0.005	$\frac{1}{5}L$ to $\frac{1}{4}L$
		5th	$D$	A on 4th tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
	Square-Threaded Taps	2	1st	$R + 0.67T$	$R$
2d			$D$	A on 1st tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
3		1st	$R + 0.41T$	$R$	$\frac{1}{8}L$ to $\frac{1}{6}L$
		2d	$R + 0.080T$	A on 1st tap - 0.005	$\frac{1}{6}L$ to $\frac{1}{4}L$
		3d	$D$	A on 2d tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
4		1st	$R + 0.32T$	$R$	$\frac{1}{8}L$
		2d	$R + 0.62T$	A on 1st tap - 0.005	$\frac{1}{6}L$
		3d	$R + 0.90T$	A on 2d tap - 0.005	$\frac{1}{5}L$
		4th	$D$	A on 3d tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$
5		1st	$R + 0.26T$	$R$	$\frac{1}{8}L$
		2d	$R + 0.50T$	A on 1st tap - 0.005	$\frac{1}{6}L$
		3d	$R + 0.72T$	A on 2d tap - 0.005	$\frac{1}{5}L$
		4th	$R + 0.92T$	A on 3d tap - 0.005	$\frac{1}{5}L$ to $\frac{1}{4}L$
		5th	$D$	A on 4th tap - 0.005	$\frac{1}{4}L$ to $\frac{1}{3}L$

Example:  $\frac{1}{2}$ -10 Acme 2G, pitch =  $1/10 = 0.1$   
 minimum diameter =  $0.5 - 0.1 = 0.4$

maximum diameter =  $0.4 + (0.05 \times 0.1) = 0.405$

drill selected = letter X or  $0.3970 + 0.0046$  (probable oversize) = 0.4016

*Diameters of Acme Centralizing Screw Threads of Classes 2C, 3C, and 4C* may be calculated from pitch = 1/number of threads per inch, and:

minimum diameter = basic major diameter  $- 0.9 \times$  pitch

maximum diameter = minimum minor diameter  $+ 0.05 \times$  pitch

*Example:*  $\frac{1}{2}$ -10 Acme 2C, pitch =  $1/10 = 0.1$

minimum diameter =  $0.5 - (0.9 \times 0.1) = 0.41$

maximum diameter =  $0.41 + (0.05 \times 0.1) = 0.415$

drill selected =  $\frac{13}{32}$  or  $0.4062 + 0.0046$  (probable oversize) = 0.4108.

*Diameters for Acme Centralizing Screw Threads of Classes 5C and 6C:* These classes are not recommended for new designs, but may be calculated from:

minimum diameter = [basic major diameter  $- (0.025 \sqrt{\text{basic major dia.}}) - 0.9 \times$  pitch

maximum diameter = minimum minor diameter  $+ 0.05 \times$  pitch

pitch = 1/number of threads per inch

*Example:*  $\frac{1}{2}$ -10 Acme 5C, pitch =  $1/10 = 0.1$

minimum diameter =  $[0.5 - (0.025 \sqrt{0.5})] - (0.9 \times 0.1) = 0.3923$

maximum diameter =  $0.3923 + (0.05 \times 0.1) = 0.3973$

drill selected =  $\frac{25}{64}$  or  $0.3906 + 0.0046$  (probable oversize) = 0.3952

**Tapping Square Threads.**—If it is necessary to tap square threads, this should be done by using a set of taps that will form the thread by a progressive cutting action, the taps varying in size in order to distribute the work, especially for threads of comparatively coarse pitch. From three to five taps may be required in a set, depending upon the pitch. Each tap should have a pilot to steady it. The pilot of the first tap has a smooth cylindrical end from 0.003 to 0.005 inch (0.076-0.127 mm) smaller than the hole, and the pilots of following taps should have teeth.

**Collapsible Taps.**—The collapsing tap shown in the accompanying illustration is one of many different designs that are manufactured. These taps are often used in turret lathe practice in place of solid taps. When using this particular style of collapsing tap, the adjustable gage A is set for the length of thread required. When the tap has been fed to this depth, the gage comes into contact with the end of the work, which causes the chasers to collapse automatically. The tool is then withdrawn, after which the chasers are again expanded and locked in position by the handle seen at the side of the holder.

Collapsing Tap

Collapsible taps do not need to be backed out of the hole at the completion of the thread, reducing the tapping time and increasing production rates.

## STANDARD TAPERS

Certain types of small tools and machine parts, such as twist drills, end mills, arbors, lathe centers, etc., are provided with taper shanks which fit into spindles or sockets of corresponding taper, providing not only accurate alignment between the tool or other part and its supporting member, but also more or less frictional resistance for driving the tool. There are several standards for "self-holding" tapers, but the American National, the Morse, and the Brown & Sharpe are the standards most widely used by American manufacturers.

The name *self-holding* has been applied to the smaller tapers—like the Morse and the Brown & Sharpe—because, where the angle of the taper is only 2 or 3 degrees, the shank of a tool is so firmly seated in its socket that there is considerable frictional resistance to any force tending to turn or rotate the tool relative to the socket. The term "self-holding" is used to distinguish relatively small tapers from the larger or *self-releasing* type. A milling machine spindle having a taper of  $3\frac{1}{2}$  inches per foot is an example of a self-releasing taper. The included angle in this case is over 16 degrees and the tool or arbor requires a positive locking device to prevent slipping, but the shank may be released or removed more readily than one having a smaller taper of the self-holding type.

**Tapers for Machine Tool Spindles.**—Various standard tapers have been used for the taper holes in the spindles of machine tools, such as drilling machines, lathes, milling machines, or other types requiring a taper hole for receiving either the shank of a cutter, an arbor, a center, or any tool or accessory requiring a tapering seat. The Morse taper represents a generally accepted standard for drilling machines. See more on this subject, page 1024.

The headstock and tailstock spindles of lathes also have the Morse taper in most cases; but the Jarno, the Reed (which is the short Jarno), and the Brown & Sharpe have also been used. Milling machine spindles formerly had Brown & Sharpe tapers in most cases.

In 1927, the milling machine manufacturers of the National Machine Tool Builders' Association adopted a standard taper of  $3\frac{1}{2}$  inches per foot. This comparatively steep taper has the advantage of insuring instant release of arbors or adapters.

National Machine Tool Builders' Association Tapers

Taper Number <sup>a</sup>	Large End Diameter	Taper Number <sup>a</sup>	Large End Diameter
30	1¼	50	2¾
40	1¾	60	4¼

<sup>a</sup> Standard taper of  $3\frac{1}{2}$  inches per foot

The British Standard for milling machine spindles is also  $3\frac{1}{2}$  inches taper per foot and includes these large end diameters:  $1\frac{3}{8}$  inches,  $1\frac{3}{4}$  inches,  $2\frac{3}{4}$  inches, and  $3\frac{1}{4}$  inches.

**Morse Taper.**—Dimensions relating to Morse standard taper shanks and sockets may be found in an accompanying table. The taper for different numbers of Morse tapers is slightly different, but it is approximately  $\frac{3}{8}$  inch per foot in most cases. The table gives the actual tapers, accurate to five decimal places. Morse taper shanks are used on a variety of tools, and exclusively on the shanks of twist drills. Dimensions for *Morse Stub Taper Shanks* are given in Table 1a, and for *Morse Standard Taper Shanks* in Table 1b. Also see Table 8 and Table 9 on page 1022.

**Brown & Sharpe Taper.**—This standard taper is used for taper shanks on tools such as end mills and reamers, the taper being approximately  $\frac{1}{2}$  inch per foot for all sizes except for taper No. 10, where the taper is 0.5161 inch per foot. Brown & Sharpe taper sockets are used for many arbors, collets, and machine tool spindles, especially milling machines and grinding machines. In many cases there are a number of different lengths of sockets corresponding to the same number of taper; all these tapers, however, are of the same diameter at the small end. See Table 10, page 1023.

All dimensions in inches.  
Radius J is 3<sup>1</sup>/<sub>64</sub>, 1<sup>1</sup>/<sub>16</sub>, 5<sup>1</sup>/<sub>64</sub>, 3<sup>1</sup>/<sub>32</sub>, and 1<sup>1</sup>/<sub>8</sub> inch respectively for Nos. 1, 2, 3, 4, and 5 tapers.

<sup>a</sup> These are basic dimensions.

<sup>b</sup> These dimensions are calculated for reference only.

**Jarno Taper.**—The Jarno taper was originally proposed by Oscar J. Beale of the Brown & Sharpe Mfg. Co. This taper is based on such simple formulas that practically no calculations are required when the number of taper is known. The taper per foot of all Jarno taper sizes is 0.600 inch on the diameter. The diameter at the large end is as many eighths, the diameter at the small end is as many tenths, and the length as many half inches as are indicated by the number of the taper. For example, a No. 7 Jarno taper is 7<sup>1</sup>/<sub>8</sub> inch in diameter at the large end; 7<sup>1</sup>/<sub>10</sub>, or 0.700 inch at the small end; and 7<sup>1</sup>/<sub>2</sub>, or 3<sup>1</sup>/<sub>2</sub> inches long; hence, diameter at large end = No. of taper ÷ 8; diameter at small end = No. of taper ÷ 10; length of taper = No. of taper ÷ 2. The Jarno taper is used on various machine tools, especially profiling machines and die-sinking machines. It has also been used for the headstock and tailstock spindles of some lathes.

Tolerances on rate of taper: all sizes 0.002 in. per foot. This tolerance may be applied on shanks only in the direction that increases the rate of taper, and on sockets only in the direction that decreases the rate of taper.

**American National Standard Machine Tapers.**—This standard includes a self-holding series (Table 2, Table 3, Table 4, Table 5 and Table 7a) and a steep taper series, Table 6. The self-holding taper series consists of 22 sizes, which are listed in Table 7a. The reference gage for the self-holding tapers is a plug gage. Table 7b gives the dimensions and tolerances for both plug and ring gages applying to this series. Table 2 through Table 5 inclusive give the dimensions for self-holding taper shanks and sockets, which are classified as to (1) means of transmitting torque from spindle to the tool shank, and (2) means of retaining the shank in the socket. The steep machine tapers consist of a preferred series (bold-face type, Table 6) and an intermediate series (light-face type). A self-holding taper is defined as “a taper with an angle small enough to hold a shank in place ordinarily by friction without holding means. (Sometimes referred to as slow taper.)” A steep taper is defined as “a taper having an angle sufficiently large to insure the easy or self-releasing feature.” The term “gage line” indicates the basic diameter at or near the large end of the taper.

**Table 2. American National Standard Taper Drive with Tang, Self-Holding Tapers ANSI/ASME B5.10-1994 (R2013)**

No. of Taper	Diameter at Gage Line (1) A	Shank		Tang

6	0.16	7.41	7.33	7.00	0.781	1.75	0.50

All dimensions are in inches. (1) See Table 7b for plug and ring gage dimensions.

**Tolerances:** For shank diameter A at gage line, +0.002, -0.000; for hole diameter A, +0.000, -0.002. For tang thickness E up to No. 5 inclusive, +0.000, -0.006; No. 6, +0.000, -0.008. For width N of tang slot up to No. 5 inclusive, +0.006, -0.000; No. 6, +0.008, -0.000. For centrality of tang E with center line of taper, 0.0025 (0.005 total indicator variation). These centrality tolerances also apply to the tang slot N. On rate of taper, all sizes 0.002 per foot. This tolerance may be applied on *shanks* only in the direction that *increases* the rate of taper and on *sockets* only in the direction that *decreases* the rate of taper. Tolerances for two-decimal dimensions are plus or minus 0.010, unless otherwise specified.

<sup>a</sup> This taper corresponds to an included angle of 16°, 35', 39.4".

<sup>b</sup> The basic diameter at gage line is at large end of taper.

All dimensions given in inches.

The tapers numbered 10, 20, 30, 40, 50, and 60 that are printed in heavy-faced type are designated as the "Preferred Series." The tapers numbered 5, 15, 25, 35, 45, and 55 that are printed in light-faced type are designated as the "Intermediate Series."

<sup>a</sup> The taper per foot and diameter A at gage line are basic dimensions. Dimensions in Column A' are calculated for reference only.

<sup>b</sup> Tolerances for diameter A are plus for plug gages and minus for ring gages.

All dimensions are in inches.

The amount of taper deviation for Class X, Class Y, and Class Z gages are the same, respectively, as the amounts shown for tolerances on diameter A. Taper deviation is the permissible allowance from true taper at any point of diameter in the length of the gage. On taper *plug* gages, this deviation may be applied only in the direction that *decreases* the rate of taper. On taper *ring* gages, this deviation may be applied only in the direction that *increases* the rate of taper. Tolerances on two-decimal dimensions are  $\pm 0.010$ .

**British Standard Tapers.**—British Standard 1660: 1972, “Machine Tapers, Reduction Sleeves, and Extension Sockets,” contains dimensions for self-holding and self-releasing tapers, reduction sleeves, extension sockets, and turret sockets for tools having Morse and metric 5 percent taper shanks. Adapters for use with  $\frac{7}{24}$  tapers and dimensions for spindle noses and tool shanks with self-release tapers and cotter slots are included in this Standard.

**Table 8. Dimensions of Morse Taper Sleeves**

A = No. Morse Taper Outside

Table 10. Brown & Sharpe Taper Shanks

The diagram illustrates the geometry of Brown & Sharpe taper shanks. It shows four types of shanks: Drill, Reamer, Arbors, and Collets. Key dimensions are labeled: P (plug depth), D (dia. of plug at small end), K (keyway from end of spindle), S (shank depth), L (length of keyways), W (width of keyways), T (length of arbor tongue), d (diameter of arbor tongue), and t (thickness of arbor tongue). A note indicates a taper of 1/4" per Ft. The table below provides the specific dimensions for each taper size.

Number of Taper	Taper per Foot (inch)	Dia. of Plug at Small End D	Plug Depth, P			Keyway from End of Spindle		Length of Keyways L	Width of Keyways W	Length of Arbor Tongue T	Diameter of Arbor Tongue d	Thickness of Arbor Tongue t

<sup>a</sup> Special lengths of keyway are used instead of standard lengths in some places. Standard lengths need not be used when keyway is for driving only and not for admitting key to force out tool.

<sup>b</sup> "B & S Standard" Plug Depths are not used in all cases.

<sup>c</sup> Adopted by American Standards Association.

**Tapers for Machine Tool Spindles.**—Most lathe spindles have Morse tapers, most milling machine spindles have American Standard tapers, almost all smaller milling machine spindles have R8 tapers, page 1033, and large vertical milling machine spindles have American Standard tapers. The spindles of drilling machines and the taper shanks of twist drills are made to fit the Morse taper. For lathes, the Morse taper is generally used, but lathes may have the Jarno, the Brown & Sharpe, or a special taper. Of 33 lathe manufacturers, 20 use the Morse taper; 5, the Jarno; 3 use special tapers of their own; 2 use modified Morse (longer than the standard but the same taper); 1 uses Reed (which is a short Jarno); 1 uses the Brown & Sharpe standard. For grinding machine centers, Jarno, Morse, and Brown & Sharpe tapers are used. Of ten grinding machine manufacturers, 3 use Brown & Sharpe; 3 use Morse; and 4 use Jarno. The Brown & Sharpe taper is used extensively for milling machine and dividing head spindles. The standard milling machine spindle adopted in 1927 by the milling machine manufacturers of the National Machine Tool Builders' Association (now The Association for Manufacturing Technology [AMT]) has a taper of 3 $\frac{1}{2}$  inches per foot. This comparatively steep taper was adopted to ensure easy release of arbors.

<sup>a</sup> The taper per foot and diameter A at gage line are basic dimensions. Dimensions in Column A' are calculated for reference only.

<sup>b</sup> Tolerances for diameter A are plus for plug gages and minus for ring gages.

All dimensions are in inches.

The amounts of taper deviation for Class X, Class Y, and Class Z gages are the same, respectively, as the amounts shown for tolerances on diameter A. Taper deviation is the permissible allowance from true taper at any point of diameter in the length of the gage. On taper *plug* gages, this deviation may be applied only in the direction that *decreases* the rate of taper. On taper *ring* gages, this deviation may be applied only in the direction that *increases* the rate of taper. Tolerances on two-decimal dimensions are  $\pm 0.010$ .

All dimensions are given in inches.

**Tolerances:**

Two-digit decimal dimensions  $\pm 0.010$  unless otherwise specified.

A—Taper: Tolerance on rate of taper to be 0.001 inch per foot applied only in direction that decreases rate of taper.

F'—Centrality of keyway with axis of taper 0.002 total at maximum material condition. (0.002 Total indicator variation)

F—Centrality of solid key with axis of taper 0.002 total at maximum material condition. (0.002 Total indicator variation)

Note 1: Holes spaced as shown and located within 0.006 inch diameter of true position.

Note 2: Holes spaced as shown and located within 0.010 inch diameter of true position.

Note 3: Maximum turnout on test plug:

0.0004 at 1-inch projection from gage line.

0.0010 at 12-inch projection from gage line.

Note 4: Squareness of mounting face measured near mounting bolt-hole circle.

Notes: Dimensions are in inches. Material: low-carbon steel. Heat treatment: carburize and harden to 0.016 to 0.028 in. effective case depth. Hardness of noted surfaces to be 56–60 RC (Rockwell C scale); core hardness 35–45 RC. Hole *J* shall not be carburized. Surfaces *C* and *R* to be free from tool marks. Deburr all sharp edges. Geometric dimension symbols are to ASME Y14.5-2018.

Data for size 60 are not part of Standard.

**Collets**

**R8 Collet.**—The dimensions in this figure are believed reliable. However, there are variations among manufacturers of R8 collets, especially regarding the width and depth of the keyway. Some sources do not agree with all dimensions in this figure. R8 collets are not always interchangeable.

All dimensions in inches.

## ARBORS, CHUCKS, AND SPINDLES

## Portable Tool Spindles

**Circular Saw Arbors.**—ASME B107.4-2005 (R2011) “Driving and Spindle Ends for Portable Hand, Air, and Air Electric Tools” calls for a round arbor of  $\frac{5}{8}$ -inch diameter for nominal saw blade diameters of 6 to 8.5 inches, inclusive, and a  $\frac{3}{4}$ -inch diameter round arbor for saw blade diameters of 9 to 12 inches, inclusive.

**Spindles for Geared Chucks.**—Recommended threaded and tapered spindles for portable tool geared chucks of various sizes are as given in the following table:

## Recommended Spindle Sizes

Chuck Sizes, Inch	Recommended Spindles	
	Threaded	Taper <sup>a</sup>
$\frac{3}{16}$ and $\frac{1}{4}$ Light	$\frac{3}{8}$ -24	1
$\frac{1}{4}$ and $\frac{5}{16}$ Medium	$\frac{3}{8}$ -24 or $\frac{1}{2}$ -20	2 Short
$\frac{3}{8}$ Light	$\frac{3}{8}$ -24 or $\frac{1}{2}$ -20	2
$\frac{3}{8}$ Medium	$\frac{1}{2}$ -20 or $\frac{5}{8}$ -16	2
$\frac{1}{2}$ Light	$\frac{1}{2}$ -20 or $\frac{5}{8}$ -16	33
$\frac{1}{2}$ Medium	$\frac{5}{8}$ -16 or $\frac{3}{4}$ -16	6
$\frac{5}{8}$ and $\frac{3}{4}$ Medium	$\frac{5}{8}$ -16 or $\frac{3}{4}$ -16	3

<sup>a</sup> Jacobs number.

**Vertical and Angle Portable Tool Grinder Spindles.**—The  $\frac{5}{8}$ -11 spindle with a length of  $1\frac{1}{8}$  inches shown on page 1040 is designed to permit the use of a jam nut with threaded cup wheels. When a revolving guard is used, the length of the spindle is measured from the wheel bearing surface of the guard. For unthreaded wheels with a  $\frac{7}{8}$ -inch hole, a safety sleeve nut is recommended. The unthreaded wheel with  $\frac{5}{8}$ -inch hole is not recommended because a jam nut alone may not resist the inertia effect when motor power is cut off.

**Straight Grinding Wheel Spindles for Portable Tools.**—Portable grinders with pneumatic or induction electric motors should be designed for the use of organic bond wheels rated 9500 ft per min (48.25 m/s). Light-duty electric grinders may be designed for vitrified wheels rated 6500 ft per min (33.0 m/s). Recommended maximum sizes of wheels of both types are as given in the following table:

## Recommended Maximum Grinding Wheel Sizes for Portable Tools

Spindle Size	Maximum Wheel Dimensions			
	9500 fpm		6500 fpm	
	Diameter <i>D</i>	Thickness <i>T</i>	Diameter <i>D</i>	Thickness <i>T</i>
$\frac{3}{8}$ -24 × $1\frac{1}{8}$	$2\frac{1}{2}$	$\frac{1}{2}$	4	$\frac{1}{2}$
$\frac{1}{2}$ -13 × $1\frac{3}{4}$	4	$\frac{3}{4}$	5	$\frac{3}{4}$
$\frac{5}{8}$ -11 × $2\frac{1}{8}$	8	1	8	1
$\frac{5}{8}$ -11 × $3\frac{1}{8}$	6	2	...	...
$\frac{5}{8}$ -11 × $3\frac{1}{8}$	8	$1\frac{1}{2}$	...	...
$\frac{3}{4}$ -10 × $3\frac{1}{4}$	8	2	...	...

Minimum *T* with the first three spindles is about  $\frac{1}{8}$  inch to accommodate cutting off wheels. Flanges are assumed to be according to ANSI B7.1 and threads to ANSI/ASME B1.1.

1 1/2	B	1.510	1.505	1.983	0.647	0.635	0.310	0.125

All dimensions in inches.

Incorporating fillet radius ( $R_M$ ) at shoulder of male tang precludes use of minimum diameter cross-hole in socket ( $E_F$ ), unless female drive end is chamfered (shown as optional).

If female drive end is not chamfered, socket cross-hole diameter ( $E_F$ ) is increased to compensate for fillet radius  $R_M$ , max.

Minimum clearance across flats male to female is 0.001 inch through 3/4-inch size; 0.002 inch in 1- and 1 1/2-inch sizes. For impact wrenches,  $A_M$  should be held as close to maximum as practical.

$C_F$ , min., for both designs A and B should be equal to  $C_M$ , max.

**Mounted Wheels and Mounted Points**

These wheels and points are used in places that are hard to access and are available with a vitrified bond. The wheels are available with aluminum oxide or silicon carbide abrasive grains. The aluminum oxide wheels are used to grind tough and tempered die steels and the silicon carbide wheels, cast iron, chilled iron, bronze, and other nonferrous metals.

The illustrations on pages 1041 and 1042 give the standard shapes of mounted wheels and points as published by the Grinding Wheel Institute. A note about the maximum operating speed for these wheels is given at the bottom of the first page of illustrations. Metric sizes are given on page 1043.

Fig. 1a. Standard Shapes and Sizes of Mounted Wheels and Points ANSI B74.2-2003

See Table 1 for inch sizes of Group W shapes and for metric sizes for all shapes.

The maximum speeds of mounted vitrified wheels and points of average grade range from about 38,000 to 152,000 rpm for diameters of 1 inch down to  $\frac{1}{4}$  inch. However, the safe operating speed usually is limited by the critical speed (speed at which vibration or whip tends to become excessive), which varies according to wheel or point dimensions, spindle diameter, and overhang.

## BROACHES AND BROACHING

## The Broaching Process

The broaching process may be applied in machining holes or other internal surfaces and also to many flat or other external surfaces. Internal broaching is applied in forming either symmetrical or irregular holes, grooves, or slots in machine parts, especially when the size or shape of the opening, or its length in proportion to diameter or width, makes other machining processes impracticable. Broaching originally was utilized for such work as cutting keyways; machining round holes into square, hexagonal, or other shapes; forming splined holes; and for a large variety of other internal operations. The development of broaching machines and broaches finally resulted in extensive application of the process to external, flat, and other surfaces. Most external or surface broaching is done on machines of vertical design, but horizontal machines are also used for some classes of work. The broaching process is very rapid and accurate, and it leaves a finish of good quality. It is employed extensively in automotive and other plants where duplicate parts must be produced in large quantities and for dimensions within small tolerances.

**Types of Broaches.**—A number of typical broaches and the operations for which they are intended are shown by the diagrams in Fig. 1. Broach *A* produces a round-cornered, square hole. Prior to broaching square holes, it is usually the practice to drill a round hole having a diameter  $d$  somewhat larger than the width of the square. Hence, the sides are not completely finished, but this unfinished part is not objectionable in most cases. In fact, this clearance space is an advantage during the broaching operation in that it serves as a channel for the broaching lubricant; moreover, the broach has less metal to remove. Broach *B* is for finishing round holes. Broaching is superior to reaming for some classes of work because the broach will hold its size for a much longer period, thus insuring greater accuracy. Broaches *C* and *D* are for cutting single and double keyways, respectively. Broach *C* is of rectangular section and, when in use, slides through a guiding bushing which is inserted in the hole. Broach *E* is for forming four integral splines in a hub. The broach at *F* is for producing hexagonal holes. Rectangular holes are finished by broach *G*. The teeth on the sides of this broach are inclined in opposite directions, which has the following advantages: The broach is stronger than it would be if the teeth were opposite and parallel to each other; thin work cannot drop between the inclined teeth, as it tends to do when the teeth are at right angles, because at least two teeth are always cutting; the inclination in opposite directions neutralizes the lateral thrust. The teeth on the edges are staggered, the teeth on one side being midway between the teeth on the other edge, as shown by the dotted line. A double-cut broach is shown at *H*. This type is for finishing, simultaneously, both sides  $f$  of a slot, and for similar work. Broach *I* is the style used for forming the teeth in internal gears. It is practically a series of gear-shaped cutters, the outside diameters of which gradually increase toward the finishing end of the broach. Broach *J* is for round holes but differs from style *B* in that it has a continuous helical cutting edge. Some prefer this form because it gives a shearing cut. Broach *K* is for cutting a series of helical grooves in a hub or bushing. In helical broaching, either the work or the broach is rotated to form the helical grooves as the broach is pulled through.

In addition to the typical broaches shown in Fig. 1, many special designs are now in use for performing more complex operations. Two surfaces on opposite sides of a casting or forging are sometimes machined simultaneously by twin broaches and, in other cases, three or four broaches are drawn through a part at the same time, for finishing as many duplicate holes or surfaces. Notable developments have been made in the design of broaches for external or "surface" broaching.

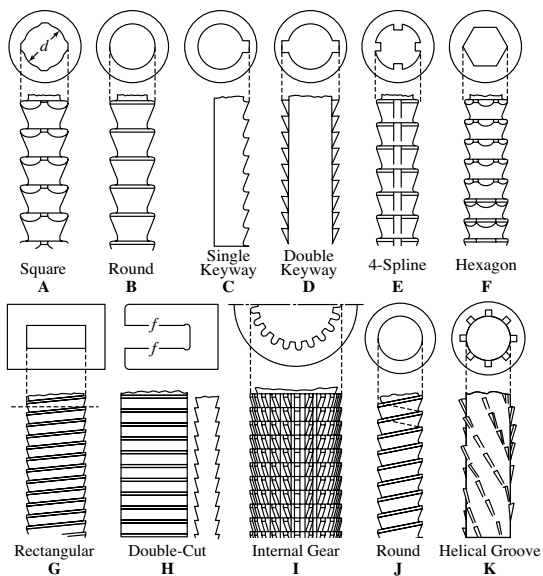

Fig. 1. Types of Broaches

**Burnishing Broach:** This is a broach having teeth or projections that are rounded on the top instead of being provided with a cutting edge, as in the ordinary type of broach. The teeth are highly polished, the tool being used for broaching bearings and for operations on other classes of work where the metal is relatively soft. The tool compresses the metal, thus making the surface hard and smooth. The amount of metal that can be displaced by a smooth-toothed burnishing broach is about the same as that removed by reaming. Such broaches are primarily intended for use on babbitt, white metal, and brass, but may also be satisfactorily used for producing a glazed surface on cast iron. This type of broach is also used when it is only required to accurately size a hole.

**Pitch of Broach Teeth.**—The pitch of broach teeth depends upon the depth of cut or chip thickness, the length of cut, the cutting force required and the power of the broaching machine. In the pitch formulas that follow

$L$  = length, in inches (mm), of layer to be removed by broaching

$d$  = depth of cut per tooth as shown by Table 1 (For internal broaches,  $d$  = depth of cut as measured on one side of broach or one-half difference in diameters of successive teeth in the case of a round broach.)

$F$  = a factor (For brittle types of material,  $F = 3$  or  $4$  for roughing teeth and  $6$  for finishing teeth. For ductile types of material,  $F = 4$  to  $7$  for roughing teeth and  $8$  for finishing teeth.)

$b$  = width in inches (mm) of layer to be removed by broaching

$P$  = pressure required in tons per square inch (MPa) of an area equal to depth of cut times width of cut, in inches (mm) (Table 2)

$T$  = usable capacity, in tons (metric tons), of broaching machine = 70 percent of maximum tonnage

**Table 1. Designing Data for Surface Broaches**

<sup>a</sup> The lower depth-of-cut values for roughing are recommended when work is not very rigid, the tolerance is small, a good finish is required, or length of cut is comparatively short.

<sup>b</sup> In broaching these materials, smooth surfaces for tooth and chip spaces are especially recommended.

**Table 2. Broaching Pressure P for Use in Pitch Formulas (2a) and (2b)**

Magnesium Alloy	35	483	35	483	...	...	...	...	...	...	...	...	...	...

The minimum pitch shown by **Formula (1)** is based upon the receiving capacity of the chip space. The minimum pitch should not be less than 0.2 inch (5.0 mm) unless a smaller pitch is required for extremely short cuts to provide at least two teeth in contact simultaneously with the part being broached. A reduction below 0.2 inch (5.0 mm) is seldom required in surface broaching but may be necessary in connection with internal broaching.

$$\text{Minimum pitch} = 3\sqrt{LdF} \quad (1)$$

Whether the minimum pitch may be used or not depends upon the power of the available machine. The factor  $F$  in the formula provides for the increase in volume as the material is broached into chips. If a broach has adjustable inserts for the finishing teeth, the pitch of the finishing teeth may be smaller than the pitch of the roughing teeth because of the smaller depth  $d$  of the cut. The higher value of  $F$  for finishing teeth prevents the pitch from becoming too small, so that the spirally curled chips will not be crowded into too small a

space. The pitch of the roughing and finishing teeth should be equal for broaches without separate inserts (notwithstanding the different values of  $d$  and  $F$ ) so that, after wear makes this necessary, some of the finishing teeth may be ground into roughing teeth.

US Units $\text{Allowable pitch} = \frac{dLbP}{T} \text{ inch (2a)}$	Metric Units $\text{Allowable pitch} = \frac{dLbP}{9810T} \text{ mm (2b)}$
---	---

If the pitch obtained by **Formula (2a)**, or **Formula (2b)** in metric calculations, is larger than the minimum obtained by **Formula (1)**, this larger value should be used because it is based upon the usable power of the machine. As the notation indicates, 70 percent of the maximum tonnage  $T$  is taken as the usable capacity. The 30 percent reduction is to provide a margin for the increase in broaching load resulting from the gradual dulling of the cutting edges. The procedure in calculating both minimum and allowable pitches will be illustrated by an example.

**Example:** Determine pitch of broach for cast iron if  $L = 220$  mm;  $d = 0.1$  mm; and  $F = 4$ .

$$\text{Minimum pitch} = 3\sqrt{220 \times 0.1 \times 4} = 28.14 \text{ mm}$$

Next, apply **Formula (2b)**. Assume that  $b = 75$  mm and  $T = 8$  metric ton; for cast iron and depth  $d$  of 0.1 mm,  $P = 1586$  MPa (**Table 2**). Then,

$$\text{Allowable pitch} = \frac{0.1 \times 220 \times 75 \times 1586}{9810(8)} = 33.34 \text{ mm}$$

This pitch is safely above the minimum. If in this case the usable tonnage of an available machine were, say, 7 metric tons instead of 8 metric tons, the pitch as shown by **Formula (2b)** might be increased to about 38.1 mm, thus reducing the number of teeth cutting simultaneously and, consequently, the load on the machine; or the cut per tooth might be reduced instead of increasing the pitch, especially if only a few teeth are in cutting contact, as might be the case with a short length of cut. If the usable tonnage in the preceding example were, say, 10 metric tons, then a pitch of 26.68 mm would be obtained by **Formula (2b)**; hence, the pitch in this case should not be less than the minimum of approximately 28.14 mm obtained from **Formula (1)**.

**Depth of Cut per Tooth.**—The term “depth of cut” as applied to surface or external broaches means the difference in the heights of successive teeth. This term, as applied to internal broaches for round, hexagonal or other holes, may indicate the total increase in the diameter of successive teeth; however, to avoid confusion, the term as here used means in all cases and regardless of the type of broach, the depth of cut as measured on one side.

In broaching free-cutting steel, the Broaching Tool Institute recommends 0.003 to 0.006 inch (0.076–0.15 mm) depth of cut for surface broaching; 0.002 to 0.003 inch (0.05–0.076 mm) for multispline broaching; and 0.0007 to 0.0015 inch (0.018–0.038 mm) for round hole broaching. The accompanying table contains data from a German source and applies specifically to surface broaches. All data relating to depth of cut are intended as a general guide only. While depth of cut is based primarily upon the machinability of the material, some reduction from the depth thus established may be required, particularly when the work-supporting fixture in surface broaching is not sufficiently rigid to resist the thrust from the broaching operation. In some cases, the pitch and cutting length may be increased to reduce the thrust force. Another possible remedy in surface broaching certain classes of work is to use a side-cutting broach instead of the ordinary depth-cutting type. A broach designed for side-cutting takes relatively deep narrow cuts that extend nearly to the full depth required. The side-cutting section is followed by teeth arranged for depth cutting to obtain the required size and surface finish on the work. In general, small tolerances in surface broaching require a reduced cut per tooth to minimize

work deflection resulting from the pressure of the cut. See *Cutting Speed for Broaching* starting on page 1142 for broaching speeds.

Terms Commonly Used in Broach Design

**Face Angle or Rake.**—The face angle (see diagram) of broach teeth affects the chip flow and varies considerably for different materials. While there are some variations in practice, even for the same material, the angles given in the accompanying table are believed to represent commonly used values. Some broach designers increase the rake angle for finishing teeth in order to improve the finish on the work.

**Clearance Angle.**—The clearance angle (see illustration) for roughing steel varies from 1.5 to 3 degrees and for finishing steel from 0.5 to 1 degree. Some recommend the same clearance angles for cast iron, and others larger clearance angles varying from 2 to 4 or 5 degrees. Additional data will be found in [Table 1](#).

**Land Width.**—The width of the land usually is about  $0.25 \times$  pitch. It varies, however, from about one-fourth to one-third of the pitch. The land width is selected so as to obtain the proper balance between tooth strength and chip space.

**Depth of Broach Teeth.**—The tooth depth as established experimentally and on the basis of experience usually varies from about 0.37 to 0.40 of the pitch. This depth is measured radially from the cutting edge to the bottom of the tooth fillet.

**Radius of Tooth Fillet.**—The “gullet” or bottom of the chip space between the teeth should have a rounded fillet to strengthen the broach, facilitate curling of the chips, and safeguard against cracking in connection with the hardening operation. One rule is to make the radius equal to one-fourth the pitch. Another is to make it equal 0.4 to 0.6 the tooth depth. A third method preferred by some broach designers is to make the radius equal one-third of the sum obtained by adding together the land width, one-half the tooth depth, and one-fourth of the pitch.

**Total Length of Broach.**—After the depth of cut per tooth has been determined, the total amount of material to be removed by a broach is divided by this decimal to ascertain the number of cutting teeth required. This number of teeth multiplied by the pitch gives the length of the active portion of the broach. By adding to this dimension the distance over three or four straight teeth, the length of a pilot to be provided at the finishing end of the broach, and the length of a shank which must project through the work and the faceplate of the machine to the draw-head, the overall length of the broach is found. This calculated length is often greater than the stroke of the machine, or greater than is practical for a broach of the diameter required. In such cases, a set of broaches must be used.

**Chipbreakers.**—The teeth of broaches frequently have rounded chipbreaking grooves located at intervals along the cutting edges. These grooves break up wide curling chips and prevent them from clogging the chip spaces, thus reducing the cutting pressure and strain on the broach. These chipbreaking grooves are on the roughing teeth only. They are staggered and applied to both round and flat or surface broaches. The grooves are formed by a round-edged grinding wheel and usually vary in width from about  $\frac{1}{32}$  to  $\frac{3}{32}$  inch (0.79 to 2.38 mm) depending upon the size of broach. The more ductile the material, the wider the chipbreaker grooves should be and the smaller the distance between

them. Narrow slotting broaches may have the right- and left-hand corners of alternate teeth beveled to obtain chipbreaking action.

**Shear Angle.**—The teeth of surface broaches ordinarily are inclined so they are not at right angles to the broaching movement. The object of this inclination is to obtain a shearing cut, which results in smoother cutting action and an improvement in surface finish. The shearing cut also tends to eliminate troublesome vibration. Shear angles for surface broaches are not suitable for broaching slots or any profiles that resist the outward movement of the chips. When the teeth are inclined, the fixture should be designed to resist the resulting thrusts unless it is practicable to incline the teeth of right- and left-hand sections in opposite directions to neutralize the thrust. The shear angle usually varies from 10 to 25 degrees.

**Types of Broaching Machines.**—Broaching machines may be divided into horizontal and vertical designs, and classified further according to the method of operation, as, for example, whether a broach in a vertical machine is pulled up or pulled down in forcing it through the work. Horizontal machines usually pull the broach through the work in internal broaching, but short rigid broaches may be pushed through. External surface broaching is also done on some machines of horizontal design, but usually vertical machines are employed for flat or other external broaching. Although parts usually are broached by traversing the broach itself, some machines are designed to hold the broach or broaches stationary during the actual broaching operation. This principle has been applied both to internal and surface broaching.

*Vertical Duplex Type:* The vertical duplex type of surface-broaching machine has two slides or rams that move in opposite directions and operate alternately. While the broach connected to one slide is moving downward on the cutting stroke, the other broach and slide is returning to the starting position, and this returning time is utilized for reloading the fixture on that side; consequently, the broaching operation is practically continuous. Each ram or slide may be equipped to perform a separate operation on the same part when two operations are required.

*Pull-up Type:* Vertical hydraulically-operated machines that pull the broach or broaches up through the work are used for internal broaching of holes of various shapes and for broaching bushings, splined holes, small internal gears, etc. A typical machine of this kind is so designed that all broach handling is done automatically.

*Pull-down Type:* The various movements in the operating cycle of a hydraulic pull-down type of machine equipped with an automatic broach-handling slide are the reverse of the pull-up type. The broaches for a pull-down type of machine have shanks on each end, an upper one for the broach-handling slide and a lower one for pulling through the work.

*Hydraulic Operation:* Modern broaching machines, as a general rule, are operated hydraulically rather than by mechanical means. Hydraulic operation is efficient, flexible in the matter of speed adjustments, low in maintenance cost, and the "smooth" action required for fine precision finishing may be obtained. The hydraulic pressures required, which frequently are 800 to 1000 pounds per square inch (5.5 to 6.9 MPa), are obtained from a motor-driven pump forming part of the machine. The cutting speeds of broaching machines frequently are between 20 and 30 feet per minute (6.1 to 9.1 m/min), and the return speeds often are double the cutting speed, or higher, to reduce the idle period.

**Ball-Broaching.**—Ball-broaching is a method of securing bushings, gears, or other components without the need for keys, pins, or splines. A series of axial grooves, separated by ridges, is formed in the bore of the workpiece by cold plastic deformation of the metal when a tool, having a row of three rotating balls around its periphery, is pressed through the parts. When the bushing is pressed into a broached bore, the ridges displace the softer material of the bushing into the grooves, thus securing the assembly. The balls can be made of high-carbon chromium steel or carbide, depending on the hardness of the component.

**Broaching Difficulties.**—The accompanying table has been compiled from information supplied by the National Broach and Machine Co. and presents some of the common broaching difficulties, their causes and means of correction.

**Causes of Broaching Difficulties**

Broaching Difficulty	Possible Causes
Stuck broach	<p>Insufficient machine capacity; dulled teeth; clogged chip gullets; failure of power during cutting stroke.</p> <p>To remove a stuck broach, remove workpiece and broach from the machine as a unit; never try to back out broach by reversing machine. If broach does not loosen by tapping workpiece lightly and trying to slide it off its starting end, mount workpiece and broach in a lathe and turn down workpiece to the tool surface. Workpiece may be sawed longitudinally into several sections in order to free the broach.</p> <p>Check broach design; perhaps tooth relief (back off) angle is too small or depth of cut per tooth is too great.</p>
Galling and pickup	<p>Lack of homogeneity of material being broached—uneven hardness, porosity; improper or insufficient coolant; poor broach design, mutilated broach; dull broach; improperly sharpened broach; improperly designed or worn fixtures.</p> <p>Good broach design will do away with possible chip build-up on tooth faces and excessive heating. Grinding of teeth should be accurate so that the correct gullet contour is maintained. Contour should be fair and smooth.</p>
Broach breakage	<p>Overloading; broach dullness; improper sharpening; interrupted cutting stroke; backing up broach with workpiece in fixture; allowing broach to pass entirely through guide hole; ill fitting and/or sharp-edged key; crooked holes; untrue locating surface; excessive hardness of workpiece; insufficient clearance angle; sharp corners on pull end of broach.</p> <p>When grinding bevels on pull end of broach, use wheel that is not too pointed.</p>
Chatter	<p>Too few teeth in cutting contact simultaneously; excessive hardness of material being broached; loose or poorly constructed tooling; surging of ram due to load variations.</p> <p>Chatter can be alleviated by changing the broaching speed, by using shear cutting teeth instead of right-angle teeth, and by changing the coolant and the face and relief angles of the teeth.</p>
Drifting or misalignment of tool during cutting stroke	<p>Lack of proper alignment when broach is sharpened in grinding machine, which may be caused by dirt in the female center of the broach; inadequate support of broach during the cutting stroke, on a horizontal machine especially; body diameter too small; cutting resistance variable around I.D. due to lack of symmetry of surfaces to be cut; variations in hardness around I.D.; too few teeth in cutting contact.</p>
Streaks in broached surface	<p>Lands too wide; presence of forging, casting or annealing scale; metal pickup; presence of grinding burrs and grinding and cleaning abrasives.</p>
Rings in the broached hole	<p>Surging resulting from uniform pitch of teeth; presence of sharpening burrs on broach; tooth clearance angle too large; locating face not smooth or square; broach not supported for all cutting teeth passing through the work. The use of differential tooth spacing or shear cutting teeth helps in preventing surging. Sharpening burrs on a broach may be removed with a wood block.</p>

## FILES AND BURS

## Files

**Definitions of File Terms.**—The following file terms apply to hand files but not to rotary files and burs.

*Axis:* Imaginary line extending the entire length of a file equidistant from faces and edges.

*Back:* The convex side of a file having the same or similar cross section as a half-round file.

*Bastard Cut:* A grade of file coarseness between coarse and second cut of American pattern files and rasps.

*Blank:* A file in any process of manufacture before being cut.

*Blunt:* A file whose cross-sectional dimensions from point to tang remain unchanged.

*Coarse Cut:* The coarsest of all American pattern file and rasp cuts.

*Coarseness:* Term describing the relative number of teeth per unit length, the coarsest having the least number of file teeth per unit length; the smoothest, the most. American pattern files and rasps have four degrees of coarseness: coarse, bastard, second and smooth. Swiss pattern files usually have seven degrees of coarseness: 00, 0, 1, 2, 3, 4, 6 (from coarsest to smoothest). Curved-tooth files have three degrees of coarseness: standard, fine and smooth.

*Curved Cut:* File teeth that are made in curved contour across the file blank.

*Cut:* Term used to describe file teeth with respect to their coarseness or their character (single, double, rasp, curved, special).

*Double Cut:* A file tooth arrangement formed by two series of cuts, namely the overcut followed, at an angle, by the upcut.

*Edge:* Surface joining faces of a file. May have teeth or be smooth.

*Face:* Widest cutting surface or surfaces that are used for filing.

*Heel or Shoulder:* That portion of a file that abuts the tang.

*Hopped:* A term used among file makers to represent a very wide skip or spacing between file teeth.

*Length:* The distance from the heel to the point.

*Overcut:* The first series of teeth put on a double-cut file.

*Point:* The front end of a file; the end opposite the tang.

*Rasp Cut:* A file tooth arrangement of round-topped teeth, usually not connected, that are formed individually by means of a narrow, punch-like tool.

*Re-cut:* A worn-out file that has been re-cut and re-hardened after annealing and grinding off the old teeth.

*Safe Edge:* An edge of a file that is made smooth or uncut, so that it will not injure that portion or surface of the workplace with which it may come in contact during filing.

*Second Cut:* A grade of file coarseness between bastard and smooth of American pattern files and rasps.

*Set:* To blunt the sharp edges or corners of file blanks before and after the overcut is made, in order to prevent weakness and breakage of the teeth along such edges or corners when the file is put to use.

*Shoulder or Heel:* See *Heel or Shoulder*.

*Single Cut:* A file tooth arrangement where the file teeth are composed of single unbroken rows of parallel teeth formed by a single series of cuts.

*Smooth Cut:* An American pattern file and rasp cut that is smoother than second cut.

*Tang:* The narrowed portion of a file which engages the handle.

*Upcut:* The series of teeth superimposed on the overcut, and at an angle to it, on a double-cut file.

**File Characteristics.**—Files are classified according to their shape or cross section and according to the pitch or spacing of their teeth and the nature of the cut.

*Cross Section and Outline:* The cross section may be quadrangular, circular, triangular, or some special shape. The outline or contour may be tapered or blunt. In the former, the point is more or less reduced in width and thickness by a gradually narrowing section that extends for one-half to two-thirds of the length. In the latter the cross section remains uniform from tang to point.

*Cut:* The character of the teeth is designated as single, double, rasp or curved. The *single-cut file* (or *float* as the coarser cuts are sometimes called) has a single series of parallel teeth extending across the face of the file at an angle of from 45 to 85 degrees with the axis of the file. This angle depends upon the form of the file and the nature of the work for which it is intended. The single-cut file is customarily used with a light pressure to produce a smooth finish. The *double-cut file* has a multiplicity of small pointed teeth inclining toward the point of the file arranged in two series of diagonal rows that cross each other. For general work, the angle of the first series of rows is from 40 to 45 degrees and of the second from 70 to 80 degrees. For *double-cut finishing files*, the first series has an angle of about 30 degrees, and the second from 80 to 87 degrees. The second, or *overcut*, is almost always deeper than the first or *overcut*. Double-cut files are usually employed, under heavier pressure, for fast metal removal and where a rougher finish is permissible. The *rasp* is formed by raising a series of individual rounded teeth from the surface of the file blank with a sharp, narrow, punch-like cutting tool and is used with a relatively heavy pressure on soft substances for fast removal of material. The curved-tooth file has teeth that are in the form of parallel arcs extending across the face of the file, the middle portion of each arc being closest to the point of the file. The teeth are usually single cut and are relatively coarse. They may be formed by steel displacement but are more commonly formed by milling.

With reference to coarseness of cut, the terms *coarse*, *bastard*, *second* and *smooth cuts* are used, the coarse or bastard files for the heavier classes of work and the second- or smooth-cut files for the finishing or more exacting work. These degrees of coarseness are only comparable when files of the same length are compared, as the number of teeth per inch of length decreases as the length of the file increases. The number of teeth per inch varies considerably for different sizes and shapes and for files of different makes. The coarseness range for the curved-tooth files is given as standard, fine and smooth. In the case of Swiss pattern files, a series of numbers is used to designate coarseness instead of names; Nos. 00, 0, 1, 2, 3, 4 and 6 being the most common with No. 00 the coarsest and No. 6 the finest.

**Classes of Files.**—There are five main classes of files: mill or saw files; machinists' files; curved-tooth files; Swiss pattern files; and rasps. The first two classes are commonly referred to as American pattern files.

*Mill or Saw Files:* These are used for sharpening mill or circular saws, and large crosscut saws; for lathe work; for draw filing; for filing brass and bronze; and for smooth filing generally. The number identifying the following files refers to the illustration in Fig. 1.

1) *Cantsaw files* have an obtuse isosceles triangular section, a blunt outline, are single cut and are used for sharpening saws having M-shaped teeth and teeth of less than 60-degree angle; 2) *Crosscut files* have a narrow triangular section with the short side rounded and a blunt outline, are single cut and are used to sharpen crosscut saws. The rounded portion is used to deepen the gullets of saw teeth, and the sides are used to sharpen the teeth themselves; 3) *Double ender files* have a triangular section, are tapered from the middle to both ends, are tangless and single cut, and are used reversibly for sharpening saws; 4) *The mill file* itself is usually single cut, tapered in width, and often has two square cutting edges in addition to the cutting sides. Either or both edges may be rounded, however, for filing the gullets of saw teeth. *The blunt mill file* has a uniform rectangular cross section from tip to tang; 5) *The triangular saw files* or *taper saw files* have an equilateral

triangular section, are tapered, are single cut and are used for filing saws with 60-degree angle teeth. They come in taper, slim taper, extra-slim taper and double-extra-slim taper thicknesses. *Blunt triangular* and *blunt hand-saw files* are without taper; and 6) *Web saw files* have a diamond-shaped section, a blunt outline, are single cut and are used for sharpening pulpwood or web saws.

*Machinists' Files:* These files are used throughout industry where metal must be removed rapidly and finish is of secondary importance. Except for certain exceptions in the round and half-round shapes, all are double cut. 7) *Flat files* have a rectangular section, are tapered in width and thickness, are cut on both sides and edges, and are used for general utility work; 8) *Half-round files* have a circular segmental section, are tapered in width and thickness, have their flat side double cut, their rounded side mostly double but sometimes single cut, and are used to file rounded holes, concave corners, etc., in general filing work; 9) *Hand files* are similar to flat files but taper in thickness only. One edge is uncut or "safe."; and 10) *Knife files* have a "knife-blade" section, are tapered in width only, are double cut, and are used by tool and die makers on work having acute angles.

*Machinist's general purpose files* have a rectangular section, are tapered and have single-cut teeth divided by angular serrations that produce short cutting edges. These edges help stock removal but still leave a smooth finish and are suitable for use on various materials, including aluminum, bronze, cast iron, malleable iron, mild steels and annealed tool steels.

11) *Pillar files* are similar to hand files but are thicker and not as wide; 12) *Round files* have a circular section, are tapered, single cut, and are generally used to file circular openings or curved surfaces; 13) *Square files* have a square section, are tapered, and are used for filing slots and keyways, and for general surface filing where a heavier section is preferred; 14) *Three-square files* have an equilateral triangular section and are tapered on all sides. They are double cut and have sharp corners, as contrasted with taper triangular files, which are single cut and have somewhat rounded corners. They are used for filing accurate internal angles, for clearing out square corners, and for filing taps and cutters; and 15) *Warding files* have a rectangular section, and taper in width to a narrow point. They are used for general narrow-space filing.

*Woodfiles* are made in the same sections as flat and half round files but with coarser teeth especially suited for working on wood.

Fig. 1. Styles of Mill or Saw Files

*Curved-Tooth Files:* Regular curved-tooth files are made in both rigid and flexible forms. The rigid type has either a tang for a conventional handle or is made plain with a hole at each end for mounting in a special holder. The flexible type is furnished for use in special holders only. Curved-tooth files come in standard fine and smooth cuts and in

parallel flat, square, pillar, pillar narrow, half-round and shell types. A special curved-tooth file is available with teeth divided by long angular serrations. The teeth are cut in an "off center" arc. When moved across the work toward one edge of the file a fast cutting action is provided; when moved toward the other edge, a smoothing action; thus the file is made to serve a dual purpose.

*Swiss Pattern Files:* These are used by tool and die makers, model makers and delicate instrument parts finishers. They are made to closer tolerances than the conventional American pattern files although with similar cross sections. The points of the Swiss pattern files are smaller, the tapers are longer, and they are available in much finer cuts. They are primarily finishing tools for removing burrs left from previous finishing operations truing up narrow grooves, notches and keyways, cleaning out corners and smoothing small parts. For very fine work, *round-* and *square-handled needle files*, available in numerous cross-sectional shapes in overall lengths from 4 to  $7\frac{3}{4}$  inches, are used. Die sinkers use *die sinkers' files* and *die sinkers' rifflers*. The files, also made in many different cross-sectional shapes, are  $3\frac{1}{2}$  inches in length and are available in the cut Nos. 0, 1, 2, and 4. The rifflers are from  $5\frac{1}{2}$  to  $6\frac{3}{4}$  inches long, have cutting surfaces on either end, and come in numerous cross-sectional shapes in cut Nos. 0, 2, 3, 4 and 6. These rifflers are used by die makers for getting into corners, crevices, holes and contours of intricate dies and molds. Used in the same fashion as die sinkers' rifflers, *silversmiths' rifflers*, that have a much heavier cross section, are available in lengths from  $6\frac{7}{8}$  to 8 inches and in cut Nos. 0, 1, 2, and 3. *Blunt machine files* in cut Nos. 00, 0, and 2 for use in ordinary and bench filing machines are available in many different cross-sectional shapes, in lengths from 3 to 8 inches.

*Rasps:* Rasps are employed for work on relatively soft substances such as wood, leather, and lead where fast removal of material is required. They come in rectangular and half round cross sections, the latter with and without a sharp edge.

*Special Purpose Files:* Falling under one of the preceding five classes of files, but modified to meet the requirements of some particular function, are a number of special-purpose files. The *long-angle lathe file* is used for filing work that is rotating in a lathe. The long tooth angle provides a clean shear, eliminates drag or tear and is self-clearing. This file has safe or uncut edges to protect shoulders of the work which are not to be filed. The *foundry file* has especially sturdy teeth with heavy-set edges for the snagging of castings—the removing of fins, sprues, and other projections. The *die-casting file* has extra-strong teeth on corners and edges as well as sides for working on die castings of magnesium, zinc, or aluminum alloys. A special file for stainless steel is designed to stand up under the abrasive action of stainless steel alloys. *Aluminum rasps and files* are designed to eliminate clogging. A special tooth construction is used in one type of aluminum tile which breaks up the filings, allows the file to clear itself and overcomes chatter. A *brass file* is designed so that with a little pressure the sharp, high-cut teeth bite deep, while, with less pressure, their short uncut angle produces a smoothing effect. The *lead float* has coarse, single-cut teeth at almost right angles to the file axis. These shear away the metal under ordinary pressure and produce a smoothing effect under light pressure. The *shear-tooth file* has a coarse single cut with a long angle for soft metals or alloys, plastics, hard rubber and wood. *Chainsaw files* are designed to sharpen all types of chainsaw teeth. These files come in round, rectangular, square and diamond-shaped sections. The round- and square-sectioned files have either double- or single-cut teeth, the rectangular files have single-cut teeth, and the diamond-shaped files have double-cut teeth.

**Effectiveness of Rotary Files and Burs.**—There is very little difference in the efficiency of rotary files or burs when used in electric tools and when used in air tools, provided the speeds have been reasonably well selected. Flexible-shaft and other machines used as a source of power for these tools have a limited number of speeds which govern the revolutions per minute at which the tools can be operated.

The carbide bur may be used on hard or soft materials with equally good results. The principle difference in construction of the carbide bur is that its teeth or flutes are provided with a negative rather than a radial rake. Carbide burs are relatively brittle and must be treated more carefully than ordinary burs. They should be kept cutting freely, in order to prevent too much pressure, which might result in crumbling of the cutting edges.

At the same speeds, both high-speed steel and carbide burs remove approximately the same amount of metal. However, when carbide burs are used at their most efficient speeds, the rate of stock removal may be as much as four times that of ordinary burs. In certain cases, speeds much higher than those shown in the table can be used. It has been demonstrated that a carbide bur will last up to 100 times as long as a high-speed steel bur of corresponding size and shape.

### Approximate Speeds of Rotary Files and Burs

Tool Diameter		Medium Cut, High-Speed Steel Bur or File					Carbide Bur	
		Mild Steel	Cast Iron	Bronze	Aluminum	Magnesium	Medium Cut	Fine Cut
inches	mm	Speed, Revolutions per Minute					Any Material	
1/8	3.2	4600	7000	15,000	20,000	30,000	45,000	30,000
1/4	6.4	3450	5250	11,250	15,000	22,500	30,000	20,000
3/8	9.5	2750	4200	9000	12,000	18,000	24,000	16,000
1/2	12.7	2300	3500	7500	10,000	15,000	20,000	13,350
5/8	15.9	2000	3100	6650	8900	13,350	18,000	12,000
3/4	19.1	1900	2900	6200	8300	12,400	16,000	10,650
7/8	22.2	1700	2600	5600	7500	11,250	14,500	9650
1	25.4	1600	2400	5150	6850	10,300	13,000	8650
1 1/8	28.6	1500	2300	4850	6500	9750	...	...
1 1/4	31.8	1400	2100	4500	6000	9000	...	...

As recommended by the Nicholson File Company.

**Steel Wool.**—Steel wool is made by shaving thin layers of steel from wire. The wire is pulled, by special machinery built for the purpose, past cutting tools or through cutting dies that shave off chips from the outside. Steel wool consists of long, relatively strong, and resilient steel shavings having sharp edges. This characteristic renders it an excellent abrasive. The fact that the cutting characteristics of steel wool vary with the size of the fiber, which is readily controlled in manufacture, has adapted it to many applications.

Metals other than steel have been made into wool by the same processes as steel, and when so manufactured have the same general characteristics. Thus wool has been made from copper, lead, aluminum, bronze, brass, monel metal, and nickel. The wire from which steel wool is made may be produced by either the Bessemer, or the basic or acid open-hearth processes. It should contain from 0.10 to 0.20 percent carbon; from 0.50 to 1.00 percent manganese; from 0.020 to 0.090 percent sulphur; from 0.050 to 0.120 percent phosphorus; and from 0.001 to 0.010 percent silicon. When drawn on a standard tensile-strength testing machine, a sample of the steel should show an ultimate strength of not less than 120,000 pounds per square inch (828 MPa).

### Steel Wool Grades

Description	Grade	Fiber Thickness		Description	Grade	Fiber Thickness	
		Inch	Millimeter			Inch	Millimeter
Super Fine	0000	0.001	0.025	Medium	1	0.0025	0.06
Extra Fine	000	0.0015	0.035	Medium Coarse	2	0.003	0.075
Very Fine	00	0.0018	0.04	Coarse	3	0.0035	0.09
Fine	0	0.002	0.05	Extra Coarse	4	0.004	0.10

## KNURLS AND KNURLING

**Standard Knurls and Knurling.**—The ANSI/ASME Standard B94.6-1984 (R2014) covers knurling tools with standardized diametral pitches and their dimensional relations with respect to the work in the production of straight, diagonal, and diamond knurling on cylindrical surfaces having teeth of uniform pitch parallel to the cylinder axis or at a helix angle not exceeding 45 degrees with the work axis.

These knurling tools and the recommendations for their use are equally applicable to general purpose and precision knurling. The advantage of this ANSI/ASME Standard system is the provision by which good tracking (the ability of teeth to mesh as the tool penetrates the work blank in successive revolutions) is obtained by tools designed on the basis of diametral pitch instead of TPI (teeth per inch) when used with work blank diameters that are multiples of  $\frac{1}{64}$  inch for 64 and 128 diametral pitch or  $\frac{1}{32}$  inch for 96 and 160 diametral pitch. The use of knurls and work blank diameters that will permit good tracking should improve the uniformity and appearance of knurling, eliminate costly trial and error methods, reduce the failure of knurling tools and the production of defective work, and decrease the number of tools required. Preferred sizes for cylindrical knurls are given in Table 1, and detailed specifications appear in Table 2.

**Table 1. ANSI Standard Preferred Sizes for Cylindrical Type Knurls**  
ANSI/ASME B94.6-1984 (R2014)

Nominal Outside Diameter $D_{nr}$	Width of Face $F$	Diameter of Hole $A$	Standard Diametral Pitches, $P$			
			64	96	128	160
			Number of Teeth, $N_r$ , for Standard Pitches			
$\frac{1}{2}$	$\frac{3}{16}$	$\frac{3}{16}$	32	48	64	80
$\frac{5}{8}$	$\frac{1}{4}$	$\frac{1}{4}$	40	60	80	100
$\frac{3}{4}$	$\frac{3}{8}$	$\frac{1}{4}$	48	72	96	120
$\frac{7}{8}$	$\frac{3}{8}$	$\frac{1}{4}$	56	84	112	140
Additional Sizes for Bench and Engine Lathe Tool Holders						
$\frac{5}{8}$	$\frac{5}{16}$	$\frac{7}{32}$	40	60	80	100
$\frac{3}{4}$	$\frac{5}{8}$	$\frac{1}{4}$	48	72	96	120
1	$\frac{3}{8}$	$\frac{5}{16}$	64	96	128	160

The 96 diametral pitch knurl should be given preference in the interest of tool simplification. Dimensions  $D_{nr}$ ,  $F$ , and  $A$  are in inches.

**Table 2. ANSI Standard Specifications for Cylindrical Knurls with Straight or Diagonal Teeth** ANSI/ASME B94.6-1984 (R2014)

Diametral Pitch $P$	Nominal Diameter, $D_{nr}$					Tracking Correction Factor $Q$	Tooth Depth, $h_t$ , +0.0015, -0.0000		Radius at Root $R$
	$\frac{1}{2}$	$\frac{5}{8}$	$\frac{3}{4}$	$\frac{7}{8}$	1		Straight	Diagonal	
	Major Diameter of Knurl, $D_{nr}$ , +0.0000, -0.0015								
64	0.4932	0.6165	0.7398	0.8631	0.9864	0.0006676	0.024	0.021	0.0070 0.0050 0.0060 0.0040
96	0.4960	0.6200	0.7440	0.8680	0.9920	0.0002618	0.016	0.014	0.0045 0.0030 0.0040 0.0025
128	0.4972	0.6215	0.7458	0.8701	0.9944	0.0001374	0.012	0.010	
160	0.4976	0.6220	0.7464	0.8708	0.9952	0.00009425	0.009	0.008	

All dimensions except diametral pitch are in inches.

Approximate angle of space between sides of adjacent teeth for both straight and diagonal teeth is 80 degrees. The permissible eccentricity of teeth for all knurls is 0.002 inch maximum (total indicator reading).

Number of teeth in a knurl equals diametral pitch multiplied by nominal diameter.

Diagonal teeth have 30-degree helix angle,  $\psi$ .

The term *Diametral Pitch* applies to the quotient obtained by dividing the total number of teeth in the circumference of the work by the basic blank diameter; in the case of the knurling tool, the diametral pitch would be the total number of teeth in the circumference divided by the *nominal* diameter. In the Standard, the diametral pitch and number of teeth are always measured in a transverse plane that is perpendicular to the axis of rotation for diagonal as well as straight knurls and knurling.

**Cylindrical Knurling Tools.**—The cylindrical type of knurling tool is comprised of a tool holder and one or more knurls. The knurl has a centrally located mounting hole and is provided with straight or diagonal teeth on its periphery. The knurl is used to reproduce this tooth pattern on the work blank as the knurl and work blank rotate together.

*\*Formulas for Cylindrical Knurls*

$$P = \text{diametral pitch of knurl} = N_t \div D_{nt} \quad (1)$$

$$D_{nt} = \text{nominal diameter of knurl} = N_t \div P \quad (2)$$

$$N_t = \text{no. of teeth on knurl} = P \times D_{nt} \quad (3)$$

$$*P_{nt} = \text{circular pitch on nominal diameter} = \pi \div P \quad (4)$$

$$*P_{ot} = \text{circular pitch on major diameter} = \pi D_{ot} \div N_t \quad (5)$$

$$D_{ot} = \text{major diameter of knurl} = D_{nt} - (N_t Q \div \pi) \quad (6)$$

$$Q = P_{nt} - P_{ot} = \text{tracking correction factor in Formula (6)} \quad (7)$$

**Tracking Correction Factor  $Q$ :** Use of the preferred pitches for cylindrical knurls, [Table 2](#), results in good tracking on all fractional work-blank diameters that are multiples of  $\frac{1}{64}$  inch for 64 and 128 diametral pitch, and  $\frac{1}{32}$  inch for 96 and 160 diametral pitch; an indication of good tracking is evenness of marking on the work surface during the first revolution of the work.

The many variables involved in knurling practice require that an empirical correction method be used to determine what actual circular pitch is needed at the major diameter of the knurl to produce good tracking and the required circular pitch on the workpiece. The empirical tracking correction factor,  $Q$ , in [Table 2](#) is used in the calculation of the major diameter of the knurl, Formula (6).

*\* Note:* For diagonal knurls,  $P_{nt}$  and  $P_{ot}$  are the transverse circular pitches that are measured in the plane perpendicular to the axis of rotation.

**Flat Knurling Tools.**—The flat type of tool is a knurling die, commonly used in reciprocating types of rolling machines. Dies may be made with either single or duplex faces having either straight or diagonal teeth. No preferred sizes are established for flat dies.

*Flat Knurling Die with Straight Teeth:*

$R$  = radius at root  
 $P = \text{diametral pitch} = N_w \div D_w$  (8)

$D_w = \text{work blank (pitch) diameter} = N_w \div P$  (9)

$N_w = \text{number of teeth on work} = P \times D_w$  (10)

$h$  = tooth depth  
 $Q$  = tracking correction factor (see Table 2)  
 $P_l = \text{linear pitch on die}$   
 = circular pitch on work pitch diameter =  $P - Q$  (11)

**Table 3. ANSI Standard Specifications for Flat Knurling Dies**  
 ANSI/ASME B94.6-1984 (R2014)

Diametral Pitch, $P$	Linear Pitch, <sup>a</sup> $P_l$	Tooth Depth, $h$		Radius at Root, $R$	Diametral Pitch, $P$	Linear Pitch, <sup>a</sup> $P_l$	Tooth Depth, $h$		Radius at Root, $R$
		Straight	Diagonal				Straight	Diagonal	
64	0.0484	0.024	0.021	0.0070	128	0.0244	0.012	0.010	0.0045
				0.0050					0.0030
96	0.0325	0.016	0.014	0.0060	160	0.0195	0.009	0.008	0.0040
				0.0040					0.0025

<sup>a</sup> The linear pitches are theoretical. The exact linear pitch produced by a flat knurling die may vary slightly from those shown, depending upon the rolling condition and the material being rolled.

All dimensions except diametral pitch are in inches.

**Formulas Applicable to Knurled Work.**—The following formulas are applicable to knurled work with straight, diagonal, and diamond knurling.

*Formulas for Straight or Diagonal Knurling with Straight- or Diagonal-Tooth Cylindrical Knurling Tools Set with Knurl Axis Parallel with Work Axis:*

$$P = \text{diametral pitch} = N_w \div D_w \quad (12)$$

$$D_w = \text{work blank diameter} = N_w \div P \quad (13)$$

$$N_w = \text{no. of teeth on work} = P \times D_w \quad (14)$$

$$a = \text{"addendum" of tooth on work} = (D_{ow} - D_w) \div 2 \quad (15)$$

$h$  = tooth depth (see Table 2)

$$D_{ow} = \text{knurled diameter (outside diameter after knurling)} = D_w + 2a \quad (16)$$

*Formulas for Diagonal and Diamond Knurling with Straight-Tooth Knurling Tools Set at an Angle to the Work Axis:*

If,  $\psi$  = angle between tool axis and work axis

$P$  = diametral pitch on tool

$P_\psi$  = diametral pitch produced on work blank (as measured in the transverse plane) by setting tool axis at an angle  $\psi$  with respect to work blank axis

$D_w$  = diameter of work blank; and

$N_w$  = number of teeth produced on work blank (as measured in the transverse plane)

then,  $P_\psi = P \cos \psi$  (17)

and,  $N = D_w P \cos \psi$  (18)

For example, if 30-degree diagonal knurling were to be produced on 1-inch diameter stock with a 160 pitch straight knurl:

$$N_w = D_w P \cos 30^\circ = 1.000 \times 160 \times 0.86603 = 138.56 \text{ teeth}$$

Good tracking is theoretically possible by changing the helix angle as follows to correspond to a whole number of teeth (138):

$$\cos \psi = N_w \div D_w P = 138 \div (1 \times 160) = 0.8625$$

$$\psi = 30 \frac{1}{2} \text{ degrees, approximately}$$

Whenever it is more practical to machine the stock, good tracking can be obtained by reducing the work blank diameter as follows to correspond to a whole number of teeth (138):

$$D_w = \frac{N_w}{P \cos \psi} = \frac{138}{160 \times 0.866} = 0.996 \text{ inch}$$

**Table 4. ANSI Standard Recommended Tolerances on Knurled Diameters**

*ANSI/ASME B94.6-1984 (R2014)*

Tolerance Class	Diametral Pitch							
	64	96	128	160	64	96	128	160
	Tolerance on Knurled Outside Diameter				Tolerance on Work-Blank Diameter Before Knurling			
I	+0.005 -0.012	+0.004 -0.010	+0.003 -0.008	+0.002 -0.006	±0.0015	±0.0010	±0.0007	±0.0005
II	+0.000 -0.010	+0.000 -0.009	+0.000 -0.008	+0.000 -0.006	±0.0015	±0.0010	±0.0007	±0.0005
III	+0.000 -0.006	+0.000 -0.005	+0.000 -0.004	+0.000 -0.003	+0.000 -0.0015	+0.0000 -0.0010	+0.000 -0.0007	+0.0000 -0.0005

**Recommended Tolerances on Knurled Outside Diameters.**—The recommended applications of the tolerance classes shown in Table 4 are as follows:

*Class I:* Tolerances in this classification may be applied to straight, diagonal and raised diamond knurling where the knurled outside diameter of the work need not be held to close dimensional tolerances. Such applications include knurling for decorative effect, grip on thumb screws, and inserts for moldings and castings.

*Class II:* Tolerances in this classification may be applied to straight knurling only and are recommended for applications requiring closer dimensional control of the knurled outside diameter than provided for by Class I tolerances.

*Class III:* Tolerances in this classification may be applied to straight knurling only and are recommended for applications requiring closest possible dimensional control of the knurled outside diameter. Such applications include knurling for close fits.

*Note:* The width of the knurling should not exceed the diameter of the blank, and knurling wider than the knurling tool cannot be produced unless the knurl starts at the end of the work.

**Marking on Knurls and Dies.**—Each knurl and die should be marked as follows: *a.* when straight to indicate its diametral pitch; *b.* when diagonal, to indicate its diametral pitch, helix angle, and hand of angle.

**Concave Knurls.**—The radius of a concave knurl should not be the same as the radius of the piece to be knurled. If the knurl and the work are of the same radius, the material compressed by the knurl will be forced down on the shoulder *D* and spoil the appearance of the work. A design of concave knurl is shown in the accompanying illustration, and all the important dimensions are designated by letters. To find these dimensions, the pitch of the knurl required must be known, and also, approximately, the throat diameter *B*. This diameter must suit the knurl holder used and be such that the circumference contains an even number of teeth with the required pitch. When these dimensions have been decided upon, all the other unknown factors can be found by the following formulas: Let *R* = radius of piece to be knurled; *r* = radius of concave part of knurl; *C* = radius of cutter or hob for cutting the teeth in the knurl; *B* = diameter over concave part of knurl (throat diameter); *A* = outside diameter of knurl; *d* = depth of tooth in knurl; *P* = pitch of knurl (number of teeth per inch circumference); *p* = circular pitch of knurl; then  $r = R + \frac{1}{2}d$ ;  $C = r + d$ ;  $A = B + 2r - (3d + 0.010 \text{ inch})$ ; and  $d = 0.5 \times p \times \cot \alpha / 2$ , where  $\alpha$  is the included angle of the teeth.

As the depth of the tooth is usually very slight, the throat diameter *B* will be accurate enough for all practical purposes for calculating the pitch, and it is not necessary to take into consideration the pitch circle. For example, assume that the pitch of a knurl is 32, that the throat diameter *B* is 0.5561 inch, that the radius *R* of the piece to be knurled is  $\frac{1}{16}$  inch, and that the angle of the teeth is 90 degrees; find the dimensions of the knurl. Using the notation given:

$$p = \frac{1}{P} = \frac{1}{32} = 0.03125 \text{ inch} \quad d = 0.5 \times 0.03125 \times \cot 45^\circ = 0.0156 \text{ inch}$$

$$r = \frac{1}{16} + \frac{0.0156}{2} = 0.0703 \text{ inch} \quad C = 0.0703 + 0.0156 = 0.0859 \text{ inch}$$

$$A = 0.5561 + 0.1406 - (0.0468 + 0.010) = 0.6399 \text{ inch}$$

## TOOL WEAR AND SHARPENING

Metal cutting tools wear constantly when they are being used. A normal amount of wear should not be a cause for concern until the size of the worn region indicates that the tool should be replaced. Normal wear cannot be avoided and should be differentiated from abnormal tool breakage or excessively fast wear. Tool breakage and an excessive rate of wear indicate that the tool is not operating correctly, and steps should be taken to correct this situation.

There are several basic mechanisms that cause tool wear. It is generally understood that tools wear as a result of abrasion caused by hard particles of work material plowing over the surface of the tool. Wear is also caused by diffusion or alloying between the work and tool material. In regions where the conditions of contact are favorable, work material reacts with tool material, causing an attrition of the tool material. The rate of this attrition is dependent upon the temperature in the region of contact and the reactivity of the tool and work materials with each other. Diffusion or alloying also occurs where particles of the work material are welded to the surface of the tool. These welded deposits are often quite visible in the form of a built-up edge, as particles or a layer of work material inside a crater, or as small mounds attached to the face of the tool. The diffusion or alloying occurring between these deposits and the tool weakens the tool material below the weld. Frequently these deposits are again rejoined to the chip by welding, or they are simply broken away by the force of collision with the passing chip. When this happens, a small amount of the tool material may remain attached to the deposit and be plucked from the surface of the tool, to be carried away with the chip. This mechanism can cause chips to be broken from the cutting edge and cause the formation of small craters, or pull-outs, on the tool face. It can also contribute to the enlargement of the larger crater that sometimes forms behind the cutting edge. Among the other mechanisms that can cause tool wear are severe thermal gradients and thermal shocks, which cause cracks to form near the cutting edge, ultimately leading to tool failure. This condition can be caused by improper tool grinding procedures, by heavy interrupted cuts, or by the improper application of cutting fluids when machining at high cutting speeds. Chemical reactions between the active constituents in some cutting fluids sometimes accelerate the rate of tool wear. Oxidation of the heated metal near the cutting edge also contributes to tool wear, particularly when fast cutting speeds and high cutting temperatures are encountered. Breakage of the cutting edge caused by overloading, heavy shock loads, or improper tool design is not normal wear and should be corrected.

The wear mechanisms described above bring about visible manifestations of wear on the tool, which should be understood so that the proper corrective measures can be taken, when required. These visible signs of wear are described in the following paragraphs, and the corrective measures that might be required are given in the table *Tool Troubleshooting Check List* on page 1083. The best procedure when troubleshooting is to try to correct only one condition at a time. When a correction has been made, it should be checked. After one condition has been corrected, work can then be started to correct the next condition.

**Flank Wear.**—Tool wear occurring on the flank of the tool below the cutting edge is called flank wear. Flank wear always takes place and cannot be avoided. It should not give rise to concern unless the rate of flank wear is too fast or the flank wear land becomes too large in size. The size of the flank wear can be measured as the distance between the top of the cutting edge and the bottom of the flank wear land. In practice, a visual estimate is usually made instead of a precise measurement, although in many instances flank wear is ignored and the tool wear is “measured” by the loss of size on the part. The best measure of tool wear, however, is flank wear. When it becomes too large, the rubbing action of the wear land against the workpiece increases and the cutting edge must be replaced. Because conditions vary, it is not possible to give an exact amount of flank wear at which the tool should be replaced. Although there are many exceptions, as a rough estimate, high-speed steel tools should be replaced when the width of the flank wear land reaches 0.005 to

0.010 inch (0.13–0.25 mm) for finish turning and 0.030 to 0.060 inch (0.76–1.52 mm) for rough turning; and for cemented carbides 0.005 to 0.010 inch (0.13–0.25 mm) for finish turning and 0.020 to 0.040 inch (0.51–1.02 mm) for rough turning.

Under ideal conditions, which, surprisingly, occur quite frequently, the width of the flank wear land will be very uniform along its entire length. When the depth of cut is uneven, such as when turning out-of-round stock, the bottom edge of the wear land may become somewhat slanted, the wear land being wider toward the nose. A jagged-appearing wear land usually is evidence of chipping at the cutting edge. Sometimes, only one or two sharp depressions of the lower edge of the wear land will appear to indicate that the cutting edge has chipped above these depressions. A deep notch will sometimes occur at the “depth of cut line,” or that part of the cutting opposite the original surface of the work. This can be caused by a hard surface scale on the work, by a work-hardened surface layer on the work, or when machining high-temperature alloys. Often the size of the wear land is enlarged at the nose of the tool. This can be a sign of crater breakthrough near the nose or of chipping in this region. Under certain conditions, when machining with carbides, it can be an indication of deformation of the cutting edge in the region of the nose.

When a sharp tool is first used, the initial amount of flank wear is quite large in relation to the subsequent total amount. Under normal operating conditions, the width of the flank wear land will increase at a uniform rate until it reaches a critical size, after which the cutting edge breaks down completely. This is called catastrophic failure, and the cutting edge should be replaced before this occurs. When cutting at slow speeds with high-speed steel tools, there may be long periods when no increase in the flank wear can be observed. For a given work material and tool material, the rate of flank wear is primarily dependent on the cutting speed and then on the feed rate.

**Cratering.**—A deep crater will sometimes form on the face of the tool, which is easily recognizable. The crater forms at a short distance behind the side cutting edge, leaving a small shelf between the cutting edge and the edge of the crater. This shelf is sometimes covered with the built-up edge and at other times it is uncovered. Often the bottom of the crater is obscured with work material that is welded to the tool in this region. Under normal operating conditions, the crater will gradually enlarge until it breaks through a part of the cutting edge. Usually this occurs on the end cutting edge just behind the nose. When this takes place, the flank wear at the nose increases rapidly and complete tool failure follows shortly. Sometimes cratering cannot be avoided, and a slow increase in the size of the crater is considered normal. However, if the rate of crater growth is rapid, leading to a short tool life, corrective measures must be taken.

**Cutting Edge Chipping.**—Small chips are sometimes broken from the cutting edge, which accelerates tool wear but does not necessarily cause immediate tool failure. Chipping can be recognized by the appearance of the cutting edge and the flank wear land. A sharp depression in the lower edge of the wear land is a sign of chipping, and, if this edge of the wear land has a jagged appearance, it indicates that a large amount of chipping has taken place. Often the vacancy or cleft in the cutting edge that results from chipping is filled up with work material that is tightly welded in place. This occurs very rapidly when chipping is caused by a built-up edge on the face of the tool. In this manner, the damage to the cutting edge is healed; however, the width of the wear land below the chip is usually increased and the tool life is shortened.

**Deformation.**—Deformation occurs on carbide cutting tools when taking a very heavy cut using a slow cutting speed and a high feed rate. A large section of the cutting edge then becomes very hot, and the heavy cutting pressure compresses the nose of the cutting edge, thereby lowering the face of the tool in the area of the nose. This reduces the relief under the nose, increases the width of the wear land in this region, and shortens tool life.

**Surface Finish.**—The finish on the machined surface does not necessarily indicate poor cutting tool performance unless there is a rapid deterioration. A good surface finish is, however, sometimes a requirement. The principal cause of a poor surface finish is the built-up edge that forms along the edge of the cutting tool. The elimination of the built-up edge will always result in an improvement of the surface finish. The most effective way to eliminate the built-up edge is to increase cutting speed. When cutting speed is increased beyond a certain critical limit, there will be a rather sudden and large improvement in the surface finish. Cemented carbide tools can operate successfully at higher cutting speeds, where the built-up edge does not occur and where a good surface finish is obtained. Whenever possible, cemented carbide tools should be operated at cutting speeds where a good surface finish will result. There are times when such speeds are not possible. Also, high-speed tools cannot be operated at the speed where the built-up edge does not form. In these conditions, the most effective method of obtaining a good surface finish is to employ a cutting fluid that has active sulphur or chlorine additives.

Cutting tool materials that do not alloy readily with the work material are also effective in obtaining an improved surface finish. Straight titanium carbide and diamond are the two principal tool materials that fall into this category.

The presence of feed marks can mar an otherwise good surface finish, and attention must be paid to the feed rate and the nose radius of the tool if a good surface finish is desired. Changes in tool geometry can also be helpful. A small "flat," or secondary cutting edge, ground on the end cutting edge behind the nose will sometimes provide the desired surface finish. When the tool is in operation, the flank wear should not be allowed to become too large, particularly in the region of the nose where the finished surface is produced.

**Sharpening Twist Drills.**—Twist drills are cutting tools designed to perform concurrently several functions, such as penetrating directly into solid material, ejecting the removed chips outside the cutting area, maintaining the essentially straight direction of the advance movement and controlling the size of the drilled hole. The geometry needed for these multiple functions is incorporated into the design of the twist drill in such a manner that it can be retained even after repeated sharpening operations. Twist drills are resharpened many times during their service life, with the practically complete restitution of their original operational characteristics. However, in order to obtain all the benefits which the design of the twist drill is capable of providing, the surfaces generated in the sharpening process must agree with the original form of the tool's operating surfaces, unless a change of shape is required for use on a different work material.

The principal elements of tool geometry essential for the adequate cutting performance of twist drills are shown in Fig. 1. The generally used values for these dimensions are the following:

*Point angle:* Commonly 118°, except for high strength steels, 118° to 135°; aluminum alloys, 90° to 140°; and magnesium alloys, 70° to 118°.

*Helix angle:* Commonly 24° to 32°, except for magnesium and copper alloys, 10° to 30°.

*Lip relief angle:* Commonly 10° to 15°, except for high strength or tough steels, 7° to 12°. The lower values of these angle ranges are used for drills of larger diameter, the higher values for the smaller diameters. For drills of diameters less than 1/4 inch (6.35 mm), the lip relief angles are increased beyond the listed maximum values up to 24°. For soft and free machining materials, 12° to 18° except for diameters less than 1/4 inch (6.35 mm), 20° to 26°.

**Relief Grinding of the Tool Flanks.**—In sharpening twist drills the tool flanks containing the two cutting edges are ground. Each flank consists of a curved surface, which provides the relief needed for the easy penetration and free cutting of the tool edges. In grinding the flanks, Fig. 2, the drill is swung around the axis *A* of an imaginary cone while resting in a support that holds the drill at one-half the point angle *B* with respect to the face of the grinding wheel. Feed *f* for stock removal is in the direction of the drill axis.

The relief angle is usually measured at the periphery of the twist drill and is also specified by that value. It is not a constant but should increase toward the center of the drill.

The relief grinding of the flank surfaces will generate the chisel angle on the web of the twist drill. The value of that angle, typically  $55^\circ$ , which can be measured, for example, with the protractor of an optical projector, is indicative of the correctness of the relief grinding.

Fig. 1. The principal elements of tool geometry on twist drills.

Fig. 2. In grinding the face of the twist drill, the tool is swung around the axis  $A$  of an imaginary cone, while resting in a support tilted by half of the point angle  $\beta$  with respect to the face of the grinding wheel. Feed  $f$  for stock removal is in the direction of the drill axis.

Fig. 3. The chisel edge  $C$  after thinning the web by grinding off area  $T$ .

Fig. 4. Split-point or "crankshaft" type web thinning.

**Drill Point Thinning.**—The chisel edge is the least efficient operating surface element of the twist drill because it does not cut, but actually squeezes or extrudes, the work material. To improve the inefficient cutting conditions caused by the chisel edge, the point width is often reduced in a drill-point thinning operation, resulting in a condition such as that shown in Fig. 3. Point thinning is particularly desirable on larger size drills and also on those which become shorter in usage, because the thickness of the web increases toward the shaft of the twist drill, thereby adding to the length of the chisel edge. The extent of point thinning is limited by the minimum strength of the web needed to avoid splitting of the drill point under the influence of cutting forces.

Both sharpening operations—the relieved face grinding and the point thinning—should be carried out in special drill-grinding machines or with twist drill-grinding fixtures mounted on general-purpose tool-grinding machines designed to assure the essential accuracy of the required tool geometry. Off-hand grinding may be used for the important web thinning when a special machine is not available; however, such operations require skill and experience.

Improperly sharpened twist drills, e.g. those with unequal edge length or asymmetrical point angle, will tend to produce holes with poor diameter and directional control.

For deep holes and for drilling into stainless steel, titanium alloys, high temperature alloys, nickel alloys, very high-strength materials and in some cases tool steels, split-point grinding, resulting in a “crankshaft” type drill point, is recommended. In this type of pointing, see Fig. 4, the chisel edge is entirely eliminated, extending the positive rake cutting edges to the center of the drill, thereby greatly reducing the required thrust in drilling. Points on modified-point drills must be restored after sharpening to maintain their increased drilling efficiency.

**Sharpening Carbide Tools.**—Cemented carbide indexable inserts are usually not re-sharpened, but sometimes they require a special grind in order to form a contour on the cutting edge to suit a special purpose. Brazed-type carbide cutting tools are resharpened after the cutting edge has become worn. On brazed carbide tools, the cutting-edge wear should not be allowed to become excessive before the tool is re-sharpened. One method of determining when brazed carbide tools need resharpening is by periodic inspection of the flank wear and the condition of the face. Another method is to determine the amount of production normally obtained before excessive wear has taken place, or to determine the equivalent period of time. One disadvantage of this method is that slight variations in the work material will often cause the wear rate not to be uniform and the number of parts machined before regrinding will not be the same each time. Usually, sharpening should not require removal of more than 0.005 to 0.010 inch (0.13–0.25 mm) of carbide.

*General Procedure in Carbide-Tool Grinding:* The general procedure depends upon the kind of grinding operation required. If the operation is to resharpen a dull tool, a diamond wheel of 100- to 120-grain size is recommended, although a finer wheel—up to 150-grain size—is sometimes used to obtain a better finish. If the tool is new or is a “standard” design and changes in shape are necessary, a 100-grit diamond wheel is recommended for roughing and a finer grit diamond wheel can be used for finishing. Some shops prefer to rough-grind the carbide with a vitrified silicon carbide wheel, the finish grinding being done with a diamond wheel. A final operation commonly designated as lapping may or may not be employed for obtaining an extra-fine finish.

*Wheel Speeds:* The speed of silicon carbide wheels usually is about 5000 feet per minute (25.4 m/s). The speeds of diamond wheels generally range from 5000–6000 fpm (25.4–30.5 m/s); yet lower speeds (550–3000 fpm or 2.8–15.2 m/s) can be effective.

*Offhand Grinding:* In grinding single-point tools (excepting chipbreakers), the common practice is to hold the tool by hand, press it against the wheel face and traverse it continuously across the wheel face while the tool is supported on the machine rest or table, which is adjusted to the required angle. This is known as “offhand grinding” to distinguish it from the machine grinding of cutters as in regular cutter-grinding practice. The selection of wheels adapted to carbide-tool grinding is very important.

**Silicon Carbide Wheels.**—The green-colored silicon carbide wheels generally are preferred to the dark gray or gray-black variety, although the latter are sometimes used.

*Grain or Grit Sizes:* For roughing, a grain size of 60 is very generally used. For finish grinding with silicon carbide wheels, a finer grain size of 100 or 120 is common. A silicon carbide wheel such as C60-I-7V may be used for grinding both the steel shank and carbide tip. However, for under-cutting steel shanks up to the carbide tip, it may be advantageous to use an aluminum oxide wheel suitable for grinding softer, carbon steel.

**Grade:** According to the standard system of marking, different grades from soft to hard are indicated by letters from A to Z. For carbide-tool grinding fairly soft grades such as G, H, I, and J are used. The usual grades for roughing are I or J and for finishing H, I, and J. The grade should be such that a sharp free-cutting wheel will be maintained without excessive grinding pressure. Harder grades than those indicated tend to overheat and crack the carbide.

**Structure:** The common structure numbers for carbide-tool grinding are 7 and 8. The larger cup-wheels (10 to 14 inches or 254–356 mm) may be of the porous type and be designated as 12P. The standard structure numbers range from 1 to 15 with progressively higher numbers indicating less density and more open wheel structure.

**Diamond Wheels.**—Wheels with diamond-impregnated grinding faces are fast and cool cutting and have a very low rate of wear. They are used extensively both for resharpening and for finish grinding of carbide tools when preliminary roughing is required. Diamond wheels are also adapted for sharpening multi-tooth cutters such as milling cutters, reamers, etc., which are ground in a cutter-grinding machine.

**Resinoid bonded** wheels are commonly used for grinding chipbreakers, milling cutters, reamers or other multi-tooth cutters. They are also applicable to precision grinding of carbide dies, gages, and various external, internal and surface grinding operations. Fast, cool cutting action is characteristic of these wheels.

**Metal bonded** wheels are often used for offhand grinding of single-point tools especially when durability or long life and resistance to grooving of the cutting face are considered more important than the rate of cutting. **Vitrified bonded** wheels are used both for roughing of chipped or very dull tools and for ordinary resharpening and finishing. They provide rigidity for precision grinding, a porous structure for fast cool cutting, sharp cutting action and durability.

**Diamond Wheel Grit Sizes.**—For roughing with diamond wheels, a grit size of 100 is the most common both for offhand and machine grinding.

Grit sizes of 120 and 150 are frequently used in offhand grinding of single-point tools 1) for resharpening; 2) for a combination roughing and finishing wheel; and 3) for chip-breaker grinding.

Grit sizes of 220 or 240 are used for ordinary finish grinding all types of tools (offhand and machine) and also for cylindrical, internal and surface finish grinding. Grits of 320 and 400 are used for “lapping” to obtain very fine finishes, and for hand hones. A grit of 500 is for lapping to a mirror finish on such work as carbide gages and boring or other tools for exceptionally fine finishes.

**Diamond Wheel Grades.**—Diamond wheels are made in several different grades to better adapt them to different classes of work. The grades vary for different types and shapes of wheels. Standard Norton grades are H, J, and L for resinoid-bonded wheels, grade N for metal-bonded wheels and grades J, L, N, and P for vitrified wheels. Harder and softer grades than standard may at times be used to advantage.

**Diamond Concentration.**—The relative amount (by carat weight) of diamond in the diamond section of the wheel is known as the “diamond concentration.” Concentrations of 100 (high), 50 (medium) and 25 (low) ordinarily are supplied. A concentration of 50 represents one-half the diamond content of 100 (if the depth of the diamond is the same in each case) and 25 equals one-fourth the content of 100 or one-half the content of 50 concentration.

**100 Concentration:** Generally interpreted to mean 72 carats of diamond/in<sup>3</sup> of abrasive section. (A 75 concentration indicates 54 carats/in<sup>3</sup>.) Recommended (especially in grit sizes up to about 220) for general machine grinding of carbides, and for grinding cutters and chipbreakers. Vitrified and metal-bonded wheels usually have 100 concentration.

**50 Concentration:** In the finer grit sizes of 220, 240, 320, 400, and 500, a 50 concentration is recommended for offhand grinding with resinoid-bonded cup-wheels.

**25 Concentration:** A low concentration of 25 is recommended for offhand grinding with resinoid-bonded cup-wheels with grit sizes of 100, 120 and 150.

**Depth of Diamond Section:** The radial depth of the diamond section usually varies from  $\frac{1}{16}$  to  $\frac{1}{4}$  inch (1.6 to 6.4 mm). The depth varies somewhat according to the wheel size and type of bond.

**Dry Versus Wet Grinding of Carbide Tools.**—In using silicon carbide wheels, grinding should be done either absolutely dry or with enough coolant to flood the wheel and tool. Satisfactory results may be obtained either by the wet or dry method. However, dry grinding is the most prevalent usually because, in wet grinding, operators tend to use an inadequate supply of coolant to obtain better visibility of the grinding operation and avoid getting wet; hence checking or cracking in many cases is more likely to occur in wet grinding than in dry grinding.

**Wet Grinding with Silicon Carbide Wheels:** One advantage commonly cited in connection with wet grinding is that an ample supply of coolant permits using wheels about one grade harder than in dry grinding, thus increasing the wheel life. Plenty of coolant also prevents thermal stresses and the resulting cracks, and there is less tendency for the wheel to load. A dust exhaust system also is unnecessary.

**Wet Grinding with Diamond Wheels:** In grinding with diamond wheels, the general practice is to use a coolant to keep the wheel face clean and promote free cutting. The amount of coolant may vary from a small stream to a coating applied to the wheel face by a felt pad.

**Coolants for Carbide Tool Grinding.**—In grinding either with silicon carbide or diamond wheels, a coolant that is used extensively consists of water plus a small amount either of soluble oil, sal soda, or soda ash to prevent corrosion. One prominent manufacturer recommends for silicon carbide wheels about 1 ounce of soda ash per gallon of water, and for diamond wheels kerosene. The use of kerosene is quite general for diamond wheels and is usually applied to the wheel face by a felt pad. Another coolant recommended for diamond wheels consists of 80 percent water and 20 percent soluble oil.

**Peripheral Versus Flat Side Grinding.**—In grinding single-point carbide tools with silicon carbide wheels, the roughing preparatory to finishing with diamond wheels may be done either by using the flat face of a cup-shaped wheel (side grinding) or the periphery of a “straight” or disk-shaped wheel. Even where side grinding is preferred, the periphery of a straight wheel may be used for heavy roughing as in grinding back-chipped or broken tools (see left-hand diagram). Reasons for preferring peripheral grinding include faster cutting with less danger of localized heating and checking especially in grinding broad surfaces. The advantages usually claimed for side grinding are that proper rake or relief angles are easier to obtain and the relief or land is ground flat. The diamond wheels used for tool sharpening are designed for side grinding. (See right-hand diagram.)

**Lapping Carbide Tools.**—Carbide tools may be finished by lapping, especially if an exceptionally fine finish is required on the work as, for example, with tools used for precision boring or turning nonferrous metals. If the finishing is done by using a diamond wheel of very fine grit (such as 240, 320, or 400), the operation is often called “lapping.” A second lapping method is by means of a power-driven lapping disk charged with diamond dust, Norbide powder, or silicon carbide finishing compound. A third method is by using a hand lap or hone usually of 320 or 400 grit. In many plants, the finishes obtained with carbide tools meet requirements without a special lapping operation. In all cases, any feather edge which may be left on tools should be removed, and it is good practice to bevel the edges of roughing tools at 45 degrees to leave a chamfer 0.005 to 0.010 inch wide (0.127–0.254 mm). This is done by hand honing, and the object is to prevent crumbling or flaking off at the edges when hard scale or heavy chip pressure is encountered.

**Hand Honing.** The cutting edge of carbide tools, and tools made from other tool materials, is sometimes hand honed before it is used in order to strengthen the cutting edge. When interrupted cuts or heavy roughing cuts are to be taken, or when the grade of carbide is slightly too hard, hand honing is beneficial because it will prevent chipping or even possibly, breakage of the cutting edge. Whenever chipping is encountered, hand honing the cutting edge before use will be helpful. It is important, however, to hone the edge lightly and only when necessary. Heavy honing will always cause a reduction in tool life. Normally, removing 0.002 to 0.004 inch (0.051–0.102 mm) from the cutting edge is sufficient. When indexable inserts are used, the use of pre-honed inserts is preferred to hand honing, although sometimes an additional amount of honing is required. Hand honing of carbide tools in between cuts is sometimes done to defer grinding or to increase the life of a cutting edge on an indexable insert. If correctly done, so as not to change the relief angle, this procedure is sometimes helpful. If improperly done, it can result in a reduction in tool life.

**Chipbreaker Grinding.**—For this operation a straight diamond wheel is used on a universal and cutter grinder, a small surface grinder, or a special chipbreaker grinder. A resinoid-bonded wheel of grade J or N commonly is used, and the tool is held rigidly in an adjustable holder or vise. The width of the diamond wheel usually varies from  $\frac{1}{8}$  to  $\frac{1}{4}$  inch (3.2–6.4 mm). A vitrified bond may be used for wheels as thick as  $\frac{1}{4}$  inch (6.35 mm), and a resinoid bond for relatively narrow wheels.

**Summary of Miscellaneous Points.**—In grinding a single-point carbide tool, traverse it across the wheel face continuously to avoid localized heating. This traverse movement should be quite rapid in using silicon carbide wheels and comparatively slow with diamond wheels. A hand traversing and feeding movement, whenever practicable, is generally recommended because of greater sensitivity. In grinding, maintain a constant, moderate pressure. Manipulating the tool so as to keep the contact area with the wheel as small as possible will reduce heating and increase the rate of stock removal. Never cool a hot tool by dipping it in a liquid, as this may crack the tip. Wheel rotation should preferably be *against* the cutting edge or from the front face toward the back. If the grinder is driven by a reversing motor, opposite sides of a cup wheel can be used for grinding right- and left-hand tools and with rotation against the cutting edge. If it is necessary to grind the top face of a single-point tool, this should precede the grinding of the side and front relief, and top-face grinding should be minimized to maintain the tip thickness. In machine grinding with a diamond wheel, limit the feed per traverse to 0.001 inch (0.025 mm) for 100 to 120 grit; 0.0005 inch (0.013 mm) for 150 to 240 grit; and 0.0002 inch (0.005 mm) for 320 grit and finer.

### Meshes, Sieves, and Screens

Sieving or screening is a method of categorizing powder particle size by running the powder through a specific size screen or screens. Powder can be separated into two or more size fractions by stacking the screens (Fig. 1), thereby determining the powder

particle size distribution. Sieves and screens are usually used for larger particle sized materials, greater than 44 micron (325 Mesh).

Fig. 1.

Two scales are frequently used to classify particle sizes; *US Sieve Series* and *Tyler Mesh Size*, also called *Tyler Standard Sieve Series*. The larger the mesh number the smaller the particle size of the powder. The Tyler mesh number indicates the number of openings in the screen per linear inch.

- A -6 mesh powder contains particles that pass through a 6 mesh screen. A -6 mesh powder has particles that measure less than 3360 microns.
- A powder that is -325 mesh has particles that measure less than 44 micron.

*Market Grade* sieves use thicker wire than other commercial grades, and are commonly used for applications where mesh strength (and therefore screen life) is important.

*Mill Grade* sieves use a thinner wire diameter, which provide more open area for a given mesh size. Therefore, Mill Grade sieves are used when throughput is more important than durability.

*Tensile Bolting Cloth* uses very fine wire diameters, and thus provides the highest fraction of open area of all sieve types; it is often used for fine sifting and screen printing.

A comparison of standard screen and sieve sizes are indicated in [Table 2](#) and [Table 5](#).

*Example 1:* A tantalum powder has the following description:

Tantalum Powder, -325 Mesh, 3N8 Purity

The minus (-) sign in the designation -325 indicates that particle sizes of less than 44 micron ( $\mu\text{m}$ ) ([Table 1](#)) are able to pass through a 325 mesh screen. Much of the powder may be considerably smaller and still qualify as a -325 mesh powder, but the designation -325 mesh simply means that the powder will pass through a 325 mesh screen.

The 3N8 Purity indicates a purity of 99.98% relative to other rare earth powders; similarly, 2N5 indicates 99.5% purity, 5N8 indicates 99.9998%, and 6N indicates 99.9999%, etc.

*Example 2:* illustrates two stacked screens. If a powder is required to fall within a specified max/min range of sizes, two mesh sizes maybe specified such as in the following:

Tantalum Powder, -40+100 Mesh, 3N8 Purity

The -40 designation indicates that the powder will pass through an 40 mesh screen, and the designation +100 indicates that particles are trapped (do not pass through) by a 100 mesh screen. Thus -40+100 indicates a range of particle sizes small enough to pass the 40 mesh and too large to pass the 100 mesh screen.

**Table 1. Commercial Sieve Mesh Dimensions**

As indicated by the fragment below from Table 1, the specified particles are therefore smaller than 40 mesh and larger than 100 mesh. Particles trapped above the 100 mesh screen range in size from greater than 149  $\mu\text{m}$  to 400  $\mu\text{m}$ . Particles smaller than 149 micron are passed through the 100 mesh screen. Approximately 90 percent of the particles trapped will fit within the specified range.

Sieve size (mm)	Opening		Standard Mesh	
	(in.)	( $\mu\text{m}$ )	US	Tyler
...	...	...	...	...
0.4	0.0165	400	40	35
0.149	0.0059	149	100	100

Sieves and screens are stacked with the largest opening (smallest mesh size) above, and the smallest opening (largest mesh size) below, as in Fig. 2.

Fig. 2.

BS 812-103.1:1985 Withdrawn replaced by BS EN 933-1:2011.

BS EN 933-1:2011 describes two methods for the determination of the particle size distribution of samples of aggregates and fillers by sieving.

**Abrasive Grit Number.**—Standard abrasive grain sizes are designated by numbers. These numbers range from number 8, which is the coarsest, to number 240, which is the finest. The allowable limits for the sizing of aluminum-oxide and silicon-carbide abrasives for grinding wheel manufacture are given in US Simplified Practice Recommendation 118. These numbers in most cases equal approximately the number of sieve openings per inch in the United States Standard Fine Sieve series. For example, a number 30 sieve has 0.0232-inch openings and a sieve wire diameter of 0.0130 inch, making the pitch equal to 0.0362 inch; hence there are 27.6 meshes per inch. The United States Standard Fine Sieve series ranges from number  $3\frac{1}{2}$  to number 400.

**Grading Abrasives:** In the actual grading of abrasives, several standard sieves are used. To illustrate, take grit No. 10. All material must pass through the coarsest sieve—in this case the No. 7. Through the next to the coarsest sieve, termed the “control sieve”—in this case the No. 8—all material may pass, but not more than 15 percent may be retained on it. At least 45 percent must pass through No. 8, and be retained on No. 10 sieve, but it is permissible to have 100 percent pass through No. 8, and remain on No. 10 sieve, the requirement being that the grain passing through No. 8, and retained on No. 10 and No. 12 must add to at least 80 percent; consequently, if 45 percent passed through No. 8 sieve and was retained on No. 10 sieve, then at least 35 percent must be retained on the No. 12 sieve. Not more than 3 percent is permitted to pass through the No. 14 sieve.

**CUTTING SPEEDS AND FEEDS**

**Work Materials.**—The large number of work materials that are commonly machined vary greatly in their basic structure and the ease with which they can be machined. Yet it is possible to group together certain materials having similar machining characteristics, for the purpose of recommending the cutting speed at which they can be cut. Most materials that are machined are metals and it has been found that the most important single factor influencing the ease with which a metal can be cut is its microstructure, followed by any cold-work that may have been done to the metal, which increases its hardness. Metals that have a similar, but not necessarily the same microstructure, will tend to have similar machining characteristics. Thus, the grouping of the metals in the accompanying tables has been done on the basis of their microstructure.

Except for a few soft and gummy metals, experience indicates that harder metals are more difficult to cut than softer metals. Also, any given metal is more difficult to cut when it is in a harder form than when it is softer. It is more difficult to penetrate the harder metal and more power is required. These factors in turn will generate a higher cutting temperature at any given cutting speed, thereby making it necessary to use a slower speed, for the cutting temperature must always be kept within the limits that can be sustained by the cutting tool without failure. Hardness, then, is an important property that must be considered when machining a given metal. Hardness alone, however, cannot be used as a measure of cutting speed. For example, if pieces of AISI 11L17 and AISI 1117 steel both have a hardness of 150 BHN (Brinell Hardness Number), their recommended cutting speeds for high-speed steel tools may be 140 fpm (0.71 m/s) and 130 fpm (0.66 m/s), respectively. In some metals, two entirely different microstructures can produce the same hardness. As an example, a fine pearlite microstructure and a tempered martensite microstructure can result in the same hardness in a steel. These microstructures will not machine alike. For practical purposes, however, information on hardness is usually easier to obtain than information on microstructure; thus, hardness alone is usually used to differentiate between different cutting speeds for machining a metal. In some situations, the hardness of a metal to be machined is not known. When the hardness is not known, the material condition can be used as a guide.

The surface of ferrous metal castings has a scale that is more difficult to machine than the metal below. Some scale is more difficult to machine than others, depending on the foundry sand used, the casting process, the method of cleaning the casting, and the type of metal cast. Special electrochemical treatments sometimes can be used that almost entirely eliminate the effect of the scale on machining, although castings so treated are not frequently encountered. Usually, when casting scale is encountered, the cutting speed is reduced approximately 5 or 10 percent. Difficult-to-machine surface scale can also be encountered when machining hot-rolled or forged steel bars.

Metallurgical differences that affect machining characteristics are often found within a single piece of metal. The occurrence of hard spots in castings is an example. Different microstructures and hardness levels may occur within a casting as a result of variations in the cooling rate in different parts of the casting. Such variations are less severe in castings that have been heat treated. Steel bar stock is usually harder toward the outside than toward the center of the bar. Sometimes there are slight metallurgical differences along the length of a bar that can affect its cutting characteristics.

**Cutting Tool Materials.**—The recommended cutting speeds and feeds in the accompanying tables are given for high-speed steel, coated and uncoated carbides, ceramics, cermets, and polycrystalline diamonds. More data are available for HSS and carbides because these materials are the most commonly used. Other materials that are used to make cutting tools are cemented oxides or ceramics, cermets, cast nonferrous alloys (Stellite), single-crystal diamonds, polycrystalline diamonds, and cubic boron nitride.

*Carbon Tool Steel:* It is used primarily to make the less expensive drills, taps, and reamers. It is seldom used to make single-point cutting tools. Hardening in carbon steels is very shallow, although some have a small amount of vanadium and chromium added to improve their hardening quality. The cutting speed to use for plain carbon tool steel should be approximately one-half of the recommended speed for high-speed steel.

*High-Speed Steel:* This designates a number of steels having several properties that enhance their value as cutting tool material. They can be hardened to a high initial or room-temperature hardness ranging from 63 to 65 RC (Rockwell C scale) for ordinary high-speed steels and up to 70 RC for the so-called super high-speed steels. They retain sufficient hardness at temperatures up to 1,000 or 1,100°F (573 or 593°C) to enable them to cut at cutting speeds that will generate these tool temperatures, and return to their original hardness when cooled to room temperature. They harden very deeply, enabling high-speed steels to be ground to the tool shape from solid stock and to be reground many times without sacrificing hardness at the cutting edge. High-speed steels can be made soft by annealing so that they can be machined into complex cutting tools such as drills, reamers, and milling cutters and then hardened.

The principal alloying elements of high-speed steels are tungsten (W), molybdenum (Mo), chromium (Cr), vanadium (V), together with carbon (C). There are a number of grades of high-speed steel that are divided into two types: tungsten high-speed steels and molybdenum high-speed steels. Tungsten high-speed steels are designated by the prefix T before the number that designates the grade. Molybdenum high-speed steels are designated by the prefix letter M. There is little performance difference between comparable grades of tungsten or molybdenum high-speed steel.

The addition of 5 to 12 percent cobalt to high-speed steel increases its hardness at the temperatures encountered in cutting, thereby improving its wear resistance and cutting efficiency. Cobalt slightly increases the brittleness of high-speed steel, making it susceptible to chipping at the cutting edge. For this reason, cobalt high-speed steels are primarily made into single-point cutting tools that are used to take heavy roughing cuts in abrasive materials and through rough abrasive surface scales.

The M40 series and T15 are a group of high-hardness or so-called super high-speed steels that can be hardened to 70 RC; however, they tend to be brittle and difficult to grind. For cutting applications, they are usually heat treated to 67–68 RC to reduce their brittleness and tendency to chip. The M40 series is appreciably easier to grind than T15. They are recommended for machining tough die steels and other difficult-to-cut materials; they are not recommended for applications where conventional high-speed steels perform well. High-speed steels made by the powder-metallurgy process are tougher and have an improved grindability when compared with similar grades made by the customary process. Tools made of these steels can be hardened about 1 RC higher than comparable high-speed steels made by the customary process without a sacrifice in toughness. They are particularly useful in applications involving intermittent cutting and where tool life is limited by chipping. All these steels augment rather than replace the conventional high-speed steels.

*Cemented Carbides* are also called sintered carbides or simply carbides. They are harder than high-speed steels and have excellent wear resistance. Information on these and other hard metal tools is included in the section *CEMENTED CARBIDES* starting on page 860.

Cemented carbides retain a very high degree of hardness at temperatures up to 1400°F (760°C) and even higher; therefore, very fast cutting speeds can be used. When used at fast cutting speeds, they produce good surface finishes on the workpiece. Carbides are more brittle than high-speed steel and, therefore, must be used with more care.

There are four distinct types of carbides: 1) straight tungsten carbides; 2) crater-resistant carbides; 3) titanium carbides; and 4) coated carbides.

*Straight Tungsten Carbide:* This is the most abrasion-resistant cemented carbide and is used to machine gray cast iron, most nonferrous metals, and nonmetallic materials, where abrasion resistance is the primary criterion. Straight tungsten carbide will rapidly form a crater on the tool face when used to machine steel, which reduces the life of the tool. Titanium carbide is added to tungsten carbide in order to counteract the rapid formation of the crater. In addition, tantalum carbide is usually added to prevent the cutting edge from deforming when subjected to the intense heat and pressure generated in taking heavy cuts.

*Crater-Resistant Carbides:* These carbides, containing titanium and tantalum carbides in addition to tungsten carbide, are used to cut steels, alloy cast irons, and other materials that have a strong tendency to form a crater.

*Titanium Carbides:* These carbides are made entirely from titanium carbide and small amounts of nickel and molybdenum. They have an excellent resistance to cratering and to heat. Their high hot hardness enables them to operate at higher cutting speeds, but they are more brittle and less resistant to mechanical and thermal shock. Therefore, they are not recommended for taking heavy or interrupted cuts. Titanium carbides are less abrasion-resistant and not recommended for cutting through scale or oxide films on steel. Although the resistance to cratering of titanium carbides is excellent, failure caused by crater formation can sometimes occur because the chip tends to curl very close to the cutting edge, thereby forming a small crater in this region that may break through.

*Coated Carbides:* These are available only as indexable inserts because the coating would be removed by grinding. The principal coating materials are titanium carbide (TiC), titanium nitride (TiN), and aluminum oxide ( $Al_2O_3$ ). A very thin layer approximately 0.0002 inch (5.08  $\mu m$ ) of coating material is deposited over a cemented carbide insert; the material below the coating is the substrate. The overall performance of the coated carbide is limited by the substrate, which provides the required toughness, resistance to deformation, and thermal shock. With an equal tool life, coated carbides can operate at higher cutting speeds than uncoated carbides. The increase may be 20 to 30 percent and sometimes up to 50 percent faster. Titanium carbide and titanium nitride coated carbides usually operate in the medium (200–800 fpm, 1.0–4.1 m/s) cutting speed range, and aluminum oxide coated carbides are used in the higher (800–1600 fpm, 4.1–8.1 m/s) cutting speed range.

*Carbide Grade Selection:* The selection of the best grade of carbide for a particular application is very important. An improper grade of carbide will result in a poor performance—it may even cause the cutting edge to fail before any significant amount of cutting has been done. Because of the many grades and the many variables that are involved, the carbide producers should be consulted to obtain recommendations for the application of their grades of carbide. A few general guidelines can be given that are useful to form an orientation. Metal cutting carbides usually range in hardness from about 89.5 to 93 RA (Rockwell A scale) with the exception of titanium carbide, which has a hardness range of 90.5 to 93.5 RA. Generally, the harder carbides are more wear-resistant and more brittle, whereas the softer carbides are less wear-resistant but tougher. A choice of hardness must be made to suit the given application. The very hard carbides are generally used for taking light finishing cuts. For other applications, select the carbide that has the highest hardness with sufficient strength to prevent chipping or breaking. Straight tungsten carbide grades should always be used unless cratering is encountered. Straight tungsten carbides are used to machine gray cast iron, ferritic malleable iron, austenitic stainless steel, high-temperature alloys, copper, brass, bronze, aluminum alloys, zinc alloy die castings, and plastics. Crater-resistant carbides should be used to machine plain carbon steel, alloy steel, tool steel, pearlitic malleable iron, nodular iron, other highly alloyed cast irons, ferritic stainless steel, martensitic stainless steel, and certain high-temperature alloys. Titanium carbides are recommended for taking high-speed finishing and semifinishing cuts on steel, especially the low-carbon, low-alloy steels, which are less abrasive and have a strong tendency to form a crater. They are also used to take light cuts on alloy cast iron and on some high-nickel alloys. Nonferrous materials, such as some aluminum alloys

and brass, that are essentially nonabrasive may also be machined with titanium carbides. Abrasive materials and others that should not be machined with titanium carbides include gray cast iron, titanium alloys, cobalt- and nickel-base superalloys, stainless steel, bronze, many aluminum alloys, fiberglass, plastics, and graphite. The feed used should not exceed about 0.020 inch/rev (0.51 mm/rev).

Coated carbides can be used to take cuts ranging from light finishing to heavy roughing on most materials that can be cut with these carbides. The coated carbides are recommended for machining all free-machining steels, all plain carbon and alloy steels, tool steels, martensitic and ferritic stainless steels, precipitation-hardening stainless steels, alloy cast iron, pearlitic and martensitic malleable iron, and nodular iron. They are also recommended for taking light finishing and roughing cuts on austenitic stainless steels. Coated carbides should not be used to machine nickel- and cobalt-base superalloys, titanium and titanium alloys, brass, bronze, aluminum alloys, pure metals, refractory metals, and nonmetals such as fiberglass, graphite, and plastics.

*Ceramic Cutting Tool Materials:* These are made from finely powdered aluminum oxide particles sintered into a hard dense structure without a binder material. Aluminum oxide is also combined with titanium carbide to form a composite, which is called a cermet. These materials have a very high hot hardness enabling very high cutting speeds to be used. For example, ceramic cutting tools have been used to cut AISI 1040 steel at a cutting speed of 18,000 fpm (91.4 m/s) with a satisfactory tool life. However, much lower cutting speeds, in the range of 1000–4000 fpm (5.1–20.3 m/s) and lower, are more common because of limitations placed by the machine tool, cutters, and chucks. Although most applications of ceramic and cermet cutting tool materials are for turning, they have also been used successfully for milling. Ceramics and cermets are relatively brittle and a special cutting edge preparation is required to prevent chipping or edge breakage. This preparation consists of honing or grinding a narrow flat land, 0.002 to 0.006 inch (50.8–152.4  $\mu\text{m}$ ) wide, on the cutting edge that is made about 30 degrees with respect to the tool face. For some heavy-duty applications, a wider land is used. The setup should be as rigid as possible and the feed rate should not normally exceed 0.020 inch (508  $\mu\text{m}$ ), although 0.030 inch (762  $\mu\text{m}$ ) has been used successfully. Ceramics and cermets are recommended for roughing and finishing operations on all cast irons, plain carbon and alloy steels, and stainless steels. Materials up to a hardness of 60 RC (Rockwell C scale) can be cut with ceramic and cermet cutting tools. These tools should not be used to machine aluminum and aluminum alloys, magnesium alloys, titanium, and titanium alloys.

*Cast Nonferrous Alloy:* Cutting tools of this alloy are made from tungsten, tantalum, chromium, and cobalt plus carbon. Other alloying elements are also used to produce materials with high temperature and wear resistance. These alloys cannot be softened by heat treatment and must be cast and ground to shape. The room-temperature hardness of cast nonferrous alloys is lower than for high-speed steel, but the hardness and wear resistance is retained to a higher temperature. The alloys are generally marketed under trade names such as Stellite, Crobalt, and Tantung. The initial cutting speed for cast nonferrous tools can be 20 to 50 percent greater than the recommended cutting speed for high-speed steel.

*Diamond Cutting Tools* are available in three forms: single-crystal natural diamonds shaped to a cutting edge and mounted on a tool holder on a boring bar; polycrystalline diamond indexable inserts made from synthetic or natural diamond powders that have been compacted and sintered into a solid mass, and chemically vapor-deposited diamond. Single-crystal and polycrystalline diamond cutting tools are very wear-resistant, and recommended for machining abrasive materials that cause other cutting tool materials to wear rapidly. Typical of abrasive materials machined with single-crystal and polycrystalline diamond tools and cutting speeds used are the following: fiberglass, 300 to 1000 fpm (1.5 to 5.1 m/s); fused silica, 900 to 950 fpm (4.6 to 4.8 m/s); reinforced melamine plastics, 350 to 1000 fpm (1.8 to 5.1 m/s); reinforced phenolic plastics, 350 to 1000 fpm (1.8 to 5.1 m/s); thermosetting plastics, 300 to 2000 fpm (1.5 to 10.2 m/s); Teflon, 600 fpm

(3.0 m/s); nylon, 200 to 300 fpm (1.0 to 1.5 m/s); mica, 300 to 1000 fpm (1.5 to 5.1 m/s); graphite, 200 to 2000 fpm (1.0 to 10.1 m/s); babbitt bearing metal, 700 fpm (3.6 m/s); and aluminum-silicon alloys, 1000 to 2000 fpm (5.1 to 10.2 m/s).

Another important application of diamond cutting tools is to produce fine surface finishes on soft nonferrous metals that are difficult to finish by other methods. Surface finishes of 1 to 2 microinches (0.025 to 0.051  $\mu\text{m}$ ) can be readily obtained with single-crystal diamond tools, and finishes down to 10 microinches (0.25  $\mu\text{m}$ ) can be obtained with polycrystalline diamond tools. In addition to babbitt and the aluminum-silicon alloys, other metals finished with diamond tools include: soft aluminum, 1000 to 2000 fpm (5.1 to 10.2 m/s); all wrought and cast aluminum alloys, 600 to 1500 fpm (3.0 to 7.6 m/s); copper, 1000 fpm (5.1 m/s); brass, 500 to 1000 fpm (2.5 to 5.1 m/s); bronze, 300 to 600 fpm (1.5 to 3.0 m/s); oilite bearing metal, 500 fpm (2.5 m/s); silver, gold, and platinum, 300 to 2500 fpm (1.5 to 12.7 m/s); and zinc, 1000 fpm (5.1 m/s). Ferrous alloys, such as cast iron and steel, should not be machined with diamond cutting tools because the high cutting temperatures generated will cause the diamond to transform into carbon.

*Chemically Vapor-Deposited (CVD) Diamond:* This tool material offers performance characteristics well suited to highly abrasive or corrosive materials, and hard-to-machine composites. CVD diamond is available in two forms: thick-film tools, which are fabricated by brazing CVD diamond tips, approximately 0.020 inch (0.51 mm) thick, to carbide substrates; and thin-film tools, having a pure diamond coating over the rake and flank surfaces of a ceramic or carbide substrate.

CVD is pure diamond, made at low temperatures and pressures, with no metallic binder phase. This diamond purity gives CVD diamond tools extreme hardness, high abrasion resistance, low friction, high thermal conductivity, and chemical inertness. CVD tools are generally used as direct replacements for PCD (polycrystalline diamond) tools, primarily in finishing, semifinishing, and continuous turning applications of extremely wear-intensive materials. The small grain size of CVD diamond (ranging from less than 1  $\mu\text{m}$  to 50  $\mu\text{m}$ ) yields superior surface finishes compared with PCD, and the higher thermal conductivity and better thermal and chemical stability of pure diamond allow CVD tools to operate at faster speeds without generating harmful levels of heat. The extreme hardness of CVD tools may also result in significantly longer tool life.

CVD diamond cutting tools are recommended for the following materials: aluminum and other ductile; nonferrous alloys such as copper, brass, and bronze; and highly abrasive composite materials such as graphite, carbon-carbon, carbon-filled phenolic, fiberglass, and honeycomb materials.

*Cubic Boron Nitride (CBN):* Next to diamond, CBN is the hardest known material. It will retain its hardness at a temperature of 1800°F and higher, making it an ideal cutting tool material for machining very hard and tough materials at cutting speeds beyond those possible with other cutting tool materials. Indexable inserts and cutting tool blanks made from this material consist of a layer, approximately 0.020 inch thick, of polycrystalline cubic boron nitride firmly bonded to the top of a cemented carbide substrate. Cubic boron nitride is recommended for rough and finish turning hardened plain carbon and alloy steels, hardened tool steels, hard cast irons, all hardness grades of gray cast iron, and superalloys. As a class, the superalloys are not as hard as hardened steel; however, their combination of high strength and tendency to deform plastically under the pressure of the cut, or gumminess, places them in the class of hard-to-machine materials. Conventional materials that can be readily machined with other cutting tool materials should not be machined with cubic boron nitride. Round indexable CBN inserts are recommended when taking severe cuts in order to provide maximum strength to the insert. When using square or triangular inserts, a large lead angle should be used, normally 15°, and whenever possible, 45°. A negative rake angle should always be used, which for most applications is negative 5°. The relief angle should be 5° to 9°. Although cubic boron nitride cutting tools can be used without a coolant, flooding the tool with a water-soluble type coolant is recommended.

**Cutting Speed, Feed, Depth of Cut, Tool Wear, and Tool Life.**—The cutting conditions that determine the rate of metal removal are the cutting speed, the feed rate, and the depth of cut. These cutting conditions and the nature of the material to be cut determine the power required to take the cut. The cutting conditions must be adjusted to stay within the power available on the machine tool to be used. Power requirements are discussed in *ESTIMATING SPEEDS AND MACHINING POWER* starting on page 1143.

Cutting conditions must also be considered in relation to the tool life. Tool life is defined as the cutting time to reach a predetermined amount of wear, usually flank wear. Tool life is determined by assessing the time—the tool life—at which a given predetermined flank wear is reached, 0.01 in. (0.25 mm), 0.015 in. (0.38 mm), 0.025 in. (0.64 mm), 0.03 in. (0.76 mm), for example. This amount of wear is called the tool wear criterion, and its size depends on the tool grade used. Usually, a tougher grade can be used with a bigger flank wear, but for finishing operations, where close tolerances are required, the wear criterion is relatively small. Other wear criteria are a predetermined value of the machined surface roughness and the depth of the crater that develops on the rake face of the tool.

ANSI/ASME B94.55M, specification for tool life testing with single-point tools, defines the end of tool life as a given amount of wear on the flank of a tool. This standard is followed when making scientific machinability tests with single-point cutting tools in order to achieve uniformity in testing procedures so that results from different machinability laboratories can be readily compared. It is not practicable or necessary to follow this standard in the shop; however, it should be understood that the cutting conditions and tool life are related.

Tool life is influenced most by cutting speed, then by feed rate, and least by depth of cut. When depth of cut is increased to about 10 times greater than the feed, a further increase in the depth of cut will have no significant effect on tool life. This characteristic of the cutting tool performance is very important in determining the operating or cutting conditions for machining metals. Conversely, if the cutting speed or feed is decreased, the increase in the tool life will be proportionately greater than the decrease in the cutting speed or the feed.

Tool life is reduced when either feed or cutting speed is increased. For example, the cutting speed and the feed may be increased if a shorter tool life is accepted; furthermore, the reduction in the tool life will be proportionately greater than the increase in the cutting speed or the feed. However, it is less well understood that a higher feed rate (feed/rev  $\times$  speed) may result in a longer tool life if a higher feed/rev is used in combination with a lower cutting speed. This principle is well illustrated in the speed tables of this section, where two sets of speed and feed data are given (labeled *optimum* and *average*) that result in the same tool life. The *optimum* set results in a greater feed rate (i.e., increased productivity) although the feed/rev is higher and cutting speed lower than the *average* set. Complete instructions for using the speed tables and for estimating tool life are given in *How to Use the Tables* starting on page 1090.

**Selecting Cutting Conditions.**—The first step in establishing cutting conditions is to select depth of cut. The depth of cut will be limited by the amount of metal to be machined from the workpiece, by the power available on the machine tool, by the rigidity of the workpiece and cutting tool, and by the rigidity of the setup. Depth of cut has the least effect upon tool life, so the heaviest possible depth of cut should always be used.

The second step is to select the feed (feed/rev for turning, drilling, and reaming, or feed/tooth for milling). The available power must be sufficient to make the required depth of cut at the selected feed. The maximum feed possible that will produce an acceptable surface finish should be selected.

The third step is to select the cutting speed. Although the accompanying tables provide recommended cutting speeds and feeds for many materials, experience in machining a certain material may form the best basis for adjusting given cutting speeds to a particular job. In general, depth of cut should be selected first, followed by feed, and last cutting speed.

**Table 1. Tool Troubleshooting Check List**

Problem	Tool Material	Remedy
Excessive flank wear—tool life too short	Carbide	<ol style="list-style-type: none"> <li>1. Change to harder, more wear-resistant grade</li> <li>2. Reduce the cutting speed</li> <li>3. Reduce the cutting speed and increase the feed to maintain production</li> <li>4. Reduce the feed</li> <li>5. For work-hardenable materials—increase the feed</li> <li>6. Increase the lead angle</li> <li>7. Increase the relief angles</li> </ol>
	HSS	<ol style="list-style-type: none"> <li>1. Use a coolant</li> <li>2. Reduce the cutting speed</li> <li>3. Reduce the cutting speed and increase the feed to maintain production</li> <li>4. Reduce the feed</li> <li>5. For work-hardenable materials—increase the feed</li> <li>6. Increase the lead angle</li> <li>7. Increase the relief angle</li> </ol>
Excessive cratering	Carbide	<ol style="list-style-type: none"> <li>1. Use a crater-resistant grade</li> <li>2. Use a harder, more wear-resistant grade</li> <li>3. Reduce the cutting speed</li> <li>4. Reduce the feed</li> <li>5. Widen the chip breaker groove</li> </ol>
	HSS	<ol style="list-style-type: none"> <li>1. Use a coolant</li> <li>2. Reduce the cutting speed</li> <li>3. Reduce the feed</li> <li>4. Widen the chip breaker groove</li> </ol>
Cutting edge chipping	Carbide	<ol style="list-style-type: none"> <li>1. Increase the cutting speed</li> <li>2. Lightly hone the cutting edge</li> <li>3. Change to a tougher grade</li> <li>4. 	Carbide and HSS	<ol style="list-style-type: none"> <li>1. Check the setup for cause if chatter occurs</li> <li>2. Check the grinding procedure for tool overheating</li> <li>3. Reduce the tool overhang</li> </ol>
Cutting edge deformation	Carbide	<ol style="list-style-type: none"> <li>1. Change to a grade containing more tantalum</li> <li>2. Reduce the cutting speed</li> <li>3. Reduce the feed</li> </ol>
Poor surface finish	Carbide	<ol style="list-style-type: none"> <li>1. Increase the cutting speed</li> <li>2. If low cutting speed must be used, use a high additive EP cutting fluid</li> <li>4. For light cuts, use straight titanium carbide grade</li> <li>5. Increase the nose radius</li> <li>6. Reduce the feed</li> <li>7. Increase the relief angles</li> <li>8. Use positive rake tools</li> </ol>

**Table 1. (Continued) Tool Troubleshooting Check List**

Problem	Tool Material	Remedy
Poor surface finish (Continued)	HSS	1. Use a high additive EP cutting fluid 2. Increase the nose radius 3. Reduce the feed 4. Increase the relief angles 5. Increase the rake angles
	Diamond	1. Use diamond tool for soft materials
Notching at the depth of cut line	Carbide and HSS	1. Increase the lead angle
		2. Reduce the feed

**Cutting Speed Formulas**

Most machining operations are conducted on machine tools having a rotating spindle. Cutting speeds are usually given in feet or meters per minute and these speeds must be converted to spindle speeds, in revolutions per minute, to operate the machine. Conversion is accomplished by use of the following formulas:

$$\begin{array}{ll}
 \text{US Units:} & \text{Metric Units:} \\
 N = \frac{12V}{\pi D} = \frac{12 \times 252}{\pi \times 8} = 120 \text{ rpm} & N = \frac{1000V}{\pi D} = 318.3 \frac{V}{D} \text{ rpm}
 \end{array}$$

where  $N$  is the spindle speed in revolutions per minute (rpm);  $V$  is the cutting speed in feet per minute (fpm) for US units and meters per minute (m/min) for metric units. In turning,  $D$  is the diameter of the workpiece; in milling, drilling, reaming, and other operations that use a rotating tool,  $D$  is the cutter diameter in inches for US units and in millimeters for metric units.  $\pi = 3.1416$ .

*Example:* The cutting speed for turning a 4-inch (101.6-mm) diameter bar has been found to be 575 fpm (175.3 m/min). Using both the inch and metric formulas, calculate the lathe spindle speed.

$$\begin{array}{ll}
 \text{US Units:} & \text{Metric Units:} \\
 N = \frac{12V}{\pi D} = \frac{12 \times 575}{3.1416 \times 4} = 549 \text{ rpm} & N = \frac{1000V}{\pi D} = \frac{1000 \times 175.3}{3.1416 \times 101.6} = 549 \text{ rpm}
 \end{array}$$

When the cutting tool or workpiece diameter and the spindle speed in rpm are known, it is often necessary to calculate the cutting speed in feet or meters per minute. In this event, the following formulas are used.

$$\begin{array}{ll}
 \text{US Units:} & \text{Metric Units:} \\
 V = \frac{\pi DN}{12} \text{ fpm} & V = \frac{\pi DN}{1000} \text{ m/min}
 \end{array}$$

As in the previous formulas,  $N$  is the rpm and  $D$  is the diameter in inches for the US Units formula and in millimeters for the metric formula.

*Example:* Calculate the cutting speed in feet per minute and in meters per minute if the spindle speed of a  $\frac{3}{4}$ -inch (19.05-mm) drill is 400 rpm.

$$\begin{array}{ll}
 \text{US Units:} & V = \frac{\pi DN}{12} = \frac{\pi \times 0.75 \times 400}{12} = 78.5 \text{ fpm} \\
 \text{Metric Units:} & V = \frac{\pi DN}{1000} = \frac{\pi \times 19.05 \times 400}{1000} = 24.9 \text{ m/min}
 \end{array}$$

## Cutting Speeds and Equivalent RPM for Drills of Number and Letter Sizes

**SPEEDS AND FEEDS TABLES****How to Use the Tables**

The principal tables of speed and feed values are listed in the table below. In this section, **Table 1 through Table 9** give data for turning, **Table 10 through Table 15e** give data for milling, and **Table 17 through Table 23** give data for reaming, drilling, threading.

The materials in these tables are categorized by description, and Brinell Hardness Number (BHN) range or material condition. So far as possible, work materials are grouped by similar machining characteristics. The types of cutting tools (HSS end mill, for example) are identified in one or more rows across the tops of the tables. Other important details concerning the use of the tables are contained in the footnotes to **Table 1**, **Table 10** and **Table 17**. Information concerning specific cutting tool grades is given in notes at the end of each table.

Table 23. Speeds and Feeds for Drilling and Reaming Copper Alloys

Each of the cutting speed tables in this section contains two distinct types of cutting speed data. The speed columns at the left of each table contain traditional Handbook cutting speeds for use with high-speed steel (HSS) tools. For many years, this extensive collection of cutting data has been used successfully as starting speed values for turning, milling, drilling, and reaming operations. Instructions and adjustment factors for use with these speeds are given in Table 5c (feed and depth-of-cut factors) for turning, and in Table 15a (feed, depth of cut, and cutter diameter) for milling. Feeds for drilling and reaming are discussed in *Using the Speeds and Feeds Tables for Drilling, Reaming, and Threading* on page 1128. With traditional speeds and feeds, tool life may vary greatly from material to material, making it very difficult to plan efficient cutting operations, in particular for setting up unattended jobs on CNC equipment where the tool life must exceed cutting time, or at least be predictable so that tool changes can be scheduled. This limitation is reduced by using the combined feed/speed data contained in the remaining columns of the speed tables.

The combined feed/speed portion of the speed tables gives two sets of speed and feed data for each material represented. These feed/speed pairs are the *optimum* and *average* data (identified by *Opt.* and *Avg.*); the *optimum* set is always on the left side of the column and the *average* set is on the right. The *optimum* feed/speed data are approximate values of speed and feed that achieve minimum-cost machining by combining a high productivity rate with low tooling cost at a fixed tool life. The *average* feed/speed data are expected to achieve approximately the same tool life and tooling costs, but productivity is usually lower, so machining costs are higher. The data in this portion of the tables are given in the form of two numbers, of which the first is the feed in thousandths of an inch per revolution (or per tooth, for milling) and the second is the cutting speed in feet per minute. For example, the feed/speed set 15/215 represents a feed of 0.015 in/rev (0.38 mm/rev) at a speed of 215 fpm (65.6 m/min). Blank cells in the data tables indicate that feed/speed data for these materials were not available at the time of publication.

Generally, the feed given in the *optimum* set should be interpreted as the maximum safe feed for the given work material and cutting tool grade, and the use of a greater feed may result in premature tool wear or tool failure before the end of the expected tool life. The primary exception to this rule occurs in milling, where the feed may be greater than the *optimum* feed if the radial depth of cut is less than the value established in the table footnote; this topic is covered later in the milling examples. Thus, except for milling, the speed and tool life adjustment tables, to be discussed later, do not permit feeds that are greater than the *optimum* feed. On the other hand, the speed and tool life adjustment factors often result in cutting speeds that are well outside the given *optimum* to *average* speed range.

The combined feed/speed data in this section were contributed by Dr. Colding of Colding International Corp., Ann Arbor, MI. The speed, feed, and tool life calculations were made by means of a special computer program and a large database of cutting speed and tool life testing data. The COMP computer program uses tool life equations that are extensions of the F. W. Taylor tool life equation, first proposed in the early 1900s. The Colding tool life equations use a concept called equivalent chip thickness (*ECT*), which simplifies cutting speed and tool life predictions, and the calculation of cutting forces, torque, and power requirements. *ECT* is a basic metal cutting parameter that combines the four basic turning variables (depth of cut, lead angle, nose radius, and feed per revolution) into one basic parameter. For other metal cutting operations (milling, drilling, and grinding, for example), *ECT* also includes additional variables such as the number of teeth, width of cut, and cutter diameter. The *ECT* concept was first presented in 1931 by Prof. R. Woxen, who showed that equivalent chip thickness is a basic metal cutting parameter for high-speed cutting tools. Dr. Colding later extended the theory to include other tool materials and metal cutting operations, including grinding.

The equivalent chip thickness is defined by  $ECT = A/CEL$ , where *A* is the cross-sectional area of the cut (approximately equal to the feed times the depth of cut), and *CEL* is the cutting edge length or tool contact rubbing length. *ECT* and several other terms related to tool

geometry are illustrated in Fig. 1 and Fig. 2. Many combinations of feed, lead angle, nose radius and cutter diameter, axial and radial depth of cut, and numbers of teeth can give the same value of *ECT*. However, for a constant cutting speed, no matter how the depth of cut, feed, or lead angle, etc., are varied, if a constant value of *ECT* is maintained, the tool life will also remain constant. A constant value of *ECT* means that a constant cutting speed gives a constant tool life and an increase in speed results in a reduced tool life. Likewise, if *ECT* were increased and cutting speed were held constant, as illustrated in the generalized cutting speed versus *ECT* graph that follows, tool life would be reduced.

Fig. 1. Cutting Geometry, Equivalent Chip Thickness, and Cutting Edge Length

Fig. 2. Cutting Geometry for Turning

In the tables, the *optimum* feed/speed data have been calculated by COMP to achieve a fixed tool life based on the maximum *ECT* that will result in successful cutting, without premature tool wear or early tool failure. The same tool life is used to calculate the *average* feed/speed data, but these values are based on one-half of the maximum *ECT*. Because the data are not linear except over a small range of values, both *optimum* and *average* sets are required to adjust speeds for feed, lead angle, depth of cut, and other factors.

Tool life is the most important factor in a machining system, so speeds and feeds cannot be selected as simple numbers, but must be considered with respect to the many parameters that influence tool life. The accuracy of the combined feed/speed data presented is believed to be very high. However, machining is a variable and complicated process and use of the speeds and feeds tables requires the user to follow the instructions carefully to achieve good predictability. The results achieved, therefore, may vary due to material condition, tool material, machine setup, and other factors, and cannot be guaranteed.

The feed values given in the tables are valid for the standard tool geometries and fixed depths of cut that are identified in the table footnotes. If the cutting parameters and tool geometry established in the table footnotes are maintained, turning operations using either the *optimum* or *average* feed/speed data (Table 1 through Table 9) should achieve a constant tool life of approximately 15 minutes; tool life for milling, drilling, reaming, and threading data (Table 10 through Table 14 and Table 17 through Table 22) should be approximately 45 minutes. The reason for the different economic tool lives is the higher tooling cost associated with milling-drilling operations than for turning. If the cutting parameters or tool geometry are different from those established in the table footnotes, the same tool life (15 or 45 minutes) still may be maintained by applying the appropriate speed adjustment factors, or tool life may be increased or decreased using tool life adjustment factors. The use of the speed and tool life adjustment factors is described in the examples that follow.

Both the *optimum* and *average* feed/speed data given are reasonable values for effective cutting. However, the *optimum* set with its higher feed and lower speed (always the left entry in each table cell) will usually achieve greater productivity. In Table 1, for example, the two entries for turning 1212 free-machining plain carbon steel with uncoated carbide are 17/805 and 8/1075. These values indicate that a feed of 0.017 in/rev and a speed of 805 ft/min, or a feed of 0.008 in/rev and a speed of 1075 ft/min can be used for this material. The tool life, in each case, will be approximately 15 minutes. If one of these speed and feed pairs is assigned an arbitrary cutting time of 1 minute, then the relative cutting time of the second pair to the first is equal to the ratio of their respective feed  $\times$  speed products. Here, the same amount of material that can be cut in 1 minute, at the higher feed and lower speed (17/805), will require 1.6 minutes at the lower feed and higher speed (8/1075) because  $17 \times 805 / (8 \times 1075) = 1.6$  minutes.

Cutting Speed versus Equivalent Chip Thickness with Tool Life as a Parameter

**Speeds and Feeds Tables for Turning.**—Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use [Table 5c](#) to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use [Table 5a](#) to adjust given speeds for other feeds, depths of cut, and lead angles; use [Table 5b](#) to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

*Examples Using the Speeds and Feeds Tables for Turning:* The examples that follow give instructions for determining cutting speeds for turning. In general, the same methods are also used to find cutting speeds for milling, drilling, reaming, and threading, so reading through these examples may bring some additional insight to those other metalworking processes as well. The first step in determining cutting speeds is to locate the work material in the left column of the appropriate table for turning, milling, or drilling, reaming, and threading.

*Example 1, Turning:* Find the cutting speed for turning SAE 1074 plain carbon steel of 225 to 275 BHN (Brinell Hardness Number), using an uncoated carbide insert, a feed of 0.015 in/rev, and a depth of cut of 0.1 inch.

In [Table 1](#), speed and feed data for two types of uncoated carbide tools are given, one for hard tool grades, the other for tough tool grades. In general, use the speed data from the tool category that most closely matches the tool to be used because there are often significant differences in the speeds and feeds for different tool grades. From the uncoated carbide hard grade values, the *optimum* and *average* feed/speed data given in [Table 1](#) are 17/615 and 8/815, or 0.017 in/rev at 615 ft/min and 0.008 in/rev at 815 ft/min. Because the selected feed (0.015 in/rev) is different from either of the feeds given in the table, the cutting speed must be adjusted to match the feed. The other cutting parameters to be used must also be compared with the general tool and cutting parameters given in the speed tables to determine if adjustments need to be made for these parameters as well. The general tool and cutting parameters for turning, given in the footnote to [Table 1](#), are depth of cut = 0.1 inch, lead angle = 15°, and tool nose radius =  $\frac{3}{64}$  inch.

[Table 5a](#) is used to adjust the cutting speeds for turning (from [Table 1](#) through [Table 9](#)) for changes in feed, depth of cut, and lead angle. The new cutting speed  $V$  is found from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the *optimum* speed from the table (always the lower of the two speeds given), and  $F_f$  and  $F_d$  are the adjustment factors from [Table 5a](#) for feed and depth of cut, respectively.

To determine the two factors  $F_f$  and  $F_d$ , calculate the ratio of the selected feed to the *optimum* feed,  $0.015/0.017 = 0.9$ , and the ratio of the two given speeds  $V_{avg}$  and  $V_{opt}$ ,  $815/615 = 1.35$  (approximately). The feed factor  $F_f = 1.07$  is found in [Table 5a](#) at the intersection of the feed ratio row and the speed ratio column. The depth-of-cut factor  $F_d = 1.0$  is found in the same row as the feed factor in the column for depth of cut = 0.1 inch and lead angle = 15°, or for a tool with a 45° lead angle,  $F_d = 1.18$ . The final cutting speed for a 15° lead angle is  $V = V_{opt} \times F_f \times F_d = 615 \times 1.07 \times 1.0 = 658$  fpm. Notice that increasing the lead angle tends to permit higher cutting speeds; such an increase is also the general effect of increasing the tool nose radius, although nose radius correction factors are not included in this table. Increasing lead angle also increases the radial pressure exerted by the cutting tool on the workpiece, which may cause unfavorable results on long, slender workpieces.

*Example 2, Turning:* For the same material and feed as the previous example, what is the cutting speed for a 0.4-inch depth of cut and a 45° lead angle?

As before, the feed is 0.015 in/rev, so  $F_f$  is 1.07, but  $F_d = 1.03$  for depth of cut equal to 0.4 inch and a 45° lead angle. Therefore,  $V = 615 \times 1.07 \times 1.03 = 676$  fpm. Increasing the lead angle from 15° to 45° permits a much greater (four times) depth of cut, at the same feed and nearly constant speed. Tool life remains constant at 15 minutes. (*Continued on page 1104*)

**Table 1. Cutting Speeds and Feeds for Turning Plain Carbon and Alloy Steels**

Material AISI/SAE Designation	Brinell Hardness Number <sup>a</sup>	Tool Material

<sup>a</sup>Brinell Hardness Number given unless otherwise indicated by RC for hardness on the Rockwell C scale.

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of 3/4 inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbides, hard = 17, tough = 19, † = 15; coated carbides, hard = 11, tough = 14; ceramics, hard = 2, tough = 3, ‡ = 4; cermet = 7.

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use Table 5a to adjust the given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbides, tough = 15; Coated carbides, hard = 11, tough = 14; ceramics, hard = 2, tough = 3; cermet = 7; CBN = 1.

Use with Table 1 through Table 9. Not for HSS tools. Table 1 through Table 9 data, except for HSS tools, are based on depth of cut = 0.1 inch, lead angle = 15 degrees, and tool life = 15 minutes. For other depths of cut, lead angles, or feeds, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds given in the tables), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Use the value of these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the table. The depth-of-cut factor  $F_d$  is found in the same row as the feed factor in the right half of the table under the column corresponding to the depth of cut and lead angle. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). See the text for examples.

**Table 5b. Tool Life Factors for Turning with Carbides, Ceramics, Cermets, CBN, and Polycrystalline Diamond**

Tool Life, $T$ (minutes)	Turning with Carbides: Workpiece < 300 BHN			Turning with Carbides: Workpiece > 300 BHN; Turning with Ceramics: Any Hardness			Turning with Mixed Ceramics: Any Workpiece Hardness		
	$f_s$	$f_m$	$f_l$	$f_s$	$f_m$	$f_l$	$f_s$	$f_m$	$f_l$
15	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0
45	0.86	0.81	0.76	0.80	0.75	0.70	0.89	0.87	0.84
90	0.78	0.71	0.64	0.70	0.63	0.56	0.82	0.79	0.75
180	0.71	0.63	0.54	0.61	0.53	0.45	0.76	0.72	0.67

Except for HSS speed tools, speeds and feeds given in Table 1 through Table 9 are based on 15-minute tool life. To adjust speeds for another tool life, multiply the cutting speed for 15-minute tool life  $V_{15}$  by the tool life factor from this table according to the following rules: for small feeds where feed  $\leq 1/2 f_{opt}$ , the cutting speed for desired tool life is  $V_T = f_s \times V_{15}$ ; for medium feeds where  $1/2 f_{opt} < \text{feed} < 3/4 f_{opt}$ ,  $V_T = f_m \times V_{15}$ ; and for larger feeds where  $3/4 f_{opt} \leq \text{feed} \leq f_{opt}$ ,  $V_T = f_l \times V_{15}$ . Here,  $f_{opt}$  is the largest (optimum) feed of the two feed/speed values given in the speed tables.

**Table 5c. Cutting-Speed Adjustment Factors for Turning with HSS Tools**

0.050	1.27	0.55	1.250	31.75	0.72
0.060	1.52	0.50	1.375	34.93	0.71

For use with HSS tool data only from [Table 1](#) through [Table 9](#). Adjusted cutting speed  $V = V_{HSS} \times F_f \times F_d$ , where  $V_{HSS}$  is the tabular speed for turning with high-speed tools.

**Example 3, Turning:** Determine the cutting speed for turning 1055 steel of 175 to 225 BHN (Brinell Hardness Number) using a hard ceramic insert, a  $15^\circ$  lead angle, a 0.04-inch depth of cut and 0.0075 in/rev feed.

The two feed/speed combinations given in [Table 5a](#) for 1055 steel are 15/1610 and 8/2780, corresponding to 0.015 in/rev at 1610 fpm and 0.008 in/rev at 2780 fpm, respectively. In [Table 5a](#), the feed factor  $F_f = 1.75$  is found at the intersection of the row corresponding to feed/ $f_{opt} = 7.5/15 = 0.5$  and the column corresponding to  $V_{avg}/V_{opt} = 2780/1610 = 1.75$  (approximately). The depth-of-cut factor  $F_d = 1.23$  is found in the same row, under the column heading for a depth of cut = 0.04 inch and lead angle =  $15^\circ$ . The adjusted cutting speed is  $V = 1610 \times 1.75 \times 1.23 = 3466$  fpm.

**Example 4, Turning:** The cutting speed for 1055 steel calculated in [Example 3](#) represents the speed required to obtain a 15-minute tool life. Estimate the cutting speed needed to obtain a tool life of 45, 90, and 180 minutes using the results of [Example 3](#).

To estimate the cutting speed corresponding to another tool life, multiply the cutting speed for 15-minute tool life  $V_{15}$  by the adjustment factor from the [Table 5b](#), Tool Life Factors for Turning. This table gives three factors for adjusting tool life based on the feed used,  $f_s$  for feeds less than or equal to  $\frac{1}{2}f_{opt}$ ,  $f_m$  for midrange feeds between  $\frac{1}{2}$  and  $\frac{3}{4}f_{opt}$  and  $f_l$  for large feeds greater than or equal to  $\frac{3}{4}f_{opt}$  and less than  $f_{opt}$ . In [Example 3](#),  $f_{opt}$  is 0.015 in/rev and the selected feed is 0.0075 in/rev =  $\frac{1}{2}f_{opt}$ . The new cutting speeds for the various tool lives are obtained by multiplying the cutting speed for 15-minute tool life  $V_{15}$  by the factor for small feeds  $f_s$  from the column for turning with ceramics in [Table 5b](#). These calculations, using the cutting speed obtained in [Example 3](#), follow.

<i>Tool Life</i>	<i>Cutting Speed</i>
15 min	$V_{15} = 3466 \text{ fpm}$
45 min	$V_{45} = V_{15} \times 0.80 = 2773 \text{ fpm}$
90 min	$V_{90} = V_{15} \times 0.70 = 2426 \text{ fpm}$
180 min	$V_{180} = V_{15} \times 0.61 = 2114 \text{ fpm}$

Depth of cut, feed, and lead angle remain the same as in Example 3. Notice, increasing the tool life from 15 to 180 minutes, a factor of 12, reduces the cutting speed by only about one-third of the  $V_{15}$  speed.

**Table 6. Cutting Speeds and Feeds for Turning Copper Alloys**

<b>Group 1</b>
Architectural bronze (C38500); Extra-high-headed brass (C35600); Forging brass (C37700); Free-cutting phosphor bronze, B2 (C54400); Free-cutting brass (C36000); Free-cutting Muntz metal (C37000); High-leaded brass (C33200; C34200); High-leaded brass tube (C35300); Leaded commercial bronze (C31400); Leaded naval brass (C48500); Medium-leaded brass (C34000)
<b>Group 2</b>
Aluminum brass, arsenical (C68700); Cartridge brass, 70% (C26000); High-silicon bronze, B (C65500); Admiralty brass (inhibited) (C44300, C44500); Jewelry bronze, 87.5% (C22600); Leaded Muntz metal (C36500, C36800); Leaded nickel silver (C79600); Low brass, 80% (C24000); Low-leaded brass (C33500); Low-silicon bronze, B (C65100); Manganese bronze, A (C67500); Muntz metal, 60% (C28000); Nickel silver, 55-18 (C77000); Red brass, 85% (C23000); Yellow brass (C26800)
<b>Group 3</b>
Aluminum bronze, D (C61400); Beryllium copper (C17000, C17200, C17500); Commercial bronze, 90% (C22000); Copper nickel, 10% (C70600); Copper nickel, 30% (C71500); Electrolytic tough pitch copper (C11000); Gilding, 95% (C21000); Nickel silver, 65-10 (C74500); Nickel silver, 65-12 (C75700); Nickel silver, 65-15 (C75400); Nickel silver, 65-18 (C75200); Oxygen-free copper (C10200); Phosphor bronze, 1.25% (C50200); Phosphor bronze, 10% D (C52400) Phosphor bronze, 5% A (C51000); Phosphor bronze, 8% C (C52100); Phosphorus deoxidized copper (C12200)

The speed recommendations for turning with HSS (high-speed steel) tools may be used as starting speeds for milling titanium alloys, using Table 15a to estimate the feed required. Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide, 15.

The speed recommendations for rough turning may be used as starting values for milling and drilling with HSS tools. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide = 15; ceramic, hard = 4, tough = 3; CBN = 1.

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use [Table 5c](#) to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{4}$  inch. Use [Table 5a](#) to adjust given speeds for other feeds, depths of cut, and lead angles; use [Table 5b](#) to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

**Speeds and Feeds Tables for Milling.**—[Table 10](#) through [Table 14](#) give speeds and feeds for milling. The data in the first speed column can be used with high-speed steel tools using the feeds given in [Table 15a](#); these are the same speeds contained in previous editions of the Handbook. The remaining data in [Table 10](#) through [Table 14](#) are combined speeds and feeds for end, face, and slit, slot, and side milling that use the speed adjustment factors given in [Table 15b](#), [Table 15c](#), and [Table 15d](#). Tool life for the combined feed/speed data can also be adjusted using the factors in [Table 15e](#). [Table 16](#) lists cutting tool grades and vendor equivalents.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{4}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Table 15b](#) and [Table 15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes.

**Using the Speeds and Feeds Tables for Milling:** The basic feed for milling cutters is the feed per tooth ( $f$ ), which is expressed in inches per tooth. There are many factors to consider in selecting the feed per tooth and no formula is available to resolve these factors. Among the factors to consider are the cutting tool material; the work material and its hardness; the width and the depth of the cut to be taken; the type of milling cutter to be used and its size; the surface finish to be produced; the power available on the milling machine; and the rigidity of the milling machine, the workpiece, the workpiece setup, the milling cutter, and the cutter mounting.

The cardinal principle is to always use the maximum feed that conditions will permit. Avoid, if possible, using a feed that is less than 0.001 inch per tooth because such low feeds reduce the tool life of the cutter. When milling hard materials with small-diameter end mills, such small feeds may be necessary, but otherwise use as much feed as possible. Harder materials in general will require lower feeds than softer materials. The width and the depth of cut also affect the feeds. Wider and deeper cuts must be fed somewhat more slowly than narrow and shallow cuts. A slower feed rate will result in a better surface finish; however, always use the heaviest feed that will produce the surface finish desired. Fine chips produced by fine feeds are dangerous when milling magnesium because spontaneous combustion can occur. Thus, when milling magnesium, a fast feed that will produce a relatively thick chip should be used. Cutting stainless steel produces a work-hardened layer on the surface that has been cut. Thus, when milling this material, the feed should

be large enough to allow each cutting edge on the cutter to penetrate below the work-hardened layer produced by the previous cutting edge. The heavy feeds recommended for face milling cutters are to be used primarily with larger cutters on milling machines having an adequate amount of power. For smaller face milling cutters, start with smaller feeds and increase as indicated by the performance of the cutter and the machine.

When planning a milling operation that requires a high cutting speed and a fast feed, always check to determine if the power required to take the cut is within the capacity of the milling machine. Excessive power requirements are often encountered when milling with cemented carbide cutters. The large metal removal rates that can be attained require a high horsepower output. An example of this type of calculation is given in the section on Machining Power that follows this section. If the size of the cut must be reduced in order to stay within the power capacity of the machine, start by reducing the cutting speed rather than the feed in inches per tooth.

The formula for calculating the table feed rate, when the feed in inches per tooth is known, is as follows:

$$f_m = f_t n_t N$$

where  $f_m$  = milling machine table feed rate in inches per minute (ipm)

$f_t$  = feed in inch per tooth (ipt)

$n_t$  = number of teeth in the milling cutter

$N$  = spindle speed of the milling machine in revolutions per minute (rpm)

*Example:* Calculate the feed rate for milling a piece of AISI 1040 steel having a hardness of 180 BHN. The cutter is a 3-inch diameter high-speed steel plain or slab milling cutter with 8 teeth. The width of the cut is 2 inches, the depth of cut is 0.062 inch, and the cutting speed from Table 11 is 85 fpm. From Table 15a, the feed rate selected is 0.008 inch per tooth.

$$N = \frac{12V}{\pi D} = \frac{12 \times 85}{3.14 \times 3} = 108 \text{ rpm}$$

$$f_m = f_t n_t N = 0.008 \times 8 \times 108$$

$$= 7 \text{ ipm (approximately)}$$

*Example 1, Face Milling:* Determine the cutting speed and machine operating speed for face milling an aluminum die casting (alloy 413) using a 4-inch polycrystalline diamond cutter, a 3-inch width of cut, a 0.10-inch depth of cut, and a feed of 0.006 inch/tooth.

Table 10 gives the speeds and feeds for milling aluminum alloys. The feed/speed pairs for face milling die-cast alloy 413 with polycrystalline diamond (PCD) are 8/2320 (0.008 in/tooth feed at 2320 fpm) and 4/4755 (0.004 in/tooth feed at 4755 fpm). These speeds are based on an axial depth of cut of 0.10 inch, an 8-inch cutter diameter  $D$ , a 6-inch radial depth (width) of cut  $ar$ , with the cutter approximately centered above the workpiece, i.e., eccentricity is low, as shown in Fig. 3. If the preceding conditions apply, the given speeds and feeds can be used without adjustment for a 45-minute tool life. The given speeds are valid for all cutter diameters if a radial depth of cut to cutter diameter ratio ( $ar/D$ ) of  $3/4$  is maintained (i.e.,  $6/8 = 3/4$ ). However, if a different feed or axial depth of cut is required, or if the  $ar/D$  ratio is not equal to  $3/4$ , the cutting speed must be adjusted for the conditions. The adjusted cutting speed  $V$  is calculated from  $V = V_{opt} \times F_f \times F_d \times F_{ar}$ , where  $V_{opt}$  is the lower of the two speeds given in the speed table, and  $F_f$ ,  $F_d$ , and  $F_{ar}$  are adjustment factors for feed, axial depth of cut, and radial depth of cut, respectively, obtained from Table 15d (face milling); except, when cutting near the end or edge of the workpiece as in Fig. 4, Table 15c (side milling) is used to obtain  $F_f$ .

Fig. 3.

Fig. 4.

In this example, the cutting conditions match the standard conditions specified in the speed table for radial depth of cut to cutter diameter (3 in/4 in), and depth of cut (0.01 in), but the desired feed of 0.006 in/tooth does not match either of the feeds given in the speed table (0.004 or 0.008). Therefore, the cutting speed must be adjusted for this feed. As with turning, the feed factor  $F_f$  is determined by calculating the ratio of the desired feed  $f$  to maximum feed  $f_{opt}$  from the speed table, and from the ratio  $V_{avg}/V_{opt}$  of the two speeds given in the speed table. The feed factor is found at the intersection of the feed ratio row and the speed ratio column in Table 15d. The speed is then obtained using the following equation:

$$\frac{\text{Chosen feed}}{\text{Optimum feed}} = \frac{f}{f_{opt}} = \frac{0.006}{0.008} = 0.75 \qquad \frac{\text{Average speed}}{\text{Optimum speed}} = \frac{V_{avg}}{V_{opt}} = \frac{4755}{2320} \approx 2.0$$

$$F_f = (1.25 + 1.43)/2 = 1.3$$

$$F_d = 1.0$$

$$F_{ar} = 1.0$$

$$V = 2320 \times 1.34 \times 1.0 \times 1.0 = 3109 \text{ fpm, and } 3.82 \times 3109 / 4 = 2970 \text{ rpm}$$

**Example 2, End Milling:** What cutting speed should be used for cutting a full slot (i.e., a slot cut from the solid, in one pass, that is the same width as the cutter) in 5140 steel with hardness of 300 BHN using a 1-inch diameter coated carbide (insert)  $0^\circ$  lead angle end mill, a feed of 0.003 in/tooth, and a 0.2-inch axial depth of cut?

The speed and feed data for end milling 5140 steel, Brinell Hardness Number = 275–325, with a coated carbide tool are given in Table 11 as 15/80 and 8/240 for *optimum* and *average* sets, respectively. The speed adjustment factors for feed and depth of cut for full slot (end milling) are obtained from Table 15b. The calculations are the same as in the previous examples:  $f/f_{opt} = 3/15 = 0.2$  and  $V_{avg}/V_{opt} = 240/80 = 3.0$ , therefore,  $F_f = 6.86$  and  $F_d = 1.0$ . The cutting speed for a 45-minute tool life is  $V = 80 \times 6.86 \times 1.0 = 548.8$ , approximately 550 ft/min.

**Example 3, End Milling:** What cutting speed should be used in Example 2 if the radial depth of cut  $ar$  is 0.02 inch and axial depth of cut is 1 inch?

In end milling, when the radial depth of cut is less than the cutter diameter (as in Fig. 4), first obtain the feed factor  $F_f$  from Table 15c, then the axial depth of cut and lead angle factor  $F_d$  from Table 15b. The radial depth of cut to cutter diameter ratio  $ar/D$  is used in Table 15c to determine the maximum and minimum feeds that guard against tool failure at high feeds and against premature tool wear caused by the tool rubbing against the work at very low feeds. The feed used should be selected so that it falls within the minimum to maximum feed range, and then the feed factor  $F_f$  can be determined from the feed factors at minimum and maximum feeds,  $F_{f1}$  and  $F_{f2}$  as explained below.

The maximum feed  $f_{max}$  is found in Table 15c by multiplying the optimum feed from the speed table by the maximum feed factor that corresponds to the  $ar/D$  ratio, which in this instance is  $0.02/1 = 0.02$ ; the minimum feed  $f_{min}$  is found by multiplying the optimum feed by the minimum feed factor. Thus,  $f_{max} = 4.5 \times 0.015 = 0.0675$  in/tooth and  $f_{min} = 3.1 \times 0.015 = 0.0465$  in/tooth. If a feed between these maximum and minimum values is selected, 0.050 in/tooth for example, then for  $ar/D = 0.02$  and  $V_{avg}/V_{opt} = 3.0$ , the feed factors at maximum and minimum feeds are  $F_{f1} = 7.90$  and  $F_{f2} = 7.01$ , respectively, and by interpolation,  $F_f = 7.90 + (0.050 - 0.0465)/(0.0675 - 0.0465) \times (7.01 - 7.90) = 7.75$ .

The depth of cut factor  $F_d$  is obtained from Table 15b, using  $f_{max}$  from Table 15c instead of the optimum feed  $f_{opt}$  for calculating the feed ratio (chosen feed/optimum feed). In this example, the feed ratio = chosen feed/ $f_{max} = 0.050/0.0675 = 0.74$ , so the feed factor is  $F_d = 0.93$  for a depth of cut = 1.0 inch and  $0^\circ$  lead angle. Therefore, the final cutting speed is  $80 \times 7.75 \times 0.93 = 577$  ft/min. Notice that  $f_{max}$  obtained from Table 15c was used instead of the optimum feed from the speed table, in determining the feed ratio needed to find  $F_d$ .

**Slit Milling.**—The tabular data for slit milling is based on an 8-tooth, 10-degree helix angle cutter with a width of 0.4 inch, a diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. The given speeds and feeds are valid for any diameters and tool widths, as long as sufficient machine power is available. Adjustments to cutting speeds for other feeds and depths of cut are made using Table 15c or Table 15d, depending on the orientation of the cutter to the work, as illustrated in Case 1 and Case 2 of Fig. 5. The situation illustrated in Case 1 is approximately equivalent to that illustrated in Fig. 3, and Case 2 is approximately equivalent to that shown in Fig. 4.

*Case 1:* If the cutter is fed directly into the workpiece, i.e., the feed is perpendicular to the surface of the workpiece, as in cutting off, then Table 15d (face milling) is used to adjust speeds for other feeds. The depth of cut portion of Table 15d is not used in this case ( $F_d = 1.0$ ), so the adjusted cutting speed  $V = V_{opt} \times F_f \times F_{ar}$ . In determining the factor  $F_{ar}$  from Table 15d, the radial depth of cut  $ar$  is the length of cut created by the portion of the cutter engaged in the work.

*Case 2:* If the cutter feed is parallel to the surface of the workpiece, as in slotting or side milling, then Table 15c (side milling) is used to adjust the given speeds for other feeds. In Table 15c, the cutting depth (slot depth, for example) is the radial depth of cut that is used to determine maximum and minimum allowable feed/tooth and the feed factor  $F_f$ . These minimum and maximum feeds are determined in the manner described previously, however, the axial depth of cut factor  $F_d$  is not required. The adjusted cutting speed, valid for cutters of any thickness (width), is given by  $V = V_{opt} \times F_f$ .

Fig. 5. Determination of Radial Depth of Cut or in Slit Milling

Abbreviations designate: A, annealed; AC, as cast; CD, cold drawn; and ST and A, solution treated and aged, respectively.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Table 15b](#) and [Table 15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 15; diamond = 9.

<sup>a</sup>Brinell Hardness Number given unless otherwise indicated by RC for hardness on the Rockwell C scale.

For HSS (high-speed steel) tools in the first speed column only, use Table 15a for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use Table 15b to adjust speeds for other feeds and axial depths of cut, and Table 15c to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle, 3/64-inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio = 3/4). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use Table 15d to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors (Table 15b and Table 15c) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter *D* of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use Table 15e to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: end and slit milling uncoated carbide = 20 except <sup>†</sup> = 15; face milling uncoated carbide = 19; end, face, and slit milling coated carbide = 10.

<sup>a</sup>Brinell Hardness Number given unless otherwise indicated by RC for hardness on the Rockwell C scale.

For HSS (high-speed steel) tools in the first speed column only, use **Table 15a** for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use **Table 15b** to adjust speeds for other feeds and axial depths of cut, and **Table 15c** to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{1}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use **Table 15d** to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors (**Table 15b** and **Table 15c**) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter *D* of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use **Table 15e** to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in **Table 16**) as follows: uncoated carbide = 20,  $\dot{\tau}$  = 15; coated carbide = 10; CBN = 1.

For HSS (high-speed steel) tools in the first speed column only, use [Table 15a](#) for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Table 15b](#) and [Table 15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 20; coated carbide = 10.

For HSS (high-speed steel) tools in the first speed column only, use [Table 15a](#) for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Table 15b](#) and [Table 15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 15 except  $\ddagger = 20$ ; end and slit milling coated carbide = 10; face milling coated carbide = 11 except  $\ddagger = 10$ , ceramic = 6; CBN = 1.

For HSS (high-speed steel) tool speeds in the first speed column of Table 10 through Table 14, use Table 15a to determine appropriate feeds and depths of cut.

Cutting speeds and feeds for end milling given in Table 11 through Table 14 (except those for high-speed steel in the first speed column) are based on milling a 0.20-inch deep full slot (i.e., radial depth of cut = end mill diameter) with a 1-inch diameter, 20-degree helix angle, 0-degree lead angle end mill. For other depths of cut (axial), lead angles, or feed, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds are given in the tables), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the Table. The depth of cut factor  $F_d$  is found in the same row as the feed factor, in the right half of the table under the column corresponding to the depth of cut and lead angle. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). See the text for examples.

If the radial depth of cut is less than the cutter diameter (i.e., for cutting less than a full slot), the feed factor  $F_f$  in the previous equation and the maximum feed  $f_{max}$  must be obtained from Table 15c. The axial depth of cut factor  $F_d$  can then be obtained from this table using  $f_{max}$  in place of the optimum feed in the feed ratio. Also see the footnote to Table 15c.

**Table 15c. End, Slit, and Side Milling Speed Adjustment Factors for Radial Depth of Cut**

Ratio of Radial Depth of Cut to Diameter	Cutting Speed, $V = V_{opt} \times F_f \times F_d$

This table is for side milling, end milling when the radial depth of cut (width of cut) is less than the tool diameter (i.e., less than full slot milling), and slit milling when the feed is parallel to the work surface (slotting). The radial depth of cut to diameter ratio is used to determine the recommended maximum and minimum values of feed/tooth, which are found by multiplying the feed/tooth factor from the appropriate column above (maximum or minimum) by feed<sub>opt</sub> from the speed tables. For example, given two feed/speed pairs 1/15 and 1/45 for end milling cast, medium-carbon, alloy steel, and a radial depth of cut to diameter ratio ar/D of 0.10 (a 0.05-inch width of cut for a 1/2-inch diameter end mill, for example), the maximum feed f<sub>max</sub> = 2.05 × 0.007 = 0.014 in/tooth and the minimum feed f<sub>min</sub> = 1.44 × 0.007 = 0.010 in/tooth. The feed selected should fall in the range between f<sub>min</sub> and f<sub>max</sub>. The feed factor F<sub>d</sub> is determined by interpolating between the feed factors F<sub>f1</sub> and F<sub>f2</sub> corresponding to the maximum and minimum feed per tooth, at the appropriate ar/D and speed ratio. In the example given, ar/D = 0.10 and V<sub>avg</sub>/V<sub>opt</sub> = 45/15 = 3, so the feed factor F<sub>f1</sub> at the maximum feed per tooth is 6.77, and the feed factor F<sub>f2</sub> at the minimum feed per tooth is 7.76. If a working feed of 0.012 in/tooth is chosen, the feed factor F<sub>f</sub> is half way between 6.77 and 7.76 or by formula, F<sub>f</sub> = F<sub>f2</sub> + (feed - f<sub>min</sub>)/(f<sub>max</sub> - f<sub>min</sub>) × (F<sub>f1</sub> - F<sub>f2</sub>) = 7.76 + (0.012 - 0.010)/(0.014 - 0.010) × (6.77 - 7.76) = 7.27. The cutting speed is V = V<sub>opt</sub> × F<sub>f</sub> × F<sub>d</sub>, where F<sub>d</sub> is the depth of cut and lead angle factor from Table 15b that corresponds to the feed ratio (chosen feed)/f<sub>max</sub>, not the ratio (chosen feed)/optimum feed. For a feed ratio = 0.012/0.014 = 0.86 (chosen feed/f<sub>max</sub>), depth of cut = 0.2 inch and lead angle = 45°, the depth of cut factor F<sub>d</sub> in Table 15b is between 0.72 and 0.74. Therefore, the final cutting speed for this example is V = V<sub>opt</sub> × F<sub>f</sub> × F<sub>d</sub> = 15 × 7.27 × 0.73 = 80 ft/min.

**Slit and Side Milling:** This table only applies when feed is parallel to the work surface, as in slotting. If feed is perpendicular to the work surface, as in cutting off, obtain the required speed-correction factor from Table 15d (face milling). The minimum and maximum feeds/tooth for slit and side milling are determined in the manner described above, however, the axial depth of cut factor F<sub>d</sub> is not required. The adjusted cutting speed, valid for cutters of any thickness (width), is given by V = V<sub>opt</sub> × F<sub>f</sub>. Examples are given in the text.

**Table 15d. Face Milling Speed Adjustment Factors for Feed, Depth of Cut, and Lead Angle**

Ratio of Chosen Feed to Optimum Feed	Ratio of the two cutting speeds (average/optimum) given in the tables							Cutting Speed $V = V_{opt} \times F_f \times F_d \times F_{ar}$										Ratio of Radial Depth of Cut/Cutter Diameter, $ar/D$

For HSS (high-speed steel) tool speeds in the first speed column, use Table 15a to determine appropriate feeds and depths of cut.

Tabular speeds and feeds data for face milling in Table 11 through Table 14 are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch cutter insert nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). For other depths of cut (radial or axial), lead angles, or feed, calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds given in the speed table), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Use these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left third of the table. The depth of cut factor  $F_d$  is found in the same row as the feed factor, in the center third of the table, in the column corresponding to the depth of cut and lead angle. The radial depth of cut factor  $F_{ar}$  is found in the same row as the feed factor, in the right third of the table, in the column corresponding to the radial depth of cut to cutter diameter ratio  $ar/D$ . The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d \times F_{ar}$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs).

The cutting speeds as calculated above are valid if the cutter axis is centered above or close to the center line of the workpiece (eccentricity is small). For larger eccentricity (i.e., the cutter axis is offset from the center line of the workpiece by about one-half the cutter diameter or more), use the adjustment factors from Table 15b and Table 15c (end and side milling) instead of the factors from this table. Use Table 15c to adjust end and face milling speeds for increased tool life up to 180 minutes.

**Slit and Slot Milling:** Tabular speeds are valid for all tool diameters and widths. Adjustments to the given speeds for other feeds and depths of cut depend on the circumstances of the cut. *Case 1:* If the cutter is fed directly into the workpiece, i.e., the feed is perpendicular to the surface of the workpiece, as in cutting off, then this table (face milling) is used to adjust speeds for other feeds. The depth of cut factor is not used for slit milling ( $F_d = 1.0$ ), so the adjusted cutting speed  $V = V_{opt} \times F_f \times F_{ar}$ . For determining the factor  $F_{ar}$ , the radial depth of cut  $ar$  is the length of cut created by the portion of the cutter engaged in the work. *Case 2:* If the cutter is fed parallel to the surface of the workpiece, as in slotting, then Table 15b and Table 15c are used to adjust the given speeds for other feeds. See Fig. 5.

**Table 15c. Tool Life Adjustment Factors for Face Milling, End Milling, Drilling, and Reaming**

Tool Life, $T$ (minutes)	Face Milling with Carbides and Mixed Ceramics			End Milling with Carbides and HSS			Twist Drilling and Reaming with HSS		
	$f_s$	$f_m$	$f_l$	$f_s$	$f_m$	$f_l$	$f_s$	$f_m$	$f_l$
15	1.69	1.78	1.87	1.10	1.23	1.35	1.11	1.21	1.30
45	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00	1.00
90	0.72	0.70	0.67	0.94	0.89	0.83	0.93	0.89	0.85
180	0.51	0.48	0.45	0.69	0.69	0.69	0.87	0.80	0.72

The speeds and feeds given in Table 11 through Table 14 and Table 17 through Table 23 (except for HSS speeds in the first speed column) are based on a 45-minute tool life. To adjust the given speeds to obtain another tool life, multiply the adjusted cutting speed for the 45-minute tool life  $V_{45}$  by the tool life factor from this table according to the following rules: for small feeds, where feed  $\leq \frac{1}{2}f_{opt}$ , the cutting speed for the desired tool life  $T$  is  $V_T = f_s \times V_{15}$ ; for medium feeds, where  $\frac{1}{2}f_{opt} < \text{feed} < \frac{3}{4}f_{opt}$ ,  $V_T = f_m \times V_{15}$ ; and for larger feeds, where  $\frac{3}{4}f_{opt} \leq \text{feed} \leq f_{opt}$ ,  $V_T = f_l \times V_{15}$ . Here,  $f_{opt}$  is the largest (optimum) feed of the two feed/speed values given in the speed tables or the maximum feed  $f_{max}$  obtained from Table 15c, if that table was used in calculating speed adjustment factors.

**Table 16. Cutting Tool Grade Descriptions and Common Vendor Equivalents**

Grade Description	Tool Identification Code	Approximate Vendor Equivalents			
		Sandvik Coromant	Kennametal	Seco	Valenite
Cubic boron nitride	1	CB50	KD050	CBN20	VC721

Uncoated carbides	15	H13A	K8, K4H	883	VC2
	16	S10T	K420, K28	CP20	VC7
	17	S1P	K45	CP20	VC7
	18	S30T	—	CP25	VC5
	19	S6	K21, K25	CP50	VC56
	20	SM30	KC710	CP25	VC35M

See Table 2 on page 866 and the section *Cemented Carbides and Other Hard Materials* for more detailed information on cutting tool grades.

The identification codes in column two correspond to the grade numbers given in the footnotes to Table 1 to Table 4b, Table 6 to Table 14, and Table 17 to Table 23.

**Using the Speeds and Feeds Tables for Drilling, Reaming, and Threading.**—The first two speed columns in Table 17 through Table 23 give traditional Handbook speeds for drilling and reaming. The following material can be used for selecting feeds for use with the traditional speeds.

The remaining columns in Table 17 through Table 23 contain combined feed/speed data for drilling, reaming, and threading, organized in the same manner as in the turning and milling tables. Operating at the given speeds and feeds is expected to result in a tool life of approximately 45 minutes, except for indexable insert drills, which have an expected tool life of approximately 15 minutes per edge. Examples of using this data follow.

Adjustments to HSS drilling speeds for feed and diameter are made using Table 22; Table 5a is used for adjustments to indexable insert drilling speeds, where one-half the drill diameter  $D$  is used for the depth of cut. Tool life for HSS drills, reamers, and thread chasers and taps may be adjusted using Table 15e and for indexable insert drills using Table 5b.

The feed for drilling is governed primarily by the size of the drill and by the material to be drilled. Other factors that also affect selection of the feed are the workpiece configuration, the rigidity of the machine tool and the workpiece setup, and the length of the chisel edge. A chisel edge that is too long will result in a very significant increase in the thrust force, which may cause large deflections to occur on the machine tool and drill breakage.

For ordinary twist drills, the feed rate used is given in the table that follows. For additional information also see the table *Approximate Cutting Speeds and Feeds for Standard Automatic Screw Machine Tools—Brown and Sharpe* on page 1235.

**Feed Rate for Twist Drills**

Drill Size, inch (mm)	Feed Rate, inch/rev (mm/rev)
smaller than $\frac{1}{8}$ inch (3.175 mm)	0.001 to 0.003 in/rev (0.025–0.08 mm/rev)
from $\frac{1}{8}$ - to $\frac{1}{4}$ -inch (3.175–6.35 mm)	0.002 to 0.006 in/rev (0.05–0.15 mm/rev)
from $\frac{1}{4}$ - to $\frac{1}{2}$ -inch (6.35–12.7 mm)	0.004 to 0.010 in/rev (0.10–0.25 mm/rev)
from $\frac{1}{2}$ - to 1-inch (12.7–25.4 mm)	0.007 to 0.015 in/rev (0.18–0.38 mm/rev)
larger than 1 inch (25.4 mm)	0.010 to 0.025 in/rev (0.25–0.64 mm/rev)

The lower values in the feed ranges should be used for hard materials such as tool steels, superalloys, and work-hardening stainless steels; the higher values in the feed ranges should be used to drill soft materials such as aluminum and brass.

*Example 1, Drilling:* Determine the cutting speed and feed for use with HSS drills in drilling 1120 steel.

Table 17 gives two sets of speed and feed parameters for drilling 1120 steel with HSS drills. These sets are 16/50 and 8/95, i.e., 0.016 in/rev feed at 50 ft/min and 0.008 in/rev at 95 fpm, respectively. These feed/speed sets are based on a 0.6-inch diameter drill. Tool life for either of the given feed/speed settings is expected to be approximately 45 minutes.

For different feeds or drill diameters, the cutting speeds must be adjusted and can be determined from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the minimum speed for this material given in the speed table (50 fpm in this example) and  $F_f$  and  $F_d$  are the adjustment factors for feed and diameter, respectively, found in Table 22.

The two leftmost speed columns in this table contain traditional Handbook speeds for drilling and reaming with HSS steel tools. The section Feed Rates for Drilling and Reaming contains useful information concerning feeds to use in conjunction with these speeds.

**HSS Drilling and Reaming:** The combined feed/speed data for drilling are based on a 0.60-inch diameter HSS drill with standard drill point geometry (2-flute with 118° tip angle). Speed adjustment factors in Table 22 are used to adjust drilling speeds for other feeds and drill diameters. Examples of using this data are given in the text. The given speeds and feeds for reaming are based on an 8-tooth,  $2\frac{5}{32}$ -inch diameter, 30° lead angle reamer, and a 0.008-inch radial depth of cut. For other feeds, the correct speed can be obtained by interpolation using the given speeds if the desired feed lies in the recommended range (between the given values of *optimum* and *average* feed). If a feed lower than the given *average* value is chosen, the speed should be maintained at the corresponding *average* speed (i.e., the highest of the two speed values given). The cutting speeds for reaming do not require adjustment for tool diameters for standard ratios of radial depth of cut to reamer diameter (i.e.,  $f_d = 1.00$ ). Speed adjustment factors to modify tool life are found in Table 15e.

**Indexable Insert Drilling:** The feed/speed data for indexable insert drilling are based on a tool with two cutting edges, an insert nose radius of  $\frac{3}{64}$  inch (1.2 mm), a 10-degree lead angle, and diameter  $D = 1$  inch (2.54 mm). Adjustments to cutting speed for feed and depth of cut are made using Table 5a on page 1103 (Adjustment Factors) using a depth of cut of  $D/2$ , or one-half the drill diameter. Expected tool life at the given speeds and feeds is approximately 15 minutes for short hole drilling (i.e., where maximum hole depth is about  $2D$  or less). Speed adjustment factors to increase tool life are found in Table 5b.

**Tapping and Threading:** The data in this column are intended for use with thread chasers and for tapping. The feed used for tapping and threading must be equal to the lead (feed = lead = pitch) of the thread being cut. The two feed/speed pairs given for each material, therefore, are representative speeds for two thread pitches, 12 and 50 threads per inch ( $1/0.083 = 12$ , and  $1/0.020 = 50$ ). Tool life is expected to be approximately 45 minutes at the given speeds and feeds. When cutting fewer than 12 threads per inch (pitch  $\geq 0.08$  inch or 2.1 mm), use the lower (*optimum*) speed; for cutting more than 50 threads per inch (pitch  $\leq 0.02$  inch or 0.51 mm), use the larger (*average*) speed; and, in the intermediate range between 12 and 50 threads per inch, interpolate between the given *average* and *optimum* speeds.

The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: coated carbide = 10.

**Example 2, Drilling:** If the 1120 steel of Example 1 is to be drilled with a 0.60-inch drill at a feed of 0.012 in/rev, what is the cutting speed in ft/min? Also, what spindle rpm of the drilling machine is required to obtain this cutting speed?

To find the feed factor  $F_d$  in Table 22, calculate the ratio of the desired feed to the *optimum* feed and the ratio of the two cutting speeds given in the speed tables. The desired feed is 0.012 in/rev and the *optimum* feed, as explained above is 0.016 in/rev, therefore,  $\text{feed}/f_{opt} = 0.012/0.016 = 0.75$  and  $V_{avg}/V_{opt} = 95/50 = 1.9$ , approximately 2.

The feed factor  $F_f$  is found at the intersection of the feed ratio row and the speed ratio column.  $F_f = 1.40$  corresponds to about halfway between 1.31 and 1.50, which are the feed factors that correspond to  $V_{avg}/V_{opt} = 2.0$  and  $\text{feed}/f_{opt}$  ratios of 0.7 and 0.8, respectively.  $F_d$ , the diameter factor, is found on the same row as the feed factor (halfway between the 0.7 and 0.8 rows, for this example) under the column for drill diameter = 0.60 inch. Because the speed table values are based on a 0.60-inch drill diameter,  $F_d = 1.0$  for this example, and the cutting speed is  $V = V_{opt} \times F_f \times F_d = 50 \times 1.4 \times 1.0 = 70$  ft/min. The spindle speed in rpm is  $N = 12 \times V/(\pi \times D) = 12 \times 70/(3.14 \times 0.6) = 445$  rpm.

**Example 3, Drilling:** Using the same material and feed as in the previous example, what cutting speeds are required for 0.079-inch and 4-inch diameter drills? What machine rpm is required for each?

Because the feed is the same as in the previous example, the feed factor is  $F_f = 1.40$  and does not need to be recalculated. The diameter factors are found in Table 22 on the same row as the feed factor for the previous example (about halfway between the diameter factors corresponding to  $\text{feed}/f_{opt}$  values of 0.7 and 0.8) in the column corresponding to drill diameters 0.079 and 4.0 inches, respectively. Results of the calculations are summarized below.

Drill diameter = 0.079 inch	Drill diameter = 4.0 inches
$F_f = 1.40$	$F_f = 1.40$
$F_d = (0.34 + 0.38)/2 = 0.36$	$F_d = (1.95 + 1.73)/2 = 1.85$
$V = 50 \times 1.4 \times 0.36 = 25.2$ fpm	$V = 50 \times 1.4 \times 1.85 = 129.5$ fpm
$12 \times 25.2/(3.14 \times 0.079) = 1219$ rpm	$12 \times 129.5/(3.14 \times 4) = 124$ rpm

*Drilling Difficulties:* A drill split at the web is evidence of too much feed or insufficient lip clearance at the center due to improper grinding. Rapid wearing away of the extreme outer corners of the cutting edges indicates that the speed is too high. A drill chipping or breaking out at the cutting edges indicates that either the feed is too heavy or the drill has been ground with too much lip clearance. Nothing will “check” a high-speed steel drill quicker than to turn a stream of cold water on it after it has been heated while in use. It is equally bad to plunge it in cold water after the point has been heated in grinding. The small checks or cracks resulting from this practice will eventually chip out and cause rapid wear or breakage. Insufficient speed in drilling small holes with hand feed greatly increases the risk of breakage, especially at the moment the drill is breaking through the farther side of the work, due to the operator's inability to gage the feed when the drill is running too slowly.

Small drills have heavier webs and smaller flutes in proportion to their size than do larger drills, so breakage due to clogging of chips in the flutes is more likely to occur. When drilling holes deeper than three times the diameter of the drill, it is advisable to withdraw the drill (peck feed) at intervals to remove the chips and permit coolant to reach the tip of the drill.

*Drilling Holes in Glass:* The simplest method of drilling holes in glass is to use a standard, tungsten carbide-tipped masonry drill of the appropriate diameter, in a gun-drill. The edges of the carbide in contact with the glass should be sharp. Kerosene or other liquid may be used as a lubricant, and a light force is maintained on the drill until just before the point breaks through. The hole should then be started from the other side if possible, or a very light force applied for the remainder of the operation, to prevent excessive breaking of material from the sides of the hole. As the hard particles of glass are abraded, they accumulate and act to abrade the hole, so it may be advisable to use a slightly smaller drill than the required diameter of the finished hole.

Alternatively, for holes of medium and large size, use brass or copper tubing, having an outside diameter equal to the size of hole required. Revolve the tube at a peripheral speed of about 100 feet per minute (30.5 m/min), and use carborundum (80 to 100 grit) and light machine oil between the end of the pipe and the glass. Insert the abrasive under the drill with a thin piece of soft wood, to avoid scratching the glass. The glass should be supported by a felt or rubber cushion, not much larger than the hole to be drilled. If practicable, it is advisable to drill about halfway through, then turn the glass over, and drill down to meet the first cut. Any fin that may be left in the hole can be removed with a round second-cut file wetted with turpentine.

Smaller-diameter holes may also be drilled with triangular-shaped cemented carbide drills that can be purchased in standard sizes. The end of the drill is shaped into a long tapering triangular point. The other end of the cemented carbide bit is brazed onto a steel shank. A glass drill can be made to the same shape from hardened drill rod or an old three-cornered file. The location at which the hole is to be drilled is marked on the workpiece. A dam of putty or glazing compound is built up on the work surface to contain the cutting fluid, which can be either kerosene or turpentine mixed with camphor. Chipping on the back edge of the hole can be prevented by placing a scrap plate of glass behind the area to be drilled and drilling into the backup glass. This procedure also provides additional support to the workpiece and is essential for drilling very thin plates. The hole is usually drilled with an electric hand drill. When the hole is being produced, the drill should be given a small circular motion using the point as a fulcrum, thereby providing a clearance for the drill in the hole.

Very small round or intricately shaped holes and narrow slots can be cut in glass by the ultrasonic machining process or by the abrasive jet cutting process.

Table 18. Speeds and Feeds for Drilling, Reaming, and Threading Tool Steels

This table is specifically for use with the combined feed/speed data for HSS twist drills in Table 17 through Table 23; use Table 5a and Table 5b to adjust speed and tool life for indexable insert drilling with carbides. The combined feed/speed data for HSS twist drilling are based on a 0.60-inch diameter HSS drill with standard drill point geometry (2-flute with  $118^\circ$  tip angle). To adjust the given speeds for different feeds and drill diameters, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds from the speed table), and the ratio of the two cutting speeds  $V_{avg}/V_{opt}$ . Use the values of these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the table. The diameter factor  $F_d$  is found in the same row as the feed factor, in the right half of the table, under the column corresponding to the drill diameter. For diameters not given, interpolate between the nearest available sizes. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). Tool life using the selected feed and the adjusted speed should be approximately 45 minutes. Speed adjustment factors to modify tool life are found in Table 15e.

**Table 23. Speeds and Feeds for Drilling and Reaming Copper Alloys**

Group 1										
Architectural bronze(C38500); Extra-high-leaded brass (C35600); Forging brass (C37700); Free-cutting phosphor bronze (B-2) (C54400); Free-cutting brass (C36000); Free-cutting Muntz metal (C37000); High-leaded brass (C33200, C34200); High-leaded brass tube (C35300); Leaded commercial bronze (C31400); Leaded naval brass (C48500); Medium-leaded brass (C34000)										
Group 2										
Aluminum brass, arsenical (C68700); Cartridge brass, 70% (C26000); High-silicon bronze, B (C65500); Admiralty brass (inhibited) (C44300, C44500); Jewelry bronze, 87.5% (C22600); Leaded Muntz metal (C36500, C36800); Leaded nickel silver (C79600); Low brass, 80% (C24000); Low-leaded brass (C33500); Low-silicon bronze, B (C65100); Manganese bronze, A (C67500); Muntz metal, 60% (C28000); Nickel silver, 55-18 (C77000); Red brass, 85% (C23000); Yellow brass (C26800)										
Group 3										
Aluminum bronze, D (C61400); Beryllium copper (C17000, C17200, C17500); Commercial bronze, 90% (C22000); Copper nickel, 10% (C70600); Copper nickel, 30% (C71500); Electrolytic tough-pitch copper (C11000); Gilding, 95% (C21000); Nickel silver, 65-10 (C74500); Nickel silver, 65-12 (C75700); Nickel silver, 65-15 (C75400); Nickel silver, 65-18 (C75200); Oxygen-free copper (C10200); Phosphor bronze, 1.25% (C50200); Phosphor bronze, 10% D (C52400); Phosphor bronze, 5% A (C51000); Phosphor bronze, 8% C (C52100); Phosphorus deoxidized copper (C12200)

Abbreviations designate: A, annealed; CD, cold drawn. The two leftmost speed columns in this table contain traditional Handbook speeds for HSS steel tools. The text contains information concerning feeds to use in conjunction with these speeds.

**HSS Drilling and Reaming:** The combined feed/speed data for drilling and Table 22 are used to adjust drilling speeds for other feeds and drill diameters. Examples are given in the text. The given speeds and feeds for reaming are based on an 8-tooth, <sup>29</sup>/<sub>32</sub>-inch diameter, 30° lead angle reamer, and a 0.008-inch radial depth of cut. For other feeds, the correct speed can be obtained by interpolation using the given speeds if the desired feed lies in the recommended range (between the given values of *optimum* and *average* feed). The cutting speeds for reaming do not require adjustment for tool diameter as long as the radial depth of cut does not become too large. Speed adjustment factors to modify tool life are found in Table 15c.

**Indexable Insert Drilling:** The feed/speed data for indexable insert drilling are based on a tool with two cutting edges, an insert nose radius of <sup>3</sup>/<sub>4</sub> inch, a 10-degree lead angle, and diameter *D* of 1 inch. Adjustments for feed and depth of cut are made using Table 5a (Turning Speed Adjustment Factors) using a depth of cut of *D*/2, or one-half the drill diameter. Expected tool life at the given speeds and feeds is 15 minutes for short hole drilling (i.e., where hole depth is about *2D* or less). Speed adjustment factors to increase tool life are found in Table 5b. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide = 15.

**Using the Speeds and Feeds Tables for Tapping and Threading.**—The feed used in tapping and threading is always equal to the pitch of the screw thread being formed. The threading data contained in the tables for drilling, reaming, and threading (Table 17

through Table 23) are primarily for tapping and thread chasing, and do not apply to thread cutting with single-point tools.

The threading data in Table 17 through Table 23 give two sets of feed (pitch) and speed values, for 12 and 50 threads/inch, but these values can be used to obtain the cutting speed for any other thread pitches. If the desired pitch falls between the values given in the tables, i.e., between 0.020 inch (50 tpi) and 0.083 inch (12 tpi), the required cutting speed is obtained by interpolation between the given speeds. If the pitch is less than 0.020 inch (more than 50 tpi), use the *average* speed, i.e., the largest of the two given speeds. For pitches greater than 0.083 inch (fewer than 12 tpi), the *optimum* speed should be used. Tool life using the given feed/speed data is intended to be approximately 45 minutes, and should be about the same for threads between 12 and 50 threads per inch.

*Example:* Determine the cutting speed required for tapping 303 stainless steel with a  $\frac{1}{2}$ -20 coated HSS tap.

The two feed/speed pairs for 303 stainless steel, in Table 19, are 83/35 (0.083 in/rev at 35 fpm) and 20/45 (0.020 in/rev at 45 fpm). The pitch of a  $\frac{1}{2}$ -20 thread is  $1/20 = 0.05$  inch, so the required feed is 0.05 in/rev. Because 0.05 is between the two given feeds (Table 19), the cutting speed can be obtained by interpolation between the two given speeds as follows:

$$V = 35 + \frac{0.05 - 0.02}{0.083 - 0.02}(45 - 35) = 40 \text{ fpm}$$

The cutting speed for coarse-pitch taps must be lower than for fine-pitch taps with the same diameter. Usually, the difference in pitch becomes more pronounced as the diameter of the tap becomes larger and slight differences in the pitch of smaller-diameter taps have little significant effect on the cutting speed. Unlike all other cutting tools, the feed per revolution of a tap cannot be independently adjusted—it is always equal to the lead of the thread and is always greater for coarse pitches than for fine pitches. Furthermore, the thread form of a coarse-pitch thread is larger than that of a fine-pitch thread; therefore, it is necessary to remove more metal when cutting a coarse-pitch thread.

Taps with a long chamfer, such as starting or taper taps, can cut faster in a short hole than short chamfer taps, such as plug taps. In deep holes, however, short chamfer or plug taps can run faster than long chamfer taps. Bottoming taps must be run more slowly than either starting or plug taps. The chamfer helps to start the tap in the hole. It also functions to involve more threads, or thread form cutting edges, on the tap in cutting the thread in the hole, thus reducing the cutting load on any one set of thread form cutting edges. In so doing, more chips and thinner chips are produced that are difficult to remove from deeper holes. Shortening the chamfer length causes fewer thread form cutting edges to cut, thereby producing fewer and thicker chips that can easily be disposed of. Only one or two sets of thread form cutting edges are cut on bottoming taps, causing these cutting edges to assume a heavy cutting load and produce very thick chips.

Spiral-pointed taps can operate at a faster cutting speed than taps with normal flutes. These taps are made with supplementary angular flutes on the end that push the chips ahead of the tap and prevent the tapped hole from becoming clogged with chips. They are used primarily to tap open or through holes although some are made with shorter supplementary flutes for tapping blind holes.

The tapping speed must be reduced as the percentage of full thread to be cut is increased. Experiments have shown that the torque required to cut a 100 percent thread form is more than twice that required to cut a 50 percent thread form. An increase in the percentage of full thread will also produce a greater volume of chips.

The tapping speed must be lowered as the length of the hole to be tapped is increased. More friction must be overcome in turning the tap and more chips accumulate in the hole. It will be more difficult to apply the cutting fluid at the cutting edges and to lubricate the

tap to reduce friction. This problem becomes greater when the hole is being tapped in a horizontal position.

Cutting fluids have a very great effect on the cutting speed for tapping. Although other operating conditions when tapping frequently cannot be changed, a free selection of the cutting fluid usually can be made. When planning the tapping operation, the selection of a cutting fluid warrants a very careful consideration and perhaps an investigation.

Taper threaded taps, such as pipe taps, must be operated at a slower speed than straight thread taps with a comparable diameter. All the thread form cutting edges of a taper threaded tap that are engaged in the work cut and produce a chip, but only those cutting edges along the chamfer length cut on straight thread taps. Pipe taps often are required to cut the tapered thread from a straight hole, adding to the cutting burden.

The machine tool used for the tapping operation must be considered in selecting the tapping speed. Tapping machines and other machines that are able to feed the tap at a rate of advance equal to the lead of the tap, and that have provisions for quickly reversing the spindle, can be operated at high cutting speeds. On machines where the feed of the tap is controlled manually—such as on drill presses and turret lathes—the tapping speed must be reduced to allow the operator to maintain safe control of the operation.

There are other special considerations in selecting the tapping speed. Very accurate threads are usually tapped more slowly than threads with a commercial grade of accuracy. Thread forms that require deep threads for which a large amount of metal must be removed, producing a large volume of chips, require special techniques and slower cutting speeds. Acme, buttress, and square threads, therefore, are generally cut at lower speeds.

**Cutting Speed for Broaching.**—Broaching offers many advantages in manufacturing metal parts, including high production rates, excellent surface finishes, and close dimensional tolerances. These advantages are not derived from the use of high cutting speeds; they are derived from the large number of cutting teeth that can be applied consecutively in a given period of time, from their configuration and precise dimensions, and from the width or diameter of the surface that can be machined in a single stroke. Most broaching cutters are expensive in their initial cost and are expensive to sharpen. For these reasons, a long tool life is desirable, and to obtain a long tool life, relatively slow cutting speeds are used. In many instances, slower cutting speeds are used because of the limitations of the machine in accelerating and stopping heavy broaching cutters. At other times, the available power on the machine places a limit on the cutting speed that can be used; i.e., the cubic inches of metal removed per minute must be within the power capacity of the machine.

The cutting speeds for high-speed steel broaches range from 3 to 50 feet per minute, although faster speeds have been used. In general, the harder and more difficult to machine materials are cut at a slower cutting speed and those that are easier to machine are cut at a faster speed. Some typical recommendations for high-speed steel broaches are: AISI 1040, 10 to 30 fpm; AISI 1060, 10 to 25 fpm; AISI 4140, 10 to 25 fpm; AISI 41L40, 20 to 30 fpm; 201 austenitic stainless steel, 10 to 20 fpm; Class 20 gray cast iron, 20 to 30 fpm; Class 40 gray cast iron, 15 to 25 fpm; aluminum and magnesium alloys, 30 to 50 fpm; copper alloys, 20 to 30 fpm; commercially pure titanium, 20 to 25 fpm; alpha and beta titanium alloys, 5 fpm; and the superalloys, 3 to 10 fpm. Surface broaching operations on gray iron castings have been conducted at a cutting speed of 150 fpm, using indexable insert cemented carbide broaching cutters. In selecting the speed for broaching, the cardinal principle of the performance of all metal cutting tools should be kept in mind; i.e., increasing the cutting speed may result in a proportionately larger reduction in tool life, and reducing the cutting speed may result in a proportionately larger increase in the tool life. When broaching most materials, a suitable cutting fluid should be used to obtain a good surface finish and a better tool life. Gray cast iron can be broached without using a cutting fluid although some shops prefer to use a soluble oil.

### ESTIMATING SPEEDS AND MACHINING POWER

**Estimating Planer Cutting Speeds.**—Whereas most planers of modern design have a means of indicating the speed at which the table is traveling, or cutting, many older planers do not. The following formulas are useful for planers that do not have a means of indicating the table or cutting speed. It is not practicable to provide a formula for calculating the exact cutting speed at which a planer is operating because the time to stop and start the table when reversing varies greatly. The formulas below will provide a reasonable estimate.

$$V_c \approx S_c L \quad \text{and} \quad S_c \approx \frac{V_c}{L}$$

where  $V_c$  = cutting speed; fpm or m/min

$S_c$  = number of cutting strokes per minute of planer table

$L$  = length of table cutting stroke; ft or m

**Cutting Speed for Planing and Shaping.**—The traditional HSS cutting tool speeds in Table 1 through Table 4b and Table 6 through Table 9, pages 1095 through 1107, can be used for planing and shaping. The feed and depth of cut factors in Table 5c should also be used, as explained previously. Very often, other factors relating to the machine or the setup will require a reduction in the cutting speed used on a specific job.

**Cutting Time for Turning, Boring, and Facing.**—The time required to turn a length of metal can be determined by the following formula in which  $T$  = time in minutes,  $L$  = length of cut in inches (or mm),  $f$  = feed in inches per revolution (or mm/min), and  $N$  = lathe spindle speed in revolutions per minute.

$$T = \frac{L}{fN}$$

When making job estimates, the time required to load and to unload the workpiece on the machine, and the machine handling time, must be added to the cutting time for each length cut to obtain the floor-to-floor time.

**Planing Time.**—The approximate time required to plane a surface can be determined from the following formula in which  $T$  = time in minutes,  $L$  = length of stroke in feet (or meter),  $V_c$  = cutting speed in feet per minute (m/min),  $V_r$  = return speed in feet per minute (m/min);  $W$  = width of surface to be planed in inches (or mm),  $F$  = feed in inches (or mm), and 0.025 = approximate reversal time factor per stroke in minutes for most planers:

$$T = \frac{W}{F} \left[ L \times \left( \frac{1}{V_c} + \frac{1}{V_r} \right) + 0.025 \right]$$

**Speeds for Metal-Cutting Saws.**—The table on page 1144 gives speeds and feeds for solid-tooth, high-speed steel, circular, metal-cutting saws as recommended by Saws International, Inc. (sfpm = surface feet per minute =  $3.142 \times$  blade diameter in inches  $\times$  rpm of saw shaft  $\div$  12). Also see page 1245 for bandsaw blade speeds.

**Speeds for Turning Unusual Materials.**—*Slate*, on account of its peculiarly stratified formation, is rather difficult to turn, but if handled carefully, can be machined in an ordinary lathe. The cutting speed should be about the same as for cast iron. A sheet of fiber or pressed paper should be interposed between the chuck or steadyrest jaws and the slate, to protect the latter. Slate rolls must not be centered and run on the tailstock. A satisfactory method of supporting a slate roll having journals at the ends is to bore a piece of lignum vitae to receive the turned end of the roll, and center it for the tailstock spindle.

*Rubber* can be turned at a peripheral speed of 200 feet per minute (61 m/min), although it is much easier to grind it with an abrasive wheel that is porous and soft. For cutting a rubber roll in two, the ordinary parting tool should not be used, but a tool shaped like a knife; such a tool severs the rubber without removing any material.

### Speeds, Feeds, and Tooth Angles for Sawing Various Material with Solid-Tooth, High-Speed Steel, Circular, Metal-cutting Saws

First entry is cutting speed, second entry is feed

$\alpha$  = Cutting angle (Front), degree

$\beta$  = Relief angle (Back), degree

Materials	Rake Angle		Stock Diameters, inches				Stock Diameters, millimeters			
	$\alpha$	$\beta$	1/4–3/4	3/4–1 1/2	1 1/2–2 1/2	2 1/2–3 1/2	6–19	19–38	38–63	63–89

Stainless Steel	15	8	66 sfpm 2 in/min	63 sfpm 1.75 in/min	60 sfpm 1.75 in/min	57 sfpm 1.5 in/min	20 m/min 51 mm/min	19 m/min 44 mm/min	18 m/min 44 mm/min	17 m/min 38 mm/min

*Gutta percha* can be turned as easily as wood, but the tools must be sharp and a good soap-and-water lubricant used.

*Copper* can be turned easily at 200 feet per minute (61 m/min). See also [Table 6](#) on page 1105.

*Limestone* such as is used in the construction of pillars for balconies, etc., can be turned at 150 feet per minute (46 m/min), and the formation of ornamental contours is quite easy. *Marble* is a treacherous material to turn. It should be cut with tools such as would be used for brass, but at a speed suitable for cast iron. It must be handled very carefully to prevent flaws in the surface.

The foregoing speeds are for high-speed steel tools. Tools tipped with tungsten carbide are adapted for cutting various non-metallic products which cannot be machined readily with steel tools, such as slate, marble, synthetic plastic materials, etc. In drilling slate and marble, use flat drills; and for plastic materials, tungsten carbide-tipped twist drills. Cutting speeds ranging from 75 to 150 feet per minute (23–46 m/min) have been used for drilling slate (without coolant) and a feed of 0.025 inch per revolution (0.64 mm/rev) for drills  $\frac{3}{4}$  and 1 inch (19.05 and 25.4 mm) in diameter.

### Estimating Machining Power

Knowledge of the power required to perform machining operations is useful when planning new machining operations, for optimizing existing machining operations, and to develop specifications for new machine tools that are to be acquired. The available power on any machine tool places a limit on the size of the cut that it can take. When much metal must be removed from the workpiece it is advisable to estimate the cutting conditions that will utilize the maximum power on the machine. Many machining operations require only light cuts to be taken for which the machine obviously has ample power; in this event, estimating the power required is a wasteful effort. Conditions in different shops may vary and machine tools are not all designed alike, so some variations between the estimated results and those obtained on the job are to be expected. However, by using the methods provided in this section a reasonable estimate of the power required can be made, which will suffice in most practical situations.

The measure of power in customary inch units is the horsepower; in SI metric units it is the kilowatt, which is used for both mechanical and electrical power. The power required to cut a material depends upon the rate at which the material is being cut and upon an experimentally determined power constant,  $K_p$ , which is also called the unit horsepower, unit power, or specific power consumption. The power constant is equal to the horsepower required to cut a material at a rate of one cubic inch per minute; in SI metric units the power constant is equal to the power in kilowatts required to cut a material at a rate of one cubic centimeter per second, or 1000 cubic millimeters per second ( $1 \text{ cm}^3 = 1000 \text{ mm}^3$ ). Different values of the power constant are required for inch and for metric units, which are related as follows: to obtain the SI metric power constant, multiply the inch power constant by 2.73; to obtain the inch power constant, divide the SI metric power constant by 2.73. Values of the power constant in Table 1a, and Table 1b can be used for all machining operations except drilling and grinding. Values given are for sharp tools.

**Table 1a. Power Constants  $K_p$  Using Sharp Cutting Tools**

The value of the power constant is essentially unaffected by the cutting speed, the depth of cut, and the cutting tool material. Factors that do affect the value of the power constant, and thereby the power required to cut a material, include the hardness and microstructure of the work material, the feed rate, the rake angle of the cutting tool, and whether the cutting edge of the tool is sharp or dull. Values are given in the power constant tables for different material hardness levels, whenever this information is available. Feed factors for the power constant are given in [Table 2](#). All metal cutting tools wear but a worn cutting edge requires more power to cut than a sharp cutting edge.

Factors to provide for tool wear are given in [Table 3](#). In this table, the extra-heavy-duty category for milling and turning occurs only on operations where the tool is allowed to wear more than a normal amount before it is replaced, such as roll turning. The effect of the rake angle usually can be disregarded. The rake angle for which most of the data in the power constant tables are given is positive 14 degrees. Only when the deviation from this angle is large is it necessary to make an adjustment. Using a rake angle that is more positive reduces the power required approximately 1 percent per degree; using a rake angle that is more negative increases the power required; again approximately 1 percent per degree.

Many indexable insert cutting tools are formed with an integral chip breaker or other cutting edge modifications, which have the effect of reducing the power required to cut a material. The extent of this effect cannot be predicted without a test of each design. Cutting fluids will also usually reduce the power required, when operating in the lower range of cutting speeds. Again, the extent of this effect cannot be predicted because each cutting fluid exhibits its own characteristics.

The machine tool transmits the power from the driving motor to the workpiece, where it is used to cut the material. The effectiveness of this transmission is measured by the machine tool efficiency factor,  $E$ . Average values of this factor are given in Table 4. Formulas for calculating the metal removal rate,  $Q$ , for different machining operations are given in Table 5. These formulas are used together with others given below. The following formulas can be used with either customary inch or with SI metric units.

$$P_c = K_p C Q W \quad (1)$$

$$P_m = \frac{P_c}{E} = \frac{K_p C Q W}{E} \quad (2)$$

where  $P_c$  = power at the cutting tool; hp, or kW

**Table 3. Tool Wear Factors,  $W$** 

Type of Operation		$W$
For all operations with sharp cutting tools		1.00
Turning:	Finish turning (light cuts)	1.10
	Normal rough and semifinish turning	1.30
	Extra-heavy-duty rough turning	1.60-2.00
Milling:	Slab milling	1.10
	End milling	1.10
	Light and medium face milling	1.10-1.25
	Extra-heavy-duty face milling	1.30-1.60
Drilling:	Normal drilling	1.30
	Drilling hard-to-machine materials and drilling with a very dull drill	1.50
Broaching:	Normal broaching	1.05-1.10
	Heavy-duty surface broaching	1.20-1.30
Planing and Shaping	Use values given for turning	

$P_m$  = power at the motor; hp, or kW

$K_p$  = power constant (see Table 1a and Table 1b)

$Q$  = metal removal rate; in<sup>3</sup>/min or cm<sup>3</sup>/s (see Table 5)

$C$  = feed factor for power constant (see Table 2)

$W$  = tool wear factor (see Table 3)

$E$  = machine tool efficiency factor (see Table 4)

$V$  = cutting speed, fpm, or m/min

$N$  = cutting speed, rpm

$f$  = feed rate for turning; in/rev or mm/rev

$f$  = feed rate for planing and shaping; in/stroke, or mm/stroke

- $f_t$  = feed per tooth; in/tooth, or mm/tooth  
 $f_m$  = feed rate; in/min or mm/min  
 $d_t$  = maximum depth of cut per tooth: inch, or mm  
 $d$  = depth of cut; inch, or mm  
 $n_t$  = number of teeth on milling cutter  
 $n_c$  = number of teeth engaged in work  
 $w$  = width of cut; inch, or mm

**Table 4. Machine Tool Efficiency Factors,  $E$** 

Type of Drive	$E$	Type of Drive	$E$
Direct Belt Drive	0.90	Geared Head Drive	0.70-0.80
Back Gear Drive	0.75	Oil-Hydraulic Drive	0.60-0.90

**Table 5. Formulas for Calculating the Metal Removal Rate,  $Q$** 

Operation	Metal Removal Rate	
	For Inch Units Only $Q = \text{in}^3/\text{min}$	For SI Metric Units Only $Q = \text{cm}^3/\text{s}$
Single-Point Tools (Turning, Planing, and Shaping)	$12Vfd$	$\frac{V}{60}fd$
Milling	$f_m wd$	$\frac{f_m wd}{60,000}$
Surface Broaching	$12Vwn_c d_t$	$\frac{V}{60}un_c d_t$

*Example:* A 180-200 BHN AISI 4130 shaft is to be turned on a geared head lathe using a cutting speed of 350 fpm (107 m/min), a feed rate of 0.016 in/rev (0.40 mm/rev), and a depth of cut of 0.100 inch (2.54 mm). Estimate the power at the cutting tool and at the motor, using both the inch and metric data.

Inch units:

$$K_p = 0.62 \text{ (from Table 1b)}$$

$$C = 0.94 \text{ (from Table 2)}$$

$$W = 1.30 \text{ (from Table 3)}$$

$$E = 0.80 \text{ (from Table 4)}$$

$$Q = 12 Vfd = 12 \times 350 \times 0.016 \times 0.100 \text{ (from Table 5)}$$

$$Q = 6.72 \text{ in}^3/\text{min}$$

$$P_c = K_p CQW = 0.62 \times 0.94 \times 6.72 \times 1.30 = 5.1 \text{ hp}$$

$$P_m = \frac{P_c}{E} = \frac{5}{0.80} = 6.4 \text{ hp}$$

SI metric units:

$$K_p = 1.69 \text{ (from Table 1b)}$$

$$C = 0.94 \text{ (from Table 2)}$$

$$W = 1.30 \text{ (from Table 3)}$$

$$E = 0.80 \text{ (from Table 4)}$$

$$Q = \frac{V}{60}fd = \frac{107}{60} \times 0.40 \times 2.54 = 1.81 \text{ cm}^3/\text{s} \text{ (from Table 5)}$$

$$P_c = K_p C Q W = 1.69 \times 0.94 \times 1.81 \times 1.30 = 3.74 \text{ kW}$$

$$P_m = \frac{P_c}{E} = \frac{3.74}{0.80} = 4.677 \text{ kW}$$

Whenever possible the maximum power available on a machine tool should be used when heavy cuts must be taken.

The cutting conditions for utilizing the maximum power should be selected in the following order: 1) select the maximum depth of cut that can be used; 2) select the maximum feed rate that can be used; and 3) estimate the cutting speed that will utilize the maximum power available on the machine. This sequence is based on obtaining the longest tool life of the cutting tool and at the same time obtaining as much production as possible from the machine.

*The life of a cutting tool is most affected by cutting speed, then by feed rate, and least of all by depth of cut.* The maximum metal removal rate that a given machine is capable of machining from a given material is used as the basis for estimating the cutting speed that will utilize all the power available on the machine.

*Example:* A 160–180 BHN gray iron casting that is 6 inches wide is to have  $\frac{1}{8}$  inch stock removed on a 10 hp milling machine, using an 8 inch diameter, 10 tooth, indexable insert cemented carbide face milling cutter. The feed rate selected for this cutter is 0.012 in/tooth, and all the stock (0.125 inch) will be removed in one cut. Estimate the cutting speed that will utilize the maximum power available on the machine.

$$K_p = 0.52 \text{ (From Table 1a)}$$

$$C = 1.00 \text{ (From Table 2)}$$

$$W = 1.20 \text{ (From Table 3)}$$

$$E = 0.80 \text{ (From Table 4)}$$

$$Q_{max} = \frac{P_m E}{K_p C W} = \frac{10 \times 0.80}{0.52 \times 1.00 \times 1.20} = 12.82 \text{ in}^3/\text{min} \quad \left( P_m = \frac{K_p C Q W}{E} \right)$$

$$f_m = \frac{Q_{max}}{wd} = \frac{12.82}{6 \times 0.125} = 17.1 \text{ in/min} \quad (Q = f_m w d)$$

$$N = \frac{f_{max}}{f_i n_t} = \frac{17}{0.012 \times 10} = 142.4 \text{ rpm} \quad (f_m = f_i n_t N)$$

$$V = \frac{\pi D N}{12} = \frac{\pi \times 8 \times 142}{12} = 298.3 \text{ fpm} \quad \left( N = \frac{12V}{\pi D} \right)$$

Calculated cutting speed of 298.3 fpm is correct, but very low for available cutting tools. Today, milling of gray irons is performed, mostly, using cubic boron nitride indexable inserts. Typical range of the cutting speed for milling with large engagement (0.8) and 0.004–0.008 inch per tooth chip load is 2700–2000 sfm. Estimating maximum productivity of cutting should be based on the recommended cutting speeds versus work materials.

*Example:* A 3.2 mm deep cut is to be taken on a 200–210 BHN AISI 1050 steel part using a 7.5 kW geared head lathe. The feed rate selected for this job is 0.45 mm/rev. Estimate the cutting speed that will utilize the maximum power available on the lathe.

$$K_p = 2.32 \text{ (From Table 1b)}$$

$$C = 0.92 \text{ (From Table 2)}$$

$$W = 1.30 \text{ (From Table 3)}$$

$$E = 0.80 \text{ (From Table 4)}$$

$$Q_{max} = \frac{P_m E}{K_p C W} = \frac{7.5 \times 0.80}{2.32 \times 0.92 \times 1.30} \quad \left( P_m = \frac{K_p C Q W}{E} \right)$$

$$= 2.16 \text{ cm}^3 / \text{sec}$$

$$V = \frac{60 Q_{max}}{f d} = \frac{60 \times 2.16}{0.45 \times 3.2} \quad \left( Q = \frac{V}{60} f d \right)$$

$$= 90.0 \text{ m/min}$$

The calculated cutting speed of 90.0 m/min is correct, but too low for carbide cutting tools. Thirty years ago, recommended cutting speed for turning AISI 1050 steel, 200–210 BHN, depth of cut 4.0 mm, was 160 m/min. Currently, using advanced coated carbide inserts, the cutting speed is increased up to 300 m/min for the depth of cut of 2.5–5.0 mm and a 0.38 mm/rev feed rate.

**Estimating Drilling Thrust, Torque, and Power.**—Although the lips of a drill cut metal and produce a chip in the same manner as the cutting edges of other metal cutting tools, the chisel edge removes the metal by means of a very complex combination of extrusion and cutting. For this reason a separate method must be used to estimate the power required for drilling. Also, it is often desirable to know the magnitude of the thrust and the torque required to drill a hole. The formulas and tabular data provided in this section are based on information supplied by the National Twist Drill Division of Regal-Beloit Corp. The values in Table 6 through Table 9 are for sharp drills and the tool wear factors are given in Table 3. For most ordinary drilling operations 1.30 can be used as the tool wear factor. When drilling most difficult-to-machine materials and when the drill is allowed to become very dull, 1.50 should be used as the value of this factor. It is usually more convenient to measure the web thickness at the drill point than the length of the chisel edge; for this reason, the approximate  $w/d$  ratio corresponding to each  $c/d$  ratio for a correctly ground drill is provided in Table 7. For most standard twist drills the  $c/d$  ratio is 0.18, unless the drill has been ground short or the web has been thinned. The  $c/d$  ratio of split-point drills is 0.03. The formulas given below can be used for spade drills, as well as for twist drills. Separate formulas are required for use with customary inch units and for SI metric units.

**Table 6. Work Material Factor,  $K_d$ , for Drilling with a Sharp Drill**

Work Material	Material Constant, $K_d$	Work Material	Material Constant, $K_d$
AISI 1117 (Resulfurized free machining mild steel)	12,000	Austenitic Stainless Steel (Type 316)	24,000 <sup>a</sup> for Torque
Steel, 200 BHN	24,000	Titanium Alloy Ti6Al4V 40R <sub>c</sub>	18,000 <sup>a</sup> for Torque
Steel, 300 BHN	31,000		29,000 <sup>a</sup> for Thrust
Steel, 400 BHN	34,000	René 41 40R <sub>c</sub>	40,000 <sup>ab</sup> min.
Cast Iron, 150 BHN	14,000	Hastelloy-C	30,000 <sup>a</sup> for Torque 37,000 <sup>a</sup> for Thrust
Most Aluminum Alloys	7,000		
Most Magnesium Alloys	4,000		
Most Brasses	14,000		
Leaded Brass	7,000		

<sup>a</sup> Values based upon a limited number of tests.

<sup>b</sup> Will increase with rapid wear.

**Table 7. Chisel Edge Factors for Torque and Thrust**

<i>c/d</i>	Approx. <i>w/d</i>	Torque Factor <i>A</i>	Thrust Factor <i>B</i>	Thrust Factor <i>J</i>	<i>c/d</i>	Approx. <i>w/d</i>	Torque Factor <i>A</i>	Thrust Factor <i>B</i>	Thrust Factor <i>J</i>
0.03	0.025	1.000	1.100	0.001	0.18	0.155	1.085	1.355	0.030
0.05	0.045	1.005	1.140	0.003	0.20	0.175	1.105	1.380	0.040
0.08	0.070	1.015	1.200	0.006	0.25	0.220	1.155	1.445	0.065
0.10	0.085	1.020	1.235	0.010	0.30	0.260	1.235	1.500	0.090
0.13	0.110	1.040	1.270	0.017	0.35	0.300	1.310	1.575	0.120
0.15	0.130	1.080	1.310	0.022	0.40	0.350	1.395	1.620	0.160

For drills of standard design, use  $c/d=0.18$ ; for split-point drills, use  $c/d=0.03$   
 $c/d$  = Length of Chisel Edge ÷ Drill Diameter.

$w/d$  = Web Thickness at Drill Point ÷ Drill Diameter.

For inch units only:

$$T = 2K_d F_f F_T B W + K_d D^2 J W \quad (1)$$

$$M = K_d F_f F_M A W \quad (2)$$

$$P_c = MN/63,025 \quad (3)$$

For SI metric units only:

$$T = 0.05 K_d F_f F_T B W + 0.007 K_d D^2 J W \quad (4)$$

$$M = \frac{K_d F_f F_M A W}{40,000} = 0.000025 K_d F_f F_M A W \quad (5)$$

$$P_c = MN/9550 \quad (6)$$

Use with either inch or metric units:

$$P_m = \frac{P_c}{E} \quad (7)$$

where  $P_c$  = Power at the cutter; hp, or kW       $P_m$  = Power at the motor; hp, or kW

$M$  = Torque; in. lb, or N.m

$T$  = Thrust; lb, or N

$K_d$  = Work material factor (See Table 6)

$F_f$  = Feed factor (See Table 8)

$F_T$  = Thrust factor for drill diameter (See Table 9)

$F_M$  = Torque factor for drill diameter (See Table 9)

$A$  = Chisel edge factor for torque (See Table 7)

$B$  = Chisel edge factor for thrust (See Table 7)

$J$  = Chisel edge factor for thrust (See Table 7)

$W$  = Tool wear factor (See Table 3)

$N$  = Spindle speed; rpm

$E$  = Machine tool efficiency factor (See Table 4)

$D$  = Drill diameter; in., or mm

$c$  = Chisel edge length; in., or mm (See Table 7)

$w$  = Web thickness at drill point; in., or mm (See Table 7)

*Example:* A standard  $\frac{1}{8}$  inch drill is to drill steel parts having a hardness of 200 BHN on a drilling machine having an efficiency of 0.80. The spindle speed to be used is 350 rpm and the feed rate will be 0.008 in/rev. Calculate the thrust, torque, and power required to drill these holes:

$$K_d = 24,000 \text{ (From Table 6)} \quad F_f = 0.021 \text{ (From Table 8)}$$

$$F_T = 0.899 \text{ (From Table 9)} \quad F_M = 0.786 \text{ (From Table 9)}$$

$$A = 1.085 \text{ (From Table 7)} \quad B = 1.355 \text{ (From Table 7)} \quad J = 0.030 \text{ (From Table 7)}$$

**Table 8. Feed Factors  $F_f$  for Drilling**

$$W = 1.30 \text{ (From Table 3)}$$

$$T = 2K_d F_f F_T B W + K_d d^2 J W$$

$$= 2 \times 24,000 \times 0.021 \times 0.899 \times 1.355 \times 1.30 + 24,000 \times 0.875^2 \times 0.030 \times 1.30$$

$$= 2313 \text{ lb}$$

$$M = K_d F_f F_M A W$$

$$= 24,000 \times 0.021 \times 0.786 \times 1.085 \times 1.30 = 559 \text{ in-lb}$$

$$P_c = \frac{MN}{63,025} = \frac{559 \times 350}{63,025} = 3.1 \text{ hp} \quad P_m = \frac{P_c}{E} = \frac{3.1}{0.80} = 3.9 \text{ hp}$$

Twist drills are generally the most highly stressed of all metal cutting tools. They must not only resist the cutting forces on the lips, but also the drill torque resulting from these forces and the very large thrust force required to push the drill through the hole. Therefore, often when drilling smaller holes, the twist drill places a limit on the power used and for very large holes, the machine may limit the power.

**Boring**

Boring is an internal turning operation performed with a boring bar to enlarge a previously drilled hole to form an internal shape of required dimensions. Boring operations range from semi-roughing to finishing.

An indexable boring bar has three basic elements: indexable cutting insert, shank, and anchor. The designation system for indexable inserts is the same as for turning. The anchor is the clamping portion of the shank that is held in the tool block. The minimum clamping length is approximately three to four diameters of the shank. The distance the boring bar extends beyond the tool block is the overhang; it determines the cutting depth. The overhang is the unsupported portion of the boring bar. Long overhang causes excessive deflection of the shank and generates vibration (chatter), which worsens the surface finish of the bore.

Eliminating chatter, especially in long-bore workpieces, is one of the greatest challenges faced by manufacturers and users of boring bars. Deflection of a boring bar depends on the mechanical properties of the shank material, the length of the overhang, and the cutting conditions.

The following equation is used for calculating deflection ( $y$ ) of a boring bar.

$$y = \frac{FL^3}{3EI} \quad (1)$$

where  $F$  = the cutting force, lbf or N

$L$  = unsupported length of a boring bar (overhang), in. or mm

$E$  = the modulus of elasticity (in tension) of a boring bar material, psi or N/mm<sup>2</sup>

$I$  = the moment of inertia of a boring bar cross-sectional area, in<sup>4</sup> or mm<sup>4</sup>.

**Cutting Force.**—Cutting force ( $F$ ) is calculated by **Formula (2)** in customary US units.

$$F = 396,000dfK_p \quad (2)$$

where  $d$  = depth of cut, in.

$f$  = a feed rate, ipm

$K_p$  = a power constant, hp/in<sup>3</sup>/min. The power constant  $K_p$  data are given on pages 1145–1147 (Table 1a and 1b). The feed rate factors,  $C$ , for power constants are given on page 1148 (Table 2).

396,000 = a conversion factor that represents a unit of power equal to 550 in-lb/min

*Example 1(a):* A workpiece is AISI 4140 chromium-molybdenum steel, 220 HB; depth of cut  $d = 0.080$  in.; feed rate  $f = 0.008$  ipr. Calculate the cutting force  $F$  in customary US units of measure.

Power constant  $K_p = 0.72$  hp/in<sup>3</sup>/min (from Table 1b, page 1147)

Feed factor  $C = 1.08$  (from Table 2, page 1148)

Adjusted power constant,  $K_{pa} = K_p \times C = 0.72 \times 1.08 = 0.78$ .

Calculating:  $F = 396,000dfK_{pa} = 396,000 \times 0.08 \times 0.008 \times 0.78 = 197.7$  lbf

Cutting force ( $F$ ) is calculated by **Formula (3)** in metric units.

$$F = 60,000dfK_p \quad (3)$$

where  $d$  = depth of cut, mm

$f$  = feed rate, mm/min.

$K_p$  = is a power constant, kW/cm<sup>3</sup>/min. The power constant  $K_p$  data are given on pages 1145–1147 (Tables 1a and 1b). The feed rate factors,  $C$ , for power constants are given on page 1148 (Table 2).

60,000 = is a conversion factor that represents a unit of power equal to 1 kW × mm/min.

*Example 1(b):* A workpiece is AISI 4140 chromium-molybdenum steel, 220 HB; depth of cut  $d = 2.03$  mm; feed rate  $f = 0.20$  mm/rev. Calculate the cutting force  $F$  in metric units.

Power constant  $K_p = 0.0328$  kW/cm<sup>3</sup>/min. (from Table 1b, page 1147)

Feed factor  $C = 1.08$  (from Table 2, page 1148)

Adjusted power constant,  $K_{pa} = K_p \times C = 0.0328 \times 1.08 \approx 0.0354$  kW/cm<sup>3</sup>/min.

Calculating:  $F = 60,000dfK_{pa} = 60,000 \times 2.03 \times 0.20 \times 0.0354 = 863.6$  N

Comparing the cutting forces calculations of Example 1(a) and 1(b), the cutting forces are approximately equivalent within about 2 percent.

**Moduli of Elasticity ( $E$ ) of Boring Bar Materials.**—Boring bar shanks are made of steels, tungsten-base metals, or cemented carbides. Most commonly used boring bar materials are alloy steels. Some boring bar manufacturers use AISI 1144 free machining medium-carbon steel. Regardless of grades, all carbon and alloy steels have approximately the same modulus of elasticity:

Customary US units,  $E = 30 \times 10^6$  psi

Metric units,  $E = 20.6 \times 10^4$  N/mm<sup>2</sup>

A common mistake is to assume that a steel shank with a higher hardness, or one made from a higher quality of steel will deflect less. As can be seen from Equation (1), the material property that determines deflection is the modulus of elasticity. Hardness does not appear in this equation.

Tungsten heavy alloys for boring bars,  $E = (45-48) \times 10^6$  psi (customary US units) and  $E = (31-33) \times 10^4$  N/mm<sup>2</sup> (metric units). Boring bars made of tungsten heavy alloys will deflect less than steel boring bars of the same diameter and overhang by 50 to 60 percent when cutting at the same depth of cut and feed rate.

Cemented carbides for boring bars,  $E = (84-89) \times 10^6$  psi (customary US units) and  $E = (52-61) \times 10^4$  N/mm<sup>2</sup> (metric units).

Boring bars made of cemented carbides provide minimum deflection because their moduli of elasticity are higher than those of steels and tungsten heavy alloys.

**Moment of Inertia ( $I$ ) of a Boring Bar Cross-Sectional Area.**—Moment of inertia is a property of areas. Since boring bars are available in a variety of diameters, it is important to calculate the moment of inertia of a bar cross section using appropriate formulas. Boring bars are usually round with a solid or tubular cross section. Moments of inertia of solid or tubular cross-sectional areas are calculated by:

$$I = \frac{\pi D^4}{64} \quad (4a)$$

$$I = \frac{\pi(D_o^4 - D_i^4)}{64} \quad (4b)$$

where  $D$  is the diameter of the bar in inches or mm,  $D_o$  is the outside diameter of the bar and  $D_i$  is the inside diameter, in inches or mm.

*Example 2:* A boring bar diameter is 1 inch. Moment of inertia  $I = \pi \times (1)^4/64 = 0.0491$  in<sup>4</sup>. Moments of inertia of cross sections are given starting on page 241.

**Deflection ( $y$ ) of the Boring Bar.**—To calculate the deflection of the boring bar, it is necessary to enter one more data point in Equation (1). It is the unsupported length of the boring bar ( $L$ ).

*Example, Boring Bar Deflection:* The unsupported length of a 1-inch diameter boring bar is 4 inches. Using  $F$  calculated in Example 1(a) and  $I$  calculated in Example 2:

$$y = \frac{FL^3}{3EI} = \frac{(197.7)4^3}{3(30 \times 10^6)0.0491} = 0.0028 \text{ inch}$$

## MICROMACHINING

## Introduction

Recent technological advancement and market need for product miniaturization demand three-dimensional (3D) microcomponents. Although microelectronic manufacturing techniques can produce pseudo 3D microdevices using silicon and other semiconducting materials, such materials are neither robust nor biocompatible for demanding applications in aerospace, medical, sensor, defense, petroleum, and transportation. Examples of robust applications include microdrilling holes for fuel or ink injection nozzles, electronic printed circuit boards, microfabrication of watch components, air bearings, cooling holes in turbomachinery, high aspect ratio features on tool steel molds and dies, etc. There are alternative nontraditional processes to produce microfeatures on robust engineering materials such as laser micromachining, electrical discharge microdrilling, electrochemical micromachining, chemical etching, electron/ion beam machining; however, these processes are either cost prohibitive, limited to conductive materials, or inferior when comparing resulting surface integrity, subsurface damage, high aspect ratio, or microfeature quality. Microfabrication with traditional processes such as micromilling, microdrilling, microturning, . . . are still the preferred choice in most applications. There is no standard that defines micromachining, but most researchers use cutting tools to produce components with key dimensions less than 1 mm (0.040 inch) or when depth of cut is comparable to tool sharpness or tool grain size in their micromachining studies.

Realizing the needs for traditional micromanufacturing, there are more commercially available machine tools and microtools in the market. However, costly equipment, lack of in-depth understanding of micromachining, and limited guidelines for effective use of microtools are still the bottleneck for full application of micromachining. Universities and research institutes worldwide have started theoretical investigation of micromachining and produced positive results from the academic point of view. Without practical guidelines on micromachining, technicians and machinists probably would make wrong and costly decisions when simply extending macroscale machining practices into microscale machining applications—a microtool simply breaks at even conservative macroscale parameters for speeds, feeds, and depth of cut. This section, while complementing other chapters in this Handbook, focuses on practicality, based on proven theories and published data, to help decision makers to understand the requirements for micromachining, and as a guide to people on the shop floor to quickly and confidently begin using the recommended parameters and techniques. Both US standard and SI metric units are included for convenience. Examples of how to use the data and equations are given throughout this chapter.

## Machine Tool Requirements

To obtain the same surface speed as in macromachining, a machine tool must:

- a) Be capable of rotating a workpiece or tool at high speeds of 25,000 rpm or above
- b) Control spindle runout to submicron level
- c) Have a very robust mechanical and thermal structure that is not affected by vibration or thermal drift
- d) Have high resolution tool positioning and feeding mechanisms

Success in micromachining depends on tool quality and precision of the machine tool. Machine spindle runout, tool concentricity and tool positioning accuracy must be in the neighborhood of 1/100th of tool diameter or less for successful operation. Tolerance stack up for spindle runout, tool eccentricity, and wandering of a microdrill causes cyclic bending of the tool that lead to catastrophic failure. At a low rotational speeds, the displacement of a spindle can be monitored with a sensitive mechanical indicator. However, this option is not applicable for machines that operates at or above a few thousands rpm. Other non-contact techniques using capacitance, magnetism, or light would be more appropriate. Fig. 1a shows an example of spindle runout measuring setup. A laser beam is

pointed at a rotating precision plug gage. The spindle displacement is then recorded on a computer for further analysis and display in either frequency or time domain. Commercial laser systems can provide displacement readings to  $\pm 0.1 \mu\text{m}$  resolution.

An example of spindle runout is shown in Fig. 1b; the spindle runout of a Haas OM2 machine was measured with a Keyence laser system to be  $\pm 1.25 \mu\text{m}$ . Care must be practiced to isolate vibration of the spindle or it would affect the sensor reading, and avoid direct eye contact with the reflected laser from the shiny plug gage.

Fig. 1a. Setup for Spindle Runout Measurement.

Fig. 1b. Spindle Runout of Haas OM2 CNC Micromilling Machine.

*Example 1, Spindle Speed for Macro versus Micro Machining:* The speed and feed table on page 1118 recommends a milling speed of 585 ft/min (178 m/min) and feed of 0.004 in/tooth (0.1 mm/tooth) for end milling 316L stainless steel using an uncoated carbide tool.

*Macromachining:* To have said surface speed for an  $\text{Ø}1/2$  inch ( $\text{Ø}12.5$  mm) end mill, the required spindle speed is

$$N = \frac{V}{\pi D} = \frac{585(\text{ft}/\text{min})}{\pi(\text{rad}/\text{rev}) \times 0.5(\text{in})} \times 12(\text{in}/\text{ft}) = 4,469 \text{ rpm}$$

*Micromachining:* To obtain the same surface speed for an  $\text{Ø}0.004$  inch ( $\text{Ø}0.1$  mm) micromill, the new spindle speed is

$$N = \frac{V}{\pi D} = \frac{585(\text{ft}/\text{min})}{\pi(\text{rad}/\text{rev}) \times 0.004(\text{in})} \times 12(\text{in}/\text{ft}) = 558,633 \text{ rpm}$$

To turn, face, or bore a stainless steel microshaft of  $\text{Ø}0.004$  inch ( $\text{Ø}0.1$  mm) at this cutting speed, a lathe spindle would need to rotate at 558,633 rpm too. A machine tool with spindle speed exceeding 500,000 rpm is rare or simply not commercially available at this time.

Applying the recommended macro feed of 0.004 in/tooth (0.1 mm/tooth) for an 0.004 inch (0.1 mm) diameter micromill would break the tool because the feed/tooth is as large as the microtool diameter.

### Microcutting Tools

**Tool Stiffness.**—It is relatively easy to have a rigid turning or facing microtool, but it requires careful planning to maintain rigidity of a micromill or a microdrill. Geometries of macroscale and macroscale drilling/milling tools are the same: tool diameter, number of cutting flutes, point included angle for microdrill, helix angle, web thickness, clearance angle, flute length, shank diameter, and overall length. A careful selection of microtools must consider the intended machined features and highest possible tool stiffness. The two most important geometries that affect the microtool stiffness are the tool diameter and flute length assuming the number of flutes has been chosen. It can be shown that the torsional stiffness of a mill/drill is proportional to (tool diameter)<sup>4</sup> and (flute length)<sup>-2</sup>. For a specific mill/drill tool dimension, the milling/drilling strategy must be adjusted accordingly to avoid tool breakage.

*Example 2, Stiffness of Microtools:* If a drill diameter of 0.8 mm is selected instead of 1.0 mm, then the 20% reduction of diameter will result in a reduction in torsional stiffness  $E$  of:

$$\Delta E = \frac{(D_2)^4 - (D_1)^4}{(D_1)^4} = \frac{0.8^4 - 1.0^4}{1.0^4} = -59\%$$

Similarly, if a flute length of 1.2 mm is chosen instead of 1.0 mm, the 20% change in flute length will lead to a decrease in torsional stiffness  $E$  of:

$$\Delta E = \frac{(L_2)^2 - (L_1)^2}{(L_1)^2} = \frac{1.2^2 - 1.0^2}{1.0^2} = -30\%$$

**Tool Sharpness.**—The tool edge radius is critical in micromachining. Fig. 2a through Fig. 2d shows two scenarios for the same microcutting tools with edge radius  $r$ . The tool can be either a turning, facing, or boring microtool that linearly engages a workpiece material at a certain depth of cut. A similar tool can move in a circular path as a microdrill or micromill, and engage a workpiece at a certain chip load (feed per tooth). If the depth of cut (or chip load) is too shallow, the tool simply plows the material and pushes it away elastically. This elastic material layer just springs back after the tool passes by. If the depth of cut is substantial (recommended), then a chip is formed and a new machined surface is generated with negligible spring back.

*Chip load* is commonly used interchangeably with feedrate for a cutting tool with multiple cutting edges (teeth) such as in milling or drilling. Chip load is defined as tool feed distance for each tooth and represents the chip size forming for each tooth. Chip load can also be interpreted as the radial depth of cut for each tooth in milling. The following equation converts chip load of a cutting edge to feedrate of a multiple-edge cutting tool:

$$f = c_L n N$$

where  $f$  = feedrate of tool (mm/min, in/min)  
 $c_L$  = chip load of a cutting edge (mm/tooth, in/tooth)  
 $n$  = number of cutting flutes or cutting edges (#teeth/rev)  
 $N$  = rotational speed (rpm)

*Example 3:* A two-flute uncoated carbide end mill with diameter  $\varnothing 1$  mm ( $\varnothing 0.040$  in) is used for micromilling pure titanium. Table 13b suggests a chip load of  $17 \mu\text{m/tooth}$  and cutting speed of 90 m/min. The rotational speed is computed as:

$$N = \frac{V}{\pi D} = \frac{90 \text{ (m/min)}}{\pi \left( \frac{\text{rad}}{\text{rev}} \right) \times 0.001 \text{ (m)}} = 28,600 \text{ rpm}$$

The feedrate for this operation is:

$$f = c_L n N = 17 \left( \frac{\mu\text{m}}{\text{tooth}} \right) \times 2 \left( \frac{\text{teeth}}{\text{rev}} \right) \times 28,600 \left( \frac{\text{rev}}{\text{min}} \right) = 972,400 \frac{\mu\text{m}}{\text{min}} \approx 972 \frac{\text{mm}}{\text{min}} \approx 38 \frac{\text{in}}{\text{min}}$$

Typical fine grain carbide tools are first sintered from submicron carbide particles in a cobalt matrix, and then ground and lapped to final geometry. Optimal edge radii of 1–4  $\mu\text{m}$  (39–156  $\mu\text{in}$ ) are typically designed for sintered tools to balance edge sharpness and edge strength. Only single crystalline diamond tools can be ground and lapped to edge radii within the nanometer range.

The threshold for minimum depth of cut has been investigated theoretically and verified experimentally by many researchers. It varies from 5 to 40 percent of the tool edge radius depending on the workpiece material and original rake angles. The threshold depth of cut or chip load, therefore, can be conservatively set to be 50 percent of the tool edge radius. When machining below this threshold, a microtool just rubs and plows the surface with negative effective rake angle and deforms it elastically during the first pass. This results in high cutting force, high specific energy, fast tool wear, rough surface finish, and significant burrs. In subsequent passes when the cumulative depth is greater than the critical depth of cut, then a tool can remove materials as chips and the cycle repeats.

### Effect of Depth of Cut (Chip Load) in Micromachining

Fig. 2a. Microfaceting, Depth of Cut  $< 0.5 r$ .

Fig. 2b. Microfaceting, Depth of Cut  $> 0.5 r$ .

Fig. 2c. Micromilling, Chip Load  $< 0.5 r$

Fig. 2d. Micromilling, Chip Load  $> 0.5 r$ .

Fig. 2a and Fig. 2c illustrate rubbing and plowing of material with negative effective rake angle at a shallow depth of cut. Fig. 2b and Fig. 2d illustrate chip removal from material with positive effective rake angle at a deep depth of cut.

It is crucial to verify the tool edge radius before deciding on cutting parameters. Measuring of tool edge radius, however, is not trivial. A tool edge radius can be estimated from a scanning electron microscopic picture when the cutting edge is parallel to the electron beam (Fig. 6), or from a scanned image at the neighborhood of a cutting edge on an atomic force microscope (Fig. 3a and Fig. 3b), or by scanning an edge on an optical microscope profiler in different views to reconstruct a 3D image of the tool edge before finding its radius.

### Tool Edge Measurement by Atomic Force Microscopy

Note the different vertical and horizontal scales.

Fig. 3a. New Polycrystalline Diamond Tool with a 750 nm Edge Radius.

Fig. 3b. New Single Crystalline Diamond Tool with a 10 nm Edge Radius.

**Tool Materials.**—Using the right microtool is essential for micromachining. A microtool that successfully drills through holes on a plastic printed circuit board is not necessarily able to drill deep blind holes on titanium alloys. Understanding the requirements and selecting the right microtool for each condition saves time, money, and frustration. It has been theoretically derived and experimentally proven that the smaller is the chip, then the higher is the stress to generate it. Microcutting tools, therefore, have to be designed for higher stress with extreme geometrical constraints. When depth of cut is smaller than the average grain size of a workpiece, each grain generates different stress on the cutting edge and eventually fatigues the tool.

Microtools as small as 25  $\mu\text{m}$  (0.001 inch) are commercially available. Common tool materials are high-speed steel (HSS), cermet, carbide, cubic boron nitride (CBN), polycrystalline diamond (PCD), and single crystalline diamond (SCD). HSS is commonly not used in micromachining of metal since it does not have required hardness and strength to resist plastic deformation. A SCD tool is available for microturning, but not for microdrilling or micromilling. Carbide and cermet, having properties between HSS and diamond, are most suitable for microcutting tools. They are sintered from random abrasive grains in either cobalt or nickel binder with a small addition of molybdenum or chromium. A higher binder content increases the tool toughness and crack resistance, but reduces the tool bulk hardness. Using ultra fine grain (submicron size) abrasives in a lesser amount of binder is the optimal solution because a tool with submicron carbide grains can maintain a high hardness while improving its crack resistance against chattering, interrupted cuts, or cyclic deflection due to spindle runout.

Microtool failure modes include shearing, chipping, and wear. To minimize shearing and catastrophic tool failure, a tool should be made from a high hardness substrate and with a geometry suitable for micromachining, i.e., large included angle and sharp cutting edge (Fig. 4). A tool with smaller than minimum included angle will be deformed and fractured in service.

Fig. 4. (a) Tool Geometry, and (b) Change of Tool Edge Radius Due to Coating.

Fig. 5. Microtool Minimum Included Angles.

*Example 4, Required Included Angle:* Find the minimum included angle for an ultra-fine grain carbide tool of 12 GPa Vicker hardness to machine the F799 Co-Cr alloy of 1500 MPa ( $0.2 \times 10^6$  psi) tensile strength.

*Solution:* Referring to Fig. 5, locate workpiece strength at point A on the vertical axis (1500 MPa). Locate point B for tool hardness on the horizontal axis (12 GPa). The intersection at C of the horizontal line from A and the vertical line from B indicates that the minimum included tool angle should be 75°.

Coating of microtools is still a technical challenge due to conflicting constraints for tool performance. Chemical or physical vapor deposition (CVD or PVD) techniques have been developed to coat cutting tools with mono/multiple layers of intermetallic or ceramic compounds (Table 1). Criteria for acceptable tool coating are numerous: uniformity, high hardness, high toughness, low friction, high wear resistance, surface smoothness, high chemical/diffusion resistance, and high temperature stability at a reasonable cost. Although a coating thickness of 2–4  $\mu\text{m}$  (79–157  $\mu\text{in}$ ) is acceptable for a macrotool, the coating thickness on a microtool should be thinner to minimize fracture and peeling of the coating. Both CVD and PVD processes not only add the coating thickness to the edge radius, but the extra coating also increases the radius at sharp corners (Fig. 4b). This is unfortunate since the thicker coating reduces the tool sharpness by enlarging the tool edge radius and causes an unfavorable plowing effect with negative effective rake angle. An uncoated microtool might perform satisfactorily, but the same machining parameters can be devastating to an over-coated microtool (Fig. 6). A thin coating of less than 1.5  $\mu\text{m}$  following by an edge sharpening process would improve the tool performance, however, at the expense of higher tool cost. Published data indicate that micrograin carbide tools with 1.5  $\mu\text{m}$  TiN coating is the best for micromilling of H13 tool steel hardened to 45 RC.

**Table 1. Commercial Coatings for Microtools**

Coating	Structure	Hardness		Coefficient of Friction	Coating Thickness		Maximum Temperature	
		GPa	$10^6$ psi		$\mu\text{m}$	$\mu\text{in}$	$^{\circ}\text{C}$	$^{\circ}\text{F}$
TiN	monolayer	24	3.5	0.55	1-5	39-197	600	1110
TiCN	gradient	37	5.4	0.20	1-4	39-157	400	750
TiAlCN	gradient	28	4.1	0.30	1-4	39-157	500	930
TiAlN	multilayer	28	4.1	0.60	1-4	39-157	700	1290
AlTiN	gradient	38	5.5	0.70	1-3	39-118	900	1650
ZrN	monolayer	20	2.9	0.40	1-4	39-157	550	1020
CrN	monolayer	18	2.6	0.30	1-4	39-157	700	1290
Diamond like	gradient	20	2.9	0.15	0.5-1.5	20-59	400	750
AlTiN/Si <sub>3</sub> N <sub>4</sub>	nanocomposite	45	6.5	0.45	1-4	39-157	1200	2190
AlCrN/Si <sub>3</sub> N <sub>4</sub>	nanocomposite	42	6.1	0.35	1-5	39-197	1100	2010

**Tool Offset and Positioning.**—Tool offset and tool positioning are crucial in micromilling and microdrilling because a tool is small and extremely fragile especially if it has a high aspect ratio (length to diameter ratio). Common shop practices to find tool offset and position often damage a tool or workpiece. Non-contact techniques using light, magnetism, capacitance, ultrasound, etc. are the preferred choice for precisely locating the relative position between tool and workpiece. Selection of a suitable sensor depends at least on following criteria:

- Better resolution compared to that of the machine tool axis
- Small working zone to cover a microtool
- Fast sampling rate for intended tool speed

Fig. 6. Peeling (a) and cracking (b) of 4 $\mu\text{m}$ -thick TiN coating layer on a WC microdrill. Back scattered electron technique shows high contrast of a dark TiN coating layer against the bright WC/Co substrate in the background.

*Example 5, Sensor Requirement:* Select a sensor for microdrilling using Microdrill: 100  $\mu\text{m}$  diameter, 1 mm flute length ( $\text{\O}0.004$  inch, 0.040 inch flute length). Machine tool: 1  $\mu\text{m}$  (40  $\mu\text{inch}$ ) repeatability and 500,000 rpm capability.

*Solution:* A laser displacement sensor is selected to satisfy the following specifications: Resolution: 0.1  $\mu\text{m}$  (4  $\mu\text{inch}$ )

Spot size: 25–75  $\mu\text{m}$  (0.001–0.003  $\mu\text{inch}$ ). Although most drill shanks are  $\text{\O}3.175$  mm ( $\text{\O}0.125$  inch), the working zone should be as small as possible to detect the shank center.

In order to make 6 measurements when a tool is rotating at 500,000 rpm, the time between measurements is:

$$t = \left( \frac{1 \text{ rev}}{6 \text{ measurements}} \right) \left( \frac{1 \text{ min}}{500,000 \text{ rev}} \right) \left( \frac{60 \text{ s}}{1 \text{ min}} \right) = 2 \times 10^{-5} \text{ s} = 20 \mu\text{s}$$

A laser with minimum 20  $\mu\text{s}$  sampling rate (50 kHz) would be sufficient.

A mechanical edge finder is adequate for most macromachining setups, but it is not suitable for micromachining especially with small and pliable parts. Fig. 7a shows a non-contact technique to detect part edge or find lateral tool offset. A rotating precision plug gage, mounted on a machine spindle, is positioned between a stationary laser sensor and the workpiece. The small laser beam is aimed at the plug gage center and on the part edge when the plug gage is withdrawn away from the beam path. These two laser sensor readings allow computing the tool center offset. A precision plug gage should be used instead of a cutting tool shank for better repeatability.

*Example 6, Lateral Tool Offset Calculation:* Use a laser displacement sensor and a  $\text{\O}3.175$  mm ( $\text{\O}1/8$  inch) plug gage to detect the edge of a ground block.

*Solution:*

- i) Mount the plug gage on the machine spindle and rotate it at 5000 rpm.
- ii) Scan a laser beam across the plug gage and stop when the distance from the laser source to the target is minimum, i.e., the beam is at the gage center. Read  $L_1 = 35$  mm.
- iii) Jog the plug gage away from the beam path, read distance to the part edge  $L_2 = 55$  mm.
- iv) The lateral offset from the spindle center to the workpiece edge is then:

$$\text{Lateral offset} = L_2 - L_1 - D/2 = 55 - 35 - (3.175/2) = 18.412 \text{ mm}$$

Fig. 7a. Setup for Lateral Edge Detection Using Laser Sensor.

Fig. 7b compares the accuracy and repeatability of the non-contact method shown in Fig. 7a against those of a mechanical edge finder.

Fig. 7b. Superior Accuracy and Repeatability of Laser Edge Detection Technique Compared to Mechanical Technique.

It is rather simple to find the lateral offset as illustrated in Example 6, but it is more difficult to find the exact vertical offset for a slender microdrill or micromill without damaging it. One can attempt to use the common “paper technique” or take a risk with an available contact sensor for z-setting. In the paper technique, one would use a hand to slide a piece of paper on top of a workpiece while gradually lowering a tool. The tool stops when a resistance on the paper is felt. The paper technique is tedious, subjective, and tool dependent. Fig. 8b shows scattering of data up to  $\pm 5 \mu\text{m}$  when finding z-offset for a center drill, but it is  $\pm 15 \mu\text{m}$  for a milling cutter with 4 teeth.

A commercial contact sensor requires a tool to move down and press against a solid surface. A pressure sensor then triggers an audible or visual signal to indicate a positive contact. The pressure level on such sensor is preset for macrotool setting and cannot be adjusted for a microtool. In both cases, the tool tip is one paper thickness or one contact sensor height above the workpiece—if the tool survives.

A non-contact sensor is more practical and reliable. The same laser displacement sensor used for lateral tool offset can also be used for vertical tool offset. Fig. 8a shows a precision ring with secured circular plastic membrane that is used for indirect measurement. The membrane center is marked with a reference (e.g., crossing lines) at which the height can be measured with the laser displacement sensor. Upon placing the fixture on top of a workpiece and then lowering a tool onto the reference mark, a slight contact of the tool and the flexible membrane is precisely detected with the laser beam pointing near the contact point. When this happens, the tool tip is at the same height as the membrane. The repeatability of tool offset using this technique is well within the positioning repeatability  $3 \mu\text{m}$  of the tested Haas OM2 machine tool (Fig. 8b).

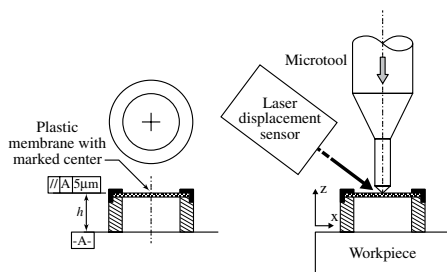

Fig. 8a. Microtool Offset and Microtool Height Detection Using Laser.

Fig. 8b. Superior Accuracy and Repeatability of Laser Offset and Height Detection Technique Compared to Paper Technique.

When a part is small or does not have a large surface for the fixture to rest on, then an indirect technique to find vertical tool offset for a microdrill or micromill is recommended. The following example illustrates this.

*Example 7, Vertical Tool Offset Calculation:* A vice or collet is used to clamp a micropart for drilling. The micropart protrudes upward a distance  $h_1 = 0.1000$  inch. If the vice surface has been qualified as a reference, it can be used to find the vertical offset of a microdrill tip (Fig. 9).

i) Measure the fixture height at the reference mark using the laser sensor,  $h_2 = 0.3500$  inch.

ii) Position the fixture on top of the vice.

iii) Lower the microdrill onto the reference mark of the membrane. Stop when the membrane is slightly deflected which can be detected easily with the laser sensor.

iv) Calculate the required drill vertical offset:

$$\text{Vertical offset} = h_2 - h_1 = 0.3500 - 0.1000 = 0.2500 \text{ inch}$$

**Tool Damage.**—Tool damage can be categorized by the relative size of the damage, ranging from submicron to hundreds of microns, as indicated in Table 2. The tool failure mechanisms include damages due to mechanical, thermal, and chemical effects, and adhesion. Examples of microtool damages are illustrated in Fig. 10a through Fig. 10d.

*Mechanical effect* is the most common source of tool damage. Abrasive wear is caused by sliding of hard particles from workpiece or tool against the cutting tool surface. Attrition wear is larger than abrasion wear; it occurs when one or a few grains of the tool are weakened at their grain boundaries and are dislodged from the tool. Microchipping and chipping are larger chunks of tool being removed due to mechanical or thermal shocks upon loading and unloading. Machining at optimal parameters and with a rigid setup will reduce vibration, shock, and mechanical damage to a microtool.

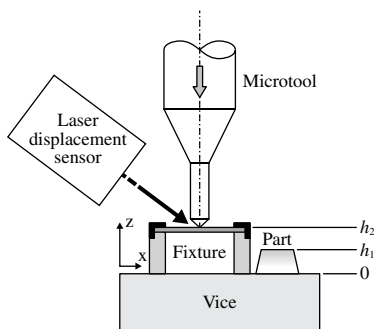

Fig. 9. Indirect Vertical Tool Offset Detection Technique.

### Microtool Damages

*Thermal effect* is the second cause of tool damage. A cutting tool edge is softened at high machining temperature, deformed plastically, and removed from the tool. Both high-speed steel tools and carbide tools with high cobalt content are vulnerable to thermal damage. High temperature also promotes diffusion, i.e., atoms from the tool and workpiece move

mutually across their interfaces, therefore degrading their properties and causing diffusion wear. Diamond with a carbon-rich matrix cannot be used with low-carbon ferrous alloys like steels or stainless steels because diamond carbonizes at temperatures exceeding 1112°F (600°C) and carbon diffuses to the steel due to its lower carbon content and high affinity to carbon. The useful life of a tool can be extended by proper application of coolant to reduce thermal damage, or by use of a protective coating that blocks undesirable thermal diffusion from/to a tool surface.

*Chemical damage* of a tool is due to a chemical reaction between a tool material and its environment like air, cutting fluid, or workpiece material. Tool oxidation is common when cutting in air at high speed. An oxidation reaction is accelerated with temperature, but can be eliminated when inert gas is used to shield the cutting tool from surrounding oxygen. A chain reaction can also occur and further degrade a tool. For example, iron in steel is first oxidized at high cutting temperature to form iron oxide; the iron oxide then weakens the aluminum oxide coating of a tool and leads to peeling and chipping of the coating.

*Adhesion tool damage* happens when a built-up-edge (BUE) welds strongly to a tool surface and then breaks away with a minute amount of tool material. When machining soft materials, a chip tends to adhere to the tool and grow in size. When the BUE is large and becomes unstable, it is removed with the chip while also shearing off part of the cutting tool due to the higher adhesion strength between BUE and tool than the intergrain binding strength of the tool. Stainless steel, nickel and titanium alloys are known for causing adhesion wear on carbide microtools. Adhesion damage can be reduced by using proper lubricant to reduce friction between chip and tool, by coating the tool with a smooth and low friction layer, by reducing tool edge radius, or by increasing cutting speed to raise the tool surface temperature and soften the BUE while reducing its weldability to the tool surface.

Microtool failures occur due to a combination of the above mechanisms. For example, peeling of tool coating might be due to coating defects, or to mechanical mechanisms when a large gradient of stress exists across a thick coating layer; the loosened coating particles then rub and cause mechanical abrasive wear on a tool. Thermal mechanisms may cause workpiece atoms to diffuse, weaken, and dislodge several tool grains as microchipping.

**Table 2. Categories of Tool Damage**

Microtool damage	Damage size		Mechanism
	μm	μinch	
Abrasion	< 1	< 39	Mechanical, thermal
Attrition	1–3	39–118	Mechanical, thermal
Peeling	1–3	39–118	Mechanical, chemical
Microchipping	3–10	118–394	Mechanical, adhesion
Chipping	10–30	394–1180	Mechanical
Fracture	> 100	> 3940	Mechanical

**Tool Life.**—Tool life criteria in macromachining are documented in ANSI/ASME B94.55M-1985 (R2019), *Tool Life Testing with Single-Point Turning Tools*. This standard suggests an end of tool life when a tool exhibits:

- An average flank wear of 300 μm (0.0118 in), or
- Any maximum flank wear land of 600 μm (0.0236 in), or
- Any tool wear notch of 1000 μm (0.0394 in), or
- A crater wear of 100 μm (0.0039 in).

It is obvious that such criteria for a macrotool cannot be applied to a microtool because (i) it would be cost prohibitive to continue testing until 300 μm flank wear, and (ii) the wear criteria are even larger than most tool dimensions.

In the absence of a microtool standard, researchers have set their own criteria based on direct observation and/or indirect monitoring of microtool tool wear effects. Published data varies on microtool wear thresholds: 5 μm flank/nose wear on diamond tools, or

50  $\mu\text{m}$  flank/nose wear on carbide tools, or chipping dimensions relative to cutting tool grain size, or peeling of tool coating, etc. A variety of techniques have been suggested for tool monitoring; the direct techniques measure the tool conditions (e.g., flank wear, crater wear) while the indirect techniques measure the consequence of tool wear (e.g., burr size, change of microhole diameter).

**Table 3. Microtool Wear and Monitoring Techniques**

Measurement		Metrology Equipment / Sensor
Direct	Tool wear	Microscope
	Tool edge conditions	
	Wear particles	Spectrophotometer, scintillator
	Particle radioactivity	
Tool-workpiece junction resistance	Voltmeter	
Indirect	Workpiece features (hole diameter, slot depth...)	Microscope Interferometer
	Cutting force, torque, power	Dynamometer Strain gage, ampere meter
	Sound emitted from tool-workpiece friction	Acoustic emission transducer Microphone
	Vibration	Accelerometer Displacement sensor
	Temperature	Thermocouple Pyrometer
	Surface roughness	Profilometer, interferometer, optical profiler...
	Burr dimension	Microscope, interferometer, optical profiler...

The importance of tool life monitoring and tool life prediction is presented in the section *MACHINING ECONOMETRICS* starting on page 1196. The following material expands from that and covers relevant information for tool life of microtools.

The general Taylor equation that relates tool life and machining parameters also applies in micromachining:

$$V^a f^b d^c T = g \quad (1)$$

where  $V$  = surface cutting speed (m/min, ft/min)

$f$  = tool feed (mm/rev, in/rev) or chip load (mm/tooth, in/tooth)

$d$  = depth of cut (mm, inch)

$T$  = tool life (min)

$g, a, b, c$  = constants

When thermal damage mechanism dominates then  $a \gg b, c$  in Equation (1). The term  $a$  dominates mathematically and the effects of feed and depth of cut are insignificant compared to speed. The general Taylor equation can be rewritten as:

$$V^a T = \frac{g}{f^b d^c} \quad (2)$$

If  $n = 1/a$ , then this equation is the same as that in the *Econometrics* section:

$$VT^n = \left( \frac{g}{f^b d^c} \right)^n = C \quad (3)$$

When tool chipping occurs then both terms  $b, c \gg a$ , therefore the feed and depth of cut are more important than surface speed. The general tool life reduces to

$$f^b v^c T = \frac{g}{V^a} = C' \quad (4)$$

Chipping is generally not acceptable since a chipped tool generates excessive burr and a very rough surface. By reducing depth of cut and feed, then chipping should be eliminated assuming micromachining with a quality tool and machine tool. When stable parameters are applied, then the only damage mechanism is thermal and tool life can be predicted with Equation (3).

It has been shown that flank wear due to abrasion is directly proportional to the magnitude of acoustic signal or feeding force. An increase of 300 percent in micromilling feeding force from an initial value was established as a threshold for reaching the tool life. A reduction in feeding force, however, might indicate gradual failure of a microtool due to fatigue crack propagation. Indirect monitoring of tool wear by monitoring feeding force for both micromilling and microdrilling would be a preferred technique since this does not interfere with the machining process and reduce productivity. In the absence of a sensitive commercial system that can reliably and accurately monitor tool force and tool life in micromachining, direct tool wear monitoring should still be a popular practice.

Traditional tests using the Taylor approach would machine at the same cutting speed until reaching the predetermined tool failure criteria. Such tests can be time consuming if a chosen speed is too low, and only applicable to turning since a constant cutting speed is required. In reality, a part must be machined with the same tool in different directions and speeds to obtain the final profile and surface finish. Several techniques were developed to accelerate the testing method since turning tests alone are tedious, expensive, and do not reflect actual part machining. The cumulative wear technique, assuming that the abrasion wear mechanism is the same at different cutting speeds, is more flexible and can reduce the testing time and cost. The proposed cumulative tool life testing technique:

- Is flexible. If an initial speed is too slow, testing speed can be increased and the cumulative time and tool wear recorded.
- Is simple. Manual machines can be used instead of CNC machines. The same rpm on a manual lathe can be used for the turning test until tool failure. Times and cutting speeds for all passes are used to calculate the equivalent time and speed.
- Is more cost-effective. Both turning and facing can be combined to completely consume an expensive workpiece material.
- Is order independent. The level of cutting speed is not important if providing the same tool wear mechanism. Experimental data for macromachining shows no difference of tool life if changing cutting speeds from low to high, or in reverse order.

Consider a tool that machines at cutting speed  $V$  and stops after machining time  $\Delta t$  before reaching its tool life  $T$ . The tool then cuts at different speeds and times until reaching the tool life criteria—for example, 50  $\mu\text{m}$  flank wear on a carbide microendmill. The fraction of tool life when cutting at each speed and time is  $\Delta t/T$ , and the total tool life fraction is

$$\frac{\Delta t_1}{T_1} + \frac{\Delta t_2}{T_2} + \dots + \frac{\Delta t_k}{T_k} = \sum_{i=1}^k \frac{\Delta t_i}{T_i} = Q \quad (5)$$

The theoretical value of the total tool life fraction  $Q$  should be one. Experimental values for  $Q$  were found to be in the range 1.2–1.5. When combined with Taylor Equation (3), then Equation (5) becomes

$$\sum_{i=1}^k \Delta t_i V_i^{1/n} = QC^{1/n} \quad (6)$$

After machining with a tool at different times and speeds in different conditions (e.g., different tool coatings), it is necessary to compare the tool performance by calculating its

equivalent tool life and equivalent tool speed. The equivalent tool life  $T_e$  is just the sum of all machining time periods:

$$T_e = \sum_{i=1}^k \Delta t_i \quad (7)$$

The equivalent tool speed must produce the same tool damage as a tool after cumulative machining. The total tool damage is given in Equation (6) as:

$$\frac{1}{Q} \sum_{i=1}^k \Delta t_i V_i^{1/n} = C^{1/n} = T_e V_e^{1/n} \quad (8a)$$

Solving for the equivalent cutting speed  $V_e$

$$V_e = \left( \frac{\sum_{i=1}^k \Delta t_i V_i^{1/n}}{\sum_{i=1}^k \Delta t_i} \right)^n \quad (8b)$$

When  $Q = 1$  then,  $(V_e)^{1/n}$  is the mathematical average of all  $(V_i)^{1/n}$  terms, by definition.

Mathematical models for cumulative tool wear are now derived for most popular machining operations, namely turning, drilling, facing, and milling.

- For turning with different cutting speeds, Equation (6) is applied. If turning speeds are kept the same from one pass to another, substitute  $V = V_i$  into Equation (6) to obtain:

$$V^{1/n} \sum_{i=1}^k \Delta t_i = QC^{1/n} \quad (9)$$

- For drilling, tool wear would be most substantial at the cutting lip where cutting speed is at the highest. Since cutting speed is constant during drilling as in turning, the tool wear model for drilling is the same as in Equation (6) for variable speeds, and Equation (9) for constant speed.
- For facing, the cutting speed reduces linearly from the maximum  $V_i$  at the outermost radius to zero at the spindle center. It can be shown that the cumulative tool life model for facing is:

$$\sum_{i=1}^k \Delta t_i V_i^{1/n} = \frac{n+1}{n} QC^{1/n} \quad (10)$$

- For milling, the actual machining time is the time during which chips are produced. The chip generating time involves geometry of a tool and milling parameters. The cumulative tool life model for face milling is

$$\sum_{i=1}^k \Delta t_i V_i^{1/n} = \frac{1}{\lambda} QC^{1/n} \quad \text{and} \quad \lambda = \frac{M \cos^{-1} \left( 1 - 2 \frac{a}{D} \right)}{360^\circ} \quad (11)$$

where  $\lambda$  = milling factor

$a$  = width of cut (radial depth) in milling

$M$  = number of teeth

$D$  = milling cutter diameter

*Example 8, Cumulative Tool Life:*

**Turning Test:** Dry turning a metal matrix composite rod ( $\varnothing 18$  mm, 100 mm long) at constant 256 rpm on a manual lathe, depth of cut 0.5 mm, feed 0.07 mm/rev. Carbide tool TNPR331M-H1, tool holder MTENN2020-33.

This Al-SiC composite is very abrasive and is ideal for tool life model testing since abrasive wear is the main mechanism and flank wear is clearly seen and measured on a carbide tool. In this test, a tool is turned at constant rpm until reaching 300  $\mu$ m flank wear. At least two data points are required to calculate the effect of speed, or the slope  $n$  in Taylor equation. From Table 4, the speed and tool life pairs are (14.48 m/min, 3.54 min) and (9.56 m/min, 5.58 min). The slope  $n$  derived from Equation (3) for these two data points is

$$n = \frac{\log(V_2/V_1)}{\log(T_1/T_2)} = \frac{\log(9.56/14.48)}{\log(3.54/5.58)} = 0.91$$

When considering many data points, the averaged value of  $n$  is 0.94. A spreadsheet such as Table 4 is a convenient way to tabulate cumulative values of each  $\Delta t$  and  $\Delta t V^{1/n}$  term and then use these to calculate the equivalent tool life  $T_e$  with Equation (7), and the equivalent tool speed  $V_e$  with Equation (8b). The plot for all experimental data at constant cutting speeds and cumulative speeds is shown in Fig. 11a. Having all data points fitting on the same line indicates the validity of cumulative tool life models.

**Facing Test:** The same material and cutting tools are used in the facing test. Tool wear and tool life plots are shown in Fig. 11b and Fig. 11c. There is no difference in tool life when machining at low then high speed or the other way around.

**Table 4. Spread Sheet for Example 8, Cumulative Tool Life in Turning**

RPM	$\Delta$ Length (mm)	Diameter (mm)	Speed (m/min)	$\Delta t$ (min)	$\Delta t V^{1/n}$	Cumulative		Flank Wear ( $\mu$ m)	Feed (mm/rev)	Equivalent

### Workpiece Materials

Micromachining is often utilized to fabricate components for miniaturized sensors, medical, optical, and electronic devices, etc. Common engineering materials for these applications include stainless steel, aluminum, titanium, copper, and tool steel for miniature molds and dies.

Workpiece materials must meet certain conditions for successful micromachining. Unlike macromachining, a micromachining tool is subjected to fluctuating cutting force when it encounters each grain since microtool size is comparable to material grain size. A microtool is more vulnerable to fatigue fracture and the resulting surface—if the tool survives—would be rough due to different spring-back protrusion from each grain due to different crystallographic orientations of the grains, and direction-dependent properties of the material. Homogenous workpiece materials with very fine and uniform grain sizes should be chosen for micromachining. Inclusions and large precipitates should be minimized to avoid damage to a fragile tool edge.

Fig. 11a. Tool life plot for turning tools. Circumference speed refers to the maximum cutting speed at the outer radius in turning. Cast A359/SiC20p; tool H1 WC (-8,0,9,5,60,30,0,4mm); 0.5 mm depth; 0.07 mm/rev feed; dry.

Fig. 11b. Cumulative flank wear of tool facing at high-to-low circumference speed. Cast A359/SiC20p; tool H1 WC (-8,0,9,5,60,30,0,4mm); 0.5 mm depth; 0.07 mm/rev feed; dry.

Fig. 11c. Tool life plot for facing tools. Circumference speed refers to the maximum cutting speed at the outer radius in facing. Cast A359/SiC20p; tool H1 WC (-8,0,9,5,60,30,0,4mm); 0.5 mm depth; 0.07 mm/rev feed; dry.

**Example 9, Grain Size Consideration:** The speed and feed table on page 1118 recommends a chip load (feed) of 0.1 mm/tooth (0.004 in/tooth) for macro-scale end milling 316L stainless steel using an uncoated carbide tool. Assume the average material grain size is 15  $\mu\text{m}$ .

**Macromilling:** Using a  $\text{\O}1/2$  inch ( $\text{\O}12.5$  mm) end mill, the number of grains being cut by each tooth would be

$$\frac{\text{chip load}}{\text{grain size}} = \frac{0.1\text{mm}}{15\ \mu\text{m}/\text{grain}} = \frac{100\ \mu\text{m}}{15\ \mu\text{m}/\text{grain}} = 6.67\ \text{grains}$$

**Micro milling:** Selecting a  $\text{\O}0.1$  mm ( $\text{\O}0.004$  in) end mill, the recommended chip load would be 13 mm for stainless steel (see Table 13b, page 1195). The number of grains being cut by each tooth is

$$\frac{\text{chip load}}{\text{grain size}} = \frac{13\ \mu\text{m}}{15\ \mu\text{m}/\text{grain}} = 0.87\ \text{grains}$$

The cutting force on the macrotool and resulting surface finish are uniform due to the averaging effect from seven grains. Because a microtool shears less than one single grain at a time, the micromachined surface is irregular due to different spring-back amounts of each individual grain, and the cutting force on the microtool fluctuates depending on each grain orientation.

### Ductile Regime Micromachining

**Crystallographic Directions and Planes.**—When machining in micro or nano scale, workpiece atom orientation affects machining performance because material properties change with crystalline orientation. Fig. 12a and Fig. 12b show blocks of the same material but with different surfaces. For example, the surface of the silicon block shown in Fig. 12a is harder, stiffer (higher elastic modulus), and is more difficult to machine than the same silicon block in Fig. 12b. Miller indices are commonly used to specify particular crystallographic orientations of atoms.

Fig. 12a. Block of Material with (110) Surface. Fig. 12b. Block of Same Material with (100) Surface.

Consider a simple cubic system where atoms are located at corners (cubic as with manganese), at corners and inside (body centered cubic as with iron and chromium), or at corners and on the surfaces (face centered cubic as with aluminum and copper) systems. For convenience, we will set a coordinate system  $Oxyz$ , as shown in Fig. 13a, and the size of the cube is set at one atomic spacing unit ( $OA = OC = OD = 1$ ).

Fig. 13a.

Fig. 13b.

Fig. 13c.

During a micro/nano machining process, a cutting tool pushes and shears a grain. The cutting action forces some atoms to slide in certain directions and planes to form chips

on the tool rake face. These specific directions and planes are called slip systems. Soft materials such as copper and aluminum have more slip systems, therefore, are easier to be machined compared to harder materials such as steel with fewer slip systems.

The directional Miller index is the coordinate of a vector representing the atom sliding direction. In Fig. 13a, if the atom slides from C to G (also the same as sliding from O to D), then this vector with corresponding coordinates are given by:

$$\vec{CG} = \vec{OD} = [x_D - x_O, y_D - y_O, z_D - z_O] = [0, 0, 1] \text{ or } [001] \text{ direction}$$

Similarly, if an atom slides from B to A (or C to O) then the Miller direction is:

$$\vec{BA} = \vec{CO} = [x_O - x_C, y_O - y_C, z_O - z_C] = [0, -1, 0] \text{ or } [0\bar{1}0] \text{ direction}$$

The Miller plane represents the planes that intersect with the coordinate system. The plane DEFG in Fig. 13a, congruent with OABC, intersects the z-axis while parallel with the x and y axes. The Miller index for this plane is represented by the inverse of the axis intersection:

$$\text{Plane DEFG} = \left( \frac{1}{x\text{-intercept}}, \frac{1}{y\text{-intercept}}, \frac{1}{z\text{-intercept}} \right) = \left( \frac{1}{\infty}, \frac{1}{\infty}, \frac{1}{1} \right) = (0,0,1) \text{ or } (001) \text{ plane}$$

The plane EGCA in Fig. 13b, congruent with DFBO, intersects the x and y axes while parallel with z axis. The Miller index for this plane is:

$$\text{Plane EGCA} = \left( \frac{1}{x\text{-intercept}}, \frac{1}{y\text{-intercept}}, \frac{1}{z\text{-intercept}} \right) = \left( \frac{1}{1}, \frac{1}{1}, \frac{1}{\infty} \right) = (1,1,0) \text{ or } (110) \text{ plane}$$

The plane DCA in Fig. 13c, congruent with BEG, intersects all the x, y, and z axes. The Miller index for this plane is:

$$\text{Plane DCA} = \left( \frac{1}{x\text{-intercept}}, \frac{1}{y\text{-intercept}}, \frac{1}{z\text{-intercept}} \right) = \left( \frac{1}{1}, \frac{1}{1}, \frac{1}{1} \right) = (1,1,1) \text{ or } (111) \text{ plane}$$

**Miller Index Nomenclature:** In both direction and plane Miller indices, any minus sign is written on top of the number, for example  $[\bar{1}\bar{1}\bar{1}]$ , and all commas are omitted for simplicity.

Square brackets “[ ]” are used to indicate a specific direction, and pointed brackets “<>” are used to indicate a family of directions with similar geometries. For example, the <100> family has 12 directions similar to [100], [001], ..., which are all the edges of the cube in Fig. 13a.

Parentheses “( )” are used to indicate a specific plane, and curly brackets “{ }” are used to indicate a family of planes with similar geometries. For example, the {100} family has 6 planes similar to (100), (001), ..., which are all the surfaces of the cube in Fig. 13a.

**Introduction.**—The concept of ductile-regime machining has been investigated since the 1960s for amorphous brittle materials such as glasses. Silicon, germanium, and glasses have become strategic materials that are widely used to fabricate intricate components in microelectronics, optical, defense industries, and recently as micro optical-electrical-mechanical systems. Silicon and other brittle materials are known for their low machinability unless they are machined in the ductile-regime conditions. When utilized at the optimal machining conditions, only minimum effort is required for the subsequent etching, grinding, or polishing to remove the damaged subsurface. This section summarizes the theory and provides practical guidance for ductile regime machining.

**Theory.**—The mechanism of ductile-regime machining has been studied by many researchers. Using a fracture mechanics approach, it can be shown that there is a threshold below which the ductile regime prevails:

$$d_c = \frac{\text{plastic flow energy}}{\text{fracture energy}} = A \left( \frac{E}{H} \right) \left( \frac{K_c}{H} \right)^2 \quad (12)$$

where  $d_c$  = critical depth of cut (m, inch)

$A$  = constant

$E$  = Young's modulus (Pa, psi)

$K_{Ic}$  = surface fracture toughness ( $\text{Pa}\cdot\text{m}^{0.5}$ ,  $\text{psi}\cdot\text{in}^{0.5}$ )

$H$  = surface microhardness (Pa, psi)

A shallow depth of cut, therefore, would energetically promote plastic flow rather than brittle fracture in the substrate and the chips. Table 5 tabulates properties of some brittle materials and their experimental critical depths of cut.

**Table 5. Selected Properties of Some Brittle Materials**

Materials	Young modulus (GPa)	Fracture toughness ( $\text{MPa}\cdot\text{m}^{0.5}$ )	Knoop hardness (GPa)	Critical depth of cut ( $\mu\text{m}$ )
$\alpha\text{-Al}_2\text{O}_3$	275–393	3.85–5.90	19.6–20.1	1.0
SiC	382–475	2.50–3.50	24.5–25.0	0.2
Si	168	0.6	10	0.5

The constant  $A$  in Equation (12) varies in the range 0.1–0.6 due to measuring uncertainty of surface toughness  $K_{Ic}$ , elastic modulus  $E$ , and microhardness  $H$  in a testing environment. These properties depend on crystalline orientation of the materials, surface conditions, and tool geometry.

- The critical resolved shear stress, on a crystalline plane due to the cutting action, is directly proportional to the Schmid factor  $\cos\lambda\cos\phi$ , where  $\phi$  and  $\lambda$  are the orientations of the slip plane and slip direction. An ideal ductile mode machining would happen when the cutting shear stress is parallel to both the slip plane and the slip direction, otherwise a pseudo ductile mode with micro cleavages occurs. True ductile-regime machining happens only along certain crystalline orientations, but brittle machining occurs at other crystalline orientations. This explains why micromachining a crystalline specimen at the same speed, depth of cut, and coolant produces ductile machined surfaces in one direction but brittle machined surfaces on others.
- Cutting fluid changes the surface properties of materials ( $K_{Ic}$ ,  $E$ , and  $H$ ) and affects conditions for ductile regime micromachining. When micromachining the (100) germanium using a single crystalline diamond tool, the critical depth of cut changes from 0.13  $\mu\text{m}$  (5  $\mu\text{in.}$ ) with distilled water as cutting fluid to 0.29  $\mu\text{m}$  (11  $\mu\text{in.}$ ) in dry machining.
- Tool geometry also affects the results. Plowing and fracture of material occurs when depth of cut is less than approximately half of the tool cutting edge radius (see *Microcutting Tools* on page 1157). Tools with negative top rake angle are usually utilized because a negative rake causes a compressive zone in the workpiece ahead of and below the tool and suppresses microcrack formation.

*Example 10, Mirror-finish Micromachining:* Diamond tools with sharp cutting edge radii are very effective for machining brittle or ductile material with the exception of ferrous alloys such as tool steels or stainless steels. The cutting speed has minimum effect on surface finish, but a reduction of the feedrate leads to improvement of surface finish.

An optical quality surface of 1.4–1.9 nm  $R_{\text{max}}$  was obtained when turning single crystalline quartz with a diamond tool ( $-20^\circ$  rake, 0.8 mm nose radius) at  $<0.3 \mu\text{m}$  depth of cut, 3 m/s speed, and 8.1  $\mu\text{m}/\text{rev}$  feedrate.

**Case Study.**—A study used polished (001) p-type silicon wafers of  $\text{Ø}100 \text{ mm}$  ( $\text{Ø}4 \text{ inch}$ ). Small grooves were faced at different constant depth of cut or gradually changing depth of cut to study the ductile behavior (Fig. 14). Single crystalline diamond tools with (001) rake surface, 10–40 nm edge sharpness,  $+5^\circ$  rake angle, and 0.51 mm or 2.00 mm nose radii were used for a facing operation. The complete tool nomenclature follows the American Standards Association (back rake angle, side rake angle, end relief angle, end clearance

angle, side relief angle, side clearance angle, end cutting edge angle, side cutting edge angle, nose radius) with the addition of edge sharpness as ( $5^\circ$ ,  $0^\circ$ ,  $0^\circ$ ,  $5^\circ$ ,  $5^\circ$ ,  $30^\circ$ ,  $0^\circ$ ,  $0.51$ – $2.00$  mm,  $10$ – $40$  nm). The ultraprecision machining process was performed on a rigid system that has  $9$  nm positioning accuracy. Compressed air was used to blow chips away from the finish machined area. Surface finish of a machined wafer was measured with an atomic force microscope (AFM) and a phase-shift interferometer (PSI).

Surface finish measurements indicated ductile or brittle chip fracture on machined surfaces. As depth of cut reduced below  $1\ \mu\text{m}$ , the surface finish was also diminished due to a higher percentage of ductile machined surfaces. Perfect ductile regime machining was achieved when depth of cut was between  $0.1$ – $0.5\ \mu\text{m}$ . A smaller depth of cut in the neighborhood of  $0.05\ \mu\text{m}$  ( $50$  nm), however, worsened the surface finish because machining at such shallow depth of cut (close to the cutting tool edge radius of  $40$  nm) would plow and fracture the material surface. At the same cutting parameters, micromachining along the silicon  $\langle 110 \rangle$  directions gave better surface finish while brittle chipping was seen when cutting along the silicon  $\langle 100 \rangle$  directions (Fig. 15, Fig. 16a, and Fig. 16b).

Fig. 14. Machining plan on (001) wafers. A wafer was faced at a constant depth in different zones (left) or changing cutting depth in a taper cut (right).

Fig. 15. Surface finish as a function of the maximum chip thickness (depth of cut) and crystalline direction of the silicon wafer. The minimum surface finish is with ductile machined surface.

Fig. 16a. Perfect ductile regime machining of (001) silicon along  $[110]$ .

Fig. 16b. Mixed mode of ductile regime and pitting along  $[100]$ .

Speed  $75$  m/min, feed  $2.5\ \mu\text{m}/\text{rev}$ ; depth  $0.5\ \mu\text{m}$ ; SCD tool ( $5^\circ$ ,  $0^\circ$ ,  $5^\circ$ ,  $5^\circ$ ,  $30^\circ$ ,  $0^\circ$ ,  $0.5$ mm,  $10$ – $40$ nm).

### Cutting Fluids in Micromachining

Micromilling and microdrilling, among the most versatile manufacturing processes, can be leveraged from existing technology to produce 3D microparts or microcavities in molds and dies for mass-replication. Although macro-scale milling and drilling technology is mature, micro-scale milling/drilling technology is yet to be fully developed. Extending common practices in macromachining to micromachining often ends up with failure. Very short tool life is experienced with micromachining, and flood cooling is

not effective in microdrilling because coolant cannot flow into a partially drilled microhole. This section recommends how to select and apply a cutting fluid for effective micro milling/drilling.

Micro milling/drilling requires high rotation speed exceeding 25,000 rpm of a small tool to achieve an acceptable surface cutting speed for material removal. When drilling steel, 50 percent of the heat generated conducts into the drill, but 80 percent of heat will go to the tool when drilling titanium. A microdrill with sharp cutting edges subjected to high temperature and high stress will fail easily if cutting fluid is not adequate. When rotating a microtool at a very high rotating speed, flood coolant is not effective since it does not have enough momentum to penetrate the boundary layer (fast moving air layer) around a fast rotating tool, or wet the bottom of a deep microhole. In addition, any unfiltered chip from recycled coolant can damage a microtool or fragile workpiece. Micromist (minimum quantity lubrication, MQL) has been studied by many researchers and is proven to provide proper cooling and lubricating in micromachining. In ideal conditions, a stream of micron-size lubricant particles in micromist:

- Does not contain any chip or solid contaminant
- Has enough momentum to penetrate the boundary layer of a fast rotating tool
- Adheres to the fast rotating tool despite high centrifugal force, and
- Wets the tool and workpiece to provide effective cooling and lubricating.

The following section discusses safety, selection of cutting fluid, application method, and recommends optimal setup for micromachining.

**Safety.**—The aspect of health and safety when using micromist is a concern. A mist does not only cause potential health issues for workers in the environment, but also contaminates other instruments and machines nearby. Biodegradable fluids must be used; polyol esters are superior to common vegetable oils because the former have higher biodegradability, are less “sticky” due to oxidizing, and increase in molecular weight with time and temperature. Due to the aerosol formation during mist flow at high pressure, an air purification unit or proper ventilating fan should be installed to minimize breathing of the aerosol particles by operators, and prevent damage to adjacent equipment.

**Benefits.**—Most conventional machining processes like turning, milling, drilling, and grinding can benefit from micromist lubrication when applied properly. Although application of micromist is limited when the mist flow is obstructed — as in gun drilling — successful microdrilling has been reported for microholes with 10:1 aspect ratio (depth/diameter). At optimal conditions, micromist significantly minimizes built-up-edges, reduces burr size and cutting force, and therefore improves tool life for both coated and uncoated tools. Depending on which cutting fluid is used and how it is applied, researchers have found the effect of micromist ranges from “the same as flood cooling” to “extending tool life 3–10 times over flood cooling.” There is yet any published paper on inferior results of micromist over dry and flood cooling.

Fig. 17. Schematic of a Micromist System for Micromachining. *Courtesy of Unist, Inc.*

Systems that can generate micromist for minimum quantity lubrication machining are commercially available. A typical design (Fig. 17) includes a reservoir for biocompatible oil, feeding tubes, and an atomizing unit that mixes a compressed air flow with a controlled volume of oil. A needle is necessary to direct the mist to a predetermined location.

The resulting oil microdroplets—size and speed—should be adjustable to effectively penetrate and wet a tool/part interface. This can be done by adjusting the air pressure, type of oil, and volume of oil released into the air stream.

**Selection of Cutting Fluid.**—A cutting fluid is selected for both cooling and lubricating purposes in micromachining. It should be environmentally friendly, should not interact chemically at high temperature with tool or workpiece, and can be cleaned and disinfected from the machined parts. It must have low surface energy relative to the surface energy of the cutting tool and workpiece material, high thermal diffusivity, and lubricity. For micromist applications, a cutting fluid must be able to flow easily in a small tube (low viscosity) and to form microdroplets.

Complete wetting is desirable for a cutting fluid because it covers large surface areas of tool and workpiece and effectively removes heat from the source. Its self-spreading capability due to the differential surface energy allows cutting fluid to penetrate deep into the chip/tool interface to effectively lubricate and cool this zone. Wetting condition can be assessed by two methods:

*Pendant drop technique:* A drop of liquid is formed and suspended vertically at the end of a solid tube. The side view of a drop is analyzed to compute the liquid surface tension using a tensiometer (Fig. 18a and Fig. 18b).

Fig. 18a. Side View of a Pendant Drop Below a Stainless Steel Tube.

Fig. 18b. Calculated Surface Tension from Starting to Full Forming of a Droplet.

*Sessile drop technique:* A drop of liquid is placed on a horizontal surface. The side view of the drop is analyzed to calculate the liquid contact angle or measure it with a goniometer (Fig. 19).

Fig. 19. Sessile Drop Technique to Assess Wetting of Cutting Fluid.

The following section presents a simpler approach to calculating the contact angle and drop size using a modified sessile drop technique. This technique uses a toolmaker's microscope, available at most manufacturing shops, to measure the top view of a drop, instead of a goniometer to measure the side view.

**Drop Size Measurement.**—A microdroplet must have sufficient momentum to penetrate the boundary air layer moving around a fast rotating microtool and to wet the tool afterward. Calculation of momentum and contact angle for wetting assessment requires the

droplet dimension. Knowing the lubricant drop size allows proper calibration of a micro-mist system to maintain the system effectiveness. Table 6 summarizes different techniques to measure the liquid drop size. The techniques are basically intrusive and nonintrusive methods to either collect the droplets for subsequent analysis, or for in situ imaging of the in-flight droplets.

Nonintrusive techniques use dedicated laboratory research instruments to provide accurate dimensions and comprehensive statistical information of microdroplets. The effect of variables like air pressure on drop size and speed can be automatically calculated and analyzed.

Intrusive techniques use less sophisticated instruments to collect and analyze droplets directly or indirectly. These simpler techniques, however, depend on operator skills for collecting reliable data.

**Table 6. Liquid Droplet Measurement Techniques**

Intrusive	Nonintrusive
<i>Slide:</i> collect droplets on a slide for microscopic assessment.	<i>Light shadowing:</i> analyze shadows of in flight droplets.
<i>Solidification:</i> transform droplets to solid for sieving or weighting.	<i>Laser Doppler Anemometry:</i> analyze visibility, intensity and phase shift of scattered laser from a small sample of droplets.
<i>Momentum:</i> analyze droplet impact.	<i>Laser Diffractometry:</i> scan and analyze a large group of droplets.
<i>Heat Transfer:</i> analyze cooling effect of droplets with a hot wire anemometer.	

The slide technique is a simple way to study drop size and its wetting characteristic. The setup is shown in Fig. 20a, in which a mask and glass plate are quickly exposed to a steady stream of micromist droplets. Only a few droplets are able to pass through the mask opening and deposit on a clean glass plate behind it.

Fig. 20a. Setup for microdroplet collection.

Fig. 20b. Analysis of droplet geometry.

It is assumed that (i) droplet volume remains the same before and after touching the glass plate, (ii) gravity effect on a microscale droplet is negligible, and (iii) the droplet forms part of a sphere on the plate to minimize its total surface energy. Using Equations (13) and (14) that follow, the average volume of a single droplet can be calculated by measuring the average projected droplet diameter  $P$  and its height  $h$  on a toolmaker's microscope:

$$V = \frac{\pi h^2}{2} \left( \frac{h}{3} + \frac{P^2}{4h} \right) = \frac{\pi D^3}{6} \quad (13)$$

$$D = \left( \frac{6V}{\pi} \right)^{1/3} = \left[ 3h^2 \left( \frac{h}{3} + \frac{P^2}{4h} \right) \right]^{1/3} \quad (14)$$

where  $V$  = volume of microdroplet ( $\text{mm}^3, \text{in}^3$ )

$P$  = projected droplet diameter ( $\text{mm}, \text{in}$ )

$h$  = height of a microdroplet ( $\text{mm}, \text{in}$ )

$D$  = air-borne diameter of microdroplet ( $\text{mm}, \text{in}$ )

Drop size varies with air pressure and volume of oil for atomization. In general, higher air pressure and velocity give more uniform and smaller drop size. Table 7 lists results of average drop sizes measured using this technique. Among different cutting fluids, the average diameter of in-flight droplets is approximately 1  $\mu\text{m}$  for the CL2210EP lubricant, but it can be as large as 9  $\mu\text{m}$  for other fluids.

**Table 7. Properties of Selected Lubricants**

Lubricant	2210EP	2210	2200	2300HD
Surface tension (mN/m)	26	29	34	34
Droplet diameter ( $\mu\text{m}$ )	0.97	2.3	6.7	8.4
Viscosity (Pa-s) @270s <sup>-1</sup> shear rate	0.016	0.014	0.023	0.061
Contact angle on 316L (°)	7	14	10	18
Contact angle on WC (°)	7	7	10	12

*Example 11. Drop Size Calculation:* Set the Unist system at 32 strokes/min, 3.6 mm stroke length, 3.78 bar pressure. Collect droplets of CL2100EP and measure with a toolmaker's microscope.

The average projected drop size is 2  $\mu\text{m}$  and average drop height is 0.3  $\mu\text{m}$ . The drop volume is calculated using Equation (13) to be

$$V = \frac{\pi h^2}{2} \left( \frac{h}{3} + \frac{P^2}{4h} \right) = \frac{\pi (0.3\mu\text{m})^2}{2} \left( \frac{0.3\mu\text{m}}{3} + \frac{(2\mu\text{m})^2}{4 \times 0.3\mu\text{m}} \right) = 0.49\mu\text{m}^3$$

Using Equation (14), the average air-borne diameter of a droplet is

$$D = \left( \frac{6V}{\pi} \right)^{1/3} = \left( \frac{6 \times 0.49\mu\text{m}^3}{\pi} \right)^{1/3} = 0.97\mu\text{m}$$

The following practical guides will assist in obtaining reliable results using the slide technique.

- The solid surface (glass plate, workpiece, or cutting tool) should be as smooth as possible, flat and polished, clean and positioned horizontally. Any surface defect such as machining marks or burrs will distort the droplet profile.
- The solid must be cleaned thoroughly before testing to avoid contamination of the tested liquid and distorted data. Ultrasonic cleaning in alcohol or degreaser following by dry air blowing should be adequate.
- For meaningful information, about 10–20 droplets should be measured. Ignore very large drops that are coalesced from smaller droplets, and very small satellite drops that are splashed off upon impact of a droplet on the glass plate.
- A measurement should be as quick as possible, using minimum light since a tiny liquid droplet might evaporate or spread when heated in bright light.

**Contact Angle Measurement.**—Droplet volume is calculated in the previous section by the sessile drop technique, and the same volume can be used for calculating the droplet contact angle. Alternatively, a predetermined droplet volume can be set and dispensed on a solid surface using a micropipette. The contact angle of a sessile droplet on a flat surface can be computed from the following equation:

$$\frac{P}{V^{1/3}} = \left[ \frac{24}{\pi} \frac{(1 - K \cos^2\theta)^{3/2}}{2 - 3 \cos\theta + \cos^3\theta} \right]^{1/3} \quad (15)$$

where  $P$  = projected droplet diameter (mm, in)

$V$  = droplet volume (mm<sup>3</sup>, in<sup>3</sup>)

$\theta$  = contact angle (°)

$K = 0$  for  $\theta$  between 90° and 180°,  $K = 1$  for  $\theta$  between 0° and 90°

The ratio  $P$  over  $V^{1/3}$  is called the *normalized diameter* of the droplet. Using the normalized diameter, the contact angle can be calculated using Equation (15), by looking up the value in a table (Table 8), or read from a graph (Fig. 22a and Fig. 22b).

Fig. 21 shows the top view of some liquid droplets on stainless steel sheets from which contact angles are calculated and plotted for comparison. The cutting fluids are chosen from different commercially available oil-based lubricants: CL2200, CL2210, CL2210EP, and CL2300HD. Other coolants were also included for comparison: water, KM, and water-soluble coolants RL1:15, BC1:5, and CL1:30. The nomenclature  $x:yy$  indicates dilution ratio of concentrated coolant in water for the water soluble fluids.

Fig. 21. Wetting of Different Cutting Fluids on 316L Stainless Steel. Constant Drop Volume = 0.25  $\mu$ L.

Table 7 and Fig. 23 compare contact angles of these cutting fluids on different solids. The oil-based CL2210EP lubricant forms the lowest contact angle of  $7^\circ$  on 316L stainless steel, uncoated carbide, and titanium. This is in contrast to  $60\text{--}70^\circ$  from other water-based fluids. Surface tension of the CL2210EP lubricant is 26 mN/m, the lowest among others, thus it easily wets a carbide microtool and workpiece surfaces during machining.

*Example 12, Contact Angle Measurement:* Set volume  $V = 0.25 \mu\text{L}$  on a micropipette and then dispense several droplets of CL2100EP on a clean titanium plate. The average size of the droplets, measured on a toolmaker's microscope, is  $P = 2.520 \text{ mm}$ . To find wetting capability of this coolant on titanium, it is necessary to calculate its contact angle.

*Graphical Solution:* Using  $1 \mu\text{L} = 10^{-6} \text{ L} = 1 \text{ mm}^3$ , the normalized diameter is

$$\frac{P}{V^{1/3}} = \frac{2.520 \text{ mm}}{(0.25 \text{ mm}^3)^{1/3}} = 4.0$$

Starting at point  $A = 4.0$  on the vertical Normalized Diameter ( $P/V^{1/3}$ ) axis of Fig. 22b, draw a horizontal line until it intersects with the curve at B.

Draw a vertical line from point B until it intersects with the Contact Angle axis at C. Read the contact angle  $\sim 9^\circ$  for this oil and titanium.

*Table Look-up Solution:* Locate drop volume of  $0.25 \mu\text{L}$  on the first row of Table 8.

Locate projected drop size of  $2.52 \text{ mm}$  on the first column. Since  $2.52 \text{ mm}$  is not available, choose the closest number,  $2.50 \text{ mm}$ .

Read the contact angle from the intersection of row and column as  $9.3^\circ$

*Example 13, Contact Angle Measurement (continued from Example 11):* In Example 11, droplets of CL2100EP were collected on a glass plate, the average projected drop size  $P = 2 \mu\text{m}$  was measured, and the average drop volume was calculated to be  $V = 0.49 \mu\text{m}^3$ . The information obtained can be used to calculate contact angle.

a) The normalized diameter is

$$\frac{P}{V^{1/3}} = \frac{2 \mu\text{m}}{(0.49 \mu\text{m}^3)^{1/3}} = 2.53$$

b) Use Fig. 22b with normalized diameter of 2.53, and read the contact angle of  $\sim 18^\circ$ .

The same cutting fluid CL2100EP forms different contact angles of  $18^\circ$  on glass and  $9^\circ$  on titanium. This is due to the different surface energies of glass and titanium.

**Dynamics of Microdroplets.**—Several models are derived to study the dynamics of a microdroplet when it approaches a fast rotating tool. To effectively wet and lubricate a rotating tool, a microdroplet must (i) have enough momentum to penetrate the boundary layer around a fast rotating tool to reach the tool surface, and then (ii) adhere and wet the tool surface despite centrifugal force acting on the microdroplet.

Fig. 24a. Propelling of Microdroplets Toward a Rotating Tool.

Fig. 24b. Force Balancing of a Microdroplet on the Rotating Tool.

*Propelling Microdroplets Toward a Rotating Tool:* The coordinates of a microdroplet after leaving a nozzle and moving toward a rotating tool can be expressed as

$$x_{pn} = V_f t + \frac{\alpha}{m} (V_0 \cos \beta - V_f) (1 - e^{-\alpha t/m}) \quad (16)$$

$$y_{pn} = \frac{\alpha}{m} V_0 \sin \beta (1 - e^{-\alpha t/m}) \quad (17)$$

where  $x_{pn}, y_{pn}$  = coordinates of a microdroplet from the nozzle

$$\alpha = 3\mu D$$

$D, m$  = diameter and mass of a droplet

$t$  = time

$V_f$  = velocity of boundary air layer

$V_0$  = velocity of a microdroplet when leaving the mist nozzle

$\mu$  = viscosity

$\beta$  = angle between microdroplet velocity and the x-axis

The distance  $y_{pn}$  away from a nozzle will reach a steady state value  $(\alpha/m)V_0\sin\beta$  after a long time ( $t \rightarrow \infty$ ). This means if a tool and nozzle distance is closer than this steady state value, then the microdroplets will reach the tool surface.

*Force Balancing of Microdroplets on a Rotating Tool:* After reaching the tool surface, a microdroplet on a rotating tool is subject to adhesion force along lubricant/solid interface and centrifugal force. The work of adhesion is given by Young-Dupre equation:

$$W_a = \sigma_s + \sigma_L - \sigma_{sL} = (1 + \cos \theta)\sigma_L \quad (18a)$$

where  $\sigma_L$  = surface tension of lubricant/air

$\sigma_s$  = surface tension of solid/air

$\sigma_{sL}$  = surface tension of solid/lubricant

$W_a$  = work of adhesion between solid/lubricant

$\theta$  = contact angle

If the adhesion force from surface tension is greater than centrifugal force, then the microdroplet will adhere and spread on the tool surface. Otherwise, the droplet will be separated from the rotating tool due to a higher centrifugal force. The condition for a microdroplet to adhere to the rotating cutting tool is given in Equation (18b) and plotted with tool surface speed and microdroplet size as two independent variables.

$$\frac{2mV_c^2}{D_t} \leq P(1 + \cos \theta)\sigma_L \quad (18b)$$

where  $\sigma_L$  = surface tension of lubricant/air (N/m)

$\theta$  = contact angle (°)

$m$  = mass of microdroplet (kg)

$V_c$  = cutting tool surface speed (m/s)

$P$  = projected drop size (m)

$D_t$  = tool diameter (m)

The plot in Fig. 25 is for CL2210EP lubricant and uncoated carbide tool with  $\phi 1$  mm flute diameter. The curve divides the plot into two regions: the upper region where adhesion is dominating, and the lower region where centrifugal force is stronger, i.e., a microdroplet is propelled radially away and does not wet the tool. With the droplet size of 1–10  $\mu\text{m}$  for all lubricants in this study, the adhesion force is dominating and a microdroplet should adhere to the rotating tool at any rotating speed of the tested machine (0–50,000 rpm or 0–150 m/min for a  $\phi 1$  mm tool). Wetting of CL2210EP microdroplets on carbide tools was also experimentally verified.

Fig. 25. Adhesion Threshold of Microdroplets on a Rotating Tool. CL2210EP lubricant, Ø1 mm uncoated carbide tool at different speeds. Note: 1 µm = 1 picometer = 10<sup>-12</sup> meter.

Simulation using computational fluid dynamics is used to study the 2D flow of microdroplets near a rotating cutting tool. Fig. 26a shows the velocity field of microdroplets moving from left to right and around a counter-clockwise rotating cylinder. A stagnant location with zero microdroplet speed is found near the top of the cylinder (cutting tool). When micromilling in MQL condition, a workpiece should not be positioned at such a stagnant location since it would receive no lubrication. Practical setups are suggested in Fig. 26b.

Fig. 26a. Computational Fluid Dynamic Simulation of Microdroplet Dynamics.

Fig. 26b. Practical Machining Setups of Tool and Workpiece to Avoid Stagnant Zone.

**Case Studies.**—Many researchers have applied micromist in their micro and macro machining studies. An example of each is given in this section.

*Use of Micromist in Micromilling of 316L Stainless Steel:* Micromilling using Ø1 mm WC tool, 10 µm/tooth chip load, 0.348 mm axial depth, 0.558 mm radial depth were performed on 316L stainless steel with different coolants. Using the cumulative tool life models (see *Tool Life* on page 1166), tool life of micromilling tools are plotted and

compared in Fig. 27. Large scattering of data and low machinability is observed when dry micromilling of 316L stainless steel. The machinability improves with flood cooling, spray mist, and micromist respectively. Fig. 27 shows the data points start at lower left corner for dry machining then shift to the upper right corner of the graph for micromilling in MQL, i.e., a tool can be used at higher speed for longer time to reach the same flank wear of 50  $\mu\text{m}$ . Scanning electron microscopy examination indicates significant built-up edges and attrition failure of dry cutting tools (Fig. 28a). In contrast, a well-defined abrasive tool wear is observed on a long lasting tool after micromilling with spray mist or in MQL conditions (Fig. 28b). Micromilling in MQL condition using CL2210EP extends tool life significantly over dry machining of 316L stainless steel.

Fig. 27. Effect of Cutting Fluid Conditions on Micromilling of 316L Stainless Steel. 10  $\mu\text{m}$ /tooth chip load, 0.348 mm axial depth, 0.558 mm radial depth,  $\emptyset$ 1 mm uncoated carbide tool.

Fig. 28a. Built-Up Edge (Lower Right) and Adhesion Wear (Upper Left) on a Carbide Tool. (dry cutting, 1.4 min @ 18 m/min)

Micromill  $\emptyset$ 1 mm, 10  $\mu\text{m}$ /tooth chip load, 0.348 mm axial depth, 0.558 mm radial depth.

Fig. 28b. Uniform Abrasive Flank Wear on a Carbide Tool.

(micromist, 21.7 min @ 15 m/min)

*Use of Micromist in Macrofaceting of 4140 Steel:* Bars of 4140 steel, 2 inch (50 mm) diameter, 6 inch (150 mm) long were faced at 54 m/min (177 ft/min) maximum surface cutting speed, 0.1 mm/rev feed (0.004 in/rev), and 0.5 mm (0.020 in.) depth of cut. Uncoated carbide inserts TNG431 were used in the study. The operation was in dry condition, flood with Rustlick 1:15 water soluble water-based coolant, and CL2210EP oil micromist. Periodic interruption of the operation was made to remove a tool for wear assessment on a toolmaker's microscope. Fig. 29 plots flank wear of all tools and Fig. 30a, Fig. 30b, and Fig. 30c compare the tool tip conditions after 75 passes. At identical machining conditions, crater, flank and nose wear are worst for dry machining. Flood cooling improves the tool wear but nose wear is still substantial. Micromist provides the best tool protection with reduced flank and crater wear, and negligible nose wear.

Fig. 29. Flank Wear of Uncoated Carbide Tools in Different Cutting Fluids. Macrofacing of 4140 steel, 54 m/min, 0.1 mm/rev feed, 0.5 mm depth of cut.

### Comparison of Tool Wear After 75 Facing Passes

Fig. 30a. Dry Machining. Fig. 30b. Rustlick 1:15 Flood Cooling. Fig. 30c. CL2210EP Micromist.

There is negligible nose wear for machining in micromist.

Macrofacing on 4140 steel, 54 m/min, 0.1 mm/rev feed, 0.5 mm depth of cut.

### Microfabrication Processes and Parameters

This section discusses three major microfabrication processes: micromilling, microdrilling, and microturning. Setup, tooling, and process parameters for common engineering materials are then recommended.

**Micromilling.**—Micromilling is among the most versatile of microfabrication processes. Although alternative nontraditional processes to produce microfeatures such as laser micromachining, electrical discharge micromachining, electrochemical micromachining, chemical microetching, electron/ion beam micromachining are available, these processes are either cost prohibitive, or inferior when comparing resulting surface and subsurface integrity, anisotropic aspect ratio or feature quality. Successful micromilling requires new tool geometry, tool material, machining parameters, and machining skills. It is technically incorrect and costly to perform micromilling by just scaling down a milling cutter, or parameters from macroscale milling. Commercial micromills are available for diameters of 25  $\mu\text{m}$  (0.001 inch) and up, see Table 9.

- Tool material. Carbide tools should be sintered from fine grains, and ground to small cutting edge radius (see *Microcutting Tools* on page 1157).
- Milling direction. Down milling is the preferred mode since a micromill will engage a workpiece and remove a wedge shape chip with decreasing chip thickness. In contrast, a tool in upmilling would rub on the workpiece until the effective chip thickness is greater than one-half of the cutting edge radius (see *Tool Sharpness* on page 1158).
- Lubrication. Micromist should be used with all micromachining, but adequate ventilation and filtering are required to avoid inhalation of micromist. The nozzle should be as close as possible to the work and positioned to let the cutting flutes pull the mist into the cutting zone. Tool and workpiece should be arranged to avoid the stagnant zone (see Fig. 26a, Fig. 26b, Fig. 31a, and Fig. 31b).

- Tool vibration. Avoid unnecessary disengaging then engaging of microtool and workpiece in a milling program when programming the tool path. Vibration and bending of a microtool when starting and ending a cut could fatigue and shorten the tool life of the microtool (Fig. 32).

**Positioning of a Micromist Nozzle in Micromilling**

Fig. 31a. Top View.

Fig. 31b. Side View.

Fig. 32. Vibration of a Micromill When Engaging and Disengaging a Workpiece. Carbide mill Ø1 mm (Ø0.040 inch), 316L stainless steel, 25000 rpm, 10 µm/tooth feed, 0.348 mm axial depth, 0.558 mm radial depth.

Fig. 33. Micromill Nomenclature.

**Table 9. Commercial Micromills**

Optional geometries include: Flute lengths: stub, standard, or optional extended length (10–80% longer); Number of flutes: 2, 3, or 4; Helix angles: 25°, 30°, 50°; End configuration: hemisphere, flat; Units: metric and US customary.

**Microdrilling.**—Microdrilling is a more complex operation compared to turning or milling. Chip removal and effective supply of cutting fluid is easy with the latter, but not with microdrilling due to extremely limited space around a microdrill.

- Tool material. As with a micromill, a carbide microdrill should be sintered from fine grains, and ground to small cutting edge radius (*Tool Sharpness* on page 1158).
- Hole quality. Spindle runout, tool eccentricity, and wandering of a microdrill causes cyclic bending of the tool that leads to catastrophic failure. To control drill wandering, precision pre-drilling of a center hole can be tried, or the drilled surface must be ground to minimize deflection of a slender drill when starting on an irregular surface.
- High aspect ratio. Pecking is essential for microhole drilling since chips have to be extracted and cutting fluid must penetrate into a small and deep microhole. The pecking depth can be deep in the beginning, but it must be reduced when drilling deeper. Start with an initial pecking depth of  $2 \times$  drill diameter and gradually reduce it to  $0.5 \times$  diameter at a depth of  $10 \times$  diameter. Pecking depth and cycles can be calculated from:

$$\frac{P}{D} = \frac{1}{9}(-1.5R + 19.5) \quad \text{for } R \leq 10$$

$$\frac{P}{D} = 0.5 \quad \text{for } R > 10$$
(19)

$P$  = incremental pecking depth (mm, in)

$D$  = drill diameter (mm, in)

$R$  = drill aspect ratio = hole depth / drill diameter

See [Example 14](#) for more on the the use of [Equation \(19\)](#).

- Apply micromist with a fixed nozzle pointing to the drill tip; making an angle of  $60\text{--}70^\circ$  with the tool axis is recommended ([Fig. 34](#)). In this way, the chip is blown away after a pecking cycle and the microdrill is re-lubricated before re-entering into the hole. Adequate ventilation and filtering are required to avoid inhaling of micromist.

Fig. 34. Positioning of a Micromist Nozzle in Microdrilling. The Nozzle and Workpiece should be Stationary.

Commercial microdrills are available for drill diameters of  $100\ \mu\text{m}$  (0.004 inch) and above ([Table 10](#)).

Fig. 35. Microdrill Nomenclature.

Optional geometries include: Flute lengths: standard or extended length (10–80% longer); Number of flutes: 2, 3, or 4; Included angles: 118°, 130°; Helix angles: 25°, 30°, 50°; Units: metric and US customary.

*Example 14:* Select a microdrill and pecking cycles to drill  $\varnothing 0.005$  inch holes to 0.050 inch depth in titanium.

From **Table 10**, select the  $\varnothing 0.005$  inch drill with the 0.060 inch standard length. A drill with extended length of 0.090 inch is unnecessary because the extra length would decrease the drill stiffness by about 56% (see **Example 2**). Use micromist to lubricate the drill and blow the extracted chips away. The pecking cycle in **Table 11** is recommended.

During the first pecking cycle, drill to 0.0100 inch depth then withdraw the tool. For the second pecking cycle, the incremental pecking depth  $P$  of 0.0092 inch is calculated from **Equation (19)**. During the 2nd pecking cycle, the drill travels to a depth of 0.0192 inch, withdraws to remove chips, then continues down for pecking cycle #3. The incremental pecking in cycle #7 should be increased by 0.0003 inch so that the pecking cycle #8 will drill the hole to the required depth of 0.0500 inch.

**Table 11. Pecking Cycle, Drill Dia.  $D = 0.005$  inch**

Pecking cycle #	Hole depth (inch)	Aspect ratio	$P/D$	Pecking depth, $P$ (inch)
1	0.0100	2.00	1.83	0.0092
2	0.0192	3.83	1.53	0.0076
3	0.0268	5.36	1.27	0.0064
4	0.0332	6.63	1.06	0.0053
5	0.0385	7.70	0.88	0.0044
6	0.0429	8.58	0.74	0.0037

9	0.0522	10.44	0.43	0.0021

**Microturning.**—Product miniaturization and the demand for ultraprecision products drives the rapid development of micro/nano turning. This technology produces polished and high quality spherical and aspherical parts from metals, ceramics, semiconductors, and polymers that cannot be economically produced by traditional grinding, lapping, or polishing processes. Micro/nano turning also produces intricate shapes with low or no subsurface damage because it operates in the ductile-regime mode (see *Ductile Regime Micromachining* on page 1172).

Diamonds are commonly used for micro/nano turning. Polycrystalline diamond (PCD) tools are sintered from microsize diamond grains. PCD tools are less expensive but with limited capability due to large edge radius (few hundred nanometers) and lower edge strength due to attrition wear. Single crystalline diamond (SCD) tools are best for micro/nano turning because they:

- Have single crystalline structure that allows a sharp cutting edge as small as 10 nm
- Have the highest thermal conductivity among all engineering materials
- Retain high strength and hardness at high temperature
- Have high elastic and shear moduli to resist plastic deformation, and
- Have a low coefficient of friction

A diamond tool, however, is costly and brittle. A tool with zero or negative rake angle (i) improves its edge strength, and (ii) forms a hydrostatic compressive stress field in the material just in front of and below the tool, and therefore, minimizes crack initiation. Single crystal diamond typically have the (110) crystal plane as the rake face and are brazed onto a steel shanks of different shapes and sizes.

Not all materials can be successfully micro/nano turned with a diamond tool. Ferrous alloys and silicon carbide (SiC) are not suitable for diamond turning because of diffusion from the highly concentrated carbon in the diamond tool to a lower concentration zone of carbon in the workpiece materials. Other materials, although machinable with diamond, should be homogeneous and contain few if no impurities. Any hard inclusions might either damage a sharp diamond edge or be sheared off and smear against the machined surface. Fig. 36a shows hard beryllides in beryllium copper CA173 that plow and smear a mirror finish surface (Fig. 36b).

**Table 12. Examples of Diamond Machinable Materials**

Semiconductor	Metal	Ceramic	Plastics
Cadmium telluride	Aluminum alloys	Aluminum oxide	Acrylic
Gallium arsenide	Copper alloys	Zirconium oxide	Fluoroplastics
Germanium	Electroless nickel	Optical glasses	Nylon
Lithium niobate	Gold	Quartz	Polycarbonate
Silicon	Magnesium		Polymethylmethacrylate
Silicon nitride	Silver		Propylene
Zinc selenide	Zinc		Styrene
Zinc sulphide			

Micromist is required to lubricate and cool both the tool and the machined surface. The micromist nozzle should move with the tool while blowing the micro/nano chips away from the machined surface. Adequate ventilation and filtering of micromist are required to avoid environmental issues.

Fig. 36a. Beryllide Particles at Grain Boundaries of Diamond Turned Beryllium Copper.

Fig. 36b. Deep Scratch on Machined Surface Caused by a Broken Beryllide. The Arrow Shows Tool Cutting Direction.

**Speeds and Feeds.**—In macromachining of engineering materials, the material grains are very small compared to the cutting tool dimensions and edge radius. Only bulk material properties such as material strength, hardness, and thermal conductivity affect machining performance. However, when the workpiece grain size is similar to the tool edge radius then the workpiece material will have more influence on micromachining performance (see *Workpiece Materials* on page 1170). Since plastically deformed materials are normally harder than the original material, machining feed must be (i) deeper than this hardened layer, and (ii) at least half of the tool edge radius (see *Microcutting Tools* on page 1157).

*Example 15, Work Hardening of Titanium Alloy:* Micromachining Ti 6Al4V alloy with a carbide tool generates a work-hardening depth of about 1–2  $\mu\text{m}$  (40–80  $\mu\text{in}$ ch). The microhardness increases 8–14% above the base material hardness to  $\sim 350$  Vicker. Chip load for microdrilling or micromilling should be greater than this hardened zone depth.

**Microturning Parameters:** Criteria for selecting turning speed and feed are tool life and surface finish, and less concern on tool fracture since a turning tool is robust and rigid. Cutting speeds for single crystalline diamond are very high and depend mostly on the rigidity of the setup and the machine tool capability. Turning at 100–500 m/min (330–1650 ft/min) is common for most metals and metal matrix composites.

Selection of feed depends on the surface finish required because this is the main objective for using diamond for turning in the ductile regime mode. Models for a macromachined surface finish have been proposed which assume:

- The depth of cut is less than tool nose radius but more than cutting edge radius
- There is no built-up-edge on the tool, therefore, effect of cutting speed is negligible
- Workpiece of polycrystalline material with fine grains is used and grain orientation does not significantly affect surface finish of large areas
- Chips are completely removed without side-burr, and
- No error is introduced from imperfect machine kinematics (such as asynchronous spindle error motion).

The theoretical surface finish values are functions of feed and tool nose radius, and can be computed from Equations (20) and (21) and plotted as in Fig. 37a and Fig. 37b.

$$R_t = R - \sqrt{R^2 - \frac{f^2}{4}} = R - R \sqrt{1 - \left(\frac{f}{2R}\right)^2} \approx 0.125 \frac{f^2}{R} \quad (20)$$

$$R_a = k(f, R) \frac{f^2}{R} \approx 0.031553 \frac{f^2}{R} \text{ for } \frac{f}{R} < 0.1 \quad (21)$$

where  $R_a$  = average surface finish (m, inch)

$R_t$  = peak-to-valley surface finish (m, inch)

$f$  = tool feed for each revolution (m, inch)

$R$  = tool nose radius (m, inch)

**Example 16, Turning Parameter Selection:** Select tool and parameters to achieve  $R_a = 1 \mu\text{m}$  when turning 6061-T6 aluminum.

**Solution:** Use a single crystalline diamond tool with tool nose radius  $R = 1 \text{ mm}$  (0.040 inch) and cutting edge radius of 80 nm ( $3 \mu\text{in}$ ).

**Depth of cut:** Depth must be between the nose radius and edge radius, so choose 0.5 mm.

**Cutting speed:** Speed does not affect surface finish, so choose 303 m/min (1000 ft/min).

**Feed:** Referring to Fig. 37b, from point A ( $R = 1 \text{ mm}$ ), draw a vertical line to intersect with  $R_a = 1 \mu\text{m}$  curve at B. Draw a horizontal line at B and intersect vertical axis at C, and read the feed = 0.18 mm/rev (0.007 in/rev). Alternatively, Equation (21) can be rearranged and used to compute the feed distance for each revolution as follows:

$$f = \sqrt{\frac{R_a R}{0.031553}} = \sqrt{\frac{1 \mu\text{m} \times 1 \text{ mm}}{0.031553}} = \frac{1 \text{ mm}}{1000 \mu\text{m}} = 0.178 \text{ mm}$$

### Effect of Tool Nose Radius and Tool Feed on Surface Finish

Fig. 37a. Peak-to-Valley Surface Finish  $R_t$ .

Fig. 37b. Average Surface Finish  $R_a$ .

**Microdrilling/Milling Parameters:** The combination of spindle runout and radial cutting force can deflect and break a tool. Finite element analysis (FEA) of a micromill shows that the critical area is the junction between the cylindrical flute and solid conical shank. Using 4.7 GPa and 93 GPa as the average values of measured flexural strength and elastic modulus of carbide, the analysis indicates that a  $\emptyset 1 \text{ mm}$  carbide micromill will break if deflected more than 34 percent of its diameter.

Fig. 38 shows crash-test and calculated data for catastrophic tool failure when micro-milling 316L stainless steel. The radial depth of cut and chip load are normalized to the tool diameter for ease of comparison. The data points form a line that divides the plane into two regions: tool failure and tool safe areas. A tool will break if milling parameters are chosen to be above this threshold line. Therefore, all milling parameters should be conservatively selected below the threshold for a production run.

Fig. 38. Catastrophic Failure Threshold of Micro-Milling Tools as Percentage of Tool Diameter. Dry milling 316L stainless steel,  $\varnothing 1$  mm tool diameter, 2 flutes, 0.348 mm axial depth of cut.

Fig. 39. Recommended Chip Load as a Function of Carbide Cutter Size for Various Materials.

Fig. 40. Relationship of Drilling versus Milling Speed Using Carbide Tools on Different Engineering Materials.

Table 13a and Table 13b tabulate starting speeds and feeds for uncoated micrograin carbide micromilling and microdrilling tools, in US customary and metric units respectively. Drilling speed is normally reduced to approximately 50 percent of the milling speed of the same material, due to the high aspect ratio and difficulty of chip evacuation in microdrilling (Fig. 40).

*Example 17, Micromill and Microdrill Selection:* Select parameters to micromill and microdrill 316L stainless steel using an uncoated carbide  $\varnothing 1$  mm, 2 flute microtool.

*Micromilling:* Speed selection depends on tool life and cutting fluid. Table 13b suggests 68 m/min for micromilling. Both radial and axial depth of cut affect selection of feed. Select 35% axial depth ( $0.35 \times$  tool diameter = 0.35 mm), and 60% radial depth ( $0.60 \times$  tool diameter = 0.6 mm). From point A (60%) on the vertical axis of Fig. 38, draw a horizontal line that intersects the threshold line at point B, then find point C on the horizontal axis. The chip load that causes immediate tool fracture would be slightly more than 5% of tool diameter ( $50 \mu\text{m/tooth}$ ). A conservative chip load would be  $13 \mu\text{m/tooth}$  as indicated in Table 13b.

*Microdrilling:* Table 13b suggests 28 m/min speed and  $13 \mu\text{m/tooth}$  feed for drilling. Reduction of drilling speed to only 50–60% (59% in this example) of milling speed is necessary to facilitate chip removal in microdrilling.

**Table 13a. Speeds and Feeds for Micro Milling/Drilling with Uncoated Carbide Tools (US Customary Units)**

## MACHINING ECONOMETRICS

## Tool Wear and Tool Life Relationships

Tool life is defined as the cutting time to reach a predetermined wear limit, called the *tool wear criterion*. The size of tool wear criterion depends on the grade used, usually a tougher grade can be used at bigger flank wear. For finishing operations, where close tolerances are required, the wear criterion is relatively small. Other alternative wear criteria are a predetermined value of the surface roughness, or a given depth of the crater which develops on the rake face of the tool. The most appropriate wear criteria depends on cutting geometry, grade, and materials.

Tool life is determined by assessing the time—the tool life—at which a given predetermined flank wear is reached, 0.25, 0.4, 0.6, 0.8 mm, etc. Fig. 1 depicts how flank wear varies with cutting time (approximately straight lines in a semi-logarithmic graph) for three combinations of cutting speeds and feeds. Alternatively, these curves may represent how variations of machinability impact on tool life, when cutting speed and feed are constant. All tool wear curves will sooner or later bend upwards abruptly and the cutting edge will break, i.e., catastrophic failure as indicated by the white arrows in Fig. 1.

Fig. 1. Flank Wear as a Function of Cutting Time

The maximum deviation from the average tool life 60 minutes in Fig. 1 is assumed to range between 40 and 95 minutes, i.e.,  $-33\%$  and  $+58\%$  variation. The positive deviation from the average (longer than expected tool life) is not important, but the negative one (shorter life) is, as the edge may break before the scheduled tool change after 60 minutes, when the flank wear is 0.6 mm.

It is therefore important to set the wear criterion at a safe level such that tool failures due to “normal” wear become negligible. This is the way machinability variations are mastered.

**Equivalent Chip Thickness (*ECT*).**—*ECT* combines the four basic turning variables, depth of cut, lead angle, nose radius and feed per revolution into one basic parameter. For all other metal cutting operations such as drilling, milling and grinding, additional variables such as number of teeth, width of cut, and cutter diameter are included in the parameter *ECT*. In turning, milling, and drilling, according to the *ECT* principle, when the product of feed times depth of cut is constant the tool life is constant no matter how the depth of cut or feed is selected, provided that the cutting speed and cutting edge length are maintained constant. By replacing the geometric parameters with *ECT*, the number of tool life tests to evaluate cutting parameters can be reduced considerably, by a factor of 4 in turning, and in milling by a factor of 7 because radial depth of cut, cutter diameter and number of teeth are additional parameters.

The introduction of the *ECT* concept constitutes a major simplification when predicting tool life and calculating cutting forces, torque, and power. *ECT* was first presented in 1931 by Professor R. Woxen, who both theoretically and experimentally proved that *ECT* is a basic metal cutting parameter for high-speed cutting tools. Dr. Colding later proved that the concept also holds for carbide tools, and extended the calculation of *ECT* to be valid for cutting conditions when the depth of cut is smaller than the tool nose radius, or for round inserts. Colding later extended the concept to all other metal cutting operations, including the grinding process.

The definition of *ECT* is:

$$ECT = \frac{Area}{CEL} \text{ (mm or inch)}$$

where  $A$  = cross sectional area of cut (approximately = feed  $\times$  depth of cut), ( $\text{mm}^2$  or  $\text{inch}^2$ )

$CEL$  = cutting edge length (tool contact rubbing length), (mm or inch), see Fig. 1 on page 1092.

An exact value of  $A$  is obtained by the product of *ECT* and  $CEL$ . In turning, milling, and drilling, *ECT* varies between 0.05 and 1 mm, and is always less than the feed/rev or feed/tooth; its value is usually about 0.7 to 0.9 times the feed.

*Example 1:* For a feed of 0.8 mm/rev, depth of cut  $a = 3$  mm, and cutting edge length  $CEL = 4$  mm, the value of *ECT* is approximately  $ECT = 0.8 \times 3 \div 4 = 0.6$  mm.

The product of *ECT*,  $CEL$ , and cutting speed  $V$  (m/min or ft/min) equals the metal removal rate *MRR*, measured in terms of the volume of chips removed per minute:

$$\begin{aligned} MRR &= 1000V \times Area = 1000V \times ECT \times CEL \text{ mm}^3/\text{min} \\ &= V \times Area \text{ cm}^3/\text{min or inch}^3/\text{min} \end{aligned}$$

The specific metal removal rate *SMRR* is the metal removal rate per mm cutting edge length  $CEL$ , thus:

$$\begin{aligned} SMRR &= 1000V \times ECT \text{ mm}^3/\text{min}/\text{mm} \\ \text{and } MRR &= V \times ECT \text{ cm}^3/\text{min}/\text{mm or inch}^3/\text{min}/\text{inch} \end{aligned}$$

*Example 2:* Using the *Example 1* data and a cutting speed of  $V = 250$  m/min, the specific metal removal rate becomes  $SMRR = 0.6 \times 250 = 150$  ( $\text{cm}^3/\text{min}/\text{mm}$ ).

*ECT in Grinding:* In grinding *ECT* is defined as in the other metal cutting processes, and is approximately equal to  $ECT = V_w \times ar \div V$ , where  $V_w$  is the work speed,  $ar$  is the depth of cut, and  $A = V_w \times ar$ . Wheel life is constant no matter how depth  $ar$ , or work speed  $V_w$ , is selected at  $V = \text{constant}$  (usually the influence of grinding contact width can be neglected). This translates into the same wheel life as long as the specific metal removal rate is constant, thus:

$$SMRR = 1000V_w \times ar \text{ mm}^3/\text{min}/\text{mm}$$

In grinding, *ECT* is much smaller than in the other cutting processes, ranging from about 0.0001 to 0.001 mm (0.000004 to 0.00004 inch). The grinding process is described in a separate chapter *GRINDING FEEDS AND SPEEDS* starting on page 1261.

**Tool Life Relationships.**—Plotting the cutting times to reach predetermined values of wear typically results in curves similar to those shown in Fig. 2 (cutting time versus cutting speed at constant feed per tooth) and Fig. 3 (cutting time versus feed per tooth at constant cutting speed). These tests were run in 1993 with mixed ceramics turn-milling 82 RC (Rockwell C scale) hard steel at the Technische Hochschule Darmstadt.

Fig. 2. Influence of Feed per Tooth on Cutting Time Fig. 3. Influence of Cutting Speed on Tool Life

Tool life has a maximum value at a particular setting of speed and feed. Economic and productive cutting speeds always occur on the right side of the curves in Fig. 2 and Fig. 4, which are called Taylor curves, represented by the so called Taylor's equation.

The variation of tool life with speed and feed constitute complicated relationships, illustrated in Fig. 6a, Fig. 6b, and Fig. 6c.

**Taylor's Equation.**—Taylor's equation is the most commonly used relationship between tool life  $T$ , and cutting speed  $V$ . It constitutes a straight line in a log-log plot, one line for each feed, nose radius, lead angle, or depth of cut, mathematically represented by:

$$V \times T^n = C \quad (1a)$$

where  $n$  = slope of the line

$C$  = constant equal to the cutting speed for  $T = 1$  minute

By transforming the equation to logarithmic axes, the Taylor lines become straight lines with slope =  $n$ . The constant  $C$  is the cutting speed on the horizontal ( $V$ ) axis at tool life  $T = 1$  minute, expressed as follows

$$\ln V + n \times \ln T = \ln C \quad (1b)$$

For different values of feed or  $ECT$ , log-log plots of Equation (1a) form approximately straight lines in which the slope decreases slightly with a larger value of feed or  $ECT$ . In practice, the Taylor lines are usually drawn parallel to each other, i.e., the slope  $n$  is assumed to be constant.

Fig. 4 illustrates the Taylor equation, tool life  $T$  versus cutting speed  $V$ , plotted in log-log coordinates, for four values of  $ECT = 0.1, 0.25, 0.5$  and  $0.7$  mm.

In Fig. 4, starting from the right, each  $T$ - $V$  line forms a generally straight line that bends off and reaches its maximum tool life, then drops off with decreasing speed (see also Fig. 2 and Fig. 3). When operating at short tool-lives, approximately when  $T$  is less than 5 minutes, each line bends a little so that the cutting speed for 1 minute life becomes less than the value calculated by constant  $C$ .

The Taylor equation is a very good approximation of the right hand side of the real tool life curve (slightly bent). The portion of the curve to the left of the maximum tool life gives shorter and shorter tool lives when decreasing the cutting speed starting from the point of maximum tool life. Operating at the maximum point of maximum tool life, or to the left of it, causes poor surface finish, high cutting forces, and sometimes vibrations.

Fig. 4. Definition of Slope  $n$  and Constant  $C$  in Taylor's Equation

**Evaluation of Slope  $n$ , and Constant  $C$ .**—When evaluating the value of the Taylor slope based on wear tests, care must be taken in selecting the tool life range over which the slope is measured, as the lines are slightly curved.

The slope  $n$  can be found in three ways:

- Calculate  $n$  from the formula  $n = (\ln C - \ln V) / \ln T$ , reading the values of  $C$  and  $V$  for any value of  $T$  in the graph.
- Alternatively, using two points on the line,  $(V_1, T_1)$  and  $(V_2, T_2)$ , calculate  $n$  using the relationship  $V_1 \times T_1^n = V_2 \times T_2^n$ . Then, solving for  $n$ ,

$$n = \frac{\ln (V_1 / V_2)}{\ln (T_2 / T_1)}$$

- Graphically,  $n$  may be determined from the graph by measuring distances  $a$  and  $b$  using a mm scale, and  $n$  is the ratio of  $a$  and  $b$ , thus,  $n = a/b$

*Example:* Using Fig. 4 and a given value of  $ECT = 0.7$  mm, calculate the slope and constant of the Taylor line.

On the Taylor line for  $ECT = 0.7$ , locate points corresponding to tool-lives  $T_1 = 15$  minutes and  $T_2 = 60$  minutes. Read off the associated cutting speeds as, approximately,  $V_1 = 110$  m/min and  $V_2 = 65$  m/min.

The slope  $n$  is then found to be  $n = \ln (110/65) / \ln (60/15) = 0.38$

The constant  $C$  can be then determined using the Taylor equation and either point  $(T_1, V_1)$  or point  $(T_2, V_2)$ , with equivalent results, as follows:

$$C = V \times T^n = 110 \times 15^{0.38} = 65 \times 60^{0.38} = 308 \text{ m/min (1027 fpm)}$$

**The Generalized Taylor Equation.**—The above calculated slope and constant  $C$  define tool life at one particular value of feed  $f$ , depth of cut  $a$ , lead angle  $LA$ , nose radius  $r$ , and other relevant factors.

The generalized Taylor equation includes these parameters and is written

$$T^n = A \times f^m \times a^p \times LA^q \times r^s \quad (2)$$

where  $A$  = area; and,  $n, m, p, q$ , and  $s$  = constants.

There are two problems with the generalized equation: 1) a great number of tests have to be run in order to establish the constants  $n, m, p, q, s$ , etc.; and 2) the accuracy is not very good because Equation (2) yields straight lines when plotted versus  $f, a, LA$ , and  $r$ , when in reality, they are parabolic curves.

The Generalized Taylor Equation Using Equivalent Chip Thickness (ECT): Due to the compression of the aforementioned geometrical variables ( $f, a, LA, r, etc.$ ) into ECT, Equation (2) can now be rewritten:

$$V \times T^n = A \times ECT^m \tag{3}$$

Experimental data confirm that Equation (3) holds, approximately, within the range of the test data, but as soon as the equation is extended beyond the test results, the error can become very great because the  $V$ -ECT curves are represented as straight lines by Equation (3) and the real curves have a parabolic shape.

**The Colding Tool Life Relationship.**—This relationship contains 5 constants,  $H, K, L, M,$  and  $N_0$ , which attain different values depending on tool grade, work material, and the type of operation, such as longitudinal turning versus grooving, face milling versus end milling, etc.

This tool life relationship is proven to describe, with reasonable accuracy, how tool life varies with ECT and cutting speed for any metal cutting and grinding operation. It is expressed mathematically as follows either as a generalized Taylor equation (4a), or, in logarithmic coordinates (4b):

$$V \times T^{(N_0 - L \times \ln ECT)} \times ECT^{\left(-\frac{H}{2M} + \frac{\ln ECT}{4M}\right)} = e^{\left(K - \frac{H}{4M}\right)} \tag{4a}$$

$$y = K - \frac{x - H}{4M} - z(N_0 - L_x) \tag{4b}$$

where  $x = \ln ECT$      $y = \ln V$      $z = \ln T$

$M$  = vertical distance between maximum point of cutting speed ( $ECT_H, V_H$ ) for  $T = 1$  minute and speed  $V_G$  at point ( $ECT_G, V_G$ ), as shown in Fig. 5.

$2M$  = horizontal distance between point ( $ECT_H, V_G$ ) and point ( $V_G, ECT_G$ )

$H$  and  $K$  = logarithms of coordinates of maximum speed point ( $ECT_H, V_H$ ) at tool life  $T = 1$  minute, thus  $H = \ln(ECT_H)$  and  $K = \ln(V_H)$

$N_0$  and  $L$  = variation of Taylor slope  $n$  with ECT:  $n = N_0 - L \times \ln(ECT)$

Fig. 5. Definitions of the Constants  $H, K, L, M,$  and  $N_0$  for Tool Life Equation in the  $V$ -ECT Plane with Tool Life Constant

The constants  $L$  and  $N_0$  are determined from the slopes  $n_1$  and  $n_2$  of two Taylor lines at  $ECT_1$  and  $ECT_2$ , and the constant  $M$  from three  $V$ -ECT values at any constant tool life. Constants  $H$  and  $K$  are then solved using the tool life equation with the above-calculated values of  $L, N_0$  and  $M$ .

**The G- and H-Curves.**—The *G*-curve defines the longest possible tool life for any given metal removal rate, *MRR*, or specific metal removal rate, *SMRR*. It also defines the point where the total machining cost is minimum, after the economic tool life  $T_E$ , or optimal tool life  $T_O$ , has been calculated, see *Optimization Models, Economic Tool Life when Feed is Constant* starting on page 1213.

The tool life relationship is depicted in the three planes: *T-V*, where *ECT* is the plotted parameter (the Taylor plane); *T-ECT*, where *V* is plotted; and, *V-ECT*, where *T* is a parameter. The latter plane is the most useful because the optimal cutting conditions are more readily understood when viewing in the *V-ECT* plane. Fig. 6a, Fig. 6b, and Fig. 6c show how the tool life curves look in these three planes in log-log coordinates.

Fig. 6a. Tool Life versus Cutting Speed *T-V, ECT* Plotted

Fig. 6a shows the Taylor lines, and Fig. 6b illustrates how tool life varies with *ECT* at different values of cutting speed, and shows the *H*-curve. Fig. 6c illustrates how cutting speed varies with *ECT* at different values of tool life. The *H*- and *G*-curves are also drawn in Fig. 6c.

Fig. 6b. Tool Life versus *ECT, T-ECT, Cutting Speed* Plotted

A simple and practical method to ascertain that machining is not done to the left of the *H*-curve is to examine the chips. When *ECT* is too small, about 0.03-0.05 mm, the chips tend to become irregular and show up more or less as dust.

Fig. 6c. Cutting Speed versus  $ECT$ ,  $V-ECT$ , Tool Life Plotted

**The  $V-ECT-T$  Graph and the Tool Life Envelope.**—The tool life envelope, in Fig. 7, is an area laid over the  $V-ECT-T$  graph, bounded by the points A, B, C, D, and E, within which successful cutting can be realized. The  $H$ - and  $G$ -curves represent two borders, lines  $\overline{AE}$  and  $\overline{BC}$ . The border curve, line  $\overline{AB}$ , shows a lower limit of tool life,  $T_{MIN} = 5$  minutes, and border curve, line  $\overline{DE}$ , represents a maximum tool life,  $T_{MAX} = 300$  minutes.

$T_{MIN}$  is usually 5 minutes due to the fact that tool life versus cutting speed does not follow a straight line for short tool-lives; it decreases sharply towards one minute tool life.  $T_{MAX}$  varies with tool grade, material, speed and  $ECT$  from 300 minutes for some carbide tools to 10,000 minutes for diamond tools or diamond grinding wheels, although systematic studies of maximum tool-lives have not been conducted.

Sometimes the metal cutting system cannot utilize the maximum values of the  $V-ECT-T$  envelope, that is, cutting at optimum  $V-ECT$  values along the  $G$ -curve, due to machine power or fixture constraints, or vibrations. Maximum  $ECT$  values,  $ECT_{MAX}$ , are related to the strength of the tool material and the tool geometry, and depend on the tool grade and material selection, and require a relatively large nose radius.

Fig. 7. Cutting Speed versus  $ECT$ ,  $V-ECT$ , Tool Life Plotted

Minimum  $ECT$  values,  $ECT_{MIN}$ , are defined by the conditions at which surface finish suddenly deteriorates and the cutting edge begins rubbing rather than cutting. These conditions begin left of the  $H$ -curve, and are often accompanied by vibrations and built-up edges on the tool. If feed or  $ECT$  is reduced still further, excessive tool wear with sparks and tool breakage, or melting of the edge occurs. For this reason, values of  $ECT$  lower

than approximately 0.03 mm should not be allowed. In Fig. 7, the  $ECT_{MIN}$  boundary is indicated by contour line  $\overline{A'E'}$ .

In milling, the minimum feed/tooth depends on the ratio  $ar/D$ , of radial depth of cut  $ar$ , and cutter diameter  $D$ . For small  $ar/D$  ratios, the chip thickness becomes so small that it is necessary to compensate by increasing the feed/tooth. See *High-Speed Machining Econometrics* starting on page 1225 for more on this topic.

Fig. 7 demonstrates, in principle, minimum cost conditions for roughing at point  $O_R$ , and for finishing at point  $O_F$ , where surface finish or tolerances have set a limit. Maintaining the speed at  $O_R$ , 125 m/min, and decreasing feed reaches a maximum tool life = 300 minutes at  $ECT = 0.2$ , and a further decrease of feed will result in shorter lives.

Similarly, starting at point X ( $V = 150$ ,  $ECT = 0.5$ ,  $T = 15$ ) and reducing feed, the  $H$ -curve will be reached at point E ( $ECT = 0.075$ ,  $T = 300$ ). Continuing to the left, tool life will decrease and serious troubles occur at point E' ( $ECT = 0.03$ ).

Starting at point  $O_F$  ( $V = 300$ ,  $ECT = 0.2$ ,  $T = 15$ ) and reducing feed, the  $H$ -curve will be reached at point E ( $ECT = 0.08$ ,  $T = 15$ ). Continuing to the left, life will decrease and serious troubles occur at  $ECT = 0.03$ .

Starting at point X ( $V = 400$ ,  $ECT = 0.2$ ,  $T = 5$ ) and reducing feed, the  $H$ -curve will be reached at point E ( $ECT = 0.09$ ,  $T = 7$ ). Continuing to the left, life will decrease and serious troubles occur at point A' ( $ECT = 0.03$ ), where  $T = 1$  minute.

**Cutting Forces and Chip Flow Angle.**—There are three cutting forces, illustrated in Fig. 8, that are associated with the cutting edge with its nose radius  $r$ , depth of cut  $a$ , lead angle  $LA$ , and feed per revolution  $f$ , or in milling feed per tooth  $f_z$ . There is one drawing for roughing and one for finishing operations.

Fig. 8. Definitions of Equivalent Chip Thickness,  $ECT$ , and Chip Flow Angle,  $CFA$ .

The cutting force  $F_C$ , or tangential force, is perpendicular to the paper plane. The other two forces are the feed or axial force  $F_A$ , and the radial force  $F_R$  directed towards the work piece. The resultant of  $F_A$  and  $F_R$  is called  $F_H$ . When finishing,  $F_R$  is bigger than  $F_A$ , while in roughing  $F_A$  is usually bigger than  $F_R$ . The direction of  $F_H$ , measured by the chip flow angle  $CFA$ , is perpendicular to the rectangle formed by the cutting edge length  $CEL$  and  $ECT$  (the product of  $ECT$  and  $CEL$  constitutes the cross sectional area of cut,  $A$ ). The important task of determining the direction of  $F_H$ , and calculation of  $F_A$  and  $F_R$ , are shown in the formulas given in the Fig. 8.

The method for calculating the magnitudes of  $F_H$ ,  $F_A$ , and  $F_R$  is described in the following. The first thing is to determine the value of the cutting force  $F_C$ . Approximate formulas to

calculate the tangential cutting force, torque and required machining power are found in the section *ESTIMATING SPEEDS AND MACHINING POWER* starting on page 1143.

**Specific Cutting Force,  $K_c$ :** The specific cutting force, or the specific energy to cut,  $K_c$ , is defined as the ratio between the cutting force  $F_C$  and the chip cross-sectional area  $A$ . Thus,  $K_c = F_C \div A \text{ N/mm}^2$ .

The value of  $K_c$  decreases when  $ECT$  increases, and when the cutting speed  $V$  increases. Usually,  $K_c$  is written in terms of its value at  $ECT = 1$ , called  $K_{c1}$ , and neglecting the effect of cutting speed, thus  $K_c = K_{c1} \times ECT^B$ , where  $B$  = slope in log-log coordinates.

Fig. 9.  $K_c$  versus  $ECT$ , Cutting Speed Plotted

A more accurate relationship is illustrated in Fig. 9, where  $K_c$  is plotted versus  $ECT$  at three different cutting speeds. In Fig. 9, the two dashed lines represent the aforementioned equation, which each have different slopes,  $B$ . For the middle value of cutting speed,  $K_c$  varies with  $ECT$  from about 1900 to 1300  $\text{N/mm}^2$  when  $ECT$  increases from 0.1 to 0.7 mm. Generally the speed effect on the magnitude of  $K_c$  is approximately 5 to 15 percent when using economic speeds.

Fig. 10.  $F_H/F_C$  versus  $ECT$ , Cutting Speed Plotted

**Determination of Axial,  $F_A$ , and Radial,  $F_R$ , Forces:** This is done by first determining the resultant force  $F_H$  and then calculating  $F_A$  and  $F_R$  using the Fig. 8 formulas.  $F_H$  is

derived from the ratio  $F_H/F_C$ , which varies with  $ECT$  and speed in a fashion similar to  $Kc$ . Fig. 10 shows how this relationship may vary.

As seen in Fig. 10,  $F_H/F_C$  is in the range 0.3 to 0.6 when  $ECT$  varies from 0.1 to 1 mm, and speed varies from 200 to 250 m/min using modern insert designs and grades. Hence, using reasonable large feeds  $F_H/F_C$  is around 0.3–0.4 and when finishing about 0.5–0.6.

**Example:** Determine  $F_A$  and  $F_R$ , based on the chip flow angle  $CFA$  and the cutting force  $F_C$ , in turning.

Using a value of  $Kc = 1500 \text{ N/mm}^2$  for roughing, when  $ECT = 0.4$ , and the cutting edge length  $CEL = 5 \text{ mm}$ , first calculate the area  $A = 0.4 \times 5 = 2 \text{ mm}^2$ . Then, determine the cutting force  $F_C = 2 \times 1500 = 3000 \text{ N}$ , and an approximate value of  $F_H = 0.5 \times 3000 = 1500 \text{ N}$ .

Using a value of  $Kc = 1700 \text{ N/mm}^2$  for finishing, when  $ECT = 0.2$ , and the cutting edge length  $CEL = 2 \text{ mm}$ , calculate the area  $A = 0.2 \times 2 = 0.4 \text{ mm}^2$ . The cutting force  $F_C = 0.4 \times 1700 = 680 \text{ N}$  and an approximate value of  $F_H = 0.35 \times 680 = 238 \text{ N}$ .

Fig. 8 can be used to estimate  $CFA$  for rough and finish turning. When the lead angle  $LA$  is 15 degrees and the nose radius is relatively large, an estimated value of the chip flow angle becomes about 30 degrees when roughing, and about 60 degrees in finishing. Using the formulas for  $F_A$  and  $F_R$  relative to  $F_H$  gives:

**Roughing:**

$$F_A = F_H \times \cos(CFA) = 1500 \times \cos 30 = 1299 \text{ N}$$

$$F_R = F_H \times \sin(CFA) = 1500 \times \sin 30 = 750 \text{ N}$$

**Finishing:**

$$F_A = F_H \times \cos(CFA) = 238 \times \cos 60 = 119 \text{ N}$$

$$F_R = F_H \times \sin(CFA) = 238 \times \sin 60 = 206 \text{ N}$$

The force ratio  $F_H/F_C$  also varies with the tool rake angle and increases with negative rakes. In grinding,  $F_H$  is much larger than the grinding cutting force  $F_C$ ; generally  $F_H/F_C$  is approximately 2 to 4, because grinding grits have negative rakes of the order  $-35$  to  $-45$  degrees.

**Forces and Tool Life.**—Forces and tool life are closely linked. The ratio  $F_H/F_C$  is of particular interest because of the unique relationship of  $F_H/F_C$  with tool life.

Fig. 11a.  $F_H/F_C$  versus  $ECT$

The results of extensive tests at Ford Motor Company are shown in Fig. 11a and Fig. 11b, where  $F_H/F_C$  and tool life  $T$  are plotted versus  $ECT$  at different values of cutting speed  $V$ . For any constant speed, tool life has a maximum at approximately the same values of  $ECT$  as has the function  $F_H/F_C$ .

Fig. 11b. Tool Life versus ECT

*The Force Relationship:* Similar tests performed elsewhere confirm that the  $F_H/F_C$  function can be determined using the 5 tool life constants ( $H, K, M, L, N_0$ ) introduced previously, and a new constant ( $L_F/L$ ).

$$\ln\left(\frac{1}{a} \cdot \frac{F_H}{F_C}\right) = \frac{K - y - \frac{(x - H)^2}{4M}}{\frac{L_F}{L}(N_0 - Lx)} \quad (5)$$

The constant  $a$  depends on the rake angle; in turning,  $a$  is approximately 0.25 to 0.5 and  $L_F/L$  is 10 to 20.  $F_C$  attains its maximum values versus ECT along the  $H$ -curve, when the tool life equation has maxima, and the relationships in the three force ratio planes look very similar to the tool life functions shown in the tool life planes in Fig. 6a, Fig. 6b, and Fig. 6c.

Fig. 12. Tool Life versus  $F_H/F_C$

Tool life varies with  $F_H/F_C$  with a simple formula according to Equation (5) as follows:

$$T = \left(\frac{F_H}{aF_C}\right)^{\frac{L_F}{L}}$$

where  $L$  is the constant in the tool life equation, Equation (4a) or (4b), and  $L_F$  is the corresponding constant in the force ratio equation, Equation (5). In Fig. 12 this function is plotted for  $a=0.5$  and for  $L_F/L=5, 10$ , and  $20$ .

Accurate calculations of aforementioned relationships require elaborate laboratory tests, or better, the design of a special test and follow-up program for parts running in the ordinary production. A software machining program, such as Colding International Corp. *COMP* program can be used to generate the values of all three forces, torque, and power requirements both for sharp and worn tools.

**Surface Finish and Tool Life.**—It is well known that the surface finish in turning decreases with a bigger tool nose radius and increases with feed; usually it is assumed that the  $R_a$  (or  $R_a$ , for roughness average) value increases with the square of the feed per revolution, and decreases inversely with increasing size of the nose radius. This formula, derived from simple geometry, gives rise to great errors. In reality, the relationship is more complicated because the tool geometry must be taken into account, and the work material and the cutting conditions also have a significant influence.

Fig. 13.  $R_a$  versus  $ECT$ , Nose Radius  $r$  Constant

Fig. 13 shows surface finish  $R_a$  versus  $ECT$  at various cutting speeds for turning cast iron with carbide tools and a nose radius  $r = 1.2$  mm. Increasing the cutting speed leads to a smaller  $R_a$  value.

Fig. 14 shows how the finish improves when the tool nose radius,  $r$ , increases at a constant cutting speed (168 m/min) in cutting nodular cast iron.

In Fig. 15,  $R_a$  is plotted versus  $ECT$  with cutting speed  $V$  for turning a 4310 steel with carbide tools, for a nose radius  $r = 1.2$  mm, illustrating that increasing the speed also leads to a smaller  $R_a$  value for steel machining.

A simple rule of thumb for the effect of increasing nose radius  $r$  on decreasing surface finish  $R_a$ , regardless of the ranges of  $ECT$  or speeds used, albeit within common practical values, is as follows. In finishing,

$$\frac{R_{a1}}{R_{a2}} = \left( \frac{r_2}{r_1} \right)^{0.5} \quad (6)$$

Fig. 14.  $R_a$  versus  $ECT$ , Cutting Speed Constant, Nose Radius  $r$  Varies

Fig. 15.  $R_a$  versus  $ECT$ , Cutting Speed Varies, Nose Radius  $r$  Constant

In roughing, multiply the finishing values found using Equation (6) by 1.5, thus,  $R_{a(Rough)} = 1.5 \times R_{a(Finish)}$  for each  $ECT$  and speed.

*Example 1:* Find the decrease in surface roughness resulting from a tool nose radius change from  $r = 0.8$  mm to  $r = 1.6$  mm in finishing. Also, find the comparable effect in roughing.

For finishing, using  $r_2 = 1.6$  and  $r_1 = 0.8$ ,  $R_{a1}/R_{a2} = (1.6/0.8)^{0.5} = 1.414$ , thus, the surface roughness using the larger tool radius is  $R_{a2} = R_{a1} \div 1.414 = 0.7R_{a1}$ .

In roughing, at the same  $ECT$  and speed,  $R_a = 1.5 \times R_{a2} = 1.5 \times 0.7R_{a1} = 1.05R_{a1}$ .

*Example 2:* Find the decrease in surface roughness resulting from a tool nose radius change from  $r = 0.8$  mm to  $r = 1.2$  mm.

For finishing, using  $r_2 = 1.2$  and  $r_1 = 0.8$ ,  $R_{a1}/R_{a2} = (1.2/0.8)^{0.5} = 1.224$ , thus, the surface roughness using the larger tool radius is  $R_{a2} = R_{a1} \div 1.224 = 0.82R_{a1}$ .

In roughing, at the same  $ECT$  and speed,  $R_a = 1.5 \times R_{a2} = 1.5 \times 0.82R_{a1} = 1.23R_{a1}$ .

It is interesting to note that, at a given  $ECT$ , the  $R_a$  curves have a minimum, see Fig. 13 and Fig. 15, while tool life shows a maximum, see Fig. 6b and Fig. 6c. As illustrated in Fig. 16,  $R_a$  increases with tool life  $T$  when  $ECT$  is constant, in principle in the same way as does the force ratio.

Fig. 16.  $R_a$  versus  $T$ , Holding  $ECT$  Constant

*The Surface Finish Relationship:*  $R_a$  is determined using the same type of mathematical relationship as tool life and force calculations:

$$y = K_{Ra} - \frac{x - H_{Ra}^2}{4M_{Ra}} - (N_{0Ra} - L_{Ra}) \ln(R_a)$$

where  $K_{Ra}$ ,  $H_{Ra}$ ,  $M_{Ra}$ ,  $N_{0Ra}$ , and  $L_{Ra}$  are the five surface finish constants.

**Shape of Tool Life Relationships for Turning, Milling, Drilling and Grinding Operations—Overview.**—A summary of the general shapes of tool life curves ( $V$ - $ECT$ - $T$  graphs) for the most common machining processes, including grinding, is shown in double logarithmic coordinates in Fig. 17a through Fig. 17h.

### Calculation of Optimized Values of Tool Life, Feed and Cutting Speed

**Minimum Cost.**—Global optimum is defined as the absolute minimum cost considering all alternative speeds, feeds and tool-lives, and refers to the determination of optimum tool life  $T_O$ , feed  $f_O$ , and cutting speed  $V_O$ , for either minimum cost or maximum production rate. When using the tool life equation,  $T = f(V, ECT)$ , determine the corresponding feed, for given values of depth of cut and operation geometry, from optimum equivalent chip thickness,  $ECT_O$ . Mathematically the task is to determine minimum cost, employing the cost function  $C_{TOT} = \text{cost of machining time} + \text{tool changing cost} + \text{tooling cost}$ . Minimum cost optima occur along the so-called *G*-curve, identified in Fig. 6c.

Another important factor when optimizing cutting conditions involves choosing the proper cost values for cost per edge  $C_E$ , replacement time per edge  $T_{RPL}$ , and not least, the hourly rate  $H_R$  that should be applied.  $H_R$  is defined as the portion of the hourly shop rate that is applied to the operations and machines in question. If optimizing all operations in the portion of the shop for which  $H_R$  is calculated, use the full rate; if only one machine is involved, apply a lower rate, as only a portion of the general overhead rate should be used, otherwise the optimum, and anticipated savings, are erroneous.

**Production Rate.**—The production rate is defined as the cutting time or the metal removal rate, corrected for the time required for tool changes, but neglecting the cost of tools.

The result of optimizing production rate is a shorter tool life, higher cutting speed, and a higher feed compared to minimum cost optimization, and the tooling cost is considerably higher. Production rate optima also occur along the  $G$ -curve.

**The Cost Function.**—There are a number of ways the total machining cost  $C_{TOT}$  can be plotted, for example, versus feed,  $ECT$ , tool life, cutting speed or other parameter. In Fig. 18a, cost for a face milling operation is plotted versus cutting time, holding feed constant, and using a range of tool-lives,  $T$ , varying from 1 to 240 minutes.

The tabulated values show the corresponding cutting speeds determined from the tool life equation, and the influence of tooling on total cost. Tooling cost,  $C_{TOOL}$  = sum of tool cost + cost of replacing worn tools, decreases the longer the cutting time, while the total cost,  $C_{TOT}$ , has a minimum at around 10 seconds of cutting time. The dashed line in the graph represents the cost of machining time: the product of hourly rate  $H_R$ , and the cutting time  $t_c$  divided by 60. The slope of the line defines the value of  $H_R$ .

The cutting time for minimum cost varies with the ratio of tooling cost and  $H_R$ . Minimum cost moves towards a longer cutting time (longer tool life) when either the price of the tooling increases, or when several tools cut simultaneously on the same part. In Fig. 18b, this is exemplified by running 2 and 4 cutters simultaneously on the same work piece, at the same feed and depth of cut, and with a similar tool as in Fig. 18a. As the tooling cost goes up 2 and 4 times, respectively, and  $H_R$  is the same, the total costs curves move up, but also moves to the right, as do the points of minimum cost and optimal cutting times. This means that going somewhat slower, with more simultaneously cutting tools, is advantageous.

**Global Optimum.**—Usually, global optimum occurs for large values of feed, heavy roughing, and in many cases the cutting edge will break trying to apply the large feeds required. Therefore, true optima cannot generally be achieved when roughing, in particular when using coated and wear resistant grades; instead, use the maximum values of feed,  $ECT_{max}$ , along the tool life envelope, see Fig. 7.

As will be shown in the following, the first step is to determine the optimal tool life  $T_O$ , and then determine the optimum values of speeds and feeds.

Fig. 19. Variation of Tooling and Total Cost with Cutting Time, Comparing Global Optimum with Minimum Cost at  $f_z = 0.1$  mm

The example in Fig. 19 assumes that  $T_O = 22$  minutes and the speed and feed optima were calculated as  $f_O = 0.6$  mm/tooth,  $V_O = 119$  m/min, and cutting time  $t_{cO} = 4.9$  sec.

The point of maximum production rate corresponds to  $f_O = 0.7$  mm/tooth,  $V_O = 163$  m/min, at tool life  $T_O = 5$  minutes, and cutting time  $t_{cO} = 3.6$  sec. The tooling cost is approximately three times higher than at minimum cost (0.059 versus 0.0186), while the piece cost is only slightly higher: \$0.109 versus \$0.087.

When comparing the global optimum cost with the minimum at feed = 0.1 mm/tooth the graph shows it to be less than half (0.087 versus 0.164), but also the tooling cost is about 1/3 lower (0.0186 versus 0.027). The reason why tooling cost is lower depends on the tooling cost term  $t_c \times C_E/T$  (see *Calculation of Cost of Cutting and Grinding Operations*

on page 1218). In this example, cutting times  $t_c = 4.9$  and 9.81 seconds, at  $T = 22$  and 30 minutes respectively, and the ratios are proportional to  $4.9/22 = 0.222$  and  $9.81/30 = 0.327$  respectively.

The portions of the total cost curve for shorter cutting times than minimum correspond to using speeds and feeds to the right of the  $G$ -curve, and those on the other side are left of this curve.

**Optimization Models, Economic Tool Life when Feed is Constant.**—Usually, optimization is performed versus the parameters tool life and cutting speed, keeping feed at a constant value. The cost of cutting as function of cutting time is a straight line with the slope  $= H_R =$  hourly rate. This cost is independent of the values of tool change and tooling. Adding the cost of tool change and tooling, gives the variation of total cutting cost which shows a minimum with cutting time that corresponds to an economic tool life,  $T_E$ . Economic tool life represents a local optima (minimum cost) at a given constant value of feed, feed/tooth, or  $ECT$ .

Using the Taylor Equation:  $V \times T = C$  and differentiating  $C_{TOT}$  with respect to  $T$  yields:

**Economic tool life:**

$$T_E = T_V \times (1/n - 1), \text{ minutes}$$

**Economic cutting speed:**

$$V_E = C/T_E^n, \text{ m/min, or sfm}$$

In these equations,  $n$  and  $C$  are constants in the Taylor equation for the given value of feed. Values of Taylor slopes,  $n$ , are estimated using the speed and feed Table 1 through Table 23 starting on page 1095 and Handbook Table 5b on page 1103 for turning, and Table 15e on page 1127 for milling and drilling;  $T_V$  is the equivalent tooling-cost time.  $T_V = T_{RPL} + 60 \times C_E \div H_R$ , minutes, where  $T_{RPL}$  = time for replacing a worn insert, or a set of inserts in a milling cutter or inserted drill, or a twist drill, reamer, thread chaser, or tap.  $T_V$  is described in detail, later;  $C_E$  = cost per edge, or set of edges, or cost per regrind including amortized price of tool; and  $H_R$  = hourly shop rate, or that rate that is impacted by the changes of cutting conditions.

In two dimensions, Fig. 20a shows how economic tool life varies with feed per tooth. In this figure, the equivalent tooling-cost time  $T_V$  is constant, however the Taylor constant  $n$  varies with the feed per tooth.

Fig. 20a. Economic Tool Life,  $T_E$  versus Feed per Tooth,  $f_c$

Economic tool life increases with greater values of  $T_V$ , either when  $T_{RPL}$  is longer, or when cost per edge  $C_E$  is larger for constant  $H_R$ , or when  $H_R$  is smaller and  $T_{RPL}$  and  $C_E$  are unchanged. For example, when using an expensive machine (which makes  $H_R$  bigger) the value of  $T_V$  gets smaller, as does the economic tool life,  $T_E = T_V \times (1/n - 1)$ . Reducing  $T_E$  results in an increase in the economic cutting speed,  $V_E$ . This means raising the cutting speed and illustrates the importance, in an expensive system, of utilizing the equipment better by using more aggressive machining data.

Fig. 20b. Tool Life versus Cutting Speed, Constant  $ECT$

As shown in Fig. 20a for a face milling operation, economic tool life  $T_E$  varies considerably with feed/tooth  $f_z$ , in spite of the fact that the Taylor lines have only slightly different slopes ( $ECT = 0.51, 0.6, 1.54$ ), as shown in Fig. 20b. The calculation is based on the following cost data:  $T_V = 6$ , hourly shop rate  $H_R = \$60/\text{hour}$ , cutter diameter  $D = 125$  mm with number of teeth  $z = 10$ , and radial depth of cut  $ar = 40$  mm.

The conclusion relating to the determination of economic tool life is that both hourly rate  $H_R$  and slope  $n$  must be evaluated with reasonable accuracy in order to arrive at good values. However, the method shown will aid in setting the trend for general machining economics evaluations.

**Global Optimum, Graphical Method.**—There are several ways to demonstrate in graphs how cost varies with the production parameters including optimal conditions. In all cases, tool life is a crucial parameter.

Cutting time  $t_c$  is inversely proportional to the specific metal removal rate,  $SMRR = V \times ECT$ , thus,  $1/t_c = V \times ECT$ . Taking the log of both sides,

$$\ln V = -\ln ECT - \ln t_c + C \quad (7)$$

where  $C$  is a constant.

Equation (7) is a straight line with slope  $(-1)$  in the  $V$ - $ECT$  graph when plotted in a log-log graph. This means that a constant cutting time is a straight 45-degree line in the  $V$ - $ECT$  graph, when plotted in log-log coordinates with the same scale on both axis (a square graph).

The points at which the constant cutting time lines (at 45-degree slope) are tangent to the tool life curves define the  $G$ -curve, along which global optimum cutting occurs.

*Note:* If the ratio  $a/CEL$  is not constant when  $ECT$  varies, the constant cutting time lines are not straight, but the cutting time deviation is quite small in most cases.

In the  $V$ - $ECT$  graph, Fig. 21, 45-degree lines have been drawn tangent to each tool life curve:  $T = 1, 5, 15, 30, 60, 100$  and 300 minutes. The tangential points define the  $G$ -curve, and the 45-degree lines represent different constant cutting times: 1, 2, 3, 10 minutes, etc. Following one of these lines and noting the intersection points with the tool life curves  $T = 1, 5, \text{etc.}$ , many different speed and feed combinations can be found that will give the same cutting time. As tool life gets longer (tooling cost is reduced),  $ECT$  (feed) increases but the cutting speed has to be reduced.

Fig. 21. Constant Cutting Time in the  $V$ - $ECT$  Plane, Tool Life Constant

**Global Optimum, Mathematical Method.**—Global optimization is the search for extremum of  $C_{TOT}$  for the three parameters:  $T$ ,  $ECT$ , and  $V$ . The results, in terms of the tool life equation constants, are:

**Optimum tool life:**

$$T_O = T_V \times \left( \frac{1}{n_O} - 1 \right)$$

$$n_O = 2M \times (L \times \ln T_O)^2 + 1 - N_0 + L \times (2M + H)$$

where  $n_O$  = slope at optimum  $ECT$ .

The same approach is used when searching for maximum production rate, but without the term containing tooling cost.

**Optimum cutting speed:**

$$V_O = e^{-M + K + (H \times L - N_0) \times \ln T_O + M \times L^2 \times (\ln T_O)^2}$$

**Optimum  $ECT$ :**

$$ECT_O = e^{H + 2M \times (L \times \ln T_O + 1)}$$

Global optimum is not reached when face milling for very large feeds, and  $C_{TOT}$  decreases continually with increasing feed/tooth, but can be reached for a cutter with many teeth, say 20 to 30. In end milling, global optimum can often be achieved for big feeds and for 3 to 8 teeth.

### Determination of Machine Settings and Calculation of Costs

Based on the rules and knowledge presented in Chapters 1 and 2, this chapter demonstrates, with examples, how machining times and costs are calculated.

Additional formulas are given, and the speed and feed tables given in *SPEEDS AND FEEDS TABLES* starting on page 1090 should be used. Finally the selection of feeds, speeds and tool-lives for optimized conditions are described with examples related to turning, end milling, and face milling.

There are an infinite number of machine settings available in the machine tool power train producing widely different results. In practice only a limited number of available settings are utilized. Often, feed is generally selected independently of the material being cut, however, the influence of material is critical in the choice of cutting speed. The tool life is normally not known or directly determined, but the number of pieces produced before the change of worn tools is better known, and tool life can be calculated using the formula for piece cutting time  $t_c$  given in this chapter.

It is well known that increasing feeds or speeds reduces the number of pieces cut between tool changes, but not how big are the changes in the basic parameter tool life. Therefore, there is a tendency to select "safe" data in order to get a long tool life. Another common practice is to search for a tool grade yielding a longer life using the current speeds and feeds, or a 10 to 20 percent increase in cutting speed while maintaining the current tool life. The reason for this old-fashioned approach is the lack of knowledge about the opportunities the metal cutting process offers for increased productivity.

For example, when somebody wants to calculate the cutting time, he/she can select a value of the feed rate (product of feed and rpm), and easily find the cutting time by dividing cutting distance by the feed rate. The number of pieces obtained out of a tool is a guesswork, however. This problem is very common and usually the engineers find desired tool-lives after a number of trial and error runs using a variety of speeds and feeds. If the user is not well familiar with the material cut, the tool life obtained could be any number of seconds or minutes, or the cutting edge might break.

There are an infinite number of speeds and feeds, giving the same feed rate, producing equal cutting time. The same cutting time per piece  $t_c$  is obtained independent of the selection of feed/rev  $f$  and cutting speed  $V$  (or rpm), as long as the feed rate  $F_R$  remains the same:  $F_R = f_1 \times \text{rpm}_1 = f_2 \times \text{rpm}_2 = f_3 \times \text{rpm}_3, \dots$ , etc. However, the number of parts before tool change  $N_{ch}$  will vary considerably, including the tooling cost  $c_{tool}$  and the total cutting cost  $c_{tot}$ .

The dilemma confronting the machining-tool engineer or the process planner is how to set speeds and feeds for either desired cycle time, or number of parts between tool changes, while balancing the process versus other operations or balancing the total times in one cell with another. These problems are addressed in this section.

#### Nomenclature

$f$  = feed/rev or tooth, mm  $f_E$  = economic feed  $f_O$  = optimum feed

$T$  = tool life, minutes  $T_E$  = economic tool life  $T_O$  = optimum tool life

$V$  = cutting speed, m/min  $V_E$  = economic cutting speed

$V_O$  = optimum cutting speed, m/min

Similarly, economic and optimum values of:

$c_{tool}$  = piece cost of tooling, \$  $C_{TOOL}$  = cost of tooling per batch, \$

$c_{tot}$  = piece total cost of cutting, \$  $C_{TOT}$  = total cost of cutting per batch, \$

$F_R$  = feed rate measured in the feeding direction, mm/rev

$N$  = batch size

$N_{ch}$  = number of parts before tool change

$t_c$  = piece cutting time, minutes  $T_C$  = cutting time per batch, minutes

$t_{cyc}$  = piece cycle time, minutes  $T_{CYC}$  = cycle time before tool change, minutes

$t_i$  = idle time (tool "air" motions during cycle), minutes

$z$  = cutter number of teeth

The following variables are used for calculating the per batch cost of cutting:

$C_C$  = cost of cutting time per batch, \$

$C_{CH}$  = cost of tool changes per batch, \$

$C_E$  = cost per edge, for replacing or regrinding, \$

$H_R$  = hourly rate, \$

$T_V$  = equivalent tooling-cost time, minutes

$T_{RPL}$  = time for replacing worn edge(s), or tool for regrinding, minutes

*Note:* In the list above, when two variables use the same name, one in capital letters and one lower case,  $T_C$  and  $t_c$  for example, the variable name in capital letters refers to batch processing and lowercase letters to per piece processing, such as  $T_C = N_{ch} \times t_c$ ,  $C_{TOT} = N_{ch} \times c_{tot}$ , etc.

### Formulas Valid for All Operation Types Including Grinding

#### Calculation of Cutting Time and Feed Rate

##### Feed rate:

$F_R = f \times \text{rpm}$  (mm/min), where  $f$  is the feed in mm/rev along the feeding direction, rpm is defined in terms of workpiece or cutter diameter  $D$  in mm, and cutting speed  $V$  in m/min, as follows:

$$\text{rpm} = \frac{1000V}{\pi D} = \frac{318V}{D}$$

##### Cutting time per piece:

*Note:* Constant cutting time is a straight 45-degree line in the  $V$ - $ECT$  graph, along which tool life varies considerably, as is shown in Fig. 21.

$$t_c = \frac{Dist}{F_R} = \frac{Dist}{f \times \text{rpm}} = \frac{Dist \times \pi D}{1000V \times f}$$

where the units of distance cut  $Dist$ , diameter  $D$ , and feed  $f$  are mm, and  $V$  is in m/min.

In terms of  $ECT$ , cutting time per piece,  $t_c$ , is as follows:

$$t_c = \frac{Dist \times \pi D}{1000V} \times \frac{a}{CEL \times ECT}$$

where  $a$  = depth of cut, because feed  $\times$  cross sectional chip area =  $f \times a = CEL \times ECT$ .

*Example 3, Cutting Time:* Given  $Dist = 105$  mm,  $D = 100$  mm,  $f = 0.3$  mm,  $V = 300$  m/min, rpm = 700,  $F_R = 210$  mm/min, find the cutting time.

Cutting time =  $t_c = 105 \times 3.1416 \times 100 \div (1000 \times 300 \times 0.3) = 0.366$  minutes = 22 seconds

#### Scheduling of Tool Changes

##### Number of parts before tool change:

$$N_{ch} = T \div t_c$$

##### Cycle time before tool change:

$T_{CYC} = N_{ch} \times (t_c + t_i)$ , where  $t_{cyc} = t_c + t_i$ , where  $t_c$  = cutting time per piece,  $t_i$  = idle time per piece

##### Tool life:

$$T = N_{ch} \times t_c$$

*Example 4:* Given tool life  $T = 90$  minutes, cutting time  $t_c = 3$  minutes, and idle time  $t_i = 3$  minutes, find the number of parts produced before a tool change is required and the time until a tool change is required.

Number of parts before tool change =  $N_{ch} = 90/3 = 30$  parts.

Cycle time before tool change =  $T_{CYC} = 30 \times (3 + 3) = 180$  minutes

*Example 5:* Given cutting time,  $t_c = 1$  minute, idle time  $t_i = 1$  minute,  $N_{ch} = 100$  parts, calculate the tool life  $T$  required to complete the job without a tool change, and the cycle time before a tool change is required.

Tool life =  $T = N_{ch} \times t_c = 100 \times 1 = 100$  minutes.

Cycle time before tool change =  $T_{CYC} = 100 \times (1 + 1) = 200$  minutes.

**Calculation of Cost of Cutting and Grinding Operations.**—When machining data varies, the cost of cutting, tool changing, and tooling will change, but the costs of idle and slack time are considered constant.

**Cost of Cutting per Batch:**

$$C_C = H_R \times T_C / 60$$

$T_C$  = cutting time per batch = (number of parts)  $\times t_c$ , minutes, or when determining time for tool change  $T_{ch} = N_{ch} \times t_c$  minutes = cutting time before tool change.

$t_c$  = cutting time/part, minutes

$H_R$  = hourly rate

**Cost of Tool Changes per Batch:**

$$C_{CH} = \frac{H_R}{60} \times T_C \times \frac{T_{RPL}}{T} \quad \frac{\$}{\text{min}} \cdot \text{min} = \$$$

where  $T$  = tool life, minutes, and  $T_{RPL}$  = time for replacing a worn edge(s), or tool for regrinding, minutes

**Cost of Tooling per Batch:**

Including cutting tools and holders, but without tool changing costs,

$$C_{TOOL} = \frac{H_R}{60} \times T_C \times \frac{60C_E}{T} \quad \frac{\$}{\text{min}} \cdot \text{min} \cdot \frac{\text{min}}{\text{hr}} \cdot \frac{\$}{\text{min}} = \$$$

**Cost of Tooling + Tool Changes per Batch:**

Including cutting tools, holders, and tool changing costs,

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_{RPL} + \frac{60C_E}{H_R}}{T}$$

**Total Cost of Cutting per Batch:**

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_{RPL} + \frac{60C_E}{H_R}}{T} \right)$$

**Equivalent Tooling-cost Time,  $T_V$ :**

The two previous expressions can be simplified by using  $T_V = T_{RPL} + \frac{60C_E}{H_R}$  thus:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T}$$

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_V}{T} \right)$$

$C_E$  = cost per edge(s) is determined using two alternate formulas, depending on whether tools are reground or inserts are replaced:

**Cost per Edge, Tools for Regrinding:**

$$C_E = \frac{\text{cost of tool} + (\text{number of regrinds} \times \text{cost/regrind})}{1 + \text{number of regrinds}}$$

**Cost per Edge, Tools with Inserts:**

$$C_E = \frac{\text{cost of insert(s)}}{\text{number of edges per insert}} + \frac{\text{cost of cutter body}}{\text{cutter body life in number of edges}}$$

*Note:* In practice allow for insert failures by multiplying the insert cost by 4/3, that is, assuming only 3 out of 4 edges can be effectively used.

*Example 6, Cost per Edge-Tools for Regrinding:* Use the data in the table below to calculate the cost per edge(s)  $C_E$ , and the equivalent tooling-cost time  $T_V$ , for a drill.

Time for cutter replacement $T_{RPL}$ , minute	Cutter Price, \$	Cost per regrind, \$	Number of regrinds	Hourly shop rate, \$	Batch size	Taylor slope, $n$	Economic cutting time, $t_{cE}$ minute
1	40	6	5	50	1000	0.25	1.5

Using the cost per edge formula for reground tools,  $C_E = (40 + 5 \times 6) / (1 + 5) = \$6.80$

When the hourly rate is \$50/hr,  $T_V = T_{RPL} + \frac{60C_E}{H_R} = 1 + \frac{60(6.8)}{50} = 9.16$  minutes

Calculate economic tool life using  $T_E = T_V \times \left( \frac{1}{n} - 1 \right)$  thus,  $T_E = 9.17 \times (1/0.25 - 1) = 9.16 \times 3 = 27.48$  minutes.

Having determined, elsewhere, the economic cutting time per piece to be  $t_{cE} = 1.5$  minutes, for a batch size = 1000 calculate:

Cost of Tooling + Tool Change per Batch:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T} = \frac{50}{60} \times 1000 \times 1.5 \times \frac{9.16}{27.48} = \$417$$

Total Cost of Cutting per Batch:

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_V}{T} \right) = \frac{50}{60} \times 1000 \times 1.5 \times \left( 1 + \frac{9.16}{27.48} \right) = \$1617$$

*Example 7, Cost per Edge-Tools with Inserts:* Use data from the table below to calculate the cost of tooling and tool changes, and the total cost of cutting.

For face milling, multiply insert price by safety factor 4/3 then calculate the cost per edge:  $C_E = 10 \times (5/3) \times (4/3) + 750/500 = 23.72$  per set of edges

When the hourly rate is \$50, equivalent tooling-cost time is  $T_V = 2 + 23.72 \times 60/50 = 30.466$  minutes (first line in table below). The economic tool life for Taylor slope  $n = 0.333$  would be  $T_E = 30.466 \times (1/0.333 - 1) = 30.466 \times 2 = 61$  minutes.

When the hourly rate is \$25, equivalent tooling-cost time is  $T_V = 2 + 23.72 \times 60/25 = 58.928$  minutes (second line in table below). The economic tool life for Taylor slope  $n = 0.333$  would be  $T_E = 58.928 \times (1/0.333 - 1) = 58.928 \times 2 = 118$  minutes.

Time for replacement of inserts $T_{RPL}$ , minutes	Number of inserts	Price per insert	Edges per insert	Cutter Price	Edges per cutter	Cost per set of edges, $C_E$	Hourly shop rate	$T_V$ minutes
Face mill								
2	10	5	3	750	500	23.72	50	30.466
2	10	5	3	750	500	23.72	25	58.928
End mill								
1	3	6	2	75	200	4.375	50	6.25
Turning								
1	1	5	3	50	100	2.72	30	6.44

With above data for the face mill, and after having determined the economic cutting time as  $t_{cE} = 1.5$  minutes, calculate for a batch size = 1000 and \$50 per hour rate:

Cost of Tooling + Tool Change per Batch:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T} = \frac{50}{60} \times 1000 \times 1.5 \times \frac{30.466}{61} = \$624$$

Total Cost of Cutting per Batch:

$$C_{TOT} = \frac{H_R}{60} \times T_C \left(1 + \frac{T_V}{T}\right) = \frac{50}{60} \times 1000 \times 1.5 \times \left(1 + \frac{30.466}{61}\right) = \$1874$$

Similarly, at the \$25/hour shop rate,  $(C_{TOOL} + C_{CH})$  and  $C_{TOT}$  are \$312 and \$937, respectively.

**Example 8, Turning:** Production parts were run in the shop at feed/rev = 0.25 mm. One series was run with speed  $V_1 = 200$  m/min and tool life was  $T_1 = 45$  minutes. Another was run with speed  $V_2 = 263$  m/min and tool life was  $T_2 = 15$  minutes. Given idle time  $t_i = 1$  minute, cutting distance  $Dist = 1000$  mm, work diameter  $D = 50$  mm.

First, calculate Taylor slope,  $n$ , using Taylor's equation  $V_1 \times T_1^n = V_2 \times T_2^n$ , as follows:

$$n = \ln \frac{V_1}{V_2} \div \ln \frac{T_2}{T_1} = \ln \frac{200}{263} \div \ln \frac{15}{45} = 0.25$$

Economic tool life  $T_E$  is next calculated using the equivalent tooling-cost time  $T_V$ , as described previously. Assuming a calculated value of  $T_V = 4$  minutes, then  $T_E$  can be calculated from

$$T_E = T_V \times \left(\frac{1}{n} - 1\right) = 4 \times \left(\frac{1}{0.25} - 1\right) = 12 \text{ minutes}$$

Economic cutting speed,  $V_E$  can be found using Taylor's equation again, this time using the economic tool life, as follows,

$$V_{E1} \times (T_E)^n = V_2 \times (T_2)^n$$

$$V_{E1} = V_2 \times \left(\frac{T_2}{T_E}\right)^n = 263 \times \left(\frac{15}{12}\right)^{0.25} = 278 \text{ m/min}$$

Using the process data, the remaining economic parameters can be calculated as follows:

$$\text{Economic spindle rpm, } \text{rpm}_E = 1000V_E/\pi D = (1000 \times 278)/(3.1416 \times 50) = 1770 \text{ rpm}$$

$$\text{Economic feed rate, } F_{RE} = f \times \text{rpm}_E = 0.25 \times 1770 = 443 \text{ mm/min}$$

$$\text{Economic cutting time, } t_{cE} = Dist/F_{RE} = 1000/443 = 2.259 \text{ minutes}$$

$$\text{Economic number of parts before tool change, } N_{chE} = T_E + t_{cE} = 12 + 2.259 = 5.31 \text{ parts}$$

$$\text{Economic cycle time before tool change, } T_{CYCE} = N_{chE} \times (t_c + t_i) = 5.31 \times (2.259 + 1) = 17.3 \text{ minutes.}$$

### Variation of Tooling and Total Cost with the Selection of Speeds and Feeds

It is a well-known fact that tool life is reduced when either feed or cutting speed is increased. When a higher feed/rev is selected, the cutting speed must be decreased in order to maintain tool life. However, a higher feed rate (feed rate = feed/rev  $\times$  rpm, mm/min) can result in a longer tool life if proper cutting data are applied. Optimized cutting data require accurate machinability databases and a computer program to analyze the options. Reasonably accurate optimized results can be obtained by selecting a large feed/rev or tooth, and then calculating the economic tool life  $T_E$ . Because the cost versus feed or *ECT* curve is shallow around the true minimum point, i.e., the global optimum, the error in applying a large feed is small compared with the exact solution.

Once a feed has been determined, the economic cutting speed  $V_E$  can be found by calculating the Taylor slope, and the time/cost calculations can be completed using the formulas described in last section.

The remainder of this section contains examples useful for demonstrating the required procedures. Global optimum may or may not be reached, and tooling cost may or may not be reduced, compared to currently used data. However, the following examples prove that significant time and cost reductions are achievable in today's industry.

*Note:* Starting values of reasonable feeds in mm/rev can be found in the Handbook speed and feed tables, see *Principal Speeds and Feeds Tables* on page 1090, by using the  $f_{avg}$  values converted to mm as follows: feed (mm/rev) = feed (inch/rev)  $\times$  25.4 (mm/inch), thus  $0.001$  inch/rev =  $0.001 \times 25.4 = 0.0254$  mm/rev. When using speed and feed [Table 1](#) through [Table 23](#), where feed values are given in thousandths of inch per revolution, simply multiply the given feed by  $25.4/1000 = 0.0254$ , thus feed (mm/rev) = feed (0.001 inch/rev)  $\times$  0.0254 (mm/0.001inch).

*Example 9, Converting Handbook Feed Values from Inches to Millimeters:* Handbook tables give feed values  $f_{opt}$  and  $f_{avg}$  for 4140 steel as 17 and  $8 \times (0.001$  inch/rev) = 0.017 and 0.009 inch/rev, respectively. Convert the given feeds to mm/rev.

$$\text{feed} = 0.017 \times 25.4 = 17 \times 0.0254 = 0.4318 \text{ mm/rev}$$

$$\text{feed} = 0.008 \times 25.4 = 8 \times 0.0254 = 0.2032 \text{ mm/rev}$$

*Example 10, Using Handbook Tables to Find the Taylor Slope and Constant:* Calculate the Taylor slope and constant, using cutting speed data for 4140 steel in [Table 1](#) starting on page 1095, and for ASTM Class 20 gray cast iron using data from [Table 4a](#) on page 1101, as follows:

For the 175–250 Brinell Hardness range, and the hard tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(525/705)}{\ln(15/45)} = 0.27 \quad C = V_1 \times (T_1)^n = 1458$$

For the 175–250 Brinell Hardness range, and the tough tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(235/320)}{\ln(15/45)} = 0.28 \quad C = V_1 \times (T_1)^n = 685$$

For the 300–425 Brinell Hardness range, and the hard tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(330/440)}{\ln(15/45)} = 0.26 \quad C = V_1 \times (T_1)^n = 894$$

For the 300–425 Brinell Hardness range, and the tough tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(125/175)}{\ln(15/45)} = 0.31 \quad C = V_1 \times (T_1)^n = 401$$

For ASTM Class 20 gray cast iron, using hard ceramic,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(1490/2220)}{\ln(15/45)} = 0.36 \quad C = V_1 \times T_1^n = 5932$$

**Selection of Optimized Data.**—Fig. 22 illustrates cutting time, cycle time, number of parts before a tool change, tooling cost, and total cost, each plotted versus feed for a constant tool life. Approximate minimum cost conditions can be determined using the formulas previously given in this section.

First, select a large feed/rev or tooth, and then calculate economic tool life  $T_E$ , and the economic cutting speed  $V_E$ , and do all calculations using the time/cost formulas as described previously.

Fig. 22. Cutting Time, Cycle Time, Number of Parts Before Tool Change, Tooling Cost, and Total Cost versus Feed for Tool Life = 15 Minutes, Idle Time = 10 s, and Batch Size = 1000 Parts

**Example 11, Step by Step Procedure: Turning—Facing out:** 1) Select a big feed/rev, in this case  $f = 0.9$  mm/rev (0.035 inch/rev). A Taylor slope  $n$  is first determined using the Handbook tables and the method described in Example 10. In this example, use  $n = 0.35$  and  $C = 280$ .

2) Calculate  $T_V$  from the tooling cost parameters:

If cost of insert = \$7.50; edges per insert = 2; cost of tool holder = \$100; life of holder = 100 insert sets; and for tools with inserts, allowance for insert failures = cost per insert by 4/3, assuming only 3 out of 4 edges can be effectively used.

Then, cost per edge =  $C_E$  is calculated as follows:

$$C_E = \frac{\text{cost of insert(s)}}{\text{number of edges per insert}} + \frac{\text{cost of cutter body}}{\text{cutter body life in number of edges}}$$

$$= \frac{7.50 \times 4/3}{2} + \frac{100}{100} = \$6.00$$

The time for replacing a worn edge of the facing insert =  $T_{RPL} = 2.24$  minutes. Assuming an hourly rate  $H_R = \$50/\text{hour}$ , calculate the equivalent tooling-cost time  $T_V$

$$T_V = T_{RPL} + 60 \times C_E/H_R = 2.24 + 60 \times 6/50 = 9.44 \text{ minutes}$$

3) Determine economic tool life  $T_E$

$$T_E = T_V \times (1/n - 1) = 9.44 \times (1/0.35 - 1) = 17.5 \text{ minutes}$$

4) Determine economic cutting speed using the Handbook tables using the method shown in Example 10,

$$V_E = \frac{C}{T_E^n} \text{ m/min} = 280 / 17.5^{0.35} = 103 \text{ m/min}$$

5) Determine cost of tooling per batch (cutting tools, holders and tool changing) then total cost of cutting per batch:

$$C_{TOOL} = H_R \times T_C \times (C_E/T)/60$$

$$C_{TOOL} + C_{CH} = H_R \times T_C \times (T_{RPL} + C_E/T)/60$$

$$C_{TOT} = H_R \times T_C (1 + (T_{RPL} + C_E)/T)$$

**Example 12, Face Milling—Minimum Cost:** This example demonstrates how a modern firm, using the formulas previously described, can determine optimal data. It is here applied to a face mill with 10 teeth, milling a 1045 type steel, and the radial depth versus the cutter diameter is 0.8. The  $V$ - $ECT$ - $T$  curves for tool-lives 5, 22, and 120 minutes for this operation are shown in Fig. 23a.

Fig. 23a. Cutting Speed versus  $ECT$ , Tool Life Constant

The global cost minimum occurs along the  $G$ -curve, see Fig. 6c and Fig. 23a, where the 45-degree lines defines this curve. Optimum  $ECT$  is in the range 1.5 to 2 mm.

For face and end milling operations,  $ECT = z \times f_z \times ar/D \times aa/CEL + \pi$ . The ratio  $aa/CEL = 0.95$  for lead angle  $LA = 0$ , and for  $ar/D = 0.8$  and 10 teeth, using the formula to calculate the feed/tooth range gives for  $ECT = 1.5$ ,  $f_z = 0.62$  mm and for  $ECT = 2$ ,  $f_z = 0.83$  mm.

Fig. 23b. Cutting Time per Part versus Feed per Tooth

Using computer simulation, the minimum cost occurs approximately where Fig. 23a indicates it should be. Total cost has a global minimum at  $f_z$  around 0.6 to 0.7 mm and a speed of around 110 m/min.  $ECT$  is about 1.9 mm and the optimal cutter life is  $T_O = 22$  minutes. Because it may be impossible to reach the optimum feed value due to tool

breakage, the maximum practical feed  $f_{max}$  is used as the optimal value. The difference in costs between a global optimum and a practical minimum cost condition is negligible, as shown in Fig. 23c and Fig. 23e. A summary of the results are shown in Fig. 23a through Fig. 23e, and Table 1.

Fig. 23c. Total Cost versus Feed/Tooth

When plotting cutting time/part,  $t_c$ , versus feed/tooth,  $f_z$ , at  $T=5, 22, 120$  in Fig. 23b, tool life  $T=5$  minutes yields the shortest cutting time, but total cost is the highest; the minimum occurs for  $f_z$  about 0.75 mm, see Fig. 23c. The minimum for  $T=120$  minutes is about 0.6 mm and for  $T_{O'}=22$  minutes around 0.7 mm.

Fig. 23d. Tooling Cost versus Feed/Tooth

Fig. 23d shows that tooling cost drops off quickly when increasing feed from 0.1 to 0.3 mm, and then diminishes slowly and is almost constant up to 0.7 to 0.8 mm/tooth. It is generally very high at the short tool life 5 minutes, while tooling cost of optimal tool life 22 minutes is about three times higher than when going slow at  $T=120$  minutes.

Fig. 23e. Total Cost versus Cutting Speed at 3 Constant Tool-Lives, Feed Varies

The total cost curves in Fig. 23e were obtained by varying feed and cutting speed in order to maintain constant tool-lives at 5, 22 and 120 minutes. Cost is plotted as a function of speed  $V$  instead of feed/tooth. Approximate optimum speeds are  $V = 150$  m/min at  $T = 5$  minutes,  $V = 180$  m/min at  $T = 120$  minutes, and the global optimum speed is  $V_0 = 110$  m/min for  $T_0 = 22$  minutes.

Table 1 displays the exact numerical values of cutting speed, tooling cost and total cost for the selected tool-lives of 5, 22, and 120 minutes, obtained from the software program.

**Table 1. Face Milling, Total and Tooling Cost versus ECT, Feed/tooth  $f_z$ , and Cutting Speed  $V$ , at Tool-lives 5, 22, and 120 minutes**

### High-Speed Machining Econometrics

**High-Speed Machining, No Mystery.**—This section describes the theory and gives the basic formulas for any milling operation and high-speed milling in particular, followed by several examples on high-speed milling econometrics. These rules constitute the basis on which selection of milling feed factors is done. Selection of cutting speeds for general milling is done using the Handbook Table 10 through Table 14, starting on page 1112.

High-speed machining is no mystery to those who understand metal cutting. Machining materials with good machinability, such as low-alloyed aluminum, has for ages been performed at cutting speeds well below the speed values at which these materials should be cut. Operating at such low speeds often results in built-up edges and poor surface finish, because the operating conditions selected are on the wrong side of the Taylor curve, i.e. to the left of the  $H$ -curve representing maximum tool life (see Fig. 4 on page 1199).

In the 1950's it was discovered that cutting speed could be raised by a factor of 5 to 10 when hobbing steel with HSS cutters. This is another example of being on the wrong side of the Taylor curve.

One of the first reports on high-speed end milling using high-speed steel (HSS) and carbide cutters for milling 6061-T651 and A356-T6 aluminum was reported in a study funded by Defense Advanced Research Project Agency (DARPA). Cutting speeds of up to 4400 m/min (14140 fpm) were used. Maximum tool-lives of 20 through 40 minutes were obtained when the feed/tooth was 0.2 through 0.25 mm (0.008 to 0.01 inch), or measured in terms of  $ECT$  around 0.07 to 0.09 mm. Lower or higher feed/tooth resulted in shorter cutter lives. The same types of previously described curves, namely  $T-ECT$  curves with maximum tool life along the  $H$ -curve, were produced.

When examining the influence of  $ECT$ , or feed/rev, or feed/tooth, it is found that too small values cause chipping, vibrations, and poor surface finish. This is caused by inadequate (too small) chip thickness, and as a result the material is not cut but plowed away or scratched, due to the fact that operating conditions are on the wrong (left) side of the tool life versus  $ECT$  curve ( $T-ECT$  with constant speed plotted).

There is a great difference in the thickness of chips produced by a tooth traveling through the cutting arc in the milling process, depending on how the center of the cutter is placed in relation to the workpiece centerline, in the feed direction. Although end and face milling cut in the same way, from a geometry and kinematics standpoint they are in practice distinguished by the cutter center placement away from, or close to, the work centerline, respectively, because of the effect of cutter placement on chip thickness. This is the criterion used to distinguish between the end and face milling processes in the following.

*Depth of Cut/Cutter Diameter,  $ar/D$*  is the ratio of the radial depth of cut  $ar$  and the cutter diameter  $D$ . In face milling when the cutter axis points approximately to the middle of the work piece axis, eccentricity is close to zero, as illustrated in Fig. 3 and Fig. 4, page 1110, and Fig. 5 on page 1111. In end milling,  $ar/D = 1$  for full slot milling.

*Mean Chip Thickness  $hm$*  is a key parameter that is used to calculate forces and power requirements in high-speed milling. If the mean chip thickness  $hm$  is too small, which may occur when feed/tooth is too small (this holds for all milling operations), or when  $ar/D$  decreases (this holds for ball nose as well as for straight end mills), then cutting occurs on the left (wrong side) of the tool life versus  $ECT$  curve, as illustrated in Fig. 6b and Fig. 6c.

In order to maintain a given chip thickness in end milling, the feed/tooth has to be increased, up to 10 times for very small  $ar/D$  values in an extreme case with no run out and otherwise perfect conditions. A 10 times increase in feed/tooth results in 10 times bigger feed rates ( $F_R$ ) compared to data for full slot milling (valid for  $ar/D = 1$ ), yet maintains a given chip thickness. The cutter life at any given cutting speed will not be the same, however.

Increasing the number of teeth from say 2 to 6 increases equivalent chip thickness  $ECT$  by a factor of 3 while the mean chip thickness  $hm$  remains the same, but does not increase the feed rate to 30 ( $3 \times 10$ ) times bigger, because the cutting speed must be reduced. However, when the  $ar/D$  ratio matches the number of teeth, such that one tooth enters when the second tooth leaves the cutting arc, then  $ECT = hm$ . Hence,  $ECT$  is proportional to the number of teeth. Under ideal conditions, an increase in number of teeth  $z$  from 2 to 6 increases the feed rate by, say, 20 times, maintaining tool life at a reduced speed. In practice about 5 times greater feed rates can be expected for small  $ar/D$  ratios (0.01 to 0.02), and up to 10 times with 3 times as many teeth. So, high-speed end milling is no mystery.

**Chip Geometry in End and Face Milling.**—Fig. 24 illustrates how the chip forming process develops differently in face and end milling, and how mean chip thickness  $hm$  varies with the angle of engagement  $AE$ , which depends on the  $ar/D$  ratio. The pertinent chip geometry formulas are given in the text that follows.

Fig. 24.

*Comparison of face milling and end milling geometry:* High-speed end milling refers to values of  $ar/D$  that are less than 0.5, in particular to  $ar/D$  ratios which are considerably smaller. When  $ar/D = 0.5$  ( $AE = 90$  degrees) and diminishing in end milling, the chip thickness gets so small that poor cutting action develops, including plowing or scratching. This situation is remedied by increasing the feed/tooth, as shown in Table 2a as an increasing  $f_z/f_{z0}$  ratio with decreasing  $ar/D$ . For end milling, the  $f_z/f_{z0}$  feed ratio is 1.0 for  $ar/D = 1$  and also for  $ar/D = 0.5$ . In order to maintain the same  $hm$  as at  $ar/D = 1$ , the feed/tooth should be increased, by a factor of 6.38 when  $ar/D$  is 0.01 and by more than 10 when  $ar/D$  is less than 0.01. Hence high-speed end milling could be said to begin when  $ar/D$  is less than 0.5

In end milling, the ratio  $f_z/f_{z0} = 1$  is set at  $ar/D = 1.0$  (full slot), a common value in vendor catalogs and handbooks, for  $hm = 0.108$  mm.

The face milling chip making process is exactly the same as end milling the side of a workpiece and  $ar/D = 0.5$  or less. However, when face milling close to and along the work centerline (eccentricity is close to zero) chip making is quite different, as shown in Fig. 24. When  $ar/D = 0.74$  ( $AE = 95$  degrees) in face milling, the  $f_z/f_{z0}$  ratio is 1 and increases up to 1.4 when the work width is equal to the cutter diameter ( $ar/D = 1$ ). The face milling  $f_z/f_{z0}$  ratio continues to diminish when the  $ar/D$  ratio decreases below  $ar/D = 0.74$ , but very insignificantly, only about 11 percent when  $ar/D = 0.01$ .

In face milling,  $f_z/f_{z0} = 1$  is set at  $ar/D = 0.74$ , a common value recommended in vendor catalogs and handbooks, for  $hm = 0.151$  mm.

Fig. 25 shows the variation of the feed/tooth-ratio in a graph for end and face milling.

Fig. 25. Feed/Tooth versus  $ar/D$  for Face and End Milling

**Table 2a. Variation of Chip Thickness and  $f_z/f_{z0}$  with  $ar/D$**

0.0100	1.146	1.000	0.170	0.025	0.890	11.478	0.100	0.017	0.064	6.377
0.0010	0.115	1.000	0.000	0.000	0.890	3.624	0.000	0.000	0.000	20.135

In Table 2a, a standard value  $f_{z0} = 0.17$  mm/tooth (commonly recommended average feed) was used, but the  $f_z/f_{z0}$  values are independent of the value of feed/tooth, and the previously mentioned relationships are valid whether  $f_{z0} = 0.17$  or any other value.

In both end and face milling,  $hm = 0.108$  mm for  $f_{z0} = 0.17$  mm when  $ar/D = 1$ . When the  $f_z/f_{z0}$  ratio is 1,  $hm = 0.15$  for face milling, and 0.108 in end milling both at  $ar/D = 1$  and 0.5. The tabulated data hold for perfect milling conditions, such as, zero run-out and accurate sharpening of all teeth and edges.

**Mean Chip Thickness  $hm$  and Equivalent Chip Thickness  $ECT$ .**—The basic formula for equivalent chip thickness  $ECT$  for any milling process is:

$ECT = f_z \times z/\pi \times (ar/D) \times aa/CEL$ , where  $f_z$  = feed/tooth,  $z$  = number of teeth,  $D$  = cutter diameter,  $ar$  = radial depth of cut,  $aa$  = axial depth of cut, and  $CEL$  = cutting edge length. As a function of mean chip thickness  $hm$ :

$ECT = hm \times (z/2) \times (AE/180)$ , where  $AE$  = angle of engagement.

Both terms are exactly equal when one tooth engages as soon as the preceding tooth leaves the cutting section. Mathematically,  $hm = ECT$  when  $z = 360/AE$ ; thus:

for face milling,  $AE = \arccos(1 - 2 \times (ar/D)^2)$

for end milling,  $AE = \arccos(1 - 2 \times (ar/D))$

**Calculation of Equivalent Chip Thickness ( $ECT$ ) versus Feed/tooth and Number of Teeth:** Table 2b is a continuation of Table 2a, showing the values of  $ECT$  for face and end milling for decreasing values  $ar/D$ , and the resulting  $ECT$  when multiplied by the  $f_z/f_{z0}$  ratio  $f_{z0} = 0.17$  (based on  $hm = 0.108$ ).

Small  $ar/D$  ratios produce too small mean chip thickness for cutting chips. In practice, minimum values of  $hm$  are approximately 0.02 through 0.04 mm for both end and face milling.

**Formulas.**—Equivalent chip thickness can be calculated for other values of  $f_z$  and  $z$  by means of the following formulas:

Face milling:  $ECT_F = ECT_{0F} \times (z/8) \times (f_z/0.17) \times (aa/CEL)$

or, if  $ECT_F$  is known calculate  $f_z$  using:

$f_z = 0.17 \times (ECT_F/ECT_{0F}) \times (8/z) \times (CEL/aa)$

**Table 2b. Variation of ECT, Chip Thickness and  $f_z/f_{z0}$  with  $ar/D$**

In face milling, the approximate values of  $aa/CEL = 0.95$  for lead angle  $LA = 0^\circ$  ( $90^\circ$  in the metric system); for other values of  $LA$ ,  $aa/CEL = 0.95 \times \sin(LA)$ , and  $0.95 \times \cos(LA)$  in the metric system.

*Example, Face Milling:* For a cutter with  $D = 250$  mm and  $ar = 125$  mm, calculate  $ECT_F$  for  $f_z = 0.1$ ,  $z = 12$ , and  $LA = 30$  degrees. First calculate  $ar/D = 0.5$ , and then use Table 2b and find  $ECT_{0F} = 0.2$ .

Calculate  $ECT_F$  with above formula:

$$ECT_F = 0.2 \times (12/8) \times (0.1/0.17) \times 0.95 \times \sin 30 = 0.084 \text{ mm.}$$

*End milling:*  $ECT_E = ECT_{0E} \times (z/2) \times (f_z/0.17) \times (aa/CEL)$ ,

or if  $ECT_E$  is known calculate  $f_z$  from:

$$f_z = 0.17 \times (ECT_E/ECT_{0E}) \times (2/z) \times (CEL/aa)$$

The approximate values of  $aa/CEL = 0.95$  for lead angle  $LA = 0^\circ$  ( $90^\circ$  in the metric system).

*Example, High-Speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 3.125$  mm, calculate  $ECT_E$  for  $f_z = 0.1$  and  $z = 6$ . First calculate  $ar/D = 0.125$ , and then use Table 2b and find  $ECT_{0E} = 0.0249$ .

Calculate  $ECT_E$  with above formula:

$$ECT_E = 0.0249 \times (6/2) \times (0.1/0.17) \times 0.95 \times 1 = 0.042 \text{ mm.}$$

*Example, High-Speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 0.75$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 0.03$ , and then use Table 2b and find  $f_z/f_{z0} = 3.694$

Then,  $f_z = 3.694 \times 0.17 = 0.58$  mm/tooth and  $ECT_E = 0.0119 \times 0.95 = 0.0113$  mm and  $0.0357 \times 0.95 = 0.0339$  mm for 2 and 6 teeth respectively. These cutters are marked HS2 and HS6 in Fig. 26a, Fig. 26d, and Fig. 26e.

*Example, High-Speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 0.25$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 0.01$ , and then use Table 2b and find  $ECT_{0E} = 0.0069$  and  $0.0207$  for 2 and 6 teeth respectively. When obtaining such small values of  $ECT$ , there is a great danger to be far on the left side of the  $H$ -curve, at least when there are only 2 teeth. Doubling the feed would be the solution if cutter design and material permit.

*Example, Full Slot Milling:* For a cutter with  $D = 25$  mm and  $ar = 25$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 1$ , and then use Table 2b and find  $ECT_E = 0.108 \times 0.95 = 0.103$  and  $3 \times 0.108 \times 0.95 = 0.308$  for 2 and 6 teeth, respectively. These cutters are marked SL2 and SL6 in Fig. 26a, Fig. 26d, and Fig. 26e.

**Physics Behind  $hm$  and  $ECT$ , Forces and Tool Life ( $T$ ).**—The  $ECT$  concept for all metal cutting and grinding operations says that the more energy put into the process, by increasing feed/rev, feed/tooth, or cutting speed, the life of the edge decreases. When increasing the number of teeth (keeping everything else constant) the work and the process are subjected to a higher energy input resulting in a higher rate of tool wear.

In high-speed milling when the angle of engagement  $AE$  is small the contact time is shorter compared to slot milling ( $ar/D = 1$ ) but the chip becomes shorter as well. Maintaining the same chip thickness as in slot milling has the effect that the energy consumption to remove the chip will be different. Hence, maintaining a constant chip thickness is a good measure when calculating cutting forces (keeping speed constant), but not when determining tool wear. Depending on cutting conditions the wear rate can either increase or decrease, this depends on whether cutting occurs on the left or right side of the  $H$ -curve.

Fig. 26a shows an example of end milling of steel with coated carbide inserts, where cutting speed  $V$  is plotted versus  $ECT$  at 5, 15, 45 and 180 minutes tool-lives. Notice that the  $ECT$  values are independent of  $ar/D$  or number of teeth or feed/tooth, or whether  $f_z$  or  $f_{z0}$  is used, as long as the corresponding  $f_z/f_{z0}$ -ratio is applied to determine  $ECT_E$ . The result is one single curve per tool life. Had cutting speed been plotted versus  $f_{z0}$ ,  $ar/D$ , or  $z$  values (number of teeth), several curves would be required at each constant tool life, one for each of these parameters. This illustrates the advantage of using the basic parameter  $ECT$  rather than  $f_z$ , or  $hm$ , or  $ar/D$  on the horizontal axis.

Fig. 26a. Cutting Speed versus  $ECT$ , Tool Life Plotted, for End Milling

**Example:** The points (HS2, HS6) and (SL2, SL6) on the 45-minute curve in Fig. 26a relate to the previous high-speed and full slot milling examples for 2 and 6 teeth, respectively.

Running a slot at  $f_{z0} = 0.17$  mm/tooth ( $hm = 0.108$ ,  $ECT_E = 0.103$  mm) with 2 teeth and for a tool life 45 minutes, the cutting speed should be selected at  $V = 340$  m/min at point SL2 and for six teeth ( $hm = 0.108$  mm,  $ECT_E = 0.308$ ) at  $V = 240$  m/min at point SL6.

When high-speed milling for  $ar/D = 0.03$  at  $f_z = 3.394 \times 0.17 = 0.58$  mm/tooth = 0.58 mm/tooth,  $ECT$  is reduced to 0.011 mm ( $hm = 0.108$ ) the cutting speed is 290 m/min to maintain  $T = 45$  minutes, point HS2. This point is far to the left of the  $H$ -curve in Fig. 26b, but if the number of teeth is increased to 6 ( $ECT_E = 3 \times 0.103 = 0.3090$ ), the cutting speed is 360 m/min at  $T = 45$  minutes and is close to the  $H$ -curve, point HS6. Slotting data using 6 teeth are on the right of this curve at point SL6, approaching the  $G$ -curve, but at a lower slotting speed of 240 m/min.

Depending on the starting  $f_z$  value, and on the combination of cutter grade and work material, the location of the  $H$ -curve plays an important role when selecting high-speed end milling data.

**Feed Rate and Tool Life in High-Speed Milling, Effect of ECT and Number of Teeth.—** Calculation of feed rate is done using the formulas previously given:

Feed Rate:

$$F_R = z \times f_z \times \text{rpm}, \text{ where } z \times f_z = f \text{ (feed/rev of cutter). Feed is measured along the feeding direction.}$$

$$\text{rpm} = 1000 \times \sqrt[3]{0.1416/D}, \text{ where } D \text{ is diameter of cutter.}$$

Fig. 26b. High-Speed Feed Rate and Cutting Speed versus  $ar/D$  at  $T = 5, 15, 45,$  and  $180$  Minutes

Fig. 26c. High-Speed Feed Rate and Cutting Speed versus  $ECT$ ,  $ar/D$  Plotted at  $T = 5, 15, 45,$  and  $180$  Minutes

Fig. 26b shows the variation of feed rate  $F_R$  plotted versus  $ar/D$  for tool-lives 5, 15, 45 and 180 minutes with a 25 mm diameter cutter and 2 teeth. Fig. 26c shows the variation of feed rate  $F_R$  when plotted versus  $ECT$ . In both graphs the corresponding cutting speeds are also plotted. The values for  $ar/D = 0.03$  in Fig. 26b correspond to  $ECT = 0.011$  in Fig. 26c.

Feed rates have a minimum around values of  $ar/D = 0.8$  and  $ECT = 0.75$  and not along the  $H$ -curve. This is due to the fact that the  $f_z/f_{z0}$  ratio to maintain a mean chip thickness = 0.108 mm changes  $F_R$  in a different proportion than the cutting speed.

Fig. 26d. Feed Rate versus  $ECT$  Comparison of Slot Milling ( $ar/D = 1$ ) and High-Speed Milling at ( $ar/D = 0.03$ ) for 2, 4, and 6 Teeth at  $T = 45$  Minutes

A comparison of feed rates for full slot ( $ar/D = 1$ ) and high-speed end milling ( $ar/D = 0.03$  and  $f_z = 3.69 \times f_{z0} = 0.628$  mm) for tool life 45 minutes is shown in Fig. 26d. The points SL2, SL4, SL6 and HS2, HS4, HS6, refer to 2, 4, and 6 teeth (2 to 6 teeth are commonly used in practice). Feed rate is also plotted versus number of teeth  $z$  in Fig. 26e, for up to 16 teeth, still at  $f_z = 0.628$  mm.

Comparing the effect of using 2 versus 6 teeth in high-speed milling shows that feed rates increase from 5250 mm/min (413 ipm) up to 18,000 mm/min (1417 ipm) at 45 minutes tool life. The effect of using 2 versus 6 teeth in full slot milling is that feed rate increases from 1480 mm/min (58 ipm) up to 3230 mm/min (127 ipm) at tool life 45 minutes. If 16 teeth could be used at  $ar/D = 0.03$ , the feed rate increases to  $F_R = 44,700$  mm/min (1760 ipm), and for full slot milling  $F_R = 5350$  mm/min (210 ipm).

Fig. 26e. Feed Rate versus Number of Teeth Comparison of Slot Milling ( $ar/D = 1$ ) and High-Speed Milling ( $ar/D = 0.03$ ) for 2, 4, and 6 Teeth at  $T = 45$  Minutes

Comparing the feed rates that can be obtained in steel cutting with the one achieved in the earlier referred DARPA investigation, using HSS and carbide cutters milling 6061-T651 and A356-T6 aluminum, it is obvious that aluminum end milling can be run at 3 to 6 times higher feed rates. This requires 3 to 6 times higher spindle speeds (cutter diameter 25 mm, radial depth of cut  $ar = 12.5$  mm, 2 teeth). Had these tests been run with 6 teeth, the feed rates would increase up to 150,000–300,000 mm/min, when feed/tooth =  $3.4 \times 0.25 = 0.8$  mm/tooth at  $ar/D = 0.03$ .

**Process Econometrics Comparison of High-Speed and Slot End Milling.**—When making a process econometrics comparison of high-speed milling and slot end milling use the formulas for total cost  $c_{tot}$  (*Determination of Machine Settings and Calculation of Costs* starting on page 1216). Total cost is the sum of the cost of cutting, tool changing, and tooling:

$$c_{tot} = H_R \times (Dist/F_R) \times (1 + T_V/T)60$$

where  $T_V = T_{RPL} + 60 \times C_E/H_R$  = equivalent tooling-cost time, minutes

$T_{RPL}$  = replacement time for a set of edges or tool for regrinding

$C_E$  = cost per edge(s)

$H_R$  = hourly rate, \$

Fig. 27 compares total cost  $c_{tot}$ , using the end milling cutters of the previous examples, for full slot milling with high-speed milling at  $ar/D = 0.03$ , and versus ECT at  $T = 45$  minutes.

Fig. 27. Cost Comparison of Slot Milling ( $ar/D = 1$ ) and High-Speed Milling at ( $ar/D = 0.03$ ) for 2, 4, and 6 Teeth at  $T = 45$  Minutes

The feed/tooth for slot milling is  $f_{z0} = 0.17$  and for high-speed milling at  $ar/D = 0.03$  the feed is  $f_z = 3.69 \times f_{z0} = 0.628$  mm.

The calculations for total cost are done according to above formula using tooling cost at  $T_V = 6, 10, \text{ and } 14$  minutes, for  $z = 2, 4, \text{ and } 6$  teeth respectively. The distance cut is  $Dist = 1000$  mm. Full slot milling costs are,

at feed rate  $F_R = 3230$  and  $z = 6$

$$c_{tot} = 50 \times (1000/3230) \times (1 + 14/45) \times 60 = \$0.338 \text{ per part}$$

at feed rate  $F_R = 1480$  and  $z = 2$

$$c_{tot} = 50 \times (1000/1480) \times (1 + 6/45) \times 60 = \$0.638 \text{ per part}$$

High-speed milling costs are,

at  $F_R = 18000, z = 6$

$$c_{tot} = 50 \times (1000/18000) \times (1 + 14/45) \times 60 = \$0.0606 \text{ per part}$$

at  $F_R = 5250, z = 2$

$$c_{tot} = 50 \times (1000/5250) \times (1 + 6/45) \times 60 = \$0.180 \text{ per part}$$

The cost reduction using high-speed milling compared to slotting is enormous. The cost for high-speed milling with 2 teeth is 61 percent ( $0.208/0.338$ ) of full slot milling with 6 teeth ( $z = 6$ ). The cost for high-speed milling with 6 teeth is 19 percent ( $0.0638/0.338$ ) of full slot for  $z = 6$ .

Aluminum end milling can be run at 3 to 6 times lower costs than when cutting steel. Costs of idle (non-machining) and slack time (waste) are not considered in the example. These data hold for perfect milling conditions such as zero run-out and accurate sharpening of all teeth and edges.

## SCREW MACHINES, BAND SAWS, CUTTING FLUIDS

## Automatic Screw Machine Tool Operations

**Speeds and Feeds for Automatic Screw Machine Tools.**—Approximate speeds and feeds for standard screw machine tools are given in [Table 1](#) on page 1235.

**Knurling in Automatic Screw Machines.**—When knurling is done from the cross slide, it is good practice to feed the knurl gradually to the center of the work, starting to feed when the knurl touches the work and then passing off the center of the work with a quick rise of the cam. The knurl should also dwell for a certain number of revolutions, depending on the pitch of the knurl and the kind of material being knurled. See also *KNURLS AND KNURLING* starting on page 1056.

When two knurls are employed for spiral and diamond knurling from the turret, the knurls can be operated at a higher rate of feed for producing a spiral than they can for producing a diamond pattern. The reason for this is that in the first case the knurls work in the same groove, whereas in the latter case they work independently of each other.

**Revolutions Required for Top Knurling.**—The depth of the teeth and the feed per revolution govern the number of revolutions required for top knurling from the cross slide. If  $R$  is the radius of the stock,  $d$  is the depth of the teeth,  $c$  is the distance the knurl travels from the point of contact to the center of the work at the feed required for knurling, and  $r$  is the radius of the knurl. Inch or metric units may be used in the following equation.

$$c = \sqrt{(R+r)^2 - (R+r-d)^2}$$

*Example:* If the stock radius  $R$  is  $\frac{5}{32}$  inch (or mm), depth of teeth  $d$  is 0.0156 inch (or mm), and radius of knurl  $r$  is 0.3125 inch (or mm), then

$$\begin{aligned} c &= \sqrt{(0.1562 + 0.3125)^2 - (0.1562 + 0.3125 - 0.0156)^2} \\ &= 0.120 \text{ inch (or mm) = cam rise required} \end{aligned}$$

*Example:* Assume that it is required to find the number of revolutions to knurl a piece of brass  $\frac{5}{16}$  inch in diameter using a 32 pitch knurl. The included angle of the teeth for brass is 90 degrees, the circular pitch is 0.03125 inch, and the calculated tooth depth is 0.0156 inch. The distance  $c$  (as determined in the previous example) is 0.120 inch. Referring to [Table 1](#) on page 1235, the feed for top knurling brass is 0.005 inch per revolution. The number of revolutions required for knurling is, therefore,  $0.120 \div 0.005 = 24$  revolutions. If conditions permit, the higher feed of 0.008 inch per revolution given in the table may be used, and 15 revolutions are then required for knurling.

**Cams for Threading.**—[Table 2](#) on page 1237 gives the revolutions required for threading various lengths and pitches and the corresponding rise for the cam lobe. To illustrate the use of this table, suppose a set of cams is required for threading a screw to the length of  $\frac{3}{8}$  inch in a Brown & Sharpe machine. Assume that the spindle speed is 2400 revolutions per minute; the number of revolutions to complete one piece, 400; time required to make one piece, 10 seconds; pitch of the thread,  $\frac{1}{32}$  inch or 32 threads per inch. By referring to [Table 2](#), under 32 threads per inch, and opposite  $\frac{3}{8}$  inch (length of threaded part), the number of revolutions required is found to be 15 and the rise required for the cam, 0.413 inch.

Threading cams are often cut on a circular milling attachment. When this method is employed, the number of minutes the attachment should be revolved for each 0.001 inch rise, is first determined. As 15 spindle revolutions are required for threading and 400 for completing one piece, that part of the cam surface required for the actual threading operation equals  $15 \div 400 = 0.0375$ , which is equivalent to 810 minutes of the circumference. The total rise, through an arc of 810 minutes is 0.413 inch, so the number of minutes for each 0.001 inch rise equals  $810 \div 413 = 1.96$  or, approximately, two minutes. If the attachment is graduated to read to five minutes, the cam will be fed laterally 0.0025 inch each time it is turned through five minutes of arc.

**Practical Points on Cam and Tool Design.**—The following general rules are given to aid in designing cams and special tools for automatic screw machines, and apply particularly to Brown and Sharpe machines:

- 1) Use the highest speeds recommended for the material used that the various tools will stand.
- 2) Use the arrangement of circular tools best suited for the class of work.
- 3) Decide on the quickest and best method of arranging the operations before designing the cams.
- 4) Do not use turret tools for forming when the cross-slide tools can be used to better advantage.
- 5) Make the shoulder on the circular cutoff tool large enough so that the clamping screw will grip firmly.
- 6) Do not use too narrow a cutoff blade.
- 7) Allow 0.005 to 0.010 inch (0.127–0.254 mm) for the circular tools to approach the work and 0.003 to 0.005 inch (0.076–0.127 mm) for the cutoff tool to pass the center.
- 8) When cutting off work, the feed of the cutoff tool should be decreased near the end of the cut where the piece breaks off.
- 9) When a thread is cut up to a shoulder, the piece should be grooved or necked to make allowance for the lead on the die. An extra projection on the forming tool and an extra amount of rise on the cam will be needed.
- 10) Allow sufficient clearance for tools to pass one another.
- 11) Always make a diagram of the cross-slide tools in position on the work when difficult operations are to be performed; do the same for the tools held in the turret.
- 12) Do not drill a hole the depth of which is more than 3 times the diameter of the drill, but rather use two or more drills as required. If there are not enough turret positions for the extra drills needed, make provision for withdrawing the drill clear of the hole and then advancing it into the hole again.
- 13) Do not run drills at low speeds. Feeds and speeds recommended in [Table 1](#) on page [1235](#) should be followed as far as is practicable.
- 14) When the turret tools operate farther in than the face of the chuck, see that they will clear the chuck when the turret is revolved.
- 15) See that the bodies of all turret tools will clear the side of the chute when the turret is revolved.
- 16) Use a balance turning tool or a hollow mill for roughing cuts.
- 17) The rise on the thread lobe should be reduced so that the spindle will reverse when the tap or die holder is drawn out.
- 18) When bringing another tool into position after a threading operation, allow clearance before revolving the turret.
- 19) Make provision to revolve the turret rapidly, especially when pieces are being made in from three to five seconds and when only a few tools are used in the turret. It is sometimes desirable to use two sets of tools.

20) When using a belt-shifting attachment for threading, clearance should be allowed, as it requires extra time to shift the belt.

21) When laying out a set of cams for operating on a piece that requires to be slotted, cross-drilled or burred, allowance should be made on the lead cam so that the transferring arm can descend and ascend to and from the work without coming in contact with any of the turret tools.

22) Always provide a vacant hole in the turret when it is necessary to use the transferring arm.

23) When designing special tools allow as much clearance as possible. Do not make them so that they will just clear each other, as a slight inaccuracy in the dimensions will often cause trouble.

24) When designing special tools having intricate movements, avoid springs as much as possible, and use positive actions.

**Stock for Screw Machine Products.**—The amount of stock required for the production of 1000 pieces on the automatic screw machine can be obtained directly from Table 3 on page 1240. To use this table, add to the length of the work the width of the cut-off tool blade; then the number of feet of material required for 1000 pieces can be found opposite the figure thus obtained, in the column headed "Feet per 1000 Parts." Screw machine stock usually comes in bars 10 feet (3.048 m) long, and in compiling this table an allowance was made for chucking on each bar.

The table can be extended by using the following formula, in which

$F$  = number of feet required for 1000 pieces

$L$  = length of piece in inches

$W$  = width of cut-off tool blade in inches

$$F = (L + W) \times 84$$

The amount to add to the length of the work, or the width of the cut-off tool, is given in the following, which is standard in a number of machine shops:

Diameter of Stock		Width of Cut-off Tool Blade	
in	mm	in	mm
0.000–0.250	0.000–6.35	0.045	1.44
0.251–0.375	6.38–9.53	0.062	1.57
0.376–0.625	9.55–15.88	0.093	2.36
0.626–1.000	15.90–25.40	0.125	3.18
1.001–1.500	25.43–38.10	0.156	3.96

It is sometimes convenient to know the weight of a certain number of pieces, when estimating the price. The weight of round bar stock can be found by means of the following formulas, in which

$W$  = weight in pounds

$D$  = diameter of stock in inches

$F$  = length in feet

For brass stock:  $W = D^2 \times 2.86 \times F$

For steel stock:  $W = D^2 \times 2.675 \times F$

For iron stock:  $W = D^2 \times 2.65 \times F$

**Table 3. Stock Required for Screw Machine Products**

The table gives the amount of stock, in feet, required for 1000 pieces, when the length of the finished part plus the thickness of the cut-off tool blade is known. Allowance has been made for chucking. To illustrate, if length of cut-off tool and work equals 0.140 inch, 11.8 feet of stock is required for the production of 1000 parts.

Length of Piece and Cut-Off Tool	Feet per 1000 Parts	Length of Piece and Cut-Off Tool	Feet per 1000 Parts	Length of Piece and Cut-Off Tool	Feet per 1000 Parts	Length of Piece and Cut-Off Tool	Feet per 1000 Parts

### Band Saw Blade Selection

The primary factors to consider in choosing a saw blade are: the pitch, or the number of teeth per inch of blade; the tooth form; and the blade type (material and construction). Tooth pitch selection depends on the size and shape of the work, whereas tooth form and blade type depend on material properties of the workpiece and on economic considerations of the job.

*Courtesy of American Saw and Manufacturing Company*

The tooth selection chart above is a guide to help determine the best blade pitch for a particular job. The tooth specifications in the chart are standard variable-pitch blade sizes as specified by the Hack and Band Saw Association. The variable-pitch blades listed are designated by two numbers that refer to the approximate maximum and minimum tooth pitch. A 4/6 blade, for example, has a maximum tooth spacing of approximately  $\frac{1}{4}$  inch (6.4 mm) and a minimum tooth spacing of about  $\frac{1}{6}$  inch (4.2 mm). Blades are available, from most manufacturers, in sizes within about  $\pm 10$  percent of the sizes listed.

To use the chart, locate the length of cut in inches on the outside circle of the table (for millimeters use the inside circle) and then find the tooth specification that aligns with the length, on the ring corresponding to the material shape. The length of cut is the distance that any tooth of the blade is in contact with the work as it passes once through the cut. For cutting solid round stock, use the diameter as the length of cut and select a blade from the ring with the solid circle. When cutting angles, channels, I-beams, tubular pieces, pipe, and hollow or irregular shapes, the length of cut is found by dividing the cross-sectional area of the cut by the distance the blade needs to travel to finish the cut. Locate the length of cut on the outer ring (inner ring for mm) and select a blade from the ring marked with the angle, I-beam, and pipe sections.

*Example:* A 4-inch pipe with a 3-inch inside diameter is to be cut. Select a variable pitch blade for cutting this material.

The area of the pipe is  $\pi/4 \times (4^2 - 3^2) = 5.5 \text{ in}^2$ . The blade has to travel 4 inches to cut through the pipe, so the average length of cut is  $5.5/4 = 1.4$  inches. On the tooth selection wheel, estimate the location of 1.4 inches on the outer ring, and read the tooth specification from the ring marked with the pipe, angle, and I-beam symbols. The chart indicates that a 4/6 variable-pitch blade is the preferred blade for this cut.

**Tooth Forms.**—Band saw teeth are characterized by a tooth form that includes the shape, spacing (pitch), rake angle, and gullet capacity of the tooth. Tooth form affects the cutting efficiency, noise level, blade life, chip-carrying capacity, and the surface finish quality of the cut. The rake angle, which is the angle between the face of the tooth and a line perpendicular to the direction of blade travel, influences the cutting speed. In general, positive rake angles cut faster. The *standard tooth* form has conventional shape teeth, evenly spaced with deep gullets and a  $0^\circ$  rake angle. Standard tooth blades are used for general-purpose cutting on a wide variety of materials. The *skip tooth* form has shallow, widely spaced teeth arranged in narrow bands and a  $0^\circ$  rake angle. Skip tooth blades are used for cutting soft metals, wood, plastics, and composite materials. The *hook tooth* form is similar to the skip tooth, but has a positive rake angle and is used for faster cutting of large sections of soft metal, wood, and plastics, as well as for cutting some metals, such as cast iron, that form a discontinuous chip. The *variable-tooth* (variable-pitch) form has a conventional tooth shape, but the tips of the teeth are spaced a variable distance (pitch) apart. The variable pitch reduces vibration of the blade and gives smoother cutting, better surface finish, and longer blade life. The *variable positive tooth* form is a variable-pitch tooth with a positive rake angle that causes the blade to penetrate the work faster. The variable positive tooth blade increases production and gives the longest blade life.

*Set* is the angle that the teeth are offset from the straight line of a blade. The set affects the blade efficiency (i.e., cutting rate), chip-carrying ability, and quality of the surface finish. *Alternate set* blades have adjacent teeth set alternately one to each side. Alternate set blades, which cut faster but with a poorer finish than other blades, are especially useful for rapid rough cutting. A *raker set* is similar to the alternate set, but every few teeth, one of the teeth is set to the center, not to the side (typically every third tooth, but sometimes every fifth or seventh tooth). The raker set pattern cuts rapidly and produces a good surface finish. The *vari-raker set*, or variable raker, is a variable-tooth blade with a raker set. The vari-raker is quieter and produces a better surface finish than a raker set standard tooth blade. *Wavy set* teeth are set in groups, alternately to one side, then to the other. Both wavy set and vari-raker set blades are used for cutting tubing and other interrupted cuts, but the blade efficiency and surface finish produced are better with a vari-raker set blade.

**Types of Blades.**—The most important band saw blade types are carbon steel, bimetal, carbide tooth, and grit blades made with embedded carbide or diamond. *Carbon steel blades* have the lowest initial cost, but they may wear out faster. Carbon steel blades are used for cutting a wide variety of materials, including mild steels, aluminum, brass, bronze, cast iron, copper, lead, and zinc, as well as some abrasive materials such as cork, fiberglass, graphite, and plastics. *Bimetal blades* are made with a high-speed steel cutting edge that is welded to a spring steel blade back. Bimetal blades are stronger and last longer, and they tend to produce straighter cuts because the blade can be tensioned higher than carbon steel blades. Because bimetal blades last longer, the cost per cut is frequently lower than when using carbon steel blades. Bimetal blades are used for cutting all ferrous and nonferrous metals, a wide range of shapes of easy to moderately machinable material, and solids and heavy wall tubing with moderate to difficult machinability. *Tungsten carbide blades* are similar to bimetal blades but have tungsten carbide teeth welded to the blade back. The welded teeth of carbide blades have greater wear and high-temperature resistance than either carbon steel or bimetal blades and produce less tooth vibration, while giving smoother, straighter, faster, and quieter cuts requiring less feed force. Carbide blades are used on tough alloys such as cobalt, nickel- and titanium-based alloys, and for

nonferrous materials such as aluminum castings, fiberglass, and graphite. The *carbide grit blade* has tungsten carbide grit metallurgically bonded to either a gulletted (serrated) or toothless steel band. The blades are made in several styles and grit sizes. Both carbide grit and diamond grit blades are used to cut materials that conventional (carbon and bimetal) blades are unable to cut such as: fiberglass, reinforced plastics, composite materials, carbon and graphite, aramid fibers, plastics, cast iron, stellites, high-hardness tool steels, and superalloys.

**Band Saw Speed and Feed Rate.**—The band speed necessary to cut a particular material is measured in feet per minute (fpm) or in meters per minute (m/min), and depends on material characteristics and size of the workpiece. Typical speeds for a bimetal blade cutting 4-inch material with coolant are given in the speed selection table that follows. For other size materials or when cutting without coolant, adjust speeds according to the instructions at the bottom of the table.

**Cutting Rates for Band Saws**

The feed or cutting rate, usually measured in square inches or square meters per minute, indicates how fast material is being removed and depends on the speed and pitch of the blade, not on the workpiece material. The graph above, based on material provided by American Saw and Mfg., gives approximate cutting rates (in<sup>2</sup>/min) for various variable-pitch blades and cutting speeds. Use the value from the graph as an initial starting value and then adjust the feed based on the performance of the saw. The size and character of the chips being produced are the best indicators of the correct feed force. Chips that are curly, silvery, and warm indicate the best feed rate and band speed. If the chips appear burned and heavy, the feed is too great, so reduce the feed rate, the band speed, or both. If the chips are thin or powdery, the feed rate is too low, so increase the feed rate or reduce the band speed. The actual cutting rate achieved during a cut is equal to the area of the cut divided by the time required to finish the cut. The time required to make a cut is equal to the area of the cut divided by the cutting rate in square inches per minute.

The speed figures given are for 4-in. material (length of cut) using a 3/4 variable-tooth bimetal blade and cutting fluid. For cutting dry, reduce speed 30–50%; for carbon steel band saw blades, reduce speed 50%. For other cutting lengths: increase speed 15% for 1/4-in. material (10/14 blade); increase speed 12% for 3/4-in. material (6/10 blade); increase speed 10% for 1 1/4-in. material (4/6 blade); decrease speed 12% for 8-in. material (2/3 blade).

Data are based on material provided by LENOX Blades, American Saw & Manufacturing Co.

**Example:** Find the band speed, the cutting rate, and the cutting time if the 4-inch pipe of the previous example is made of 304 stainless steel.

The preceding blade speed table gives the band speed for 4-inch 304 stainless steel as 120 fpm (feet per minute). The average length of cut for this pipe (see the previous example) is 1.4 inches, so increase the band saw speed by about 10 percent (see table footnote on page 1245) to 130 fpm to account for the size of the piece. On the cutting rate graph above, locate the point on the 4/6 blade line that corresponds to the band speed of 130 fpm and then read the cutting rate from the left axis of the graph. The cutting rate for this example is approximately 4 in<sup>2</sup>/min. The cutting time is equal to the area of the cut divided by the cutting rate, so cutting time = 5.5/4 = 1.375 minutes.

**Band Saw Blade Break-In.**—A new band saw blade must be broken in gradually before it is allowed to operate at its full recommended feed rate. Break-in relieves the blade of residual stresses caused by the manufacturing process so that the blade retains its cutting ability longer. Break-in requires starting the cut at the material cutting speed with a low feed rate and then gradually increasing the feed rate over time until enough material has been cut. A blade should be broken in with the material to be cut.

To break in a new blade, first set the band saw speed at the recommended cutting speed for the material and start the first cut at the feed indicated on the starting feed rate graph below. After the saw has penetrated the work to a distance equal to the width of the blade, increase the feed slowly. When the blade is about halfway through the cut, increase the feed again slightly and finish the cut without increasing the feed again. Start the next and each successive cut with the same feed rate that ended the previous cut, and increase the feed rate slightly again before the blade reaches the center of the cut. Repeat this procedure until the area cut by the new blade is equal to the total area required as indicated on the graph below. At the end of the break-in period, the blade should be cutting at the recommended feed rate, otherwise adjusted to that rate.

Starting Feed Rate

### Cutting Fluids for Machining

The goal in all conventional metal-removal operations is to raise productivity and reduce costs by machining at the highest practical speed consistent with long tool life, fewest rejects, and minimum downtime, and with the production of surfaces of satisfactory accuracy and finish. Many machining operations can be performed "dry," but the proper application of a cutting fluid generally makes possible: higher cutting speeds, higher feed rates, greater depths of cut, lengthened tool life, decreased surface roughness, increased dimensional accuracy, and reduced power consumption. Selecting the proper cutting fluid for a specific machining situation requires knowledge of fluid functions, properties, and limitations. Cutting fluid selection deserves as much attention as the choice of machine tool, tooling, speeds, and feeds.

To understand the action of a cutting fluid it is important to realize that almost all the energy expended in cutting metal is transformed into heat, primarily by the deformation of the metal into the chip and, to a lesser degree, by the friction of the chip sliding against the tool face. With these factors in mind it becomes clear that the primary functions of any

cutting fluid are: cooling of the tool, workpiece, and chip; reducing friction at the sliding contacts; and reducing or preventing welding or adhesion at the contact surfaces, which forms the "built-up edge" on the tool. Two other functions of cutting fluids are flushing away chips from the cutting zone and protecting the workpiece and tool from corrosion.

The relative importance of the functions is dependent on the material being machined, the cutting tool and conditions, and the finish and accuracy required on the part. For example, cutting fluids with greater lubricity are generally used in low-speed machining and on most difficult-to-cut materials. Cutting fluids with greater cooling ability are generally used in high-speed machining on easier-to-cut materials.

**Types of Cutting and Grinding Fluids.**—In recent years a wide range of cutting fluids has been developed to satisfy the requirements of new materials of construction and new tool materials and coatings.

There are four basic types of cutting fluids; each has distinctive features, as well as advantages and limitations. Selection of the right fluid is made more complex because the dividing line between types is not always clear. Most machine shops try to use as few different fluids as possible and prefer fluids that have long life, do not require constant changing or modifying, have reasonably pleasant odors, do not smoke or fog in use, and, most important, are neither toxic nor cause irritation to the skin. Other issues in selection are the cost and ease of disposal. The major divisions and subdivisions used in classifying cutting fluids are:

*Cutting Oils*, including straight and compounded mineral oils plus additives.

*Water-Miscible Fluids*, including emulsifiable oils; chemical or synthetic fluids; and semichemical fluids.

*Gases*.

*Paste and Solid Lubricants*.

Since cutting oils and water-miscible types are the most commonly used cutting fluids in machine shops, discussion will be limited primarily to these types. It should be noted, however, that compressed air and inert gases, such as carbon dioxide, nitrogen, and Freon, are sometimes used in machining. Paste, waxes, soaps, graphite, and molybdenum disulfide may also be used, either applied directly to the workpiece or as an impregnant in the tool, such as in a grinding wheel.

**Cutting Oils.**—Cutting oils are generally compounds of mineral oil with the addition of animal, vegetable, or marine oils to improve the wetting and lubricating properties. Sulfur, chlorine, and phosphorous compounds, sometimes called extreme pressure (EP) additives, provide for even greater lubricity. In general, these cutting oils do not cool as well as water-miscible fluids.

**Water-Miscible Fluids.**—*Emulsions or soluble oils* are a suspension of oil droplets in water. These suspensions are made by blending the oil with emulsifying agents (soap and soaplike materials) and other materials. These fluids combine the lubricating and rust-prevention properties of oil with water's excellent cooling properties. Their properties are affected by the emulsion concentration, with "lean" concentrations providing better cooling but poorer lubrication, and with "rich" concentrations having the opposite effect. Additions of sulfur, chlorine, and phosphorus, as with cutting oils, yield "extreme pressure" (EP) grades.

*Chemical fluids* are true solutions composed of organic and inorganic materials dissolved in water. Inactive types are usually clear fluids combining high rust inhibition, high cooling, and low lubricity characteristics with high surface tension. Surface-active types include wetting agents and possess moderate rust inhibition, high cooling, and moderate lubricating properties with low surface tension. They may also contain chlorine and/or sulfur compounds for extreme pressure properties.

*Semichemical fluids* are combinations of chemical fluids and emulsions. These fluids have a lower oil content but a higher emulsifier and surface-active-agent content than

emulsions, producing oil droplets of much smaller diameter. They possess low surface tension, moderate lubricity and cooling properties, and very good rust inhibition. Sulfur, chlorine, and phosphorus also are sometimes added.

**Selection of Cutting Fluids for Different Materials and Operations.**—The choice of a cutting fluid depends on many complex interactions including the machinability of the metal; the severity of the operation; the cutting tool material; metallurgical, chemical, and human compatibility; fluid properties, reliability, and stability; and finally cost. Other factors affect results. Some shops standardize on a few cutting fluids which have to serve all purposes. In other shops, one cutting fluid must be used for all the operations performed on a machine. Sometimes, a very severe operating condition may be alleviated by applying the “right” cutting fluid manually while the machine supplies the cutting fluid for other operations through its coolant system. Several voluminous textbooks are available with specific recommendations for the use of particular cutting fluids for almost every combination of machining operation and workpiece and tool material. In general, when experience is lacking, it is wise to consult the material supplier and/or any of the many suppliers of different cutting fluids for advice and recommendations. Another excellent source is the Machinability Data Center, one of the many information centers supported by the US Department of Defense. While the following recommendations represent good practice, they are to serve as a guide only, and it is not intended to say that other cutting fluids will not, in certain specific cases, also be effective.

**Steels:** Caution should be used when using a cutting fluid on steel that is being turned at a high cutting speed with cemented carbide cutting tools. See *Application of Cutting Fluids to Carbides* later. Frequently this operation is performed dry. If a cutting fluid is used, it should be a soluble oil mixed to a consistency of about 1 part oil to 20 to 30 parts water. A sulfurized mineral oil is recommended for reaming with carbide tipped reamers although a heavy-duty soluble oil has also been used successfully.

The cutting fluid recommended for machining steel with high speed cutting tools depends largely on the severity of the operation. For ordinary turning, boring, drilling, and milling on medium and low strength steels, use a soluble oil having a consistency of 1 part oil to 10 to 20 parts water. For tool steels and tough alloy steels, a heavy-duty soluble oil having a consistency of 1 part oil to 10 parts water is recommended for turning and milling. For drilling and reaming these materials, a light sulfurized mineral-fatty oil is used. For tough operations such as tapping, threading, and broaching, a sulfochlorinated mineral-fatty oil is recommended for tool steels and high-strength steels, and a heavy sulfurized mineral-fatty oil or a sulfochlorinated mineral oil can be used for medium- and low-strength steels. Straight sulfurized mineral oils are often recommended for machining tough, stringy low carbon steels to reduce tearing and produce smooth surface finishes.

**Stainless Steel:** For ordinary turning and milling a heavy-duty soluble oil mixed to a consistency of 1 part oil to 5 parts water is recommended. Broaching, threading, drilling, and reaming produce best results using a sulfochlorinated mineral-fatty oil.

**Copper Alloys:** Most brasses, bronzes, and copper are stained when exposed to cutting oils containing active sulfur and chlorine; thus, sulfurized and sulfochlorinated oils should not be used. For most operations a straight soluble oil, mixed to 1 part oil and 20 to 25 parts water is satisfactory. For very severe operations and for automatic screw machine work a mineral-fatty oil is used. A typical mineral-fatty oil might contain 5 to 10 percent lard oil with the remainder mineral oil.

**Monel Metal:** When turning this material, an emulsion gives a slightly longer tool life than a sulfurized mineral oil, but the latter aids in chip breakage, which is frequently desirable.

**Aluminum Alloys:** Aluminum and aluminum alloys are frequently machined dry. When a cutting fluid is used it should be selected for its ability to act as a coolant. Soluble oils mixed to a consistency of 1 part oil to 20 to 30 parts water can be used. Mineral oil-base

cutting fluids, when used to machine aluminum alloys, are frequently cut back to increase their viscosity so as to obtain good cooling characteristics and to make them flow easily to cover the tool and the work. For example, a mineral-fatty oil or a mineral plus a sulfurized fatty oil can be cut back by the addition of as much as 50 percent kerosene.

**Cast Iron:** Ordinarily, cast iron is machined dry. Some increase in tool life can be obtained or a faster cutting speed can be used with a chemical cutting fluid or a soluble oil mixed to consistency of 1 part oil and 20 to 40 parts water. A soluble oil is sometimes used to reduce the amount of dust around the machine.

**Magnesium:** Magnesium may be machined dry, or with an air blast for cooling. A light mineral oil of low acid content may be used on difficult cuts. Coolants containing water should not be used on magnesium because of the danger of releasing hydrogen caused by reaction of the chips with water. Proprietary water-soluble oil emulsions containing inhibitors that reduce the rate of hydrogen generation are available.

**Grinding:** Soluble oil emulsions or emulsions made from paste compounds are used extensively in precision grinding operations. For cylindrical grinding, 1 part oil to 40 to 50 parts water is used. Solution type fluids and translucent grinding emulsions are particularly suited for many fine finish grinding applications. Mineral oil-base grinding fluids are recommended for many applications where a fine surface finish is required on the ground surface. Mineral oils are used with vitrified wheels but are not recommended for wheels with rubber or shellac bonds. Under certain conditions the oil vapor mist caused by the action of the grinding wheel can be ignited by the grinding sparks and explode. To quench the grinding spark a secondary coolant line to direct a flow of grinding oil below the grinding wheel is recommended.

**Broaching:** For steel, a heavy mineral oil such as sulfurized oil of 300 to 500 Saybolt viscosity at 100°F (38°C) can be used to provide adequate lubricating effect and a dampening of the shock loads. Soluble oil emulsions may be used for the lighter broaching operations.

**Cutting Fluids for Turning, Milling, Drilling and Tapping.**—The following table, *Cutting Fluids Recommended for Machining Operations*, gives specific cutting oil recommendations for common machining operations.

**Soluble Oils:** Types of oil paste compounds that form emulsions when mixed with water. Soluble oils are used extensively in machining both ferrous and nonferrous metals when the cooling quality is paramount and the chip-bearing pressure is not excessive. Care should be taken in selecting the proper soluble oil for precision grinding operations. Grinding coolants should be free from fatty materials that tend to load the wheel, thus affecting the finish on the machined part. Soluble coolants should contain rust preventive constituents to prevent corrosion.

**Base Oils:** Various types of highly sulfurized and chlorinated oils containing inorganic, animal, or fatty materials. This “base stock” usually is “cut back” or blended with a lighter oil, unless the chip-bearing pressures are high, as when cutting alloy steel. Base oils usually have a viscosity range of from 300 to 900 seconds at 100°F (38°C).

**Mineral Oils:** This group includes all types of oils extracted from petroleum such as paraffin oil, mineral seal oil, and kerosene. Mineral oils are often blended with base stocks, but they are generally used in the original form for light machining operations on both free-machining steels and nonferrous metals. The coolants in this class should be of a type that has a relatively high flash point. Care should be taken to see that they are nontoxic so that they will not be injurious to the operator. The heavier mineral oils (paraffin oils) usually have a viscosity of about 100 seconds at 100°F (38°C). Mineral seal oil and kerosene have a viscosity of 35 to 60 seconds at 100°F (38°C).

Cast Iron <sup>c</sup>	Dry	(or) Dry 25 Percent Lard Oil with 75 Percent Mineral Oil
Malleable Iron	Soluble Oil	Soluble Oil
Bronze	Soluble Oil	20 Percent Lard Oil with 80 Percent Mineral Oil
Magnesium <sup>d</sup>	60-second Mineral Oil	20 Percent Lard Oil with 80 Percent Mineral Oil

<sup>a</sup>In machining aluminum, several varieties of coolants may be used. For rough machining, where the stock removal is sufficient to produce heat, water soluble mixtures can be used with good results to dissipate the heat. Other oils that may be recommended are straight mineral seal oil; a 50-50 mixture of mineral seal oil and kerosene; a mixture of 10 percent lard oil with 90 percent kerosene; and a 100-second mineral oil cut back with mineral seal oil or kerosene.

<sup>b</sup>The sulfur-base oil referred to contains  $4\frac{1}{2}$  percent sulfur compound. Base oils are usually dark in color. As a rule, they contain sulfur compounds resulting from a thermal or catalytic refinery process. When so processed, they are more suitable for industrial coolants than when they have had such compounds as flowers of sulfur added by hand. The adding of sulfur compounds by hand to the coolant reservoir is of temporary value only, and the non-uniformity of the solution may affect the machining operation.

<sup>c</sup>A soluble oil or low-viscosity mineral oil may be used in machining cast iron to prevent excessive metal dust.

<sup>d</sup> When a cutting fluid is needed for machining magnesium, low or nonacid mineral seal or lard oils are recommended. Coolants containing water should not be used because of the fire danger when magnesium chips react with water, forming hydrogen gas.

<sup>e</sup> Sulfurized oils ordinarily are not recommended for tapping aluminum; however, for some tapping operations they have proved very satisfactory, although the work should be rinsed in a solvent right after machining to prevent discoloration.

**Application of Cutting Fluids to Carbides.**—Turning, boring, and similar operations on lathes using carbides are performed dry or with the help of soluble oil or chemical cutting fluids. The effectiveness of cutting fluids in improving tool life or by permitting higher cutting speeds to be used is less with carbides than with high-speed steel tools. Furthermore, the effectiveness of the cutting fluid is reduced as the cutting speed is increased. Cemented carbides are very sensitive to sudden changes in temperature and to temperature gradients within the carbide. Thermal shocks to the carbide will cause thermal cracks to form near the cutting edge, which are a prelude to tool failure. An unsteady or interrupted flow of the coolant reaching the cutting edge will generally cause these thermal cracks. The flow of the chip over the face of the tool can cause an interruption to the flow of the coolant reaching the cutting edge even though a steady stream of coolant is directed at the tool. When a cutting fluid is used and frequent tool breakage is encountered, it is often best to cut dry. When a cutting fluid must be used to keep the workpiece cool for size control or to allow it to be handled by the operator, special precautions must be used. Sometimes applying the coolant from the front and the side of the tool simultaneously is helpful. On lathes equipped with overhead shields, it is very effective to apply the coolant from below the tool into the space between the shoulder of the work and the tool flank, in addition to applying the coolant from the top. Another method is not to direct the coolant stream at the cutting tool at all but to direct it at the workpiece above or behind the cutting tool.

The danger of thermal cracking is great when milling with carbide cutters. The nature of the milling operation itself tends to promote thermal cracking because the cutting edge is constantly heated to a high temperature and rapidly cooled as it enters and leaves the workpiece. For this reason, carbide milling operations should be performed dry.

Lower cutting-edge temperatures diminish the danger of thermal cracking. The cutting-edge temperatures usually encountered when reaming with solid carbide or carbide-tipped reamers are generally such that thermal cracking is not apt to occur except when reaming certain difficult-to-machine metals. Therefore, cutting fluids are very effective when used on carbide reamers. Practically every kind of cutting fluid has been used, depending on the job material encountered. For difficult surface-finish problems in holes, heavy duty soluble oils, sulfurized mineral-fatty oils, and sulfochlorinated mineral-fatty oils have been used successfully. On some work, the grade and the hardness of the carbide also have an effect on the surface finish of the hole.

Cutting fluids should be applied where the cutting action is taking place and at the highest possible velocity without causing splashing. As a general rule, it is preferable to supply from 3 to 5 gallons per minute (11–19 liter/min) for each single-point tool on a machine such as a turret lathe or automatic. The temperature of the cutting fluid should be kept below 110°F (43°C). If the volume of fluid used is not sufficient to maintain the proper temperature, means of cooling the fluid should be provided.

**Cutting Fluids for Machining Magnesium.**—In machining magnesium, it is the general but not invariable practice in the United States to use a cutting fluid. In other places, magnesium usually is machined dry except where heat generated by high cutting speeds would not be dissipated rapidly enough without a cutting fluid. This condition may exist when, for example, small tools without much heat-conducting capacity are employed on automatics.

The cutting fluid for magnesium should be an anhydrous oil having, at most, a very low acid content. Various mineral-oil cutting fluids are used for magnesium.

**Metalworking Fluids**

The term *metalworking fluids* (MWFs) describes coolants and lubricants used during the fabrication of products from metals and metal substitutes. These fluids are used to prolong the life of machine tools, carry away debris, and protect or treat the surfaces of the material being processed. MWFs reduce friction between the cutting tool and work surfaces, reduce wear and galling, protect surface characteristics, reduce surface adhesion or welding, carry away generated heat, and flush away swarf, chips, fines, and residues. Table 1 describes the four different classes of metalworking fluids:

**Table 1. Classes of Metalworking Fluids (MWFs)**

MWF	Description	Dilution factor
<b>Straight oil</b> (neat oil or cutting oil)	Highly refined petroleum oils (lubricant-base oils) or other animal, marine, vegetable, or synthetic oils used singly or in combination with or without additives. These are lubricants, or function to improve the finish on the metal cut, and prevent corrosion.	none
<b>Soluble oil</b> (emulsifiable oil)	Combinations of 30 to 85% highly refined, high-viscosity lubricant-base oils and emulsifiers that may include other performance additives. Soluble oils are diluted with water before use at ratios of parts water.	1 part concentrate to 5 to 40 parts water
<b>Semisynthetic</b>	Contain smaller amounts of severely refined lubricant-base oil (5 to 30% in the concentrate), a higher proportion of emulsifiers that may include other performance additives, and 30 to 50% water.	1 part concentrate to 10 to 40 parts water
<b>Synthetic<sup>a</sup></b>	Contain no petroleum oils and may be water soluble or water dispersible. The simplest synthetics are made with organic and inorganic salts dissolved in water. Offer good rust protection and heat removal but usually have poor lubricating ability. May be formulated with other performance additives. Stable, can be made bioreistant.	1 part concentrate to 10 to 40 parts water

<sup>a</sup> Over the last several decades major changes in the US machine tool industry have increased the consumption of MWFs. Specifically, the use of synthetic MWFs increased as tool and cutting speeds increased.

**Occupational Exposures to Metalworking Fluids (MWFs).**—Workers can be exposed to MWFs by inhalation of aerosols (mists) or by skin contact resulting in an increased risk of respiratory (lung) and skin disease. Health effects vary based on the type of MWF, route of exposure, concentration, and length of exposure.

Skin contact usually occurs when the worker dips his/her hands into the fluid, floods the machine tool, or handling parts, tools, equipment or workpieces coated with the fluid, without the use of personal protective equipment such as gloves and apron. Skin contact can also result from fluid splashing onto the worker from the machine if guarding is absent or inadequate.

Inhalation exposures result from breathing MWF mist or aerosol. The amount of mist generated (and the severity of the exposure) depends on a variety of factors: the type of MWF and its application process; the MWF temperature; the specific machining or grinding operation; the presence of splash guarding; and the effectiveness of the ventilation system. In general, the exposure will be higher if the worker is in close proximity to the machine, the operation involves high tool speeds and deep cuts, the machine is not enclosed, or if ventilation equipment was improperly selected or poorly maintained. In addition, high-pressure and/or excessive fluid application, contamination of the fluid with tramp oils, and improper fluid selection and maintenance will tend to result in higher exposure.

Each MWF class consists of a wide variety of chemicals used in different combinations and the risk these chemicals pose to workers may vary because of different manufacturing processes, various degrees of refining, recycling, improperly reclaimed chemicals, different degrees of chemical purity, and potential chemical reactions between components.

Exposure to hazardous contaminants in MWFs may present health risks to workers. Contamination may occur from: process chemicals and ancillary lubricants inadvertently introduced; contaminants, metals, and alloys from parts being machined; water and cleaning agents used for routine housekeeping; and, contaminants from other environmental sources at the worksite. In addition, bacterial and fungal contaminants may metabolize and degrade the MWFs to hazardous end-products as well as produce endotoxins.

The improper use of biocides to manage microbial growth may result in potential health risks. Attempts to manage microbial growth solely with biocides may result in the emergence of biocide-resistant strains from complex interactions that may occur among different member species or groups within the population. For example, the growth of one species, or the elimination of one group of organisms may permit the overgrowth of another. Studies also suggest that exposure to certain biocides can cause either allergic or contact dermatitis.

**Fluid Selection, Use, and Application.**—The MWFs selected should be as nonirritating and nonsensitizing as possible while remaining consistent with operational requirements. Petroleum-containing MWFs should be evaluated for potential carcinogenicity using ASTM E1687-10 (R2014), “Standard Test Method for Determining Carcinogenic Potential of Virgin Base Oils in Metalworking Fluids”. If soluble oil or synthetic MWFs are used, ASTM Standard E1497-17, “Standard Practice for Selection and Safe Use of Water-Miscible and Straight Oil Metal Removal Fluids” should be consulted for safe use guidelines, including those for product selection, storage, dispensing, and maintenance. To minimize the potential for nitrosamine formation, nitrate-containing materials should not be added to MWFs containing ethanalamines.

Many factors influence the generation of MWF mists, which can be minimized through the proper design and operation of the MWF delivery system. ANSI Technical Report B11 TR2-1997, “Mist Control Considerations for the Design, Installation and Use of Machine Tools Using Metalworking Fluids” provides directives for minimizing mist and vapor generation. These include minimizing fluid delivery pressure, matching the fluid to the application, using MWF formulations with low oil concentrations, avoiding contamination with tramp oils, minimizing the MWF flow rate, covering fluid reservoirs and return systems where possible, and maintaining control of the MWF chemistry. Also, proper application of MWFs can minimize splashing and mist generation. Proper application includes: applying MWFs at the lowest possible pressure and flow volume consistent with provisions for adequate part cooling, chip removal, and lubrication; applying MWFs at the tool/workpiece interface to minimize contact with other rotating equipment; ceasing fluid delivery when not performing machining; not allowing MWFs to flow over the unprotected hands of workers loading or unloading parts; and using mist collectors engineered for the operation and specific machine enclosures.

Properly maintained filtration and delivery systems provide cleaner MWFs, reduce mist, and minimize splashing and emissions. Proper maintenance of the filtration and delivery systems includes: the selection of appropriate filters; ancillary equipment such as chip handling operations, dissolved air-flotation devices, belt-skimmers, chillers or plate and frame heat exchangers, and decantation tanks; guard coolant return trenches to prevent dumping of floor wash water and other waste fluids; covering sumps or coolant tanks to prevent contamination with waste or garbage (e.g., cigarette butts, food, etc.); and, keeping the machine(s) clean of debris. Parts washing before machining can be an important part of maintaining cleaner MWFs.

Since all additives will be depleted with time, the MWF and additives concentrations should be monitored frequently so that components and additives can be made up as

needed. The MWF should be maintained within the pH and concentration ranges recommended by the formulator or supplier. MWF temperature should be maintained at the lowest practical level to slow the growth of microorganisms, reduce water losses and changes in viscosity, and—in the case of straight oils—reduce fire hazards.

**Fluid Maintenance.**—Drums, tanks, or other containers of MWF concentrates should be stored appropriately to protect them from outdoor weather conditions and exposure to low or high temperatures. Extreme temperature changes may destabilize the fluid concentrates, especially in the case of concentrates mixed with water, and cause water to seep into unopened drums encouraging bacterial growth. MWFs should be maintained at as low a temperature as is practical. Low temperatures slow the growth of microorganisms, reduce water losses and change in viscosity, and in the case of straight oils, reduce the fire hazard risks.

To maintain proper MWF concentrations, neither water nor concentrate should be used to top off the system. The MWF mixture should be prepared by first adding the concentrate to the clean water (in a clean container) and then adding the emulsion to that mixture in the coolant tank. MWFs should be mixed just before use; large amounts should not be stored, as they may deteriorate before use.

**Personal Protective Clothing:** Personal protective clothing and equipment should always be worn when removing MWF concentrates from the original container, mixing and diluting concentrate, preparing additives (including biocides), and adding MWF emulsions, biocides, or other potentially hazardous ingredients to the coolant reservoir. Personal protective clothing includes eye protection or face shields, gloves, and aprons which do not react with but shed MWF ingredients and additives.

**System Service:** Coolant systems should be regularly serviced, and the machines should be rigorously maintained to prevent contamination of the fluids by tramp oils (e.g., hydraulic oils, gear box oils, and machine lubricants leaking from the machines or total loss slideway lubrication). Tramp oils can destabilize emulsions, cause pumping problems, and clog filters. Tramp oils can also float to the top of MWFs, effectively sealing the fluids from the air, allowing metabolic products such as volatile fatty acids, mercaptols, scatols, ammonia, and hydrogen sulfide produced by the anaerobic and facultative anaerobic species growing within the biofilm to accumulate in the reduced state.

When replacing the fluids, thoroughly clean all parts of the system to inhibit the growth of microorganisms growing on surfaces. Some bacteria secrete layers of slime that may grow in stringy configurations that resemble fungal growth. Many bacteria secrete polymers of polysaccharide and/or protein, forming a glycocalyx which cements cells together much as mortar holds bricks. Fungi may grow as masses of hyphae-forming mycelial mats. The attached community of microorganisms is called a biofilm and may be very difficult to remove by ordinary cleaning procedures.

**Biocide Treatment:** Biocides are used to maintain the functionality and efficacy of MWFs by preventing microbial overgrowth. These compounds are often added to the stock fluids as they are formulated, but over time the biocides are consumed by chemical and biological demands. Biocides with a wide spectrum of biocidal activity should be used to suppress the growth of the widely diverse contaminant population. Only the concentration of biocide needed to meet fluid specifications should be used since overdosing could lead to skin or respiratory irritation in workers, and under-dosing could lead to an inadequate level of microbial control.

**Ventilation Systems:** The ventilation system should be designed and operated to prevent the accumulation or recirculation of airborne contaminants in the workplace. The ventilation system should include a positive means of bringing in at least an equal volume of air from the outside, conditioning it, and evenly distributing it throughout the exhausted area.

Exhaust ventilation systems function through suction openings placed near a source of contamination. The suction opening or exhaust hood creates air motion sufficient to overcome room air currents and any airflow generated by the process. This airflow

captures the contaminants and conveys them to a point where they can either be discharged or removed from the airstream. Exhaust hoods are classified by their position relative to the process as canopy, side draft, down draft or enclosure. ANSI Technical Report B11 TR 2-1997 contains guidelines for exhaust ventilation of machining and grinding operations. Enclosures are the only type of exhaust hood recommended by the ANSI committee. They consist of physical barriers between the process and the worker's environment. Enclosures can be further classified by the extent of the enclosure: close capture (enclosure of the point of operation, total enclosure (enclosure of the entire machine), or tunnel enclosure (continuous enclosure over several machines).

If no fresh make up air is introduced into the plant, air will enter the building through open doors and windows, potentially causing cross-contamination of all process areas. Ideally, all air exhausted from the building should be replaced by tempered air from an uncontaminated location. By providing a slight excess of make up air in relatively clean areas and slight deficit of make up air in dirty areas, cross-contamination can be reduced. In addition, this air can be channeled directly to operator work areas, providing the cleanest possible work environment. Ideally, this fresh air should be supplied in the form of a low-velocity air shower (<100 ft/min or <30 m/min) to prevent interference with the exhaust hoods) directly above the worker.

**Protective Clothing and Equipment:** Engineering controls are used to reduce worker exposure to MWFs. But in the event of airborne exposures that exceed the NIOSH REL or dermal contact with the MWFs, the added protection of chemical protective clothing (CPC) and respirators should be provided. Maintenance staff may also need CPC because their work requires contact with MWFs during certain operations. All workers should be trained in the proper use and care of CPC. After any item of CPC has been in routine use, it should be examined to ensure that its effectiveness has not been compromised.

Selection of the appropriate respirator depends on the operation, chemical components, and airborne concentrations in the worker's breathing zone. Table 2 lists the NIOSH-recommended respiratory protection for workers exposed to MWF aerosol.

**Table 2. Respiratory Protection for Workers Exposed to MWF Aerosols<sup>a</sup>**

Concentration of MWF aerosol (mg/m <sup>3</sup> )	Minimum respiratory protection <sup>a</sup>
#0.5 mg/m <sup>3</sup> (1 REL) <sup>b</sup>	No respiratory protection required for healthy workers <sup>c</sup>
#5.0 mg/m <sup>3</sup> (10 REL)	Any air-purifying, half-mask respirator including a disposable respirator <sup>d,e</sup> equipped with any P- or R-series particulate filter (P95, P99, P100, R95, R99, or R100) number
#12.5 mg/m <sup>3</sup> (25 REL)	Any powered, air-purifying respirator equipped with a hood or helmet and a HEPA filter <sup>f</sup>

<sup>a</sup> Respirators with higher assigned protection factors (APFs) may be substituted for those with lower APFs [NIOSH 1987a].

<sup>b</sup> APF times the NIOSH REL for total particulate mass. The APF [NIOSH 1987b] is the minimum anticipated level of protection provided by each type of respirator.

<sup>c</sup> See text for recommendations regarding workers with asthma and for other workers affected by MWF aerosols.

<sup>d</sup> A respirator that should be discarded after the end of the manufacturer's recommended period of use or after a noticeable increase in breathing resistance or when physical damage, hygiene considerations, or other warning indicators render the respirator unsuitable for further use.

<sup>e</sup> An APF of 10 is assigned to disposable particulate respirators if they have been properly fitted.

<sup>f</sup> High-efficiency particulate air filter. When organic vapors are a potential hazard during metalworking operations, a combination particulate and organic vapor filter is necessary.

<sup>g</sup> Only NIOSH/MSHA-approved or NIOSH-approved (effective date July 10, 1995) respiratory equipment should be used.

**MACHINING NONFERROUS METALS  
AND NON-METALLIC MATERIALS****Nonferrous Metals**

**Machining Aluminum.**—Some of the alloys of aluminum have been machined successfully without any lubricant or cutting compound, but some form of lubricant is desirable to obtain the best results. For many purposes, a soluble cutting oil is good.

Tools for aluminum and aluminum alloys should have larger relief and rake angles than tools for cutting steel. For high-speed steel turning tools the following angles are recommended: relief angles, 14 to 16 degrees; back rake angle, 5 to 20 degrees; side rake angle, 15 to 35 degrees. For very soft alloys even larger side rake angles are sometimes used. High silicon aluminum alloys and some others have a very abrasive effect on the cutting tool. While these alloys can be cut successfully with high-speed steel tools, cemented carbides are recommended because of their superior abrasion resistance. The tool angles recommended for cemented carbide turning tools are: relief angles, 12 to 14 degrees; back rake angle, 0 to 15 degrees; side rake angle, 8 to 30 degrees.

Cut-off tools and necking tools for machining aluminum and its alloys should have from 12 to 20 degrees back rake angle and the end relief angle should be from 8 to 12 degrees. Excellent threads can be cut with single-point tools in even the softest aluminum. Experience seems to vary somewhat regarding the rake angle for single-point thread cutting tools. Some prefer to use a rather large back and side rake angle although this requires a modification in the included angle of the tool to produce the correct thread contour. When both rake angles are zero, the included angle of the tool is ground equal to the included angle of the thread. Excellent threads have been cut in aluminum with zero rake angle thread-cutting tools using large relief angles, which are 16 to 18 degrees opposite the front side of the thread and 12 to 14 degrees opposite the back side of the thread. In either case, the cutting edges should be ground and honed to a keen edge. It is sometimes advisable to give the face of the tool a few strokes with a hone between cuts when chasing the thread to remove any built-up edge on the cutting edge.

Fine surface finishes are often difficult to obtain on aluminum and aluminum alloys, particularly the softer metals. When a fine finish is required, the cutting tool should be honed to a keen edge and the surfaces of the face and the flank will also benefit by being honed smooth. Tool wear is inevitable, but it should not be allowed to progress too far before the tool is changed or sharpened. A sulphurized mineral oil or a heavy-duty soluble oil will sometimes be helpful in obtaining a satisfactory surface finish. For best results, however, a diamond cutting tool is recommended. Excellent surface finishes can be obtained on even the softest aluminum and aluminum alloys with these tools.

Although ordinary milling cutters can be used successfully in shops where aluminum parts are only machined occasionally, the best results are obtained with coarse-tooth, large helix-angle cutters having large rake and clearance angles. Clearance angles up to 10 to 12 degrees are recommended. When slab milling and end milling a profile, using the peripheral teeth on the end mill, climb milling (also called down milling) will generally produce a better finish on the machined surface than conventional (or up) milling. Face milling cutters should have a large axial rake angle. Standard twist drills can be used without difficulty in drilling aluminum and aluminum alloys although high helix-angle drills are preferred. The wide flutes and high helix-angle in these drills helps to clear the chips. Sometimes split-point drills are preferred. Carbide tipped twist drills can be used for drilling aluminum and its alloys and may afford advantages in some production applications. Ordinary hand and machine taps can be used to tap aluminum and its alloys although spiral-fluted ground thread taps give superior results. Experience has shown that such taps should have a right-hand ground flute when intended to cut right-hand threads and the helix angle should be similar to that used in an ordinary twist drill.

**Machining Magnesium.**—Magnesium alloys are readily machined and with relatively low power consumption per cubic inch of metal removed. The usual practice is to employ high cutting speeds with relatively coarse feeds and deep cuts. Exceptionally fine finishes can be obtained so that grinding to improve the finish usually is unnecessary. The horsepower normally required in machining magnesium varies from 0.15 to 0.30 hp per cubic inch per minute (0.41–0.82 kW/cm<sup>3</sup>/s). While this value is low, especially in comparison with power required for cast iron and steel, the total amount of power for machining magnesium usually is high because of the exceptionally rapid rate at which metal is removed.

Carbide tools are recommended for maximum efficiency, although high-speed steel frequently is employed. Tools should be designed so as to dispose of chips readily or without excessive friction, by employing polished chip-bearing surfaces, ample chip spaces, large clearances, and small contact areas. *Keen-edged tools should always be used.*

*Speeds and Feeds for Magnesium:* Speeds ordinarily range up to 5000 ft/min (1524 m/min) for rough- and finish-turning, up to 3000 ft/min (915 m/min) for rough-milling, and up to 9000 ft/min (2743 m/min) for finish-milling. The following combinations of speed, feed per revolution, and depth of cut are recommended:

Process	Speed		Feed		Depth of Cut	
	ft/min	m/min	in/rev	mm/rev	inch	mm
Rough Turning	300–600	90–185	0.030–0.100	0.76–2.5	0.5	12.7
	600–1000	185–305	0.020–0.080	0.50–2.0	0.4	10
	1000–1500	305–460	0.010–0.060	0.25–1.5	0.3	7.6
	1500–2000	460–610	0.010–0.040	0.25–1.0	0.2	5.0
	2000–5000	610–1525	0.010–0.030	0.25–0.76	0.1	3.8
Rough Milling	up to 900	up to 275	0.005–0.025	0.13–0.64	up to 0.5	up to 12.7
	900–1500	275–455	0.005–0.020	0.13–0.51	up to 0.375	up to 9.5
	1500–3000	455–915	0.005–0.010	0.13–0.25	up to 0.2	up to 5.1

*Lathe Tool Angles for Magnesium:* The true or actual rake angle resulting from back and side rakes usually varies from 10 to 15 degrees. Back rake varies from 10 to 20, and side rake from 0 to 10 degrees. Reduced back rake may be employed to obtain better chip breakage. The back rake may also be reduced to from 2 to 8 degrees on form tools or other broad tools to prevent chatter.

*Parting Tools:* For parting tools, the back rake varies from 15 to 20 degrees, the front end relief 8 to 10 degrees, the side relief measured perpendicular to the top face 8 degrees, the side relief measured in the plane of the top face from 3 to 5 degrees.

*Milling Magnesium:* In general, the coarse-tooth type of cutter is recommended. The number of teeth or cutting blades may be one-third to one-half the number normally used; however, the two-blade fly-cutter has proved to be very satisfactory. As a rule, the land relief or primary peripheral clearance is 10 degrees followed by secondary clearance of 20 degrees. The lands should be narrow, the width being about  $\frac{3}{64}$  to  $\frac{1}{16}$  inch (1.19 to 1.59 mm). The rake, which is positive, is about 15 degrees.

*Drilling Magnesium:* If the depth of a hole is less than five times the drill diameter, an ordinary twist drill with highly polished flutes may be used. The included angle of the point may vary from 70 degrees to the usual angle of 118 degrees. The relief angle is about 12 degrees. The drill should be kept sharp and the outer corners rounded to produce a smooth finish and prevent burr formation. For deep hole drilling, use a drill having a helix angle of 40 to 45 degrees with large polished flutes of uniform cross section throughout the drill length to facilitate the flow of chips. A pyramid-shaped “spur” or “pilot point” at the tip of the drill will reduce the “spiraling or run-off.”

Drilling speeds vary from 300 to 2000 feet per minute (90–610 m/min) with feeds per revolution ranging from 0.015 to 0.050 inch (0.38–1.27 mm).

*Reaming Magnesium:* Reamers up to 1 inch in diameter should have four flutes; larger sizes, six flutes. These flutes may be either parallel with the axis or have a negative helix

angle of 10 degrees. The positive rake angle varies from 5 to 8 degrees, the relief angle from 4 to 7 degrees, and the clearance angle from 15 to 20 degrees.

**Tapping Magnesium:** Standard taps may be used unless Class 3B tolerances are required, in which case the tap should be designed for use in magnesium. A high-speed steel concentric type with a ground thread is recommended. The concentric form, which eliminates the radial thread relief, prevents jamming of chips while the tap is being backed out of the hole. The positive rake angle at the front may vary from 10 to 25 degrees and the "heel rake angle" at the back of the tooth from 3 to 5 degrees. The chamfer extends over two to three threads. For holes up to  $\frac{1}{4}$  inch (6.35 mm) in diameter, two-fluted taps are recommended; for sizes from  $\frac{1}{2}$  to  $\frac{3}{4}$  inch (12.7–19.05 mm), three flutes; and for larger holes, four flutes. Tapping speeds ordinarily range from 75 to 200 feet per minute (23–61 m/min), and mineral oil cutting fluid should be used.

**Threading Dies for Magnesium** should have about the same cutting angles as taps. Narrow lands should be used to provide ample chip space. Either solid or self-opening dies may be used. The latter type is recommended when maximum smoothness is required. Threads may be cut at speeds up to 1000 feet per minute (305 m/min).

**Grinding Magnesium:** As a general rule, magnesium is ground dry. The highly inflammable dust should be formed into a sludge by means of a spray of water or low-viscosity mineral oil. Accumulations of dust or sludge should be avoided. For surface grinding, when a fine finish is desirable, a low-viscosity mineral oil may be used.

**Machining Zinc Alloy Die Castings.**—Machining of zinc alloy die castings is mostly done without a lubricant. For particular work, especially deep drilling and tapping, a lubricant such as lard oil and kerosene (about half and half) or a 50-50 mixture of kerosene and machine oil may be used to advantage. A mixture of turpentine and kerosene has been found effective on certain difficult jobs.

**Reaming:** In reaming, tools with six straight flutes are commonly used, although tools with eight flutes irregularly spaced have been found to yield better results by one manufacturer. Many standard reamers have a land that is too wide for best results. A land about 0.015 inch (0.38 mm) wide is recommended but this may often be ground down to around 0.007 or even 0.005 inch (0.18 or even 0.127 mm) to obtain freer cutting, less tendency to loading, and reduced heating.

**Turning:** Tools of high-speed steel are commonly employed although the application of Stellite and carbide tools, even on short runs, is feasible. For steel or Stellite, a positive top rake of from 0 to 20 degrees and an end clearance of about 15 degrees are commonly recommended. Where side cutting is involved, a side clearance of about 4 degrees minimum is recommended. With carbide tools, the end clearance should not exceed 6 to 8 degrees and the top rake should be from 5 to 10 degrees positive. For boring, facing, and other lathe operations, rake and clearance angles are about the same as for tools used in turning.

**Machining Monel and Nickel Alloys.**—These alloys are machined with high-speed steel and with cemented carbide cutting tools. High-speed steel lathe tools usually have a back rake of 6 to 8 degrees, a side rake of 10 to 15 degrees, and relief angles of 8 to 12 degrees. Broad-nose finishing tools have a back rake of 20 to 25 degrees and an end relief angle of 12 to 15 degrees. In most instances, standard commercial cemented carbide tool holders and tool shanks can be used which provide an acceptable tool geometry. Honing the cutting edge lightly will help if chipping is encountered.

The most satisfactory tool materials for machining Monel and the softer nickel alloys, such as Nickel 200 and Nickel 230, are M2 and T5 for high-speed steel and crater resistant grades of cemented carbides. For the harder nickel alloys such as K Monel, Permannickel, Duranickel, and Nitinol alloys, the recommended tool materials are T15, M41, M42, M43, and for high-speed steel, M42. For carbides, a grade of crater resistant carbide is recommended when the hardness is less than 300 BHN, and when the hardness is more than

300 BHN, a grade of straight tungsten carbide will often work best, although some crater resistant grades will also work well.

A sulfurized oil or a water-soluble oil is recommended for rough and finish turning. A sulfurized oil is also recommended for milling, threading, tapping, reaming, and broaching. Recommended cutting speeds for Monel and the softer nickel alloys are 70 to 100 fpm (20–30 m/min) for high-speed steel tools and 200 to 300 fpm (60–90 m/min) for cemented carbide tools. For the harder nickel alloys, the recommended speed for high-speed steel is 40 to 70 fpm (12–21 m/min) for a hardness up to 300 BHN and for a higher hardness, 10 to 20 fpm (3–6 m/min); for cemented carbides, 175 to 225 fpm (55–70 m/min) when the hardness is less than 300 BHN and for a higher hardness, 30 to 70 fpm (9–21 m/min).

Nickel alloys have a high tendency to work harden. To minimize work hardening caused by machining, the cutting tools should be provided with adequate relief angles and positive rake angles. Furthermore, the cutting edges should be kept sharp and replaced when dull to prevent burnishing of the work surface. The depth of cut and feed should be sufficiently large to ensure that the tool penetrates the work without rubbing.

**Machining Copper Alloys.**—Copper alloys can be machined by tooling and methods similar to those used for steel, but at higher surface speeds. Machinability of copper alloys is discussed in [Table 2](#) on page 512 and [Table 3](#) on page 516. Machinability is based on a rating of 100 percent for the free-cutting alloy C35000, which machines with small, easily broken chips. As with steels, copper alloys containing lead have the best machining properties, with alloys containing tin and lead having machinability ratings of 80 and 70 percent. Tellurium and sulphur are added to copper alloys to increase machinability with minimum effect on conductivity. Lead additions are made to facilitate machining, as their effect is to produce easily broken chips.

Copper alloys containing silicon, aluminum, manganese and nickel become progressively more difficult to machine, and produce long, stringy chips, the latter alloys having only 20 percent of the machinability of the free-cutting alloys. Although copper is frequently machined dry, a cooling compound is recommended. Other lubricants that have been used include tallow for drilling, gasoline for turning, and beeswax for threading.

### Machining Non-Metals

**Machining Hard Rubber.**—Tools suitable for steel may be used for hard rubber, with no top or side rake angles and 10 to 20 degree clearance angles, of high-speed steel or tungsten carbide. Without coolant, surface speeds of about 200 ft/min (60m/min) are recommended for turning, boring and facing; with coolant, increase up to 300 surface ft/min (90 m/min).

*Drilling of hard rubber* requires high-speed steel drills of 35 to 40 degree helix angle to obtain maximum cutting speeds and drill life. Feed rates for drilling range up to 0.015 in/rev (0.38 mm/rev). Deep-fluted taps are best for threading hard rubber, and should be 0.002 to 0.005 inch (0.05-0.13 mm) oversize if close tolerances are to be held. Machine oil is used for a lubricant. Hard rubber may be sawn with band saws having 5 to 10 teeth per inch (2–4 teeth/cm), running at about 3000 ft/min (914 m/min) or cut with abrasive wheels. Use of coolant in grinding rubber gives a smoother finish.

*Piercing and blanking* of sheet rubber is best performed with the rubber or dies heated. Straightening of the often-distorted blanks may be carried out by dropping them into a pan of hot water.

**Formica Machining.**—Blanks can be cut from sheets of “Formica” either by a band saw or by trepanning tools in a boring mill or a drill press. To saw blanks, first describe a circle as a guide line, then use a 21-gage  $3\frac{1}{2}$ -point saw running at a speed of 5000 ft/min (1525 m/min). The saw should be sharp, with a  $\frac{1}{64}$ -inch (0.4 mm) set on both sides. In drilling, use an ordinary high-speed drill whose point is ground to an included angle of 55 to 60 degrees. Another method is to grind the drill point slightly off center. The feed

must be rapid and caution used to prevent the drill from lagging in its work, and the speed must be 1200 rpm. For all machining operations on "Formica" gear material, provision must be made in grinding for the tools to clear themselves. For reaming, the entry of the reamer and the reaming process must be rapid. There must not be a lag between the end of the reaming operation and the withdrawal of the reamer. In turning the outside diameter and the sides of blanks, the tools must be sharp and have 3 to 5 degrees more rake than is common practice for metal. A cutting speed of 750 fpm (228.6 m/min), equal to 720 rpm on a 4-inch diameter blank, is recommended. The depth of the cut can be  $\frac{1}{16}$  to  $\frac{1}{8}$  inch (1.6–3.2 mm), but the feed should be 0.010 inch (0.25 mm), regardless of the depth of the cut. Teeth may be cut on a hobbing machine, shaper, or milling machine. The speed of the cutter should be 150 fpm (46 m/min) and the feed from 0.023 to 0.040 inch per revolution (0.59–1.02 mm/rev). It is advisable to back up the blank to prevent fraying or breaking out of the material as the cutter comes through. The backing plates can be economically made from hard wood.

**Micarta Machining.**—In cutting blanks from sheets of "micarta" a band saw running at a speed of 350 revolutions per minute has been found suitable. The saw should be of the bevel-tooth type, seven teeth to the inch. For large quantities a trepanning tool should be used. In trepanning blanks, the tool should be fed so as to cut part way through all of the "layouts"; then the micarta plate should be turned over, and the cutting completed from the reverse side.

Turning tools should be high-speed steel cutting at speeds similar to those for bronze or cast iron. If two cuts are taken, about 0.010 inch (0.254 mm) of stock should be left for the finishing cut.

Drilling at right angles to the layers is done with a standard drill, which should be backed off sufficiently to provide plenty of clearance. When drilling parallel to layers, a "flat" or "bottom" drill should be used. In rough-drilling, the hole should preferably be drilled partly through the material from each side to prevent possible splitting as the tool protrudes. If this is impracticable, the hole can be drilled all the way through the material, provided the material is "backed up" with wood, stiff cardboard, or any other material that is sufficiently rigid to support the under surface at the point where the drill comes through.

The methods described for drilling apply as well to tapping, except that when the tapping is done parallel to the layers, it is advisable to clamp the material to equalize the stress on the layers and prevent possible splitting.

In milling, a standard tool may be used at a speed and feed corresponding to that used in working bronze or soft steel. The cutting angle of the cutter will give better results if ground with a slight rake.

While there is a wide range of practice as to speeds and feeds in cutting gears on hobbing machines, a hob speed of not less than 140 revolutions per minute has given satisfaction. In machining gear teeth on a gear shaper, a speed of about 100 to 130 strokes per minute with a fairly fine feed has given good results. Backing-up plates should be used in machining micarta gears.

**Ultrasonic Machining.**—This method of cutting and engraving hard materials such as glass, precious stones, and carbides uses a transducer (vibratory unit) to obtain the necessary mechanical vibrations needed. The transducer converts the input energy, in this case electrical, into another form of energy, in this case mechanical.

A tool of the required size and shape is made of brass or other soft material and is attached to the transducer. The tool is lowered until it just barely touches the work, and current is applied. At the same time, a slurry of water and fine abrasive, usually boron carbide, is pumped over the work. The tool does not actually touch the work, but the vibrations literally hammer the particles of abrasive into the surface and chip off tiny fragments. Some wear does take place in the tool, but it is very slight and, as it is equally distributed, it does not change the shape. The method is commonly applied to cutting designs in stones of signet rings, and also applied to cutting intricately shaped holes in carbide or hardened steel.

### GRINDING FEEDS AND SPEEDS

Grinding data are scarcely available in handbooks, which usually recommend a small range of depths and work speeds at constant wheel speed, including small variations in wheel and work material composition. Wheel life or grinding stiffness are seldom considered.

Grinding parameter recommendations typically range as follows:

- Wheel speeds are usually recommended in the 1200 to 1800 m/min (4000 to 6000 fpm) range, or in rare cases up to 3600 m/min (12000 fpm)
- Work speeds are in the range 20 to 40 m/min (70 to 140 fpm); and, depths of cut of 0.01 to 0.025 mm (0.0004 to 0.001 inch) for roughing, and around 0.005 mm (.0002 in.) for finish grinding.
- Grit sizes for roughing are around 46 to 60 for easy-to-grind materials, and for difficult-to-grind materials higher such as 80 grit. In finishing, a smaller grit size (higher grit number) is recommended. Internal grinding grit sizes for small holes are approximately 100 to 320.
- Specific metal removal rate,  $SMRR$ , represents the rate of material removal per unit of wheel contact width and are commonly recommended from 200 to 500 mm<sup>3</sup>/mm width/min (0.3 to 0.75 in<sup>3</sup>/inch width/min).
- Grinding stiffness is a major variable in determining wheel-life and spark-out time. A typical value of system stiffness in outside-diameter grinding, for 10:1 length/diameter ratio, is approximately  $K_{ST} = 30\text{--}50 \text{ N}/\mu\text{m}$ . System stiffness  $K_{ST}$  is calculated from the stiffness of the part,  $K_w$  and the machine and fixtures,  $K_m$ . Machine values can be obtained from manufacturers, or can be measured using simple equipment along with the part stiffness.
- Generally a lower wheel hardness (soft wheel) is recommended when the system stiffness is poor or when a better finish is desired.

#### Basic Rules

The wheel speed  $V$  and *equivalent chip thickness*  $ECT = SMRR \div V \div 1000$  are the primary parameters that determine wheel-life, forces and surface finish in grinding. The following general rules and recommendations, using  $ECT$ , are based on extensive laboratory and industry tests both in Europe and the United States. The relationships and shapes of curves pertaining to grinding tool life, grinding time, and cost are similar to those of any metal cutting operation such as turning, milling and drilling.

In turning and milling, the  $ECT$  theory says that if the product of feed times depth of cut is constant, the tool life is constant no matter how the depth of cut or feed is varied, provided that the cutting speed and cutting edge length are maintained constant.

In grinding, wheel-life  $T$  remains constant for constant cutting speed  $V$ , regardless of how depth of cut  $a_r$  or work speed  $V_w$  are selected as long as the specific metal removal rate  $SMRR = V_w \times a_r$  is held constant (neglecting the influence of grinding contact width).

$ECT$  is much smaller in grinding than in milling, ranging from about 0.0001 to 0.001 mm (0.000004 to 0.00004 inch). See the section **MACHINING ECONOMETRICS** starting on page 1196 for a detailed explanation of the role of  $ECT$  in conventional machining.

**Wheel Life and Grinding Ratio.**—A commonly used measure of relative wheel-life in grinding is the *grinding ratio*, which is used to compare grindability when varying grinding wheel composition and work material properties under otherwise constant cutting conditions.

The *grinding ratio* is defined as the slope of the wear curve versus metal removal rate:  $\text{grinding ratio} = MRR \div W^*$ , where  $MRR$  is the metal removal rate, and  $W^*$  is the volume wheel wear at which the wheel has to be dressed. The grinding ratio is not a measure of wheel-life, but a relationship between *grinding ratio* and wheel-life  $T$  can be obtained

from the formula  $\text{grinding ratio} = SMRR \times T + W^*$ , where  $SMRR$  (specific metal removal rate) is determined from  $MRR = SMRR \times T$  or from  $ECT = SMRR \div V + 1000$ .

Thus,  $\text{grinding ratio} = 1000 \times ECT \times V \div T + W^*$ , and  $T = \text{grinding ratio} \times W^* \div (1000 \times ECT \times V)$ , provided that the wheel wear criterion  $W^*$  is valid for all data combinations.

*Example 1:* If  $W^*$  in one test is found to be  $500 \text{ mm}^3$  for  $ECT = 0.00033 \text{ mm}$  and  $V = 3600 \text{ m/min}$ , and  $\text{grinding ratio} = 10$ , then wheel-life will vary with measured grinding ratios, wheel speed, and  $ECT$  as follows:  $T = 500 \times \text{grinding ratio} \div (V \times ECT) = 4.2$  minutes.

In the remainder of this section the  $\text{grinding ratio}$  will not be used, and wheel-life is expressed in terms of  $ECT$  or  $SMRR$  and wheel speed  $V$ .

**ECT in Grinding.**—In turning and milling,  $ECT$  is defined as the volume of chips removed per unit cutting edge length per revolution of the work or cutter. In milling specifically,  $ECT$  is defined as the ratio of (number of teeth  $z \times$  feed per tooth  $f_z \times$  radial depth of cut  $a_r \times$  and axial depth of cut  $a_d$ ) and (cutting edge length  $CEL$  divided by  $\pi D$ ), where  $D$  is the cutter diameter, thus,

$$ECT = \frac{\pi D z f_z a_r a_d}{CEL}$$

In grinding, the same definition of  $ECT$  applies if we replace the number of teeth with the average number of grits along the wheel periphery, and replace the feed per tooth by the average feed per grit. This definition is not very practical, however, and  $ECT$  is better defined by the ratio of the specific metal removal rate  $SMRR$ , and the wheel speed  $V$ . Thus,  $ECT = 1000 \times SMRR \div V$ . Keeping  $ECT$  constant when varying  $SMRR$  requires that the wheel speed must be changed proportionally.

In milling and turning  $ECT$  can also be redefined in terms of  $SMRR$  divided by the work and the cutter speeds, respectively, because  $SMRR$  is proportional to the feed rate  $F_R$ .

**Work Speed and Depth of Cut Selection:** Work speed  $V_w$  is determined by dividing  $SMRR$  by the depth of cut  $a_r$ , or by using the graph in Fig. 1.

Fig. 1. Work Speed  $V_w$  versus Depth of Cut  $a_r$ .

Referring to Fig. 1, for depths of cuts of 0.01 and 0.0025 mm, a specific metal removal rate  $SMRR = 1000 \text{ mm}^3/\text{mm width/min}$  is achieved at work speeds of 100 and 400 m/min, respectively, and for  $SMRR = 100 \text{ mm}^3/\text{mm width/min}$  at work speeds of 10 and 40 m/min, respectively.

Unfortunately, the common use of low values of work speed (20 to 40 m/min) in finishing cause thermal surface damage, disastrous in critical parts such as aircraft components. As the grains slide across the work they generate surface heat and fatigue-type loading may cause residual tensile stresses and severe surface cracks. Proper finish grinding

conditions are obtained by increasing the work speed 5 to 10 times higher than the above recommendations indicate. These higher work speeds will create compressive stresses that are not detrimental to the surface. The by-product of higher work speeds is much higher *SMRR* values and thereby much shorter grinding times. Compressive stresses are also obtained by reducing the depth of cut  $a_r$ .

**Wheel Life Relationships and Optimum Grinding Data.**—Fig. 2a, Fig. 2b, and Fig. 2c show, in three planes, the 3-dimensional variation of wheel-life  $T$  with wheel speed  $V$  and  $ECT$  when grinding a hardened tool steel. Fig. 2a depicts wheel-life versus wheel speed (the  $T$ - $V$  plane) with constant  $ECT$  appearing as approximately straight lines when plotted in log-log coordinates.

In grinding, the wheel-life variation follows curves similar to those obtained for conventional metal cutting processes, including a bend-off of the Taylor lines ( $T$ - $V$  graph) towards shorter life and lower cutting speeds when a certain maximum life is achieved for each value of  $ECT$ . In the two other planes ( $T$ - $ECT$ , and  $V$ - $ECT$ ) we usually find smooth curves in which the maximum values of wheel-life are defined by points along a curve called the  $H$ -curve.

Fig. 2a. Taylor Lines:  $T$  versus  $V$ ,  $ECT$  Plotted for Grinding M4 Tool Steel, Hardness 64 RC

**Example 2:** The variation of  $SMRR = V \times ECT \times 1000$  and wheel-life at various wheel speeds can be obtained from Fig. 2a. Using sample values of  $ECT = 33 \times 10^{-5}$  mm and  $V = 1300$  and  $1900$  m/min,  $SMRR = 1300 \times 33 \times 10^{-5} \times 1000 = 429$ , and  $1900 \times 33 \times 10^{-5} \times 1000 = 627$  mm<sup>3</sup>/mm width/min, respectively; the corresponding wheel lives are read off as approximately 70 and 30 minutes, respectively.

Fig. 2b.  $T$  versus  $ECT$ ,  $V$  Plotted

Fig. 2b depicts wheel-life  $T$  versus  $ECT$  with constant wheel speed  $V$  shown as curves plotted in log-log coordinates, similar to those for the other cutting operations.

*Example 3:* Fig. 2b shows that maximum values of wheel-life occur along the *H*-curve. For the 3 speeds 1800, 2700, and 3600 m/min, maximum wheel lives are approximately 70, 14 and 4 minutes, respectively, at *ECT* around  $17 \times 10^{-5}$  through  $20 \times 10^{-5}$  mm along the *H*-curve. Left and right of the *H*-curve wheel-life is shorter.

Fig. 2c depicts wheel speed *V* versus *ECT* with wheel-life *T* parameter shown as curves in log-log coordinates, similar to those for the other cutting operations, with the characteristic *H*- and *G*-curves.

Fig. 2c. *V* versus *ECT*, *T* Plotted

*Optimum grinding data for roughing* occur along the *G*-curve, which is determined from the *V-ECT* graph by drawing 45-degree lines tangent to the *T*-curves, as shown in Fig. 2c, and drawing a line (the *G*-curve) through the points of tangency on the respective *T*-curves, thus the location and direction of the *G*-curve is determined. Globally optimum data correspond to the *T*-curve for which wheel-life is calculated using the corresponding equivalent tooling-cost time,  $T_V = T_{RPL} + 60 \times C_E + H_R$ , minutes, where  $T_{RPL}$  is the time required to replace wheel,  $C_E$  = cost per wheel dressing = wheel cost + cost per dressing, and  $H_R$  is the hourly rate.

*Minimum cost conditions* occur along the *G*-curve; if optimum life  $T_O$  was determined at either 10 or 30 minutes then  $V_O = 1500$  or  $1100$  m/min, respectively, and *ECT* is around  $65 - 70 \times 10^{-5}$  mm in both cases. The corresponding optimum values of *SMRR* are  $1000 \times 1500 \times 67 \times 10^{-5} = 1000$  and  $1000 \times 1100 \times 67 \times 10^{-5} = 740$  mm<sup>3</sup>/min/mm wheel contact width (1.5 to 1.1 in<sup>3</sup>/in/min).

Using Fig. 1 we find optimum work speeds for depths of cut  $a_p = 0.01$  and  $0.005$  mm to be  $V_w = 100$  and  $75$  m/min, and  $200$  and  $150$  m/min (330 and 250 fpm, and 660 and 500 fpm) respectively for 10- and 30-minute wheel-life.

These high work speeds are possible using proper dressing conditions, high system stiffness, good grinding fluid quality and wheel composition.

Fig. 3 shows the variation of specific metal removal rate with wheel speed for several materials and a range of *ECT*s at 10- and 30-minutes wheel-life. *ECT* decreases when moving to the left and down along each curve. The two curves for unhardened 1020 steel have the largest values of *SMRR*, and represent the most productive grinding conditions, while the heat resistant alloy Inconel yields the least productive grinding conditions. Each

branch attains a maximum  $SMRR$  along the  $G$ -curve (compare with the same curve in the  $V$ - $ECT$  graph, Fig. 2c) and a maximum speed region along the  $H$ -curve. When the  $SMRR$ -values are lower than the  $H$ -curve the  $ECT$  values for each branch decrease towards the bottom of the graph, then the speed for constant wheel-life must be reduced due to the fact that the  $ECT$  values are to the left of their respective  $H$ -curves in  $V$ - $ECT$  graphs.

Fig. 3. Specific Metal Removal Rate versus Cutting Speed at  $T=10$  and 30 Minutes Wheel Life  
In the figure, IncX is Inconel; M4, and T-15 are tool steels; and 1020 Unh is unhardened 1020 steel.

**Surface Finish,  $R_a$ .**—The finish is improved by decreasing the value of  $ECT$  as shown in Fig. 4, where the  $R_a$  value (or  $R_{\sigma}$ , for roughness average) is plotted versus  $ECT$  at 3 different wheel lives 1, 10 and 30 minutes at constant wheel speed. Because  $ECT$  is proportional to the depth of cut, a smaller depth of cut is favorable for reducing surface roughness when the work speed is constant.

Fig. 4. Surface Finish,  $R_a$  versus  $ECT$ , Wheel-Life  $T$  Plotted

In Fig. 5,  $R_a$  is plotted versus wheel-life at 5 different  $ECT$ 's. Both Fig. 4 and Fig. 5 illustrate that a shorter life improves the surface finish, which means that either an increased wheel speed (wheel-life decreases) at constant  $ECT$ , or a smaller  $ECT$  at constant speed (wheel-life increases), will result in an improved finish. For a required surface finish,  $ECT$  and wheel-life have to be selected appropriately in order to also achieve an optimum grinding time or cost. In cylindrical grinding a reduction of side feed  $f_s$  improves  $R_a$  as well.

In terms of specific metal removal rate, reducing  $SMRR$  will improve the surface finish  $R_a$ .

Fig. 5. Surface Roughness,  $R_a$  versus Wheel Life  $T$ ,  $ECT$  Plotted

*Example 4, Specific Metal Removal Rates and Work Speeds in Rough and Finish Grinding:* The tabulated values in the following table indicate that a decreasing  $ECT$  combined with a higher wheel speed for 10 minutes wheel-life will decrease the metal removal rate and thereby increasing the grinding time. This change is accompanied by a better finish in both roughing and finishing operations. Note the high work speeds when finishing.

$ECT$ mm	Tool Life $T = 10$ minutes		Roughing Depth $a_r = 0.025$ mm	Finishing Depth $a_f = 0.0025$ mm
	Wheel speed $V_{10}$ m/min	Removal Rate $SMRR_{10}$ mm <sup>3</sup> /mm <sup>3</sup> /min	Work speed $V_w$ m/min	
0.00050	1970	985	39	390
0.00033	2580	850	34	340
0.00017	2910	500	20	200

The grit size, however, is a major parameter. Fig. 6, shows that a high wheel speed, combined with a small grit size, say 320 Mesh, can achieve  $R_a$  values as small as 0.03 micron.

Fig. 6. Wheel Speed versus Wheel Mesh,  $R_a$  Plotted

**Spark-Out Time.**—Fig. 7 shows how spark-out time varies with system stiffness. As with surface finish, when wheel-life is short (high wear rate) the spark-out time decreases.

Fig. 7. Sparkout Time versus System Stiffness, Wheel-Life  $T$  Plotted

**Equivalent Diameter (Work Conformity) Factor:** The difference in curvature of the work and wheel in the contact region, determined by the equivalent diameter or work conformity formula, is an important factor for calculating spark-out time and forces, but has a negligible influence on wheel-life. Therefore, an equivalent diameter,  $D_e = D/(1 \pm D/D_w)$ , with the minus sign for internal grinding and the plus sign for external grinding operations, is used to consider the effect of conformity when using internal and external grinding with varying work and wheel diameters.  $D_e$  is equal to the wheel diameter in surface grinding (work flat); in internal grinding, the wheel conforms closely to the work and  $D_e$  is therefore larger than in external grinding.

**Grinding Cutting Forces, Torque and Power.**—Formulas to calculate the tangential cutting force, torque and required machining power are found in *Estimating Machining Power* on page 1145, but the values of  $K_c$ , specific cutting force or specific energy, are approximately 30 to 40 times higher in grinding than in turning, milling and drilling. This is primarily due to the fact that the  $ECT$  values in grinding are 1000 to 10000 times smaller, and also due to the negative rake angles of the grit. Average grinding rake angles are around  $-35$  to  $-45$  degrees.  $K_c$  for grinding unhardened steel is around 50000 to 70000  $N/mm^2$  and up to 150000 to 200000  $N/mm^2$  for hardened steels and heat resistant alloys. The grinding cutting forces are relatively small because the chip area is very small.

Fig. 8. Specific Grinding Force  $K_c$  versus  $ECT$ ;  $V$  Plotted

As in the other metal cutting operations, the forces vary with  $ECT$  and to a smaller extent with the wheel speed  $V$ . An example is shown in Fig. 8, where  $K_c$ , specific cutting force, is plotted versus  $ECT$  at wheel speeds between 1000 and 6000 m/min. The material is medium unhardened carbon steel ground by an aluminum oxide wheel. The impact of wheel speed is relatively small (2 to 5 percent lower with increasing speed).

*Example 5:* Find the cutting force when  $ECT = 0.00017$  mm, the cutting edge length (width of cut)  $CEL$  is 10 mm, and  $K_c = 150000$  N/mm<sup>2</sup>.

The chip area is  $ECT \times CEL = 0.0017$  mm<sup>2</sup>. For  $K_c = 150000$ , the cutting force is  $0.0017 \times 150000 = 255$  Newton.

Another difference compared to turning is the influence of the negative rake angles, illustrated by the ratio of  $F_H/F_C$ , where  $F_H$  is the normal force and  $F_C$  the tangential grinding force acting in the wheel speed direction.  $F_H$  is much larger than the grinding cutting force, generally  $F_H/F_C$  ratio is approximately 2 to 4. An example is shown in Fig. 9, where  $F_H/F_C$  is plotted versus  $ECT$  at wheel speeds between 1000 and 6000 m/min, under the same conditions as in Fig. 8.

Fig. 9.  $F_H/F_C$  versus  $ECT$ ; Cutting Speed Plotted

In both Fig. 8 and Fig. 9, it is apparent that both  $K_c$  and  $F_H/F_C$  attain maximum values for given small values of  $ECT$ , in this case approximately  $ECT = 0.00005$  mm. This fact illustrates that forces and wheel-life are closely linked; for example, wheel speed has a maximum for constant wheel-life at approximately the same values of  $ECT$  shown in the two graphs (compare with the trends illustrated in Fig. 2a, Fig. 2b, Fig. 2c, and Fig. 3). As a matter of fact, force relationships obey the same type of relationships as those of wheel-life. Colding's force relationship uses the same 5 constants as the tool life equation, but requires values for the specific cutting force at  $ECT = 0.001$  and an additional constant, obtained by a special data base generator. This requires more elaborate laboratory tests, or better, the design of a special test and follow-up program for parts running in the ordinary production.

### Grinding Data Selection Including Wheel Life

The first estimate of machine settings is based on dividing work materials into 10 groups, based on grindability, as given in Table 1. Compositions of these work materials are found in the Handbook in the section *STANDARD STEELS* starting on page 393.

Grinding wheel nomenclature is described in *American National Standard Grinding Wheel Markings* starting on page 1282. The wheel compositions are selected according to the grade recommendations in the section *The Selection of Grinding Wheels* starting on page 1283. Grinding fluid recommendations are given in *Cutting Fluids for Machining* starting on page 1246.

*Note:* Maximum wheel speeds should always be checked using the safety standards in the section *Safe Operating Speeds* starting on page 1312, because the recommendations will sometimes lead to speeds above safety levels.

The material in this section is based on the use of a typical standard wheel composition such as 51-A-46-L-5-V-23, with wheel grade (wheel hardness) = L or above, and mesh (grit size) = 46 or above.

**Table 1. Grindability Groups**

Group	Examples
Group 1 Unhardened Steels	
Group 2 Stainless Steels	SAE 30201-30347, 51409-51501
Group 3 Cast Iron	
Group 4 Tool Steels	M1, M8, T1, H, O, L, F, 52100
Group 5 Tool Steels	M2, T2, T5, T6, D2, H41, H42, H43, M50
Group 6 Tool Steels	M3, M4, T3, D7
Group 7 Tool Steels	T15, M15
Group 8 Heat Resistant Steels	Inconel, Rene etc.
Group 9 Carbide Materials	P30 Diamond Wheel
Group 10 Ceramic Materials	

For each grindability group there is one table and 2 graphs (one with Taylor lines and the other with  $SMRR$  versus wheel speed  $V$ ) that are used to get a first estimate of standardized machine settings, assuming a good system stiffness ( $K_{ST} > 30 \text{ N}/\mu\text{m}$ ). These data are then calibrated with the users own data in order to refine the estimate and optimize the grinding process, as discussed in *User Calibration of Recommendations*. The recommendations are valid for all grinding processes such as plunge grinding, cylindrical, and surface grinding with periphery or side of wheel, as well as for creep feed grinding.

The grinding data machinability system is based on the basic parameters equivalent chip thickness  $ECT$ , and wheel speed  $V$ , and is used to determine specific metal removal rates  $SMRR$  and wheel-life  $T$ , including the work speed  $V_w$  after the grinding depths for roughing and finishing are specified.

For each material group, the grinding data machinability system consists of  $T$ - $V$  Taylor lines in log-log coordinates for 3 wheel speeds at wheel lives of 1, 10 and 100 minutes wheel-life with 4 different values of equivalent chip thickness  $ECT$ . The wheel speeds are designated  $V_1$ ,  $V_{10}$ , and  $V_{100}$  respectively. In each table the corresponding specific metal removal rates  $SMRR$  are also tabulated and designated as  $SMRR_1$ ,  $SMRR_{10}$  and  $SMRR_{100}$  respectively. The user can select any value of  $ECT$  and interpolate between the Taylor lines. These curves look the same in grinding as in the other metal cutting processes and the slope is set at  $n = 0.26$ , so each Taylor line is formulated by  $V \times T^{0.26} = C$ , where  $C$  is a constant tabulated at four  $ECT$  values,  $ECT = 17, 33, 50$  and  $75 \times 10^{-5} \text{ mm}$ , for each material group. Hence, for each value of  $ECT$ ,  $V_1 \times 1^{0.26} = V_{10} \times 10^{0.26} = V_{100} \times 100^{0.26} = C$ .

**Side Feed, Roughing and Finishing.**—In cylindrical grinding, the side feed,  $f_s = C \times \text{Width}$ , does not impact on the values in the tables, but on the feed rate  $F_R$ , where the fraction of the wheel width  $C$  is usually selected for roughing and in finishing operations, as shown in the following table.

Work Material	Roughing, C	Finishing, C
Unhardened Steel	2/3-3/4	1/3-3/8
Stainless Steel	1/2	1/4
Cast Iron	3/4	3/8
Hardened Steel	1/2	1/4

**Finishing:** The depth of cut in rough grinding is determined by the allowance and usually set at  $a_r = 0.01$  to  $0.025 \text{ mm}$ . The depth of cut for finishing is usually set at  $a_f = 0.0025 \text{ mm}$  and accompanied by higher wheel speeds in order to improve surface finish. However, the most important criterion for critical parts is to increase the work speed in order to avoid thermal damage and surface cracks. In cylindrical grinding, a reduction of side feed  $f_s$  improves  $R_a$  as well. Small grit sizes are very important when very small finishes are required. See Fig. 4, Fig. 5, and Fig. 6 for reference.

*Terms and Definitions* $a_a$  = depth of cut $a_r$  = radial depth of cut, mm $C$  = fraction of grinding wheel width $CEL$  = cutting edge length, mm $C_U$  = Taylor constant $D$  = wheel diameter, mm $DIST$  = grinding distance, mm $d_w$  = work diameter, mm $ECT$  = equivalent chip thickness =  $f(a_r, V, V_w f_s)$ , mm

$$= 1 \div (V \div V_w \div a_r + 1 \div f_s) = \frac{V_w f_s (a_r + 1)}{V}$$

**Relative Grindability.**—An overview of grindability of the data base, which must be based on a constant wheel wear rate, or wheel-life, is demonstrated using 10 minutes wheel-life shown in [Table 2](#).

Table 2. Grindability Overview

Material Group	$ECT \times 10^{-5}$	$V_{10}$	$SMRR_{10}$	$V_w$	
				Roughing Depth $a_r = 0.025$	Finishing Depth $a_r = 0.0025$
1 Unhardened	33	3827	1263	50	500
2 Stainless	33	1080	360	15	150
3 Cast Iron	33	4000	1320	53	530
4 Tool Steel	33	3190	1050	42	420
5 Tool Steel	33	2870	950	38	380
6 Tool Steel	33	2580	850	35	350
7 Tool Steel	33	1080	360	15	150
8 Heat resistant	33	1045	345	14	140
9 Carbide with Diamond Wheel	5	$V_{600} = 1200$	$SMRR_{600} = 50$	2	20
10 Ceramics with Diamond Wheel	5	$V_{600} = 411$	$SMRR_{600} = 21$	0.84	84

**Procedure to Determine Data.**—The following wheel-life recommendations are designed for 4 values of  $ECT = 0.00017, 0.00033, 0.00050$  and  $0.00075$  mm (shown as 17, 33, 50 and 75 in the tables). Lower values of  $ECT$  than  $0.00010$  mm ( $0.000004$  in.) are not recommended as these may lie to the left of the  $H$ -curve.

The user selects any one of the  $ECT$  values, or interpolates between these, and selects the wheel speed for 10 or 100 minutes life, denoted by  $V_{10}$  and  $V_{100}$ , respectively. For other desired wheel lives the wheel speed can be calculated from the tabulated Taylor constants  $C$  and  $n = 0.26$  as follows:

$(V \times T_{(desired)})^{0.26} = C$ , the value of which is tabulated for each  $ECT$  value.  $C$  is the value of cutting speed  $V$  at  $T = 1$  minute, hence is the same as for the speed  $V_1$ .  
 $V_1 \times 1^{0.26} = C$ , thus  $V_1 = C$

$$V_1 = C \div 1^{0.26} = C$$

$$V_{10} = C \div 10^{0.26} = C \div 1.82$$

$$V_{100} = C \div 100^{0.26} = C \div 3.31.$$

**Example 6:** A tool steel in material group 6 with  $ECT = 0.00033$ , has constant  $C = 4690$ ,  $V_{10} = 2578$  m/min, and  $V_{100} = 1417$  m/min. From this information, find the wheel speed for desired wheel-life of  $T = 15$  minutes and  $T = 45$  minutes.

For  $T = 15$  minutes we get  $V_{15} = 4690 \div 15^{0.26} = 2319$  m/min (7730 fpm) and for  $T = 45$  minutes  $V_{45} = 4690 \div 45^{0.26} = 1743$  m/min (5810 fpm).

#### The Tables are arranged in 3 sections:

1. Speeds  $V_{10}$  and  $V_1 = \text{Constant CST(standard)}$  for 4  $ECT$  values  $0.00017, 0.00033, 0.00050$  and  $0.00075$  mm. Values  $C_U$  and  $V_{10U}$  refer to user calibration of the standard values in each material group, explained in the following.

2. Speeds  $V_{100}$  (first row of 3),  $V_{10}$  and  $V_1$  (last in row) corresponding to wheel lives 100, 10 and 1 minutes, for 4  $ECT$  values  $0.00017, 0.00033, 0.00050$  and  $0.00075$  mm.

3. Specific metal removal rates  $SMRR_{100}$ ,  $SMRR_{10}$  and  $SMRR_1$  corresponding to wheel lives 100, 10 and 1 minutes, for the 4  $ECT$  values  $0.00017, 0.00033, 0.00050$ , and  $0.00075$  mm.

The 2 Graphs show: wheel life versus wheel speed in double logarithmic coordinates (Taylor lines); and,  $SMRR$  versus wheel speed in double logarithmic coordinates for 4  $ECT$  values:  $0.00017, 0.00033, 0.00050$  and  $0.00075$  mm.

### User Calibration of Recommendations

It is recommended to copy or redraw the standard graph for any of the material groups before applying the data calibration method described below. The method is based on the user's own experience and data. The procedure is described in the following and illustrated in Table 11 and Fig. 12.

Only one shop data set is needed to adjust all four Taylor lines as shown below. The required shop data is the user's wheel-life  $T_U$  obtained at the user's wheel speed  $V_U$ , the user's work speed  $V_{wU}$ , and depth of cut  $a_r$ .

1) First the user finds out which wheel-life  $T_U$  was obtained in the shop, and the corresponding wheel speed  $V_U$ , depth of cut  $a_r$ , and work speed  $V_{wU}$ .

2) Second, calculate:

a)  $ECT = V_{wU} \times ar + V_U$

b) the user Taylor constant  $C_U = V_U \times T_U^{0.26}$

c)  $V_{100U} = C_U + 100^{0.26}$

d)  $V_{10U} = C_U + 10^{0.26}$

3) Thirdly, the user Taylor line is drawn in the pertinent graph. If the user wheel-life  $T_U$  is longer than that in the standard graph the speed values will be higher, or if the user wheel-life is shorter the speeds  $C_U$ ,  $V_{10U}$ ,  $V_{100U}$  will be lower than the standard values  $C$ ,  $V_{10}$  and  $V_{100}$ .

The results are a series of lines moved to the right or to the left of the standard Taylor lines for  $ECT = 17, 33, 50$  and  $75 \times 10^{-5}$  mm. Each standard table contains the values  $C = V_1, V_{10}, V_{100}$  and empty spaces for filling out the calculated user values:  $C_U = V_U \times T_U^{0.26}$ ,  $V_{10U} = C_U + 10^{0.26}$  and  $V_{100U} = C_U + 100^{0.26}$ .

*Example 7:* Assume the following test results on a Group 6 material: user speed is  $V_U = 1800$  m/min, wheel-life  $T_U = 7$  minutes, and  $ECT = 0.00017$  mm. The Group 6 data is repeated below for convenience.

#### Standard Table Data, Group 6 Material

Tool Life $T$ (min)	$ECT = 0.00017$ mm		$ECT = 0.00033$ mm		$ECT = 0.00050$ mm		$ECT = 0.00075$ mm	
	Constant $C = 5290$		Constant $C = 4690$		Constant $C = 3585$		Constant $C = 2395$	
	$V_T$	$SMRR$	$V_T$	$SMRR$	$V_T$	$SMRR$	$V_T$	$SMRR$
100	1600	270	1415	465	1085	540	725	540
10	2910	495	2580	850	1970	985	1315	985
1	5290	900	4690	1550	3585	1795	2395	1795

Fig. 11a. Group 6 Tool Steels,  $T$ - $V$

Fig. 11b.  $SMRR$  versus  $V$ ,  $T = 100, 10, 1$  minutes

## Calculation Procedure

1) Calculate  $V_{1U}$ ,  $V_{10U}$ ,  $V_{100U}$  and  $SMRR_{1U}$ ,  $SMRR_{10U}$ ,  $SMRR_{100U}$  for  $ECT=0.00017$  mm

a)  $V_{1U}$  = the user Taylor constant  $C_U = V_U \times T_U^{0.26} = 1800 \times 7^{0.26} = 2985$  m/min,  
and  $SMRR_{1U} = 1000 \times 2985 \times 0.00017 = 507$  mm<sup>3</sup>/mm width/min

b)  $V_{10U} = C_U \div 10^{0.26} = 2985 \div 10^{0.26} = 1640$  m/min, and  $SMRR_{10U} = 1000 \times 1640 \times 0.00017 = 279$  mm<sup>3</sup>/mm width/min

c)  $V_{100U} = C_U \div 100^{0.26} = 2985 \div 100^{0.26} = 900$  m/min, and  $SMRR_{100U} = 1000 \times 900 \times 0.00017 = 153$  mm<sup>3</sup>/mm width/min

2) For  $ECT = 0.00017$  mm, calculate the ratio of user Taylor constant to standard Taylor constant from the tables  $= C_U \div C_{ST} = C_U \div V_1 = 2985 \div 5290 = 0.564$  (see Table 6 for the value of  $C_{ST} = V_1$  at  $ECT = 0.00017$  mm).

3) For  $ECT = 0.00033$ ,  $0.00050$ , and  $0.00075$  mm calculate the user Taylor constants from  $C_U = C_{ST} \times$  (the ratio calculated in step 2)  $= V_1 \times 0.564 = V_{1U}$ . Then, calculate  $V_{10U}$  and  $V_{100U}$  and  $SMRR_{1U}$ ,  $SMRR_{10U}$ ,  $SMRR_{100U}$  using the method in items 1b) and 1c) above.

a) For  $ECT = 0.00033$  mm

$$V_{1U} = C_U = 4690 \times 0.564 = 2645 \text{ m/min}$$

$$V_{10U} = C_U \div 10^{0.26} = 2645 \div 10^{0.26} = 1455 \text{ m/min}$$

$$V_{100U} = C_U \div 100^{0.26} = 2645 \div 100^{0.26} = 800 \text{ m/min}$$

$$SMRR_{1U}, SMRR_{10U}, \text{ and } SMRR_{100U} = 876, 480, \text{ and } 264 \text{ mm}^3/\text{mm width/min}$$

b) For  $ECT = 0.00050$  mm

$$V_{1U} = C_U = 3590 \times 0.564 = 2025 \text{ m/min}$$

$$V_{10U} = C_U \div 10^{0.26} = 2025 \div 10^{0.26} = 1110 \text{ m/min}$$

$$V_{100U} = C_U \div 100^{0.26} = 2025 \div 100^{0.26} = 610 \text{ m/min}$$

$$SMRR_{1U}, SMRR_{10U}, \text{ and } SMRR_{100U} = 1013, 555, \text{ and } 305 \text{ mm}^3/\text{mm width/min}$$

c) For  $ECT = 0.00075$  mm

$$V_{1U} = C_U = 2395 \times 0.564 = 1350 \text{ m/min}$$

$$V_{10U} = C_U \div 10^{0.26} = 1350 \div 10^{0.26} = 740 \text{ m/min}$$

$$V_{100U} = C_U \div 100^{0.26} = 1350 \div 100^{0.26} = 405 \text{ m/min}$$

$$SMRR_{1U}, SMRR_{10U}, \text{ and } SMRR_{100U} = 1013, 555, \text{ and } 305 \text{ mm}^3/\text{mm width/min}$$

Thus, the wheel speed for any desired wheel-life at a given  $ECT$  can be calculated from  $V = C_U \div T^{0.26}$ . For example, at  $ECT = 0.00050$  mm and desired tool life  $T = 9$ ,  $V_0 = 2025 \div 9^{0.26} = 1144$  m/min. The corresponding specific metal removal rate is  $SMRR = 1000 \times 1144 \times 0.0005 = 572$  mm<sup>3</sup>/mm width/min (0.886 in<sup>3</sup>/inch width/min).

**Table 11. User Calculated Data, Group 6 Material**

Tool Life $T$ (min)	$ECT = 0.00017$ mm		$ECT = 0.00033$ mm		$ECT = 0.00050$ mm		$ECT = 0.00075$ mm	
	User Constant $C_U = 2985$		User Constant $C_U = 2645$		User Constant $C_U = 2025$		User Constant $C_U = 1350$	
	$V_T$	$SMRR$	$V_T$	$SMRR$	$V_T$	$SMRR$	$V_T$	$SMRR$

<b>10</b>	<b>1640</b>	<b>279</b>	<b>1455</b>	<b>480</b>	<b>1110</b>	<b>555</b>	<b>740</b>	<b>555</b>
1	2985	507	2645	876	2025	1013	1350	1013

Fig. 12. Calibration of User Grinding Data to Standard Taylor Lines  
User Input:  $V_U = 1800$  m/min,  $T_U = 7$  minutes,  $ECT = 0.00017$  mm

**Optimization.**—As shown, a global optimum occurs along the  $G$ -curve, in selected cases for values of  $ECT$  around 0.00075, i.e. at high metal removal rates as in other machining operations. It is recommended to use the simple formula for economic life:  $T_E = 3 \times T_V$  minutes.  $T_V = T_{RPL} + 60 \times C_E + H_R$ , minutes, where  $T_{RPL}$  is the time required to replace wheel,  $C_E$  = cost per wheel dressing = wheel cost + cost per dressing, and  $H_R$  is the hourly rate.

In grinding, values of  $T_V$  range between 2 and 5 minutes in conventional grinders, which means that the economic wheel lives range between 6 and 15 minutes indicating higher metal removal rates than are commonly used. When wheels are sharpened automatically after each stroke as in internal grinding, or when grits are continually replaced as in abrasive grinding (machining),  $T_V$  may be less than one minute. This translates into wheel lives around one minute in order to achieve minimum cost grinding.

**Grinding Cost, Optimization and Process Planning:** More accurate results are obtained when the firm collects and systemizes the information on wheel lives, wheel and work speeds, and depths of cut from production runs. A computer program can be used to plan the grinding process and apply the rules and formulas presented in this chapter. A complete grinding process planning program, such as that developed by Colding International Corporation, can be used to optimize machine settings for various feed-speed preferences corresponding wheel-life requirements, minimum cost or maximum production rate grinding, required surface finish and sparkout time; machine and fixture requirements based on the grinding forces, torque and power for sharp and worn grinding wheels; and, detailed time and cost analysis per part and per batch including wheel dressing and wheel changing schedules.

Table 12 summarizes the time and cost savings per batch as it relates to tool life. The sensitivity of how grinding parameters are selected is obvious. Minimum cost conditions yield a 51 percent reduction of time and 44 percent reduction of cost, while maximum production rate reduces total time by 65 percent but, at the expense of heavy wheel consumption (continuous dressing), cost by only 18 percent.

Table 12. Wheel Life versus Cost

Preferences	Time per Batch, minutes	Cost per Batch, \$		Reduction from Long Life, %	
		Tooling	Total Cost	Time	Cost
Long Life	2995	39	2412	—	—
Economic Life	2433	252	2211	19	8
Minimum Cost	1465	199	1344	51	44
Max Production Rate	1041	1244	1980	65	18

### GRINDING AND OTHER ABRASIVE PROCESSES

Processes and equipment discussed under this heading use abrasive grains for shaping workpieces by means of machining or related methods. Abrasive grains are hard crystals either found in nature or manufactured. The most commonly used materials are aluminum oxide, silicon carbide, cubic boron nitride and diamond. Other materials such as garnet, zirconia, glass and even walnut shells are used for some applications. Abrasive products are used in three basic forms by industry:

- a) *Bonded* to form solid-shaped tools, such as disks (the basic shape of grinding wheels), cylinders, rings, cups, segments, or sticks to name a few.
- b) *Coated* on backings made of paper or cloth, in the form of sheets, strips, or belts.
- c) *Loose*, held in some liquid or solid carrier (for lapping, polishing, tumbling), or propelled by centrifugal force, air, or water pressure against the work surface (blast cleaning).

The applications for abrasive processes are multiple and varied. They include:

- a) *Cleaning* of surfaces, also the coarse removal of excess material—such as rough off-hand grinding in foundries to remove gates and risers.
- b) *Shaping*, such as in form grinding and tool sharpening.
- c) *Sizing*, a general objective, but of primary importance in precision grinding.
- d) *Surface finish improvement*, either primarily as in lapping, honing, and polishing or as a secondary objective in other types of abrasive processes.
- e) *Separating*, as in cut-off or slicing operations.

The main field of application of abrasive processes is in metalworking, because of the capacity of abrasive grains to penetrate into even the hardest metals and alloys. However, the great hardness of the abrasive grains also makes the process preferred for working other hard materials, such as stones, glass, and certain types of plastics. Abrasive processes are also chosen for working relatively soft materials, such as wood, rubber, etc., for such reasons as high stock removal rates, long-lasting cutting ability, good form control, and fine finish of the worked surface.

#### Grinding Wheels

**Abrasive Materials.**—In earlier times, only natural abrasives were available. From about the beginning of this century, however, manufactured abrasives, primarily silicon carbide and aluminum oxide, have replaced the natural materials; even natural diamonds have been almost completely supplanted by synthetics. Superior and controllable properties, and dependable uniformity characterize the manufactured abrasives.

Both silicon carbide and aluminum oxide abrasives are very hard and brittle. This brittleness, called friability, is controllable for different applications. Friable abrasives break easily, thus forming sharp edges. This decreases the force needed to penetrate into the work material and the heat generated during cutting. Friable abrasives are most commonly used for precision and finish grinding. Tough abrasives resist fracture and last longer. They are used for rough grinding, snagging, and off-hand grinding.

As a general rule, although subject to variation:

- 1) Aluminum oxide abrasives are used for grinding plain and alloyed steel in a soft or hardened condition.
- 2) Silicon carbide abrasives are selected for cast iron, nonferrous metals, and nonmetallic materials.
- 3) Diamond is the best type of abrasive for grinding cemented carbides. It is also used for grinding glass, ceramics, and hardened tool steel.

4) Cubic Boron Nitride (CBN) is known by several trade names including Borazon (General Electric Co.), ABN (De Beers), Sho-bon (Showa-Denko), and Elbor (USSR). CBN is a synthetic superabrasive used for grinding hardened steels and wear-resistant superalloys. (See *Cubic Boron Nitride (CBN)* starting on page 1081.) CBN grinding wheels have long lives and can maintain close tolerances with superior surface finishes.

**Bond Properties and Grinding Wheel Grades.**—The four main types of bonds used for grinding wheels are the vitrified, resinoid, rubber, and metal.

*Vitrified bonds* are used for more than half of all grinding wheels made, and are preferred because of their strength and other desirable qualities. Being inert, glass-like materials, vitrified bonds are not affected by water or by the chemical composition of different grinding fluids. Vitrified bonds also withstand the high temperatures generated during normal grinding operations. The structure of vitrified wheels can be controlled over a wide range of strength and porosity. Vitrified wheels, however, are more sensitive to impact than those made with organic bonds.

*Resinoid bonds* are selected for wheels subjected to impact, or sudden loads, or very high operating speeds. They are preferred for snagging, portable grinder uses, or roughing operations. The higher flexibility of this type of bond—essentially a filled thermosetting plastic—helps it withstand rough treatment.

*Rubber bonds* are even more flexible than the resinoid type, and for that reason are used for producing a high finish and for resisting sudden rises in load. Rubber bonded wheels are commonly used for wet cut-off wheels because of the nearly burr-free cuts they produce, and for centerless grinder regulating wheels to provide a stronger grip and more reliable workpiece control.

*Metal bonds* are used in CBN and diamond wheels. In metal bonds produced by electro-deposition, a single layer of superabrasive material (diamond or CBN) is bonded to a metal core by a matrix of metal, usually nickel. The process is so controlled that about 30–40 percent of each abrasive particle projects above the deposited surface, giving the wheel a very aggressive and free-cutting action. With proper use, such wheels have remarkably long lives. When dulled, or worn down, the abrasive can be stripped off and the wheel renewed by a further deposit process. These wheels are also used in electrical discharge grinding and electrochemical grinding where an electrically conductive wheel is needed.

In addition to the basic properties of the various bond materials, each can also be applied in different proportions, thereby controlling the grade of the grinding wheel.

*Grinding wheel grades* commonly associated with hardness, express the amount of bond material in a grinding wheel, and hence the strength by which the bond retains the individual grains.

During grinding, the forces generated when cutting the work material tend to dislodge the abrasive grains. As the grains get dull and if they don't fracture to resharpen themselves, the cutting forces will eventually tear the grains from their supporting bond. For a "soft" wheel the cutting forces will dislodge the abrasive grains before they have an opportunity to fracture. When a "hard" wheel is used, the situation is reversed. Because of the extra bond in the wheel the grains are so firmly held that they never break loose and the wheel becomes glazed. During most grinding operations it is desirable to have an intermediate wheel where there is a continual slow wearing process composed of both grain fracture and dislodgement.

The grades of the grinding wheels are designated by capital letters used in alphabetical order to express increasing "hardness" from A to Z.

**Grinding Wheel Structure.**—The individual grains, which are encased and held together by the bond material, do not fill the entire volume of the grinding wheel; the intermediate open space is needed for several functional purposes such as heat dissipation, coolant application, and particularly, for the temporary storage of chips. It follows that the spacing of the grains must be greater for coarse grains which cut thicker chips and

for large contact areas within which the chips have to be retained on the surface of the wheel before being disposed of. On the other hand, a wide spacing reduces the number of grains that contact the work surface within a given advance distance, thereby producing a coarser finish.

In general, denser structures are specified for grinding hard materials, for high-speed grinding operations, when the contact area is narrow, and for producing fine finishes and/or accurate forms. Wheels with open structure are used for tough materials, high stock removal rates, and extended contact areas, such as grinding with the face of the wheel. There are, however, several exceptions to these basic rules, an important one being the grinding of parts made by powder metallurgy, such as cemented carbides; although they represent one of the hardest industrial materials, grinding carbides requires wheels with an open structure.

Most kinds of general grinding operations, when carried out with the periphery of the wheel, call for medium spacing of the grains. The structure of the grinding wheels is expressed by numerals from 1 to 16, ranging from dense to open. Sometimes, "induced porosity" is used with open structure wheels. This term means that the grinding wheel manufacturer has placed filler material (which later burns out when the wheel is fired to vitrify the bond) in the grinding wheel mix. These fillers create large "pores" between grain clusters without changing the total volume of the "pores" in the grinding wheel. Thus, an A46-H12V wheel and an A46H12VP wheel will contain the same amounts of bond, abrasive, and air space. In the former, a large number of relatively small pores will be distributed throughout the wheel. The latter will have a smaller number of larger pores.

**American National Standard Grinding Wheel Markings.**—ANSI B74.13-2016 "Markings for Identifying Grinding Wheels and Other Bonded Abrasives," applies to grinding wheels and other bonded abrasives, segments, bricks, sticks, hones, rubs, and other shapes that are for removing material, or producing a desired surface or dimension. It does not apply to specialities such as sharpening stones and provides only a standard system of markings. Wheels having the same standard markings but made by different wheel manufacturers may not—and probably will not—produce exactly the same grinding action. This desirable result cannot be obtained because of the impossibility of closely correlating any measurable physical properties of bonded abrasive products in terms of their grinding action.

Symbols for designating diamond and cubic boron wheel compositions are given on page 1307.

**Sequence of Markings.**—The accompanying illustration taken from ANSI B74.13-2016 shows the make-up of a typical wheel or bonded abrasive marking.

Prefix	1 Abrasive Type	2 Grain Size	3 Grade	4 Structure	5 Bond Type	6 Manufacturer's Record
	<b>51</b>	<b>— A —</b>	<b>36</b>	<b>— L —</b>	<b>5</b>	<b>— V — 23</b>

The meaning of each letter and number in this or other markings is indicated by the following complete list.

1) *Abrasive Letters:* The letter (A) is used for aluminum oxide, (C) for silicon carbide, and (Z) for aluminum zirconium. The manufacturer may designate some particular type in any one of these broad classes, by using his own symbol as a prefix (example, 51).

2) *Grain Size:* The grain sizes commonly used and varying from coarse to very fine are indicated by the following numbers: 8, 10, 12, 14, 16, 20, 24, 30, 36, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 220. The following additional sizes are used occasionally: 240, 280, 320, 400, 500, and 600. The wheel manufacturer may add to the regular grain number an additional symbol to indicate a special grain combination.

3) *Grade*: Grades are indicated by letters of the alphabet from A to Z in all bonds or processes. Wheel grades from A to Z range from soft to hard.

4) *Structure*: The use of a structure symbol is optional. The structure is indicated by Nos. 1 to 16 (or higher, if necessary) with progressively higher numbers indicating a progressively wider grain spacing (more open structure).

5) *Bond or Process*: Bonds are indicated by the following letters: V, vitrified; S, silicate; E, shellac or elastic; R, rubber; RF, rubber reinforced; B, resinoid (synthetic resins); BF, resinoid reinforced; O, oxychloride; P, Epoxy/Polyester.

6) *Manufacturer's Record*: The sixth position may be used for manufacturer's private factory records; this is optional.

**Standard Shapes and Sizes of Grinding Wheels.**—ANSI B74.2-2003 which includes shapes and sizes of grinding wheels, gives a wide variety of grinding wheel shape and size combinations. These are suitable for the majority of applications. Although grinding wheels can be manufactured to shapes and dimensions different from those listed, it is advisable, for reasons of cost and inventory control, to avoid using special shapes and sizes, unless technically warranted.

Standard shapes and size ranges as given in this Standard together with typical applications are shown in [Table 1a](#) for inch dimensions and in [Table 1b](#) for metric dimensions.

The operating surface of the grinding wheel is often referred to as the wheel face. In the majority of cases it is the periphery of the grinding wheel which, when not specified otherwise, has a straight profile. However, other face shapes can also be supplied by the grinding wheel manufacturers, and also reproduced during usage by appropriate truing. ANSI B74.2-2003 standard offers 15 different shapes for grinding wheel faces, which are shown in [Table 2](#).

**The Selection of Grinding Wheels.**—In selecting a grinding wheel, the determining factors are the composition of the work material, the type of grinding machine, the size range of the wheels used, and the expected grinding results, in this approximate order.

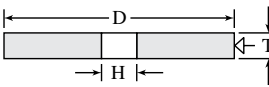

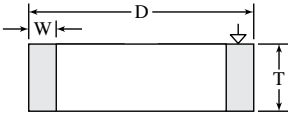

The Norton Company has developed, as the result of extensive test series, a method of grinding wheel recommendation that is more flexible and also better adapted to taking into consideration pertinent factors of the job, than are listings based solely on workpiece categories. This approach is the basis for [Table 3](#) through [Table 6](#), inclusive. Tool steels and constructional steels are considered in the detailed recommendations presented in these tables.

[Table 3](#) assigns most of the standardized tool steels to five different grindability groups. The AISI-SAE tool steel designations are used.

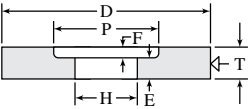

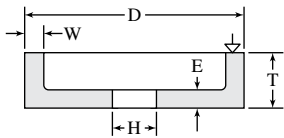

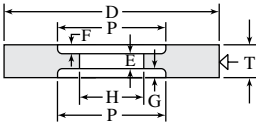

After having defined the grindability group of the tool steel to be ground, the operation to be carried out is found in the first column of [Table 4](#). The second column in this table distinguishes between different grinding wheel size ranges, because wheel size is a factor in determining the contact area between wheel and work, thus affecting the apparent hardness of the grinding wheel. Distinction is also made between wet and dry grinding.

Finally, the last two columns define the essential characteristics of the recommended types of grinding wheels under the headings of first and second choice, respectively. Where letters are used *preceding* A, the standard designation for aluminum oxide, they indicate a degree of friability different from the regular, thus: SF = semi friable (Norton equivalent 16A) and F = friable (Norton equivalent 33A and 38A). The suffix P, where applied, expresses a degree of porosity that is more open than the regular.

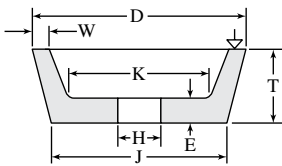

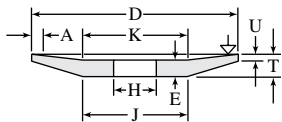

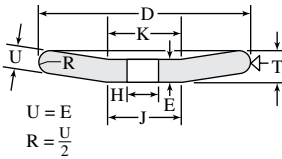

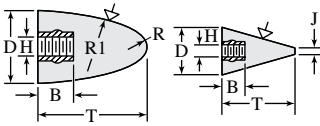

**Table 1a. Standard Shapes and Inch Size Ranges of Grinding Wheels**  
ANSI B74.2-2003

Applications	Size Ranges of Principal Dimensions, Inches		
	D = Dia.	T = Thick.	H = Hole
 <p><b>Type 1. Straight Wheel</b> For peripheral grinding.</p>			
CUTTING OFF (Organic bonds only)	1 to 48	1/4 to 3/8	1/16 to 6

	<p><b>TYPES 27 &amp; 27A. Wheel, Depressed Center</b> 27. <i>Portable Grinding:</i> Grinding normally done by contact with work at approx. a 15° angle with face of the wheel. 27A. <i>Cutting-off:</i> Using the periphery as grinding face.</p>		
<p>CUTTING OFF Reinforced organic bonds only</p>	16 to 30	$U = E = \frac{1}{2}$ to $\frac{3}{4}$	1 or 1 $\frac{1}{2}$
<p>SNAGGING Portable machine</p>	3 to 9	$U =$ Uniform thick. $\frac{1}{8}$ to $\frac{3}{8}$	$\frac{3}{8}$ or $\frac{7}{8}$
	<p><b>Type 28. Wheel, Depressed Center (Saucer-Shaped Grinding Face)</b> Grinding at approx. 15° angle with wheel face.</p>		
<p>SNAGGING Portable machine</p>	7 or 9	$U =$ Uniform thickness $\frac{1}{4}$	$\frac{7}{8}$

Throughout table large open-head arrows indicate grinding surfaces.

**Table 1b. Standard Shapes and Metric Size Ranges of Grinding Wheels**  
ANSI B74.2-2003

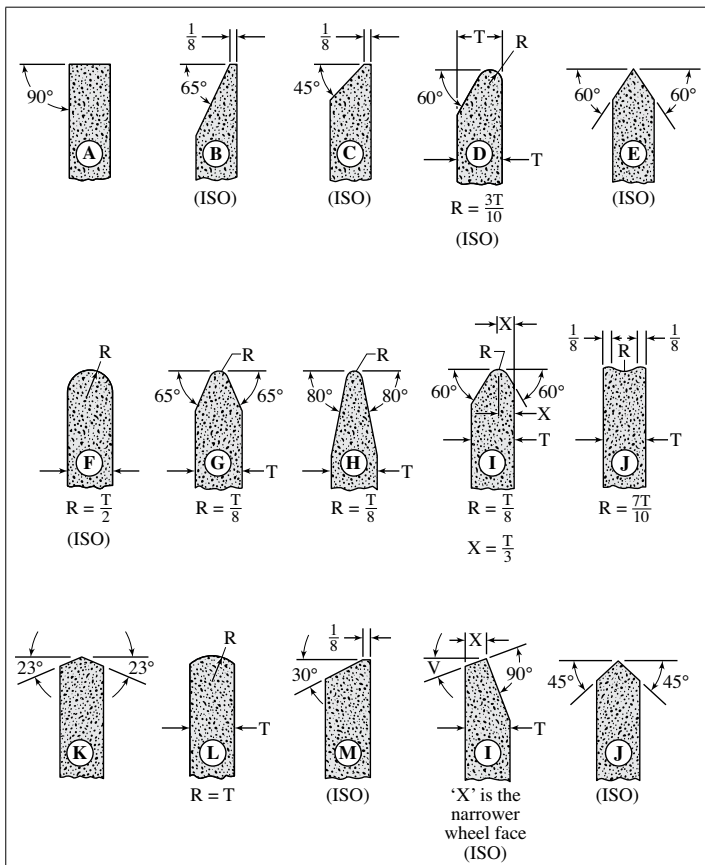

Applications	Size Ranges of Principal Dimensions, Millimeters		
	D = Diam.	T = Thick.	H = Hole
<b>Type 1. Straight Wheel*</b>			
CUTTING OFF (nonreinforced and reinforced organic bonds only)	150 to 1250	0.8 to 10	16 to 152.4
CYLINDRICAL GRINDING Between centers	300 to 1250	20 to 160	127 to 508
CYLINDRICAL GRINDING Centerless grinding wheels	350 to 750	25 to 500	127 or 304.8
CYLINDRICAL GRINDING Centerless regulating wheels	200 to 350	25 to 315	76.2 to 152.4
INTERNAL GRINDING	6 to 100	6 to 50	2.5 to 25
OFFHAND GRINDING Grinding on the periphery			
General purpose	150 to 900	13 to 100	20 to 76.2
For wet tool grinding only	750 or 900	80 or 100	508
SAW GUMMING (F-type face)	150 to 300	6 to 40	32
SNAGGING Floor stand machines	300 to 600	25 to 80	32 to 76.2
SNAGGING Floor stand machines(organic bond, wheel speed over 33 meters per second)	500 to 900	50 to 100	152.4 or 304.8
SNAGGING Mechanical grinders (organic bond, wheel speed up to 84 meters per second)	600	50 to 80	304.8
SNAGGING Portable machines	80 to 200	6 to 25	10 to 16
SNAGGING Swing frame machines (organic bond)	300 to 600	50 to 80	88.9 to 304.8
SURFACE GRINDING Horizontal spindle machines	150 to 600	13 to 160	32 to 304.8
TOOL GRINDING Broaches, cutters, mills, reamers, taps, etc.	150 to 250	6 to 20	32 to 127
<b>Type 2. Cylindrical Wheels*</b>			
			W = Wall
SURFACE GRINDING Vertical spindle machines	200 to 500	100 or 125	25 to 100

**Table 1b. (Continued) Standard Shapes and Metric Size Ranges of Grinding Wheels**  
ANSI B74.2-2003

Applications	Size Ranges of Principal Dimensions, Millimeters		
	D = Diam.	T = Thick.	H = Hole
<b>Type 5. Wheel, recessed one side<sup>a</sup></b>			
CYLINDRICAL GRINDING Between centers	300 to 900	40 to 100	127 or 304.8
CYLINDRICAL GRINDING Centerless regulating wheels	200 to 350	80 to 160	76.2 or 127
INTERNAL GRINDING	10 to 100	10 to 50	3.18 to 25
<b>Type 6. Straight-Cup Wheel<sup>a</sup></b>			
			W = Wall
SNAGGING Portable machines, organic bond only (hole is $\frac{5}{16}$ -11 UNC-2B)	100 to 150	50	20 to 40
TOOL GRINDING Broaches, cutters, mills, reamers, taps, etc. (Hole is 13 to 32 mm)	50 to 150	32 to 50	8 or 10
<b>Type 7. Wheel, recessed two sides<sup>a</sup></b>			
CYLINDRICAL GRINDING Between centers	300 to 900	40 to 100	127 or 304.8
CYLINDRICAL GRINDING Centerless regulating wheels	200 to 350	100 to 500	76.2 to 152.4
<b>Type 11. Flaring-Cup Wheel<sup>a</sup></b>			
SNAGGING Portable machines, organic bonds only, threaded hole	100 to 150	50	$\frac{5}{16}$ -11 UNC-2B
TOOL GRINDING Broaches, cutters, mills, reamers, taps, etc.	50 to 125	32 to 50	13 to 32
<b>Type 12. Dish Wheel<sup>a</sup></b>			
TOOL GRINDING Broaches, cutters, mills, reamers, taps, etc.	80 to 200	13 or 20	13 to 32
<b>Type 27 and 27A. Wheel, depressed center<sup>a</sup></b>			
CUTTING OFF Reinforced organic bonds only	400 to 750	$U = E = 6$	25.4 or 38.1
SNAGGING Portable machines	80 to 230	$U = E = 3.2$ to 10	9.53 or 22.23

<sup>a</sup> See Table 1a for diagrams and descriptions of each wheel type.  
All dimensions in millimeters.

Table 2. Standard Shapes of Grinding Wheel Faces ANSI B74.2-2003

Recommendations, similar in principle, yet somewhat less discriminating have been developed by the Norton Company for *constructional steels*. These materials can be ground either in their original state (soft) or in their after-hardened state (directly or following carburization). Constructional steels must be distinguished from structural steels which are used primarily by the building industry in mill shapes, without or with a minimum of machining.

Constructional steels are either plain carbon or alloy type steels assigned in the AISI-SAE specifications to different groups, according to the predominant types of alloying elements. In the following recommendations no distinction is made because of different compositions since that factor generally, has a minor effect on grinding wheel choice in constructional steels. However, separate recommendations are made for soft (Table 5) and hardened (Table 6) constructional steels. For the relatively rare instance

where the use of a single type of wheel for both soft and hardened steel materials is considered more important than the selection of the best suited types for each condition of the work materials, Table 5 lists "All Around" wheels in its last column.

For applications where cool cutting properties of the wheel are particularly important, Table 6 lists, as a second alternative, porous-type wheels. The sequence of choices as presented in these tables does not necessarily represent a second, or third best; it can also apply to conditions where the first choice did not provide optimum results and by varying slightly the composition of the grinding wheel, as indicated in the subsequent choices, the performance experience of the first choice might be improved.

**Table 3. Classification of Tool Steels by their Relative Grindability**

Relative Grindability Group	AISI-SAE Designation of Tool Steels
<p><i>GROUP 1—Any area of work surface</i></p> <p>High grindability tool and die steels (Grindability index greater than 12)</p>	<p>W1, W2, W5 S1, S2, S4, S5, S6, S7 O1, O2, O6, O7 H10, H11, H12, H13, H14 L2, L6</p>
<p><i>GROUP 2—Small area of work surface (as found in tools)</i></p> <p>Medium grindability tool and die steels (Grindability index 3 to 12)</p>	<p>H19, H20, H21, H22, H23, H24, H26 P6, P20, P21 T1, T7, T8 M1, M2, M8, M10, M33, M50 D1, D2, D3, D4, D5, D6 A2, A4, A6, A8, A9, A10</p>
<p><i>GROUP 3—Small area of work surface (as found in tools)</i></p> <p>Low grindability tool and die steels (Grindability index between 1.0 and 3)</p>	<p>T4, T5, T6, T8 M3, M6, M7, M34, M36, M41, M42, M46, M48, M52, M62 D2, D5 A11</p>
<p><i>GROUP 4—Large area of work surface (as found in dies)</i></p> <p>Medium and low grindability tool and die steels (Grindability index between 1.0 and 12)</p>	<p>All steels found in Groups 2 and 3</p>
<p><i>GROUP 5—Any area of work surface</i></p> <p>Very low grindability tool and die steels (Grindability index less than 1.0)</p>	<p>D3, D4, D7 M4 A7 T15</p>

**Cubic Boron Nitride (CBN) Grinding Wheels.**—Although CBN is not quite as hard, strong, and wear-resistant as a diamond, it is far harder, stronger, and more resistant to wear than aluminum oxide and silicon carbide. As with diamond, CBN materials are available in different types for grinding workpieces of 50 RC (Rockwell C scale) and above, and for superalloys of 35 RC and harder. Microcrystalline CBN grinding wheels are suitable for grinding mild steels, medium-hard alloy steels, stainless steels, cast irons, and forged steels. Wheels with larger mesh size grains (up to 20/30), now available, provide for higher rates of metal removal.

Special types of CBN are produced for resin, vitrified, and electrodeposited bonds. Wheel standards and nomenclature generally conform to those used for diamond wheels (page 1304), except that the letter **B** instead of **D** is used to denote the type of abrasive. Grinding machines for CBN wheels are generally designed to take full advantage of the ability of CBN to operate at high surface speeds of 9,000–25,000 sfm (2745–7620 m/min). CBN is very responsive to changes in grinding conditions, and an increase in wheel speed from 5,000 to 10,000 sfm (1525–3050 m/min) can increase wheel life by a factor of 6 or more. A change from a water-based coolant to a coolant such as a sulfochlorinated or sulfurized straight grinding oil can increase wheel life by a factor of 10 or more.

Machines designed specifically for use with CBN grinding wheels generally use either electrodeposited wheels or have special truing systems for other CBN bond wheels, and are totally enclosed so they can use oil as a coolant. Numerical control systems are used, often running fully automatically, including loading and unloading. Machines designed for CBN grinding with electrodeposited wheels are extensively used for form and gear grinding, special systems being used to ensure rapid mounting to exact concentricity and truth in running, no truing or dressing being required. CBN wheels can produce workpieces having excellent accuracy and finish, with no truing or dressing for the life of the wheel, even over many hours or days of production grinding of hardened steel components.

Resin-, metal-, and vitrified-bond wheels are used extensively in production grinding, in standard and special machines. Resin-bonded wheels are used widely for dry tool and cutter resharpening on conventional hand-operated tool and cutter grinders. A typical wheel for such work would be designated 11V9 cup type, 100/120 mesh, 75 concentration, with a  $\frac{1}{16}$  or  $\frac{1}{8}$  inch (1.6 or 3.2 mm) rim section. Special shapes of resin-bonded wheels are used on dedicated machines for cutting tool manufacture. These types of wheels are usually self-dressing, and allow full machine control of the operation without the need for an operator to see, hear, or feel the action.

Metal-bonded CBN wheels are usually somewhat cheaper than those using other types of bond because only a thin layer of abrasive is present. Metal bonding is also used in manufacture of CBN honing stones. Vitrified-bond CBN wheels are a recent innovation, and high-performance bonds are still being developed. These wheels are used for grinding cams, internal diameters, and bearing components, and can be easily redressed.

An important aspect of grinding with CBN and diamond wheels is reduced heating of the workpiece, thought to result from their superior thermal conductivity compared with aluminum oxide, for instance. CBN and diamond grains also are harder, which means that they stay sharp longer than aluminum oxide grains. The superior ability to absorb heat from the workpiece during the grinding process reduces formation of untempered martensite in the ground surface, caused by overheating followed by rapid quenching. At the same time, a higher compressive residual stress is induced in the surface, giving increased fatigue resistance, compared with the tensile stresses found in surfaces ground with aluminum oxide abrasives. Increased fatigue resistance is of particular importance for gear grinding, especially in the root area.

**Variations from General Grinding Wheel Recommendations.**—Recommendations for the selection of grinding wheels are usually based on average values with regard to

both operational conditions and process objectives. With variations from such average values, the composition of the grinding wheels must be adjusted to obtain optimum results. Although it is impossible to list and to appraise all possible variations and to define their effects on the selection of the best suited grinding wheels, some guidance is obtained from experience. The following tabulation indicates the general directions in which the characteristics of the initially selected grinding wheel may have to be altered in order to approach optimum performance. Variations in a sense opposite to those shown will call for wheel characteristic changes in reverse.

Conditions or Objectives	Direction of Change
To increase cutting rate	Coarser grain, softer bond, higher porosity
To retain wheel size and/or form	Finer grain, harder bond
For small or narrow work surface	Finer grain, harder bond
For larger wheel diameter	Coarser grain
To improve finish on work	Finer grain, harder bond, or resilient bond
For increased work speed or feed rate	Harder bond
For increased wheel speed	Generally, softer bond, except for high-speed grinding, which requires a harder bond for added wheel strength
For interrupted or coarse work surface	Harder bond
For thin walled parts	Softer bond
To reduce load on the machine drive motor	Softer bond

**Dressing and Truing Grinding Wheels.**—The perfect grinding wheel operating under ideal conditions will be self sharpening, i.e., as the abrasive grains become dull, they will tend to fracture and be dislodged from the wheel by the grinding forces, thereby exposing new, sharp abrasive grains. Although in precision machine grinding this ideal sometimes may be partially attained, it is almost never attained completely. Usually, the grinding wheel must be dressed and trued after mounting on the precision grinding machine spindle and periodically thereafter.

Dressing may be defined as any operation performed on the face of a grinding wheel that improves its cutting action. Truing is a dressing operation but is more precise, i.e., the face of the wheel may be made parallel to the spindle or made into a radius or special shape. Regularly applied truing is also needed for accurate size control of the work, particularly in automatic grinding. The tools and processes generally used in grinding wheel dressing and truing are listed and described in [Table 1](#).

**Table 1. Tools and Methods for Grinding Wheel Dressing and Truing**

Designation	Description	Application
Rotating Hand Dressers	Freely rotating discs, either star-shaped with protruding points or discs with corrugated or twisted perimeter, supported in a fork-type handle, the lugs of which can lean on the tool rest of the grinding machine.	Preferred for bench- or floor-type grinding machines; also for use on heavy portable grinders (snagging grinders) where free-cutting properties of the grinding wheel are primarily sought and the accuracy of the trued profile is not critical.
Abrasive Sticks	Made of silicon carbide grains with a hard bond. Applied directly or supported in a handle. Less frequently abrasive sticks are also made of boron carbide.	Usually hand held and use limited to smaller-size wheels. Because it also shears the grains of the grinding wheel, or preshaping, prior to final dressing with, e.g., a diamond.

**Table 1. (Continued) Tools and Methods for Grinding Wheel Dressing and Truing**

Designation	Description	Application
Abrasive Wheels (Rolls)	Silicon carbide grains in a hard vitrified bond are cemented on ball-bearing mounted spindles. Use either as hand tools with handles or rigidly held in a supporting member of the grinding machine. Generally freely rotating; also available with adjustable brake for diamond wheel dressing.	Preferred for large grinding wheels as a diamond saver, but also for improved control of the dressed surface characteristics. By skewing the abrasive dresser wheel by a few degrees out of parallel with the grinding wheel axis, the basic crushing action is supplemented with wiping and shearing, thus producing the desired degree of wheel surface smoothness.
Single-Point Diamonds	A diamond stone of selected size is mounted in a steel nib of cylindrical shape with or without head, dimensioned to fit the truing spindle of specific grinding machines. Proper orientation and retainment of the diamond point in the setting is an important requirement.	The most widely used tool for dressing and truing grinding wheels in precision grinding. Permits precisely controlled dressing action by regulating infeed and cross feed rate of the truing spindle when the latter is guided by cams or templates for accurate form truing.
Single-Point Form Truing Diamonds	Selected diamonds having symmetrically located natural edges with precisely lapped diamond points, controlled cone angles and vertex radius, and the axis coinciding with that of the nib.	Used for truing operations requiring very accurately controlled, and often steeply inclined wheel profiles, such as are needed for thread and gear grinding, where one or more diamond points participate in generating the resulting wheel periphery form. Dependent on specially designed and made truing diamonds and nibs.
Cluster-Type Diamond Dresser	Several, usually seven, smaller diamond stones are mounted in spaced relationship across the working surface of the nib. In some tools, more than a single layer of such clusters is set at parallel levels in the matrix, the deeper positioned layer becoming active after the preceding layer has worn away.	Intended for straight-face dressing and permits the utilization of smaller, less expensive diamond stones. In use, the holder is canted at a 3° to 10° angle, bringing two to five points into contact with the wheel. The multiple-point contact permits faster cross feed rates during truing than may be used with single-point diamonds for generating a specific degree of wheel-face finish.
Impregnated Matrix-Type Diamond Dressers	The operating surface consists of a layer of small, randomly distributed, yet rather uniformly spaced diamonds that are retained in a bond holding the points in an essentially common plane. Supplied either with straight or canted shaft, the latter being used to cancel the tilt of angular truing posts.	For the truing of wheel surfaces consisting of a single or several flat elements. The nib face should be held tangent to the grinding wheel periphery or parallel with a flat working surface. Offers economic advantages where technically applicable because of using less expensive diamond splinters presented in a manner permitting efficient utilization.
